## ROM CODE PROTECTION (83CE654)

The 83CE654 has an additional security feature. ROM code protection may be selected by setting a mask-programmable security bit (i.e., user dependent). This feature may be requested during ROM code submission. When selected, the ROM code is protected and cannot be read out at any time by any test mode or by any instruction in the external program memory space.

The MOV<sub>C</sub> instructions are the only instructions that have access to program code in the internal or external program memory. The EA input is latched during RESET and is "don't care" after RESET (also if the security bit is not set). This implementation prevents reading internal program code by switching from external program memory to internal program memory during a MOV<sub>C</sub> instruction or any other instruction that uses immediate data.

Table 2 lists the access to the internal and external program memory by the MOV<sub>C</sub> instructions when the security bit has been set to a logical "1".

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol, page 992.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

## Power-on Reset (See Figure 1.)

When V<sub>DD</sub> is turned on, and provided its rise-time does not exceed 10ms, an automatic reset can be obtained by connecting the RST pin to V<sub>DD</sub> via a 2.2μF capacitor. When the power is switched on, the voltage on the RST pin is equal to V<sub>DD</sub> minus the capacitor voltage, and decreases from V<sub>DD</sub> as the capacitor charges through the internal resistor (R<sub>RST</sub>) to ground. The larger the capacitor, the more slowly V<sub>RST</sub> decreases. V<sub>RST</sub> must remain above the lower threshold of the Schmitt trigger long enough to effect a complete reset. The time required is the oscillator start-up time, plus 2 machine cycles.

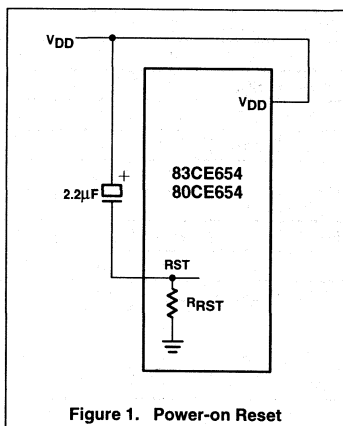

Figure 1. Power-on Reset

## Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## Power-Down Mode

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way

to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 3 shows the state of the I/O ports during low current operating modes.

## Power Control Register PCON

These special modes are activated by software via the Special Function Register PCON. Its hardware address is 87H. PCON is not bit addressable. The reset value of PCON is (0x0x0000).

|--------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCON.7 | SMOD   | Double Baud rate bit.<br>When set to logic 1 the baud rate is doubled when Timer 1 is used to generate baud rate, and the Serial Port is used in modes 1, 2 or 3. |
| PCON.6 | -      | (reserved for future use*)                                                                                                                                        |
| PCON.5 | RFI    | When set to logic 1 the toggling of ALE pin is prohibited. This bit is cleared on RESET.                                                                          |
| PCON.4 | -      | (reserved for future use*)                                                                                                                                        |
| PCON.3 | GF1    | General purpose flag bit.                                                                                                                                         |
| PCON.2 | GF0    | General purpose flag bit.                                                                                                                                         |
| PCON.1 | PD     | Power-down bit. Setting this bit activates Power-down mode.                                                                                                       |
| PCON.0 | IDL    | Idle mode bit. Setting this bit activates the Idle mode. If 1s are written to PD and IDL at the same time, PD takes precedence.                                   |

## NOTE:

\* User software should not write 1s to reserved bits. These bits may be used in future 80C51 family products to invoke new features. In that case, the reset or inactive value of the new bit will be 0, and its active value will be 1. The value read from a reserved bit is indeterminate.

## I<sup>2</sup>C Serial Communication—SIO1

The I<sup>2</sup>C serial port is identical to the I<sup>2</sup>C serial port on the 8XC552. The operation of this subsystem is described in detail in the 8XC552 section of this manual.

Note that in both the 8XC652/4 and the 8XC552 the I<sup>2</sup>C pins are alternate functions to port pins P1.6 and P1.7. Because of this, P1.6 and P1.7 on these parts do not have a pull-up structure as found on the 80C51. Therefore P1.6 and P1.7 have open drain outputs on the 8XC652/4.

### NOTES FOR DC ELECTRICAL CHARACTERISTICS:

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\overline{\text{EA}} = \text{RST} = \text{Port } 0 = \text{P1.6} = \text{P1.7} = V_{DD}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\text{Port } 0 = \text{P1.6} = \text{P1.7} = V_{DD}$ ;  $\overline{\text{EA}} = \text{RST} = V_{SS}$ .
- The power-down current is measured with all output pins disconnected; XTAL2 not connected;  $\text{Port } 0 = \text{P1.6} = \text{P1.7} = V_{DD}$ ;  $\overline{\text{EA}} = \text{XTAL1} = \text{RST} = V_{SS}$ .
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading  $> 100\text{pF}$ ), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below  $0.3V_{DD}$  will be recognized as a logic 0 while an input voltage above  $0.7V_{DD}$  will be recognized as a logic 1.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows: Maximum  $I_{OL} = 10\text{mA}$  per port pin; Maximum  $I_{OL} = 26\text{mA}$  total for Port 0; Maximum  $I_{OL} = 15\text{mA}$  total for Ports 1, 2, and 3; Maximum  $I_{OL} = 71\text{mA}$  total for all output pins. If  $I_{OL}$  exceeds the test conditions,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- $I_{DD\text{MAX}}$  for the 80/83CE654 at the other frequencies can be derived from Figure 1, where FREQ is the external oscillator frequency in MHz.  $I_{DD\text{MAX}}$  is given in mA.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Test condition:  $T_{amb} = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ ;  $V_{DD} = 5\text{V} + 10\%$ ;  $V_{SS} = 0\text{V}$ ; load capacitance = 80pF.

| $t_{FD}$                          | SDA fall time                             | $\leq 0.3\mu s$    | $< 0.3\mu s^3$           |

**NOTES:**

- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be  $< 1\mu s$ .
- Spikes on the SDA and SCL lines with a duration of less than  $3 t_{CLCL}$  will be filtered out. Maximum capacitance on bus-lines SDA and SCL = 400pF.
- $t_{CLCL} = 1/f_{OSC}$  = one oscillator clock period at pin XTAL1. For  $62ns < t_{CLCL} < 285ns$  ( $16MHz > f_{OSC} > 3.5MHz$ ) the SIO1 interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

## TIMING SIO1 (I<sup>2</sup>C) INTERFACE

**Oscillator Circuitry**

The capacitors connected to the crystal should be: C1 = C2 = 20pF.

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

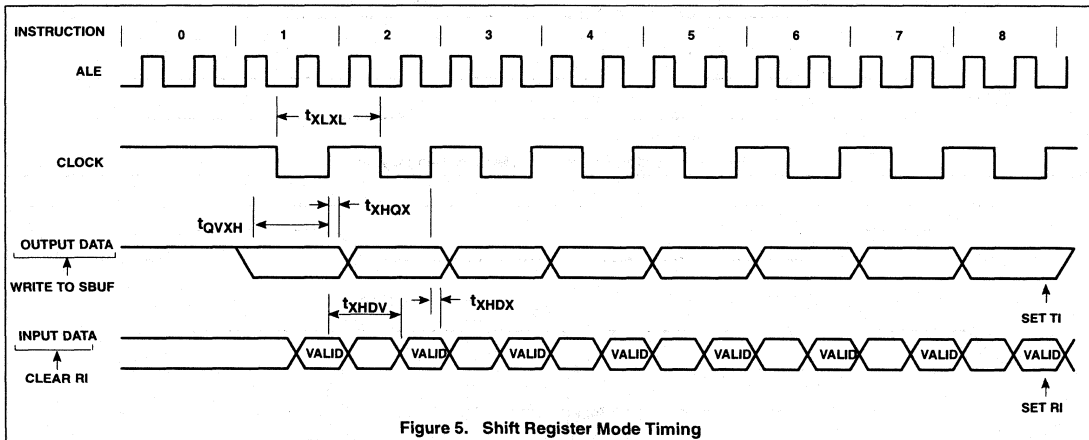

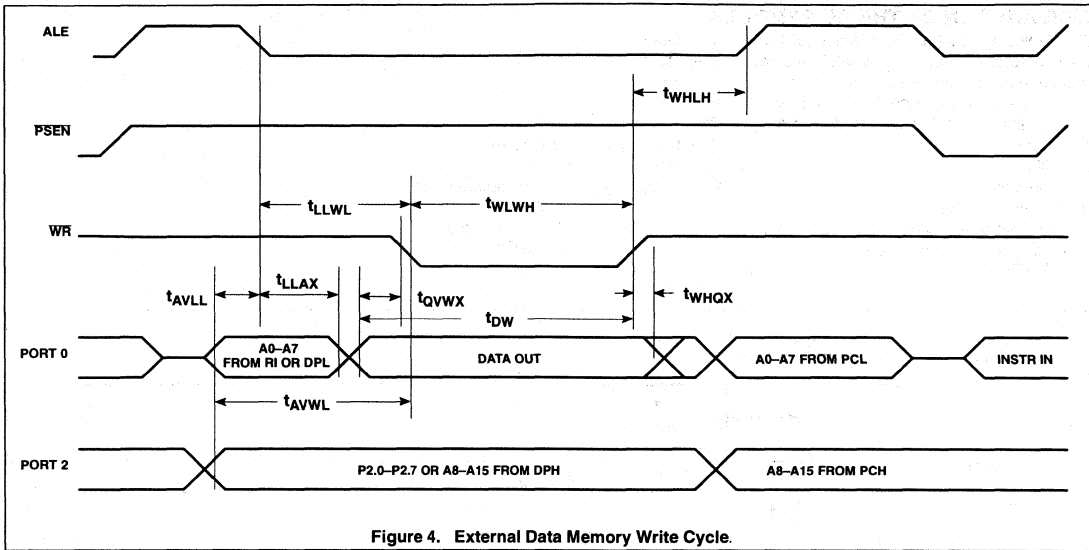

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontrollers

# 83C750/87C750

## DESCRIPTION

The Philips 8XC750 offers the advantages of the 80C51 architecture in a small package and at low cost.

The 8XC750 Microcontroller is fabricated with Philips high-density CMOS technology. Philips epitaxial substrate minimizes CMOS latch-up sensitivity.

The 87C750 contains a 1k x 8 EPROM, a 64 x 8 RAM, 19 I/O lines, a 16-bit auto-reload counter/timer, a five-source, fixed-priority level interrupt structure and an on-chip oscillator.

## FEATURES

- 80C51 based architecture
- Wide oscillator frequency range—up to 40MHz
- Small package sizes
  - 24-pin DIP (300 mil “skinny DIP”)
  - 28-pin PLCC
- 87C750 available in erasable quartz lid or one-time programmable plastic packages
- Low power consumption:
  - Normal operation: less than 11mA @ 5V, 12MHz
  - Idle mode
  - Power-down mode
- 1k x 8 EPROM (87C750)
- 64 x 8 RAM
- 16-bit auto reloadable counter/timer
- Boolean processor
- CMOS and TTL compatible
- Well suited for logic replacement, consumer and industrial applications
- LED drive outputs

## CMOS single-chip 8-bit microcontrollers

## 83C750/87C750

**OSCILLATOR CHARACTERISTICS**

X1 and X2 are the input and output, respectively, of an inverting amplifier which can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, X1 should be driven while X2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**RESET**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-up, the voltage on V<sub>CC</sub> and RST must come up at the same time for a proper start-up.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON.

**Table 1. External Pin Status During Idle and Power-Down Modes**

| MODE       | Port 0 | Port 1 | Port 2 |
|------------|--------|--------|--------|
| Idle       | Data   | Data   | Data   |
| Power-down | Data   | Data   | Data   |

**DIFFERENCES BETWEEN THE 8XC750 AND THE 80C51****Program Memory**

On the 8XC750, program memory is 1024 bytes long and is not externally expandable, so the 80C51 instructions MOVX, LJMP, and LCALL are not implemented. The only fixed locations in program memory are the addresses at which execution is taken up in response to reset and interrupts, which are as follows:

| Event           | Program Memory Address |
|-----------------|------------------------|
| Reset           | 000                    |
| External INT0   | 003                    |
| Counter/timer 0 | 00B                    |
| External INT1   | 013                    |

**Counter/Timer Subsystem**

The 87C750 has one counter/timer called timer/counter 0. Its operation is similar to mode 2 operation on the 80C51, but is extended to 16 bits with 16 bits of autoloader. The controls for this counter are centralized in a single register called TCON.

**Interrupt Subsystem – Fixed Priority**

The IP register and the 2-level interrupt system of the 80C51 are eliminated. Simultaneous interrupt conditions are resolved by a single-level, fixed priority as follows:

Highest priority: Pin INT0  
Counter/timer flag 0  
Pin INT1

**Special Function Register Addresses**

Special function registers for the 8XC750 are identical to those of the 80C51, except for the changes listed below:

80C51 special function registers not present in the 8XC750 are TMOD (89), P2 (A0) and IP (B8). The 80C51 registers TH1 and TL1 are replaced with the 87C750 registers RTH and RTL respectively (refer to Table 2).

# SFRs are modified from or added to the 80C51 SFRs.

ABSOLUTE MAXIMUM RATINGS<sup>1, 2</sup>

| PARAMETER                                                         | RATING                        | UNIT |
|-------------------------------------------------------------------|-------------------------------|------|
| Storage temperature range                                         | -65 to +150                   | °C   |
| Voltage from V <sub>CC</sub> to V <sub>SS</sub>                   | -0.5 to +6.5                  | V    |
| Voltage from any pin to V <sub>SS</sub> (except V <sub>PP</sub> ) | -0.5 to V <sub>CC</sub> + 0.5 | V    |
| Power dissipation                                                 | 1.0                           | W    |
| Voltage on V <sub>PP</sub> pin to V <sub>SS</sub>                 | 0 to +13.0                    | V    |
| Maximum I <sub>OL</sub> per I/O pin                               | 10                            | mA   |

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:  
Maximum  $I_{OL}$  per port pin: 10mA (NOTE: This is  $85^{\circ}\text{C}$  spec.)  
Maximum  $I_{OL}$  per 8-bit port: 26mA  
Maximum total  $I_{OL}$  for all outputs: 67mA  
If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Pins of ports 1 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Power-down  $I_{CC}$  is measured with all output pins disconnected; port 0 =  $V_{CC}$ ; X2, X1 n.c.; RST =  $V_{SS}$ .
- Active  $I_{CC}$  is measured with all output pins disconnected; X1 driven with  $t_{CLCH}$ ,  $t_{CHCL} = 5\text{ns}$ ,  $V_{IL} = V_{SS} + 0.5\text{V}$ ,  $V_{IH} = V_{CC} - 0.5\text{V}$ ; X2 n.c.; RST = port 0 =  $V_{CC}$ .  $I_{CC}$  will be slightly higher if a crystal oscillator is used.
- Idle  $I_{CC}$  is measured with all output pins disconnected; X1 driven with  $t_{CLCH}$ ,  $t_{CHCL} = 5\text{ns}$ ,  $V_{IL} = V_{SS} + 0.5\text{V}$ ,  $V_{IH} = V_{CC} - 0.5\text{V}$ ; X2 n.c.; port 0 =  $V_{CC}$ ; RST =  $V_{SS}$ .

## AC ELECTRICAL CHARACTERISTICS

 $T_{amb} = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$  or  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ ,  $V_{CC} = 5\text{V} \pm 10\%$ ,  $V_{SS} = 0\text{V}^{1, 2}$

# 83C750/87C750

## EXPLANATION OF THE AC SYMBOLS

In defining the clock waveform, care must be taken not to exceed the MIN or MAX limits of the AC electrical characteristics table. Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

C – Clock  
D – Input data

H – Logic level high  
L – Logic level low  
Q – Output data  
T – Time  
V – Valid  
X – No longer a valid logic level  
Z – Float

Figure 1. External Clock Drive

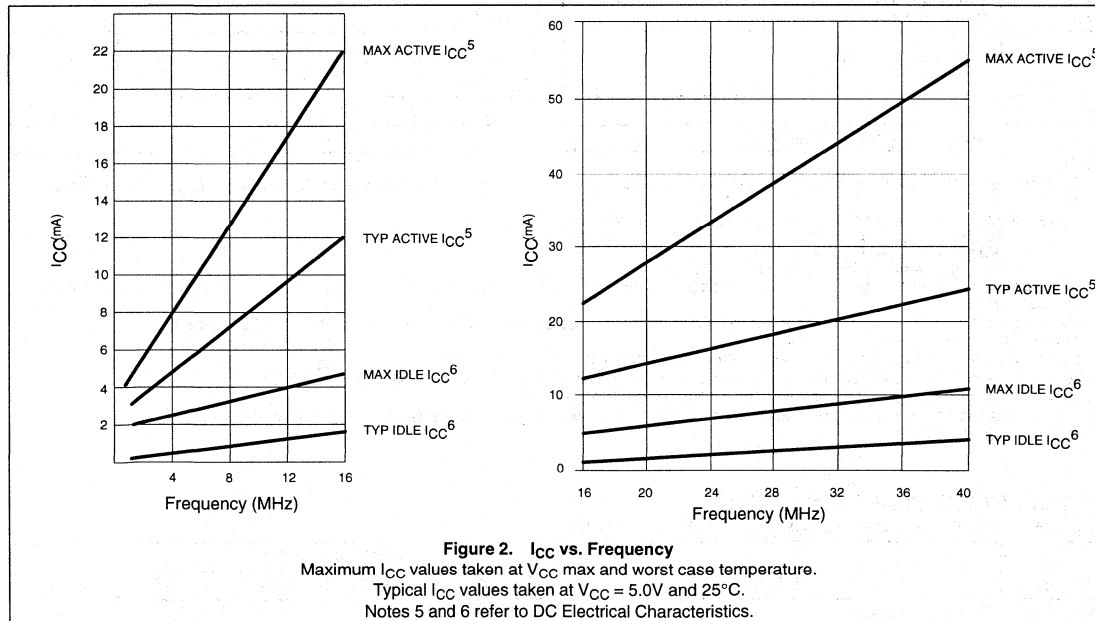

Figure 2.  $I_{CC}$  vs. Frequency

Maximum  $I_{CC}$  values taken at  $V_{CC}$  max and worst case temperature.

Typical  $I_{CC}$  values taken at  $V_{CC} = 5.0V$  and  $25^{\circ}C$ .

Notes 5 and 6 refer to DC Electrical Characteristics.

## CMOS single-chip 8-bit microcontrollers

## 83C750/87C750

**87C750 PROGRAMMING CONSIDERATIONS****EPROM Characteristics**

The 87C750 is programmed by using a modified Quick-Pulse Programming algorithm similar to that used for devices such as the 87C451 and 87C51. It differs from these devices in that a serial data stream is used to place the 87C750 in the programming mode.

Figure 3 shows a block diagram of the programming configuration for the 87C750. Port pin P0.2 is used as the programming voltage supply input ( $V_{PP}$  signal). Port pin P0.1 is used as the program (PGM) signal. This pin is used for the 25 programming pulses.

Port 3 is used as the address input for the byte to be programmed and accepts both the high and low components of the eleven bit address. Multiplexing of these address components is performed using the ASEL input. The user should drive the ASEL input high and then drive port 3 with the high order bits of the address. ASEL should remain high for at least 13 clock cycles. ASEL may then be driven low which latches the high order bits of the address internally, the high address should remain on port 3 for at least two clock cycles after ASEL is driven low. Port 3 may then be driven with the low byte of the address. The low address will be internally stable 13 clock cycles later. The address will remain stable provided that the low byte placed on port 3 is held stable and ASEL is kept low. **Note:** ASEL needs to be pulsed high only to change the high byte of the address.

Port 1 is used as a bidirectional data bus during programming and verify operations. During programming mode, it accepts the byte to be programmed. During verify mode, it provides the contents of the EPROM location specified by the address which has been supplied to Port 3.

The XTAL1 pin is the oscillator input and receives the master system clock. This clock should be between 1.2 and 6MHz.

The RESET pin is used to accept the serial data stream that places the 87C750 into various programming modes. This pattern consists of a 10-bit code with the LSB sent first. Each bit is synchronized to the clock input, X1.

**Programming Operation**

Figures 4 and 5 show the timing diagrams for the program/verify cycle. RESET should

initially be held high for at least two machine cycles. P0.1 (PGM) and P0.2 ( $V_{PP}$ ) will be at  $V_{OH}$  as a result of the RESET operation. At this point, these pins function as normal quasi-bidirectional I/O ports and the programming equipment may pull these lines low. However, prior to sending the 10-bit code on the RESET pin, the programming equipment should drive these pins high ( $V_{IH}$ ). The RESET pin may now be used as the serial data input for the data stream which places the 87C750 in the programming mode. Data bits are sampled during the clock high time and thus should only change during the time that the clock is low. Following transmission of the last data bit, the RESET pin should be held low.

Next the address information for the location to be programmed is placed on port 3 and ASEL is used to perform the address multiplexing, as previously described. At this time, port 1 functions as an output.

A high voltage  $V_{PP}$  level is then applied to the  $V_{PP}$  input (P0.2). (This sets Port 1 as an input port). The data to be programmed into the EPROM array is then placed on Port 1. This is followed by a series of programming pulses applied to the PGM/ pin (P0.1). These pulses are created by driving P0.1 low and then high. This pulse is repeated until a total of 25 programming pulses have occurred. At the conclusion of the last pulse, the PGM/ signal should remain high.

The  $V_{PP}$  signal may now be driven to the  $V_{OH}$  level, placing the 87C750 in the verify mode. (Port 1 is now used as an output port). After four machine cycles (48 clock periods), the contents of the addressed location in the EPROM array will appear on Port 1.

The next programming cycle may now be initiated by placing the address information at the inputs of the multiplexed buffers, driving the  $V_{PP}$  pin to the  $V_{PP}$  voltage level, providing the byte to be programmed to Port1 and issuing the 26 programming pulses on the PGM/ pin, bringing  $V_{PP}$  back down to the  $V_C$  level and verifying the byte.

**Programming Modes**

The 87C750 has four programming features incorporated within its EPROM array. These include the USER EPROM for storage of the application's code, a 16-byte encryption key array and two security bits. Programming and verification of these four elements are selected by a combination of the serial data stream applied to the RESET pin and the voltage levels applied to port pins P0.1 and

P0.2. The various combinations are shown in Table 3.

**Encryption Key Table**

The 87C750 includes a 16-byte EPROM array that is programmable by the end user. The contents of this array can then be used to encrypt the program memory contents during a program memory verify operation. When a program memory verify operation is performed, the contents of the program memory location is XNOR'ed with one of the bytes in the 16-byte encryption table. The resulting data pattern is then provided to port 1 as the verify data. The encryption mechanism can be disable, in essence, by leaving the bytes in the encryption table in their erased state (FFH) since the XNOR product of a bit with a logical one will result in the original bit. The encryption bytes are mapped with the code memory in 16-byte groups. the first byte in code memory will be encrypted with the first byte in the encryption table; the second byte in code memory will be encrypted with the second byte in the encryption table and so forth up to and including the 16th byte. The encryption repeats in 16-byte groups; the 17th byte in the code memory will be encrypted with the first byte in the encryption table, and so forth.

**Security Bits**

Two security bits, security bit 1 and security bit 2, are provided to limit access to the USER EPROM and encryption key arrays. Security bit 1 is the program inhibit bit, and once programmed performs the following functions:

1. Additional programming of the USER EPROM is inhibited.
2. Additional programming of the encryption key is inhibited.
3. Verification of the encryption key is inhibited.
4. Verification of the USER EPROM and the security bit levels may still be performed.

(If the encryption key array is being used, this security bit should be programmed by the user to prevent unauthorized parties from reprogramming the encryption key to all logical zero bits. Such programming would provide data during a verify cycle that is the logical complement of the USER EPROM contents).

Security bit 2, the verify inhibit bit, prevents verification of both the USER EPROM array and the encryption key arrays. The security bit levels may still be verified.

## CMOS single-chip 8-bit microcontrollers

## 83C750/87C750

**Programming and Verifying Security Bits**

Security bits are programmed employing the same techniques used to program the USER EPROM and KEY arrays using serial data streams and logic levels on port pins indicated in Table 3. When programming either security bit, it is not necessary to provide address or data information to the 87C750 on ports 1 and 3.

Verification occurs in a similar manner using the RESET serial stream shown in Table 3. Port 3 is not required to be driven and the results of the verify operation will appear on ports 1.6 and 1.7.

Ports 1.7 contains the security bit 1 data and is a logical one if programmed and a logical zero if erased. Likewise, P1.6 contains the security bit 2 data and is a logical one if programmed and a logical zero if erased.

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent

erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Flourless part number 2345-5 or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 3. Implementing Program/Verify Modes**

| OPERATION              | SERIAL CODE | P0.1 (PGM/)     | P0.2 (V <sub>PP</sub> ) |
|------------------------|-------------|-----------------|-------------------------|
| Program user EPROM     | 296H        | -1              | V <sub>PP</sub>         |

| t <sub>ADSTA</sub>             | Low address to valid data                            |                            | 48t <sub>CLCL</sub> |      |

**NOTES:**

1. Address should be valid at least 24t<sub>CLCL</sub> before the rising edge of P0.2 (V<sub>PP</sub>).
2. For a pure verify mode, i.e., no program mode in between, t<sub>AVQV</sub> is 14t<sub>CLCL</sub> maximum.

CMOS single-chip 8-bit microcontrollers

83C750/87C750

## CMOS single-chip 8-bit microcontroller

83C751/87C751

## DESCRIPTION

The Philips 83C751/87C751 offers the advantages of the 80C51 architecture in a small package and at low cost.

The 8XC751 Microcontroller is fabricated with Philips high-density CMOS technology. Philips epitaxial substrate minimizes CMOS latch-up sensitivity.

The 8XC751 contains a 2k × 8 ROM (83C751) EPROM (87C751), a 64 × 8 RAM, 19 I/O lines, a 16-bit auto-reload counter/timer, a five-source, fixed-priority level interrupt structure, a bidirectional inter-integrated circuit (I<sup>2</sup>C) serial bus interface, and an on-chip oscillator.

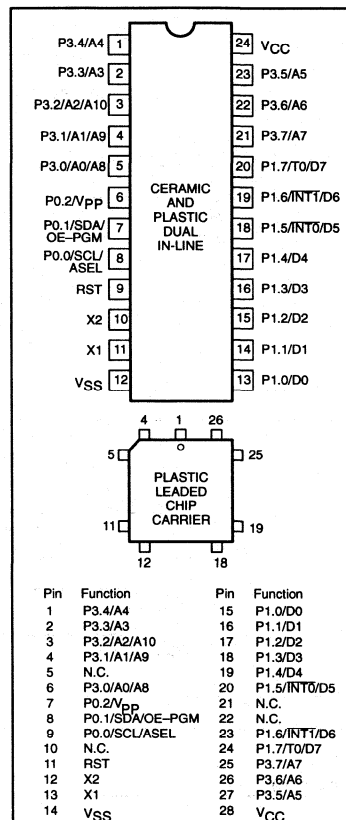

The on-board inter-integrated circuit (I<sup>2</sup>C) bus interface allows the 8XC751 to operate as a master or slave device on the I<sup>2</sup>C small area network. This capability facilitates I/O and RAM expansion, access to EEPROM, processor-to-processor communication, and efficient interface to a wide variety of dedicated I<sup>2</sup>C peripherals.

## FEATURES

- 80C51 based architecture
- Inter-Integrated Circuit (I<sup>2</sup>C) serial bus interface
- Small package sizes
  - 24-pin DIP (300 mil "skinny DIP")
  - 28-pin PLCC
- 87C751 available in erasable quartz lid or one-time programmable plastic packages
- Wide oscillator frequency range
- Low power consumption:
  - Normal operation: less than 11mA @ 5V, 12MHz
  - Idle mode
  - Power-down mode
- 2k × 8 ROM (83C751)  
2k × 8 EPROM (87C751)
- 64 × 8 RAM
- 16-bit auto reloadable counter/timer
- Fixed-rate timer
- Boolean processor
- CMOS and TTL compatible
- Well suited for logic replacement, consumer and industrial applications
- LED drive outputs

## PIN CONFIGURATIONS

## ORDERING INFORMATION

| ROM          | EPROM <sup>1</sup> |     | TEMPERATURE RANGE °C AND PACKAGE         | FREQUENCY MHz | DRAWING NUMBER |
|--------------|--------------------|-----|------------------------------------------|---------------|----------------|
|              | S87C751-1F24       | UV  | 0 to +70, Ceramic Dual In-line Package   | 3.5 to 12     | 0586B          |

| P0.0–P0.2       | 8–6           | 9–7              | I/O  | <p><b>Port 0:</b> Port 0 is a 3-bit open-drain, bidirectional port. Port 0 pins that have 1s written to them float, and in that state can be used as high-impedance inputs. Port 0 also serves as the serial I<sup>2</sup>C interface. When this feature is activated by software, SCL and SDA are driven low in accordance with the I<sup>2</sup>C protocol. These pins are driven low if the port register bit is written with a 0 or if the I<sup>2</sup>C subsystem presents a 0. The state of the pin can always be read from the port register by the program.</p> <p>To comply with the I<sup>2</sup>C specification, P0.0 and P0.1 are open drain bidirectional I/O pins with the electrical characteristics listed in the tables that follow. While these differ from "standard TTL" characteristics, they are close enough for the pins to still be used as general-purpose I/O in non-I<sup>2</sup>C applications. Port 0 also provides alternate functions for programming the EPROM memory as follows:</p> <p><b>V<sub>PP</sub> (P0.2)</b> – Programming voltage input.<br/> <b>OE/PGM (P0.1)</b> – Input which specifies verify mode (output enable) or the program mode.<br/> OE/PGM = 1 output enabled (verify mode).<br/> OE/PGM = 0 program mode.<br/> <b>ASEL (P0.0)</b> – Input which indicates which bits of the EPROM address are applied to port 3.<br/> ASEL = 0 low address byte available on port 3.<br/> ASEL = 1 high address byte available on port 3 (only the three least significant bits are used).<br/> <b>SDA (P0.1)</b> – I<sup>2</sup>C data.<br/> <b>SCL (P0.0)</b> – I<sup>2</sup>C clock.</p> |

|                 | 8             | 9                | I/O  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| P1.0–P1.7       | 13–20         | 15–20,<br>23, 24 | I/O  | <p><b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I<sub>IL</sub>). Port 1 serves to output the addressed EPROM contents in the verify mode and accepts as inputs the value to program into the selected address during the program mode. Port 1 also serves the special function features of the 80C51 family as listed below:</p> <p><b>INT0 (P1.5):</b> External interrupt.<br/> <b>INT1 (P1.6):</b> External interrupt.<br/> <b>T0 (P1.7):</b> Timer 0 external input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| P3.0–P3.7       | 5–1,<br>23–21 | 4–1, 6,<br>27–25 | I/O  | <p><b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I<sub>IL</sub>). Port 3 also functions as the address input for the EPROM memory location to be programmed (or verified). The 11-bit address is multiplexed into this port as specified by P0.0/ASEL.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| RST             | 9             | 11               | I    | <p><b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to V<sub>SS</sub> permits a power-on RESET using only an external capacitor to V<sub>CC</sub>. After the device is reset, a 10-bit serial sequence, sent LSB first, applied to RESET, places the device in the programming state allowing programming address, data and V<sub>PP</sub> to be applied for programming or verification purposes. The RESET serial sequence must be synchronized with the X1 input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## CMOS single-chip 8-bit microcontroller

83C751/87C751

**ABSOLUTE MAXIMUM RATINGS**<sup>1, 2</sup>

| PARAMETER                                                         | RATING                        | UNIT |
|-------------------------------------------------------------------|-------------------------------|------|
| Storage temperature range                                         | -65 to +150                   | °C   |
| Voltage from V <sub>CC</sub> to V <sub>SS</sub>                   | -0.5 to +6.5                  | V    |
| Voltage from any pin to V <sub>SS</sub> (except V <sub>PP</sub> ) | -0.5 to V <sub>CC</sub> + 0.5 | V    |
| Power dissipation                                                 | 1.0                           | W    |
| Voltage on V <sub>PP</sub> pin to V <sub>SS</sub>                 | 0 to +13.0                    | V    |
| Maximum I <sub>OL</sub> per I/O pin                               | 10                            | mA   |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.

**DC ELECTRICAL CHARACTERISTICS**

T<sub>amb</sub> = 0°C to +70°C or -40°C to +85°C, V<sub>CC</sub> = 5V ±10% for 87C751, V<sub>CC</sub> = 5V ±20% for 83C751, V<sub>SS</sub> = 0V<sup>1</sup>

**NOTES TO DC ELECTRICAL CHARACTERISTICS ON NEXT PAGE**

# CMOS single-chip 8-bit microcontroller

# 83C751/87C751

**NOTES TO DC ELECTRICAL CHARACTERISTICS:**

- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
  - Maximum  $I_{OL}$  per port pin: 10mA (NOTE: This is 85°C spec.)
  - Maximum  $I_{OL}$  per 8-bit port: 26mA
  - Maximum total  $I_{OL}$  for all outputs: 67mA
 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Pins of ports 1 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Power-down  $I_{CC}$  is measured with all output pins disconnected; port 0 =  $V_{CC}$ ; X2, X1 n.c.; RST =  $V_{SS}$ .
- Active  $I_{CC}$  is measured with all output pins disconnected; X1 driven with  $t_{CLCH}$ ,  $t_{CHCL} = 5ns$ ,  $V_{IL} = V_{SS} + 0.5V$ ,  $V_{IH} = V_{CC} - 0.5V$ ; X2 n.c.; RST = port 0 =  $V_{CC}$ .  $I_{CC}$  will be slightly higher if a crystal oscillator is used.
- Idle  $I_{CC}$  is measured with all output pins disconnected; X1 driven with  $t_{CLCH}$ ,  $t_{CHCL} = 5ns$ ,  $V_{IL} = V_{SS} + 0.5V$ ,  $V_{IH} = V_{CC} - 0.5V$ ; X2 n.c.; port 0 =  $V_{CC}$ ; RST =  $V_{SS}$ .

**AC ELECTRICAL CHARACTERISTICS**

$T_{amb} = 0^{\circ}C$  to  $+70^{\circ}C$  or  $-40^{\circ}C$  to  $+85^{\circ}C$ ,  $V_{CC} = 5V \pm 10\%$  for 87C751,  $V_{CC} = 5V \pm 20\%$  for 83C751,  $V_{SS} = 0V^{1,2}$

| SYMBOL                           | PARAMETER             | 12MHz CLOCK |     | VARIABLE CLOCK |     | UNIT |

| $t_{CHCL}$                       | Fall time             |             | 20  |                | 20  | ns   |

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.
- Load capacitance for ports = 80pF.

# CMOS single-chip 8-bit microcontroller

83C751/87C751

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:  
 C – Clock  
 D – Input data

H – Logic level high  
 L – Logic level low  
 Q – Output data  
 T – Time  
 V – Valid  
 X – No longer a valid logic level  
 Z – Float

Figure 1. External Clock Drive

Figure 2.  $I_{CC}$  vs. FREQ

Maximum  $I_{CC}$  values taken at  $V_{CC}$  max and worst case temperature.  
 Typical  $I_{CC}$  values taken at  $V_{CC} = 5.0V$  and  $25^{\circ}C$ .  
 Notes 5 and 6 refer to DC Electrical Characteristics.

## CMOS single-chip 8-bit microcontroller

## 83C751/87C751

**OSCILLATOR CHARACTERISTICS**

X1 and X2 are the input and output, respectively, of an inverting amplifier which can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, X1 should be driven while X2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**RESET**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-up, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON.

**Table 1. External Pin Status During Idle and Power-Down Modes**

| MODE       | Port 0 | Port 1 | Port 2 |
|------------|--------|--------|--------|
| Idle       | Data   | Data   | Data   |
| Power-down | Data   | Data   | Data   |

**DIFFERENCES BETWEEN THE 83C751 AND THE 80C51****Memory Organization**

The central processing unit (CPU) manipulates operands in two address spaces as shown in Figure 3. The part's internal memory space consists of 2k bytes of program memory, and 64 bytes of data RAM overlapped with the 128-byte special function register area. The differences from the 80C51 are in RAM size (64 bytes vs. 128 bytes), in external RAM access (not available on the 83C751), in internal ROM size (2k bytes vs. 4k bytes), and in external program memory expansion (not available on the 83C751). The 128-byte special function register (SFR) space is accessed as on the 80C51 with some of the registers having been changed to reflect changes in the 83C751 peripheral functions. The stack may be located anywhere in internal RAM by loading the 8-bit stack pointer (SP). It should be noted that stack depth is limited to 64 bytes, the amount of available RAM. A reset loads the stack

pointer with 07 (which is pre-incremented on a PUSH instruction).

**Program Memory**

On the 83C751, program memory is 2048 bytes long and is not externally expandable, so the 80C51 instructions MOVX, LJMP, and LCALL are not implemented. The only fixed locations in program memory are the addresses at which execution is taken up in response to reset and interrupts, which are as follows:

| Event                   | Program Memory Address |
|-------------------------|------------------------|
| Reset                   | 000                    |
| External INT0           | 003                    |
| Counter/timer 0         | 00B                    |
| External INT1           | 013                    |
| Timer 1                 | 01B                    |
| I <sup>2</sup> C serial | 023                    |

**Counter/Timer Subsystem**

The 83C751 has one counter/timer called timer/counter 0. Its operation is similar to mode 2 operation on the 80C51, but is extended to 16 bits with 16 bits of autoloader. The controls for this counter are centralized in a single register called TCON.

A watchdog timer, called Timer 1, is for use with the I<sup>2</sup>C subsystem. In I<sup>2</sup>C applications, this timer is dedicated to time-generation and bus monitoring of the I<sup>2</sup>C. In non-I<sup>2</sup>C applications, it is available for use as a fixed time-base.

**Counter Timer – Special Function Register**

The counter/timer has only one mode of operation, so the TMOD SFR is not used. There is also only one counter/timer, so there is no need for the TL1 and TH1 SFRs found on the 80C51. These have been replaced on the 83C751 by RTL and RTH, the counter/timer reload registers. Table 3 shows the special function registers, their locations, and reset values.

**Figure 3. Memory Map**

## CMOS single-chip 8-bit microcontroller

83C751/87C751

**Interrupt Subsystem – Fixed Priority**

The IP register and the 2-level interrupt system of the 80C51 are eliminated. Simultaneous interrupt conditions are resolved by a single-level, fixed priority as follows:

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| Highest priority: | Pin INT0<br>Counter/timer flag 0<br>Pin INT1<br>Timer 1 |
| Lowest priority:  | Serial I <sup>2</sup> C                                 |

**Special Function Register – Interrupt Subsystem**

Because the interrupt structure is single level on the 83C751, there is no need for the IP SFR, so it is not used.

**Serial Communications**

The 83C751 contains an I<sup>2</sup>C serial communications port instead of the 80C51 UART. The I<sup>2</sup>C serial port is a single bit

hardware interface with all of the hardware necessary to support multimaster and slave operations. Also included are receiver digital filters and timer (timer 1) for communication watch-dog purposes. The I<sup>2</sup>C serial port is controlled through four special function registers; I<sup>2</sup>C control, I<sup>2</sup>C data, I<sup>2</sup>C status, and I<sup>2</sup>C configuration.

**Special Function Register – Serial Communications**

The 83C751 contains many of the special function registers (SFR) that are found on the 80C51. Due to the different peripheral features on the 83C751, there are several additional SFRs and several that have been changed.

Since the standard UART found on the 80C51 has been replaced by the I<sup>2</sup>C serial interface, the UART SFRs, SCON, and SBUF have been replaced by I2CON and I2DAT, and two additional I<sup>2</sup>C registers have been added (I2STA and I2CFG).

**I/O Port Latches (P0, P1, P3)**

The port latches function the same as those on the 80C51. Since there is no port 2 on the 83C751, the P2 latch is not used. Port 0 on the 83C751 has only 3 bits, so only 3 bits of the P0 SFR have a useful function.

**Special Function Register – I/O Port Latches**

There is no Port2 on the 83C751, so P2 is not used. Also, only 3 bits of P0 SFR have a useful function.

**Data Pointer (DPTR)**

The data pointer (DPTR) consists of a high byte (DPH) and a low byte (DPL). In the 80C51 this register allows the access of external data memory using the MOVX instruction. Since the 83C751 does not support MOVX or external memory accesses, this register is generally used as a 16-bit offset pointer of the accumulator in a MOVC instruction. DPTR may also be manipulated as two independent 8-bit registers.

**Table 2. I<sup>2</sup>C Special Function Register Addresses**

| REGISTER ADDRESS               |        |         | BIT ADDRESS |    |    |    |     |    |    |    |

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

# CMOS single-chip 8-bit microcontroller

# 83C751/87C751

### I/O Port Structure

The 8XC751 has two 8-bit ports (ports 1 and 3) and one 3-bit port (port 0). All three ports on the 8XC751 are bidirectional. Each consists of a latch (special function register P0, P1, P3), an output driver, and an input buffer. Three port 1 pins and two port 0 pins are multifunctional. In addition to being port pins, these pins serve the function of special features as follows:

| Port Pin | Alternate Function                |
|----------|-----------------------------------|
| P0.0     | I <sup>2</sup> C clock (SCL)      |
| P0.1     | I <sup>2</sup> C data (SDA)       |
| P1.5     | INT0 (external interrupt 0 input) |
| P1.6     | INT1 (external interrupt 1 input) |
| P1.7     | T0 (timer 0 external input)       |

Ports 1 and 3 are identical in structure to the same ports on the 80C51. The structure of port 0 on the 8XC751 is similar to that of the 80C51 but does not include address/data input and output circuitry. As on the 80C51, ports 1 and 3 are quasi-bidirectional while port 0 is bidirectional with no internal pullups.

### Timer/Counter

The 8XC751 has two timers: a 16-bit timer/counter and a 10-bit fixed-rate timer. The 16-bit timer/counter's operation is similar to mode 2 operation on the 80C51, but is extended to 16 bits. The timer/counter is clocked by either 1/12 the oscillator frequency or by transitions on the T0 pin. The C/T pin in special function register TCON selects between these two modes. When the TCON TR bit is set, the timer/counter is enabled. Register pair TH and TL are incremented by the clock source. When the register pair overflows, the register pair is reloaded with the values in registers RTH and

RTL. The value in the reload registers is left unchanged. See the 83C751 counter/timer block diagram in Figure 4. The TF bit in special function register TCON is set on counter overflow and, if the interrupt is enabled, will generate an interrupt.

### TCON Register

|      | INT1 is edge triggered.                                           |     |    |    |     |     |     |     |
|      | 0                                                                 |     |    |    |     |     |     |     |
|      | INT1 is level sensitive.                                          |     |    |    |     |     |     |     |

These flags are functionally identical to the corresponding 80C51 flags, except that there is only one timer on the 83C751 and the flags are therefore combined into one register.

Note that the positions of the IE0/IT0 and IE1/IT1 bits are transposed from the positions used in the standard 80C51 TCON register.

Timer 1 is used to control the timing of the I<sup>2</sup>C bus and also to detect a "bus locked" condition, by causing an interrupt when nothing happens on the I<sup>2</sup>C bus for an inordinately long period of time while a transmission is in progress. If the interrupt does not occur, the program can attempt to correct the fault and allow the last I<sup>2</sup>C transmission to be repeated.

The I<sup>2</sup>C watchdog timer, timer 1, is also available as a general-purpose fixed-rate timer when the I<sup>2</sup>C interface is not being used. A clock rate of 1/12 the oscillator frequency forms the input to the timer. Timer 1 has a timeout interval of 1024 machine cycles when used as a fixed-rate timer.

### I<sup>2</sup>C Serial Interface

The I<sup>2</sup>C bus uses two wires (SDA and SCL) to transfer information between devices connected to the bus. The main features of the bus are:

- Bidirectional data transfer between masters and slaves
- Serial addressing of slaves (no added wiring)
- Acknowledgment after each transferred byte
- Multimaster bus
- Arbitration between simultaneously transmitting masters without corruption of serial data on bus
- The 82B715 extends communication distance to 100 feet (30M).

A large family of I<sup>2</sup>C compatible ICs is available. See the I<sup>2</sup>C section of this manual for more details on the bus and available ICs.

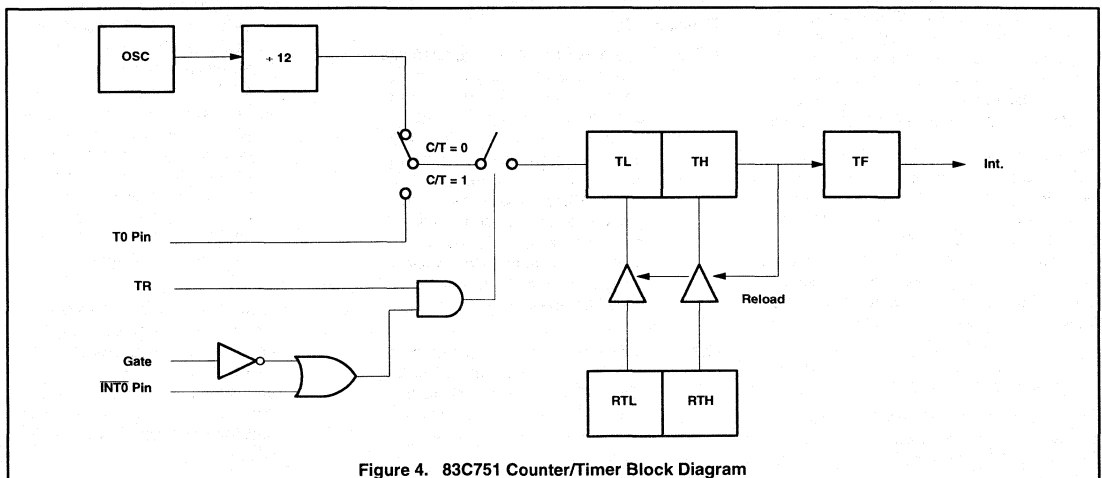

Figure 4. 83C751 Counter/Timer Block Diagram

# CMOS single-chip 8-bit microcontroller

# 83C751/87C751

The 83C751 I<sup>2</sup>C subsystem includes hardware to simplify the software required to drive the I<sup>2</sup>C bus. The hardware is a single bit interface which in addition to including the necessary arbitration and framing error checks, includes clock stretching and a bus timeout timer. The interface is synchronized to software either through polled loops or interrupts. Refer to the application note AN422, in Section 4, entitled "Using the 8XC751 Microcontroller as an I<sup>2</sup>C Bus Master" for additional discussion of the 83C751 I<sup>2</sup>C interface and sample driver routines.

Six time spans are important in I<sup>2</sup>C operation and are insured by timer I:

- The MINIMUM HIGH time for SCL when this device is the master.
- The MINIMUM LOW time for SCL when this device is a master. This is not very important for a single-bit hardware interface like this one, because the SCL low time is stretched until the software responds to the I<sup>2</sup>C flags. The software response time normally meets or exceeds the MIN LO time. In cases where the software responds within MIN HI + MIN LO) time, timer I will ensure that the minimum time is met.
- The MINIMUM SCL HIGH TO SDA HIGH time in a stop condition.
- The MINIMUM SDA HIGH TO SDA LOW time between I<sup>2</sup>C stop and start conditions (4.7µs, see spec.).
- The MINIMUM SDA LOW TO SCL LOW time in a start condition.
- The MAXIMUM SCL CHANGE time while an I<sup>2</sup>C frame is in progress. A frame is in progress between a start condition and the following stop condition. This time span serves to detect a lack of software response on this 8XC751 as well as external I<sup>2</sup>C problems. SCL "stuck low" indicates a faulty master or slave. SCL "stuck high" may mean a faulty device, or that noise induced onto the I<sup>2</sup>C bus caused all masters to withdraw from I<sup>2</sup>C arbitration.

The first five of these times are 4.7µs (see I<sup>2</sup>C specification) and are covered by the low order three bits of timer I. Timer I is clocked by the 8XC751 oscillator, which can vary in frequency from 0.5 to 16MHz. Timer I can be preloaded with one of four values to optimize timing for different oscillator frequencies. At lower frequencies, software response time is increased and will degrade maximum performance of the I<sup>2</sup>C bus. See special function register I2CFG description for prescale values (CT0, CT1).

The MAXIMUM SCL CHANGE time is important, but its exact span is not critical. The complete 10 bits of timer I are used to

count out the maximum time. When I<sup>2</sup>C operation is enabled, this counter is cleared by transitions on the SCL pin. The timer does not run between I<sup>2</sup>C frames (i.e., whenever reset or stop occurred more recently than the last start). When this counter is running, it will carry out after 1020 to 1023 machine cycles have elapsed since a change on SCL. A carry out causes a hardware reset of the 83C751 I<sup>2</sup>C interface and generates an interrupt if the timer I interrupt is enabled. In cases where the bus hangup is due to a lack of software response by this 83C751, the reset releases SCL and allows I<sup>2</sup>C operation among other devices to continue.

### I<sup>2</sup>C Interrupts

If I<sup>2</sup>C interrupts are enabled (EA and EI2 are both set to 1), an I<sup>2</sup>C interrupt will occur whenever the ATN flag is set by a start, stop, arbitration loss, or data ready condition (refer to the description of ATN following). In practice, it is not efficient to operate the I<sup>2</sup>C interface in this fashion because the I<sup>2</sup>C interrupt service routine would somehow have to distinguish between hundreds of possible conditions. Also, since I<sup>2</sup>C can operate at a fairly high rate, the software may execute faster if the code simply waits for the I<sup>2</sup>C interface.

Typically, the I<sup>2</sup>C interrupt should only be used to indicate a start condition at an idle slave device, or a stop condition at an idle master device (if it is waiting to use the I<sup>2</sup>C bus). This is accomplished by enabling the I<sup>2</sup>C interrupt only during the aforementioned conditions.

### I<sup>2</sup>C Register I2CON

|       | 7    | 6    | 5    | 4    | 3    | 2    | 1      | 0    |
|-------|------|------|------|------|------|------|--------|------|
| Read  | RDAT | ATN  | DRDY | ARL  | STR  | STP  | MASTER | -    |
| Write | CXA  | IDLE | CDR  | CARL | CSTR | CSTP | XSTR   | XSTP |

#### Reading I2CON

**RDAT** The data from SDA is captured into "Receive DATa" whenever a rising edge occurs on SCL. RDAT is also available (with seven low-order zeros) in the I2DAT register. The difference between reading it here and there is that reading I2DAT clears DRDY, allowing the I<sup>2</sup>C to proceed on to another bit. Typically, the first seven bits of a received byte are read from I2DAT, while the 8th is read here. Then I2DAT can be written to send the Ack bit and clear DRDY.

**ATN** "ATteNtion" is 1 when one or more of DRDY, ARL, STR, or STP is 1. Thus, ATN comprises a single bit that can be tested to release the I<sup>2</sup>C service routine from a "wait loop."

**DRDY** "Data Ready" (and thus ATN) is set when a rising edge occurs on SCL, except at idle slave. DRDY is cleared by writing CDR = 1, or by writing or reading the I2DAT register. The following low period on SCL is stretched until the program responds by clearing DRDY.

#### Checking ATN and DRDY

When a program detects ATN = 1, it should next check DRDY. If DRDY = 1, then if it receives the last bit, it should capture the data from RDAT (in I2DAT or I2CON). Next, if the next bit is to be sent, it should be written to I2DAT. One way or another, it should clear DRDY and then return to monitoring ATN. Note that if any of ARL, STR, or STP is set, clearing DRDY will not release SCL to high, so that the I<sup>2</sup>C will not go on to the next bit. If a program detects ATN = 1, and DRDY = 0, it should go on to examine ARL, STR, and STP.

**ARL** "Arbitration Loss" is 1 when transmit Active was set, but this 83C751 lost arbitration to another transmitter. Transmit Active is cleared when ARL is 1. There are four separate cases in which ARL is set.

1. If the program sent a 1 or repeated start, but another device sent a 0, or a stop, so that SDA is 0 at the rising edge of SCL. (If the other device sent a stop, the setting of ARL will be followed shortly by STP being set.)
2. If the program sent a 1, but another device sent a repeated start, and it drove SDA low before the 83C751 could drive SCL low. (This type of ARL is always accompanied by STR = 1.)
3. In master mode, if the program sent a repeated start, but another device sent a 1, and it drove SCL low before this 83C751 could drive SDA low.
4. In master mode, if the program sent stop, but it could not be sent because another device sent a 0.

**STR** "STaRt" is set to a 1 when an I<sup>2</sup>C start condition is detected at a non-idle slave or at a master. (STR is not set when an idle slave becomes active due to a start bit; the slave has nothing useful to do until the rising edge of SCL sets DRDY.)

# CMOS single-chip 8-bit microcontroller

# 83C751/87C751

**STP** "SToP" is set to 1 when an I<sup>2</sup>C stop condition is detected at a non-idle slave or at a master. (STP is not set for a stop condition at an idle slave.)

**MASTER "MASTER"** is 1 if this 83C751 is currently a master on the I<sup>2</sup>C. MASTER is set when MASTRQ is 1 and the bus is not busy (i.e., if a start bit hasn't been received since reset or a "Timer 1" time-out, or if a stop has been received since the last start). MASTER is cleared when ARL is set, or after the software writes MASTRQ = 0 and then XSTP = 1.

### Writing I2CON

Typically, for each bit in an I<sup>2</sup>C message, a service routine waits for ATN = 1. Based on DRDY, ARL, STR, and STP, and on the current bit position in the message, it may then write I2CON with one or more of the following bits, or it may read or write the I2DAT register.

**CXA** Writing a 1 to "Clear Xmit Active" clears the Transmit Active state. (Reading the I2DAT register also does this.)

### Regarding Transmit Active

Transmit Active is set by writing the I2DAT register, or by writing I2CON with XSTR = 1 or XSTP = 1. The I<sup>2</sup>C interface will only drive the SDA line low when Transmit Active is set, and the ARL bit will only be set to 1 when Transmit Active is set. Transmit Active is cleared by reading the I2DAT register, or by writing I2CON with CXA = 1. Transmit Active is automatically cleared when ARL is 1.

**IDLE** Writing 1 to "IDLE" causes a slave's I<sup>2</sup>C hardware to ignore the I<sup>2</sup>C until the next start condition (but if MASTRQ is 1, then a stop condition will make the 83C751 into a master).

**CDR** Writing a 1 to "Clear Data Ready" clears DRDY. (Reading or writing the I2DAT register also does this.)

**CARL** Writing a 1 to "Clear Arbitration Loss" clears the ARL bit.

**CSTR** Writing a 1 to "Clear STaRt" clears the STR bit.

**CSTP** Writing a 1 to "Clear SToP" clears the STP bit. Note that if one or more of DRDY, ARL, STR, or STP is 1, the low time of SCL is stretched until the service routine responds by clearing them.

**XSTR** Writing 1s to "Xmit repeated STaRt" and CDR tells the I<sup>2</sup>C hardware to send a repeated start condition.

This should only be at a master. Note that XSTR need not and should not be used to send an "initial" (nonrepeated) start; it is sent automatically by the I<sup>2</sup>C hardware. Writing XSTR = 1 includes the effect of writing I2DAT with XDAT = 1; it sets Transmit Active and releases SDA to high during the SCL low time. After SCL goes high, the I<sup>2</sup>C hardware waits for the suitable minimum time and then drives SDA low to make the start condition.

**XSTP** Writing 1s to "Xmit SToP" and CDR tells the I<sup>2</sup>C hardware to send a stop condition. This should only be done at a master. If there are no more messages to initiate, the service routine should clear the MASTRQ bit in I2CFG to 0 before writing XSTP with 1. Writing XSTP = 1 includes the effect of writing I2DAT with XDAT = 0; it sets Transmit Active and drives SDA low during the SCL low time. After SCL goes high, the I<sup>2</sup>C hardware waits for the suitable minimum time and then releases SDA to high to make the stop condition.

**NOTE:** Because of the manner in which register bit addressing is implemented in the 80C51 family, the I2CON register should never be altered by use of the SETB, CLR, CPL, MOV (bit), or JBC instructions. This is due to the fact that read and write functions of this register are different. Testing of I2CON bits via the JB and JNB instructions is supported.

### I<sup>2</sup>C Register I2DAT

|       | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|------|---|---|---|---|---|---|---|
| Read  | RDAT | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Write | XDAT | X | X | X | X | X | X | X |

**RDAT** "Receive DATa" is captured from SDA every rising edge of SCL. Reading I2DAT also clears DRDY and the Transmit Active state.

**XDAT** "Xmit Data" sets the data for the next bit. Writing I2DAT also clears DRDY and sets the Transmit Active state.

### Regarding Software Response Time

Because the 83C751 can run at 16MHz, and because the I<sup>2</sup>C interface is optimized for high-speed operation, it is quite likely that an I<sup>2</sup>C service routine will sometimes respond to DRDY (which is set at a rising edge of SCL) and write I2DAT before SCL has gone low again. If XDAT were applied directly to SDA, this situation would produce an I<sup>2</sup>C protocol violation. The programmer need not worry

about this possibility because XDAT is applied to SDA only when SCL is low.

Conversely, a program that includes an I<sup>2</sup>C service routine may take a long time to respond to DRDY. Typically, an I<sup>2</sup>C routine operates on a flag-polling basis during a message, with interrupts from other peripheral functions enabled. If an interrupt occurs, it will delay the response of the I<sup>2</sup>C service routine. The programmer need not worry about this very much either, because the I<sup>2</sup>C hardware stretches the SCL low time until the service routine responds. The only constraint on the response is that it must not exceed the Timer 1 time-out, which is at least 765 microseconds.

### I<sup>2</sup>C Register I2CFG

|       | 7      | 6      | 5     | 4     | 3 | 2 | 1   | 0   |
|-------|--------|--------|-------|-------|---|---|-----|-----|
| Read  | SLAVEN | MASTRQ | 0     | TIRUN | - | - | CT1 | CT0 |
| Write | SLAVEN | MASTRQ | CLRTI | TIRUN | - | - | CT1 | CT0 |

**SLAVEN** Writing a 1 to "SLaVe ENable" enables the slave functions of the I<sup>2</sup>C subsystem. If SLAVEN and MASTRQ are 0, the I<sup>2</sup>C hardware is disabled. This bit is cleared to 0 by reset and by an I<sup>2</sup>C time-out.

**MASTRQ** Writing a 1 to "MASTRQ" requests mastership of the I<sup>2</sup>C. If a frame from another master is in progress when this bit is changed from 0 to 1, action is delayed until a stop condition is detected. Then, or immediately if a frame is not in progress, a start condition is sent and DRDY is set (thus making ATN 1 and generating an I<sup>2</sup>C interrupt). When a master wishes to release mastership status of the I<sup>2</sup>C, it writes a 1 to XSTP in I2CON. MASTRQ is cleared by reset and by an I<sup>2</sup>C time-out.

**CLRTI** Writing a 1 to this bit clears the Timer 1 interrupt flag. This bit position always reads as 0.

**TIRUN** Writing a 1 to this bit lets Timer 1 run; a zero stops and clears it. Together with SLAVEN, MASTRQ, and MASTER, this bit determines operational modes as shown in Table 4.

**CT1,0** These two bits are programmed as a function of the OSC rate, to optimize the MIN HI and LO time of SCL when this 83C751 is a master on the I<sup>2</sup>C. The time value determined by these bits controls both of these parameters, and also the timing for stop and start conditions. These bits are cleared to 00 by reset.

CMOS single-chip 8-bit microcontroller

83C751/87C751

**Table 4. Interaction of TIRUN with SLAVEN, MASTRQ, and MASTER**

| SLAVEN, MASTRQ, MASTER | TIRUN | OPERATING MODE                                                                                                                                                                                                                                                                 |
|------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All 0                  | 0     | The I <sup>2</sup> C interface is disabled. Timer I is cleared and does not run. This is the state assumed after a reset. If an I <sup>2</sup> C application wants to ignore the I <sup>2</sup> C at certain times, it should write SLAVEN, MASTRQ, and TIRUN all to zero.     |
| All 0                  | 1     | The I <sup>2</sup> C interface is disabled. Timer I operates as a free-running time base. Use this mode only in non-I <sup>2</sup> C applications.                                                                                                                             |
| Any or all 1           | 0     | The I <sup>2</sup> C interface is enabled. The 3 low-order bits of Timer I run for min-time generation, but the hi-order bits do not, so that there is no checking for I <sup>2</sup> C being "hung." This configuration can be used for very slow I <sup>2</sup> C operation. |
| Any or all 1           | 1     | The I <sup>2</sup> C interface is enabled. Timer I runs during frames on the I <sup>2</sup> C, and is cleared by transitions on SCL, and by Start and Stop conditions. This is the normal state for I <sup>2</sup> C operation.                                                |

Values to be used in the CT1 and CT0 bits are shown in Table 5. To allow the I<sup>2</sup>C bus to run at the maximum rate for a particular oscillator frequency, compare the actual oscillator rate to the f<sub>OSC</sub> max column in the table. The value for CT1 and CT0 is found in the first line of the table where f<sub>OSC</sub> max is greater than or equal to the actual frequency.

The table also shows the osc/12 count for various settings of CT1/CT0. This allows calculation of the actual minimum high and low times for SCL as follows:

$$SCL \text{ min high/low time} = \frac{12 \cdot \text{count}}{\text{osc (in MHz)}}$$

(in microseconds)

For instance, at a 16MHz frequency, with CT1/CT0 set to 10, the minimum SCL high and low times will be 5.25µs

The table also shows the Timer I timeout period (given in machine cycles) for each CT1/CT0 combination. The timeout period varies because of the way in which minimum SCL high and low times are measured. When the I<sup>2</sup>C interface is operating, Timer I is preloaded at every SCL transition with a value dependent upon CT1/CT0. The preload value is chosen such that a minimum SCL high or low time has elapsed when Timer I reaches a count of 008 (the actual value preloaded into Timer I is 8 minus the osc/12 count).

**I<sup>2</sup>C Register I2STA**

This register is read only and reflects the internal status of the I<sup>2</sup>C hardware. IDLE, XSTR, and XSTP reflect the status of the like named bits in the I2CON register.

- XDATA The content of the transmitter buffer.
- XACTV Transmitter active.
- MAKSTR This bit is high while the hardware is effecting a start condition.
- MAKSTP This bit is high while the hardware is effecting a stop condition.
- XSTR This bit is active while the hardware is effecting a repeated start condition.
- XSTP This bit is active while the hardware is effecting a repeated stop condition.

**Interrupts**  
The interrupt structure is a five-source, one-level interrupt system. Interrupt sources

common to the 80C51 are the external interrupts (INT0, INT1) and the timer/counter interrupt (ET0). The I<sup>2</sup>C interrupt (EI2) and Timer I interrupt (ETI) are the other two interrupt sources. The interrupt sources are listed below in their order of polling sequence priority.

Upon interrupt or reset the program counter is loaded with specific values for the appropriate interrupt service routine in program memory. These values are:

| Event            | Program Memory Address | Priority |
|------------------|------------------------|----------|
| Reset            | 000                    | Highest  |
| INT0             | 003                    |          |
| Counter/Timer 0  | 00B                    |          |
| INT1             | 013                    |          |
| Timer I          | 01B                    |          |
| I <sup>2</sup> C | 023                    | Lowest   |

The interrupt enable register (IE) is used to individually enable or disable the five sources. Bit E $\bar{A}$  in the interrupt enable register can be used to globally enable or disable all interrupt sources. The interrupt enable register is described below. All other interrupt details are based on the 80C51 interrupt architecture.

**Table 5. CT1, CT0 Values**

| CT1, CT0 | OSC/12 COUNT | f <sub>osc</sub> MAX | TIMEOUT PERIOD |
|----------|--------------|----------------------|----------------|
| 10       | 7            | 16.8MHz              | 1023 cycles    |
| 01       | 6            | 14.4MHz              | 1022 cycles    |
| 00       | 5            | 12.0MHz              | 1021 cycles    |
| 11       | 4            | 9.6MHz               | 1020 cycles    |

## CMOS single-chip 8-bit microcontroller

83C751/87C751

## Interrupt Enable Register

|    |   |   |     |     |     |     |     |
|----|---|---|-----|-----|-----|-----|-----|
| EA | X | X | EI2 | ETI | EX1 | ET0 | EX0 |
|----|---|---|-----|-----|-----|-----|-----|

| Symbol | Position | Function                                                                                                                                                                          |
|--------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EA     | IE.7     | Disables all interrupts. If EA = 0, no interrupt will be acknowledged. If EA = 1, each interrupt source is individually enabled or disabled by setting or clearing its enable bit |
| –      | IE.6     | Reserved                                                                                                                                                                          |
| –      | IE.5     | Reserved                                                                                                                                                                          |
| EI2    | IE.4     | Enables or disables the I <sup>2</sup> C interrupt. If EI2 = 0, the I <sup>2</sup> C interrupt is disabled                                                                        |
| ETI    | IE.3     | Enables or disables the Timer I overflow interrupt. If ETI = 0, the Timer I interrupt is disabled.                                                                                |
| EX1    | IE.2     | Enables or disables external interrupt 1. If EX1 = 0, external interrupt 1 is disabled.                                                                                           |

## CMOS single-chip 8-bit microcontroller

## 83C751/87C751

**87C751 PROGRAMMING CONSIDERATIONS****EPROM Characteristics**

The 87C751 is programmed by using a modified Quick-Pulse Programming algorithm similar to that used for devices such as the 87C451 and 87C51. It differs from these devices in that a serial data stream is used to place the 87C751 in the programming mode.

Figure 5 shows a block diagram of the programming configuration for the 87C751. Port pin P0.2 is used as the programming voltage supply input ( $V_{PP}$  signal). Port pin P0.1 is used as the program (PGM) signal. This pin is used for the 25 programming pulses.

Port 3 is used as the address input for the byte to be programmed and accepts both the high and low components of the eleven bit address. Multiplexing of these address components is performed using the ASEL input. The user should drive the ASEL input high and then drive port 3 with the high order bits of the address. ASEL should remain high for at least 13 clock cycles. ASEL may then be driven low which latches the high order bits of the address internally. The high address should remain on port 3 for at least two clock cycles after ASEL is driven low. Port 3 may then be driven with the low byte of the address. The low address will be internally stable 13 clock cycles later. The address will remain stable provided that the low byte placed on port 3 is held stable and ASEL is kept low. **Note:** ASEL needs to be pulsed high only to change the high byte of the address.

Port 1 is used as a bidirectional data bus during programming and verify operations. During programming mode, it accepts the byte to be programmed. During verify mode, it provides the contents of the EPROM location specified by the address which has been supplied to Port 3.

The XTAL1 pin is the oscillator input and receives the master system clock. This clock should be between 1.2 and 6MHz.

The RESET pin is used to accept the serial data stream that places the 87C751 into various programming modes. This pattern consists of a 10-bit code with the LSB sent first. Each bit is synchronized to the clock input, X1.

**Programming Operation**

Figures 6 and 7 show the timing diagrams for the program/verify cycle. RESET should

initially be held high for at least two machine cycles. P0.1 (PGM) and P0.2 ( $V_{PP}$ ) will be at  $V_{OH}$  as a result of the RESET operation. At this point, these pins function as normal quasi-bidirectional I/O ports and the programming equipment may pull these lines low. However, prior to sending the 10-bit code on the RESET pin, the programming equipment should drive these pins high ( $V_{IH}$ ). The RESET pin may now be used as the serial data input for the data stream which places the 87C751 in the programming mode. Data bits are sampled during the clock high time and thus should only change during the time that the clock is low. Following transmission of the last data bit, the RESET pin should be held low.

Next the address information for the location to be programmed is placed on port 3 and ASEL is used to perform the address multiplexing, as previously described. At this time, port 1 functions as an output.

A high voltage  $V_{PP}$  level is then applied to the  $V_{PP}$  input (P0.2). (This sets Port 1 as an input port). The data to be programmed into the EPROM array is then placed on Port 1. This is followed by a series of programming pulses applied to the PGM/ pin (P0.1). These pulses are created by driving P0.1 low and then high. This pulse is repeated until a total of 25 programming pulses have occurred. At the conclusion of the last pulse, the PGM/ signal should remain high.

The  $V_{PP}$  signal may now be driven to the  $V_{OH}$  level, placing the 87C751 in the verify mode. (Port 1 is now used as an output port). After four machine cycles (48 clock periods), the contents of the addressed location in the EPROM array will appear on Port 1.

The next programming cycle may now be initiated by placing the address information at the inputs of the multiplexed buffers, driving the  $V_{PP}$  pin to the  $V_{PP}$  voltage level, providing the byte to be programmed to Port 1 and issuing the 26 programming pulses on the PGM/ pin, bringing  $V_{PP}$  back down to the  $V_C$  level and verifying the byte.

**Programming Modes**

The 87C751 has four programming features incorporated within its EPROM array. These include the USER EPROM for storage of the application's code, a 16-byte encryption key array and two security bits. Programming and verification of these four elements are selected by a combination of the serial data stream applied to the RESET pin and the voltage levels applied to port pins P0.1 and

P0.2. The various combinations are shown in Table 6.

**Encryption Key Table**

The 87C751 includes a 16-byte EPROM array that is programmable by the end user. The contents of this array can then be used to encrypt the program memory contents during a program memory verify operation. When a program memory verify operation is performed, the contents of the program memory location is XNOR'ed with one of the bytes in the 16-byte encryption table. The resulting data pattern is then provided to port 1 as the verify data. The encryption mechanism can be disable, in essence, by leaving the bytes in the encryption table in their erased state (FFH) since the XNOR product of a bit with a logical one will result in the original bit. The encryption bytes are mapped with the code memory in 16-byte groups. The first byte in code memory will be encrypted with the first byte in the encryption table; the second byte in code memory will be encrypted with the second byte in the encryption table and so forth up to and including the 16th byte. The encryption repeats in 16-byte groups; the 17th byte in the code memory will be encrypted with the first byte in the encryption table, and so forth.

**Security Bits**

Two security bits, security bit 1 and security bit 2, are provided to limit access to the USER EPROM and encryption key arrays. Security bit 1 is the program inhibit bit, and once programmed performs the following functions:

1. Additional programming of the USER EPROM is inhibited.
2. Additional programming of the encryption key is inhibited.
3. Verification of the encryption key is inhibited.
4. Verification of the USER EPROM and the security bit levels may still be performed.

(If the encryption key array is being used, this security bit should be programmed by the user to prevent unauthorized parties from reprogramming the encryption key to all logical zero bits. Such programming would provide data during a verify cycle that is the logical complement of the USER EPROM contents).

Security bit 2, the verify inhibit bit, prevents verification of both the USER EPROM array and the encryption key arrays. The security bit levels may still be verified.

## CMOS single-chip 8-bit microcontroller

83C751/87C751

### Programming and Verifying Security Bits

Security bits are programmed employing the same techniques used to program the USER EPROM and KEY arrays using serial data streams and logic levels on port pins indicated in Table 6. When programming either security bit, it is not necessary to provide address or data information to the 87C751 on ports 1 and 3.

Verification occurs in a similar manner using the RESET serial stream shown in Table 6. Port 3 is not required to be driven and the results of the verify operation will appear on ports 1.6 and 1.7.

Ports 1.7 contains the security bit 1 data and is a logical one if programmed and a logical zero if erased. Likewise, P1.6 contains the security bit 2 data and is a logical one if programmed and a logical zero if erased.

### Erasure Characteristics

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent

erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Flourless part number 2345-5 or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 6. Implementing Program/Verify Modes**

| OPERATION              | SERIAL CODE | P0.1 (PGM/)     | P0.2 (V <sub>PP</sub> ) |
|------------------------|-------------|-----------------|-------------------------|
| Program user EPROM     | 296H        | —*              | V <sub>PP</sub>         |
| Verify user EPROM      | 296H        | V <sub>IH</sub> | V <sub>IH</sub>         |

## CMOS single-chip 8-bit microcontroller

## 83C752/87C752

## CMOS single-chip 8-bit microcontroller with A/D, PWM

## DESCRIPTION

The Philips 83C752/87C752 offers many of the advantages of the 80C51 architecture in a small package and at low cost.

The 8XC752 Microcontroller is fabricated with Philips high-density CMOS technology. Philips epitaxial substrate minimizes CMOS latch-up sensitivity.

The 8XC752 contains a  $2k \times 8$  ROM (83C752) EPROM (87C752), a  $64 \times 8$  RAM, 21 I/O lines, a 16-bit auto-reload counter/timer, a fixed-priority level interrupt structure, a bidirectional inter-integrated circuit ( $I^2C$ ) serial bus interface, an on-chip oscillator, a five channel multiplexed 8-bit A/D converter, and an 8-bit PWM output.

The onboard inter-integrated circuit ( $I^2C$ ) bus interface allows the 8XC752 to operate as a master or slave device on the  $I^2C$  small area network. This capability facilitates I/O and RAM expansion, access to EEPROM, processor-to-processor communication, and efficient interface to a wide variety of dedicated  $I^2C$  peripherals.

The EPROM version of this device, the 87C752, is also available in both quartz-lid erasable and plastic one-time programmable (OTP) packages. Once the array has been programmed, it is functionally equivalent to the masked ROM 83C752. Thus, unless explicitly stated otherwise, all references made to the 83C752 apply equally to the 87C752.

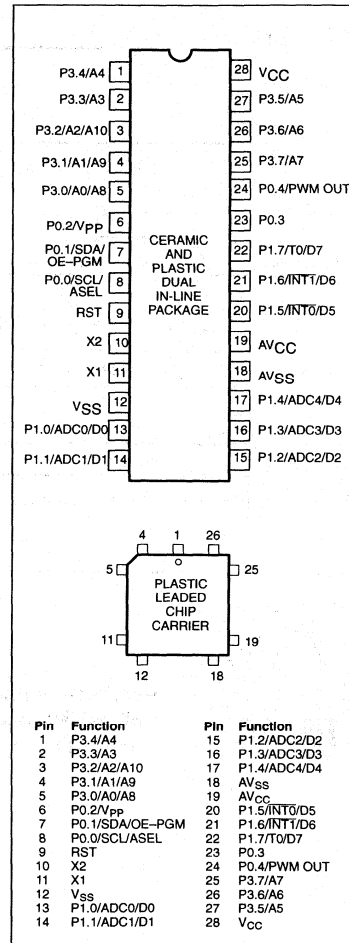

The 83C752 supports two power reduction modes of operation referred to as the idle mode and the power-down mode.

## FEATURES

- Available in erasable quartz lid or One-Time Programmable plastic packages
- 80C51 based architecture
- Inter-integrated Circuit ( $I^2C$ ) serial bus interface
- Small package sizes
  - 28-pin DIP
  - 28-pin PLCC
- Wide oscillator frequency range
- Low power consumption:
  - Normal operation: less than 11mA @ 5V, 12MHz
  - Idle mode
  - Power-down mode
- $2k \times 8$  ROM (83C752) EPROM (87C752)
- $64 \times 8$  RAM
- 16-bit auto reloadable counter/timer
- 5-channel 8-bit A/D converter
- 8-bit PWM output/timer
- Fixed-rate timer
- Boolean processor
- CMOS and TTL compatible
- Well suited for logic replacement, consumer and industrial applications

| V <sub>SS</sub>               | 12              | I    | <b>Circuit Ground Potential.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| V <sub>CC</sub>               | 28              | I    | <b>Supply voltage during normal, idle, and power-down operation.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| P0.0–P0.4                     | 8–6<br>23, 24   | I/O  | <p><b>Port 0:</b> Port 0 is a 5-bit bidirectional port. Port 0.0–P0.2 are open drain. Port 0.0–P0.2 pins that have 1s written to them float, and in that state can be used as high-impedance inputs. P0.3–P0.4 are bidirectional I/O port pins with internal pull-ups. Port 0 also serves as the serial I<sup>2</sup>C interface. When this feature is activated by software, SCL and SDA are driven low in accordance with the I<sup>2</sup>C protocol. These pins are driven low if the port register bit is written with a 0 or if the I<sup>2</sup>C subsystem presents a 0. The state of the pin can always be read from the port register by the program. Port 0.3 and 0.4 have internal pull-ups that function identically to port 3. Pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs.</p> <p>To comply with the I<sup>2</sup>C specification, P0.0 and P0.1 are open drain bidirectional I/O pins with the electrical characteristics listed in the tables that follow. While these differ from "standard TTL" characteristics, they are close enough for the pins to still be used as general-purpose I/O in non-I<sup>2</sup>C applications.</p> <p><b>V<sub>PP</sub> (P0.2)</b> – Programming voltage input.</p> <p><b>OE/PGM (P0.1)</b> – Input which specifies verify mode (output enable) or the program mode.<br/>OE/PGM = 1 output enabled (verify mode).<br/>OE/PGM = 0 program mode.</p> <p><b>ASEL (P0.0)</b> – Input which indicates which bits of the EPROM address are applied to port 3.<br/>ASEL = 0 low address byte available on port 3.<br/>ASEL = 1 high address byte available on port 3 (only the three least significant bits are used).</p> |
| P1.0–P1.7                     | 13–17,<br>20–22 | I/O  | <p><b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. P0.3–P0.4 pins are bidirectional I/O port pins with internal pull-ups. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I<sub>IL</sub>). Port 1 also serves the special function features of the SC80C51 family as listed below:</p> <p><b>INT0 (P1.5):</b> External interrupt.</p> <p><b>INT1 (P1.6):</b> External interrupt.</p> <p><b>T0 (P1.7):</b> Timer 0 external input.</p> <p><b>ADC0 (P1.0)–ADC4 (P1.4):</b> Port 1 also functions as the inputs to the five channel multiplexed A/D converter. These pins can be used as outputs only if the A/D function has been disabled. These pins can be used as inputs while the A/D converter is enabled.</p> <p>Port 1 serves to output the addressed EPROM contents in the verify mode and accepts as inputs the value to program into the selected address during the program mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| P3.0–P3.7                     | 5–1,<br>27–25   | I/O  | <p><b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I<sub>IL</sub>). Port 3 also functions as the address input for the EPROM memory location to be programmed (or verified). The 11-bit address is multiplexed into this port as specified by P0.0/ASEL.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| RST                           | 9               | I    | <p><b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running resets the device. An internal diffused resistor to V<sub>SS</sub> permits a power-on RESET using only an external capacitor to V<sub>CC</sub>. After the device is reset, a 10-bit serial sequence, sent LSB first, applied to RESET, places the device in the programming state allowing programming address, data and V<sub>PP</sub> to be applied for programming or verification purposes. The RESET serial sequence must be synchronized with the X1 input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## NOTE:

1. AV<sub>SS</sub> (reference ground) must be connected to 0V (ground). AV<sub>CC</sub> (reference input) cannot differ from V<sub>CC</sub> by more than ±0.2V, and must be in the range 4.5V to 5.5V.

## CMOS single-chip 8-bit microcontroller

## 83C752/87C752

## OSCILLATOR CHARACTERISTICS

X1 and X2 are the input and output, respectively, of an inverting amplifier which can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, X1 should be driven while X2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## IDLE MODE

The 83C752 includes the 80C51 power-down and idle mode features. In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals except the A/D and PWM stay active. The functions that continue to run while in the idle mode are Timer 0, the I<sup>2</sup>C interface including Timer 1, and the interrupts. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset. Upon powering-up the circuit, or exiting from idle mode, sufficient time must be allowed for stabilization of the internal analog reference voltages before an A/D conversion is started.

## Special Function Registers

The special function registers (directly addressable only) contain all of the 83C751 registers except the program counter and the four register banks. Most of the 21 special function registers are used to control the on-chip peripheral hardware. Other registers include arithmetic registers (ACC, B, PSW), stack pointer (SP) and data pointer registers (DPH, DPL). Nine of the SFRs are bit addressable.

## Data Pointer

The data pointer (DPTR) consists of a high byte (DPH) and a low byte (DPL). In the 80C51 this register allows the access of external data memory using the MOVX instruction. Since the 83C752 does not support MOVX or external memory accesses, this register is generally used as a 16-bit offset pointer of the accumulator in a MOVC instruction. DPTR may also be manipulated as two independent 8-bit registers.

## POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON.

**Table 1. External Pin Status During Idle and Power-Down Modes**

| MODE       | Port 0* | Port 1 | Port 2 |
|------------|---------|--------|--------|
| Idle       | Data    | Data   | Data   |
| Power-down | Data    | Data   | Data   |

\* Except for PWM output (P0.4).

## DIFFERENCES BETWEEN THE 83C752 AND THE 80C51

### Program Memory

On the 83C752, program memory is 2048 bytes long and is not externally expandable, so the 80C51 instructions MOVX, LJMP, and LCALL are not implemented. If these instructions are executed, the appropriate number of instruction cycles will take place along with external fetches; however, no operation will take place. The LJMP may not respond to all program address bits. The only fixed locations in program memory are the addresses at which execution is taken up in response to reset and interrupts, which are as follows:

| Event                   | Program Memory Address |
|-------------------------|------------------------|
| Reset                   | 000                    |
| External INT0           | 003                    |
| Counter/timer 0         | 00B                    |
| External INTT           | 013                    |
| Timer 1                 | 01B                    |
| I <sup>2</sup> C serial | 023                    |
| ADC                     | 02B                    |
| PWM                     | 033                    |

### Memory Organization

The 83C752 manipulates operands in three memory address spaces. The first is the program memory space which contains program instructions as well as constants such as look-up tables. The program memory space contains 2k bytes in the 83C752.

The second memory space is the data memory array which has a logical address space of 128 bytes. However, only the first 64 (0 to 3FH) are implemented in the 83C752.

The third memory space is the special function register array having a 128-byte address space (80H to FFH). Only selected locations in this memory space are used (see

Table 1). Note that the architecture of these memory spaces (internal program memory, internal data memory, and special function registers) is identical to the 80C51, and the 83C752 varies only in the amount of memory physically implemented.

The 83C752 does not directly address any external data or program memory spaces. For this reason, the MOVX instructions in the 80C51 instruction set are not implemented in the 83C752, nor are the alternate I/O pin functions RD and WR.

### I/O Ports

The I/O pins provided by the 83C752 consist of port 0, port 1, and port 3.

#### Port 0

Port 0 is a 5-bit bidirectional I/O port and includes alternate functions on some pins of this port. Pins P0.3 and P0.4 are provided with internal pullups while the remaining pins (P0.0, P0.1, and P0.2) have open drain output structures. The alternate functions for port 0 are:

P0.0 SCL – the I<sup>2</sup>C bus clock  
P0.1 SDA – the I<sup>2</sup>C bus data  
P0.4 PWM – the PWM output

If the alternate functions, I<sup>2</sup>C and PWM, are not being used, then these pins may be used as I/O ports.

#### Port 1

Port 1 is an 8-bit bidirectional I/O port whose structure is identical to the 80C51, but also includes alternate input functions on all pins. The alternate pin functions for port 1 are:

P1.0-P1.4 - ADC0-ADC4 - A/D converter analog inputs  
P1.5 INT0 - external interrupt 0 input  
P1.6 INT1 - external interrupt 1 input  
P1.7 - T0 - timer 0 external input

If the alternate functions INT0, INT1, or T0 are not being used, these pins may be used as standard I/O ports, provided that the A/D is disabled. It is necessary to connect AV<sub>CC</sub> and AV<sub>SS</sub> to V<sub>CC</sub> and V<sub>SS</sub>, respectively, in order to use these pins as standard I/O pins. When the A/D converter is enabled, the analog channel connected to the A/D may not be used as a digital input; however, the remaining analog inputs may be used as digital inputs. They may not be used as digital outputs. While the A/D is enabled, the analog inputs are floating.

#### Port 3

Port 3 is an 8-bit bidirectional I/O port whose structure is identical to the 80C51. Note that the alternate functions associated with port 3 of the 80C51 have been moved to port 1 of the 83C752 (as applicable). See Figure 1 for port bit configurations.

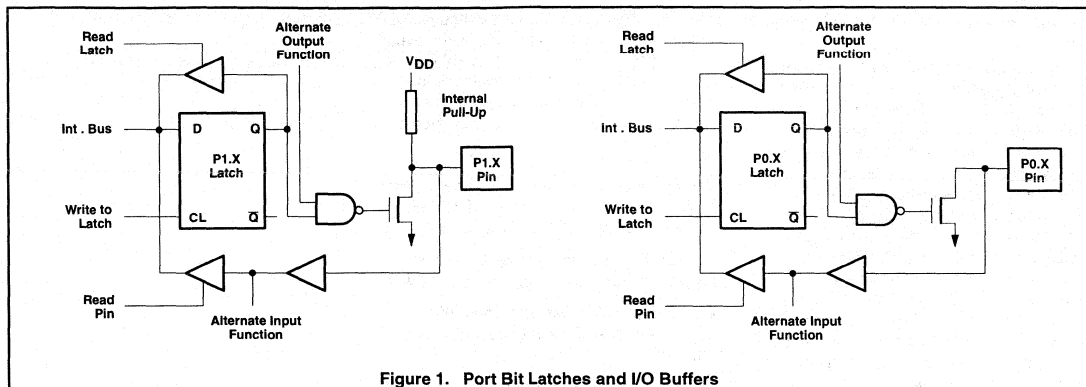

Figure 1. Port Bit Latches and I/O Buffers

### Counter/Timer Subsystem

The 8XC752 has one counter/timer called timer/counter 0. Its operation is similar to mode 2 operation on the 80C51, but is extended to 16 bits with 16 bits of autoloader. The controls for this counter are centralized in a single register called TCON.

A watchdog timer, called Timer 1, is for use with the I<sup>2</sup>C subsystem. In I<sup>2</sup>C applications, this timer is dedicated to time-generation and bus monitoring of the I<sup>2</sup>C. In non-I<sup>2</sup>C applications, it is available for use as a fixed time-base.

### Interrupt Subsystem—Fixed Priority

The IP register and the 2-level interrupt system of the 80C51 are eliminated. The interrupt structure is a seven-source, one-level interrupt system similar to the 8XC751. Simultaneous interrupt conditions are resolved by a single-level, fixed priority as follows:

- Highest priority: Pin INT0
- Counter/timer flag 0
- Pin INT1
- PWM
- Timer 1
- Serial I<sup>2</sup>C
- Lowest priority: ADC

The vector addresses are as follows:

| Source  | Vector Address |
|---------|----------------|
| INT0    | 0003H          |
| TF0     | 000BH          |
| INT1    | 0013H          |
| TIMER 1 | 001BH          |
| SIO     | 0023H          |
| ADC     | 002BH          |
| PWM     | 0033H          |

### Interrupt Control Registers

The 80C51 interrupt enable register is modified to take into account the different interrupt sources of the 8XC752.

### Interrupt Enable Register

| MSB |     |     |    |      |     |     | LSB |  |
|-----|-----|-----|----|------|-----|-----|-----|--|
| EA  | EAD | ETI | ES | EPWM | EX1 | ET0 | EX0 |  |

| Position | Symbol | Function                             |
|----------|--------|--------------------------------------|
| IE.7     | EA     | Global interrupt disable when EA = 0 |
| IE.6     | EAD    | A/D conversion complete              |
| IE.5     | ETI    | Timer 1                              |
| IE.4     | ES     | I <sup>2</sup> C serial port         |
| IE.3     | EPWM   | PWM counter overflow                 |
| IE.2     | EX1    | External interrupt 1                 |
| IE.1     | ET0    | Timer 0 overflow                     |
| IE.0     | EX0    | External interrupt 0                 |

### Serial Communications

The 8XC752 contains an I<sup>2</sup>C serial communications port instead of the 80C51 UART. The I<sup>2</sup>C serial port is a single bit hardware interface with all of the hardware necessary to support multimaster and slave operations. Also included are receiver digital filters and timer (timer 1) for communication watch-dog purposes. The I<sup>2</sup>C serial port is controlled through four special function

registers; I<sup>2</sup>C control, I<sup>2</sup>C data, I<sup>2</sup>C status, and I<sup>2</sup>C configuration.

The I<sup>2</sup>C bus uses two wires (SDA and SCL) to transfer information between devices connected to the bus. The main technical features of the bus are:

- Bidirectional data transfer between masters and slaves
- Serial addressing of slaves
- Acknowledgment after each transferred byte
- Multimaster bus
- Arbitration between simultaneously transmitting master without corruption of transfer data on bus
- With 82B715, communication distance is extended to excess of 100 feet (30M)

A large family of I<sup>2</sup>C compatible ICs is available. See the I<sup>2</sup>C section for more details on the bus and available ICs.

The 83C752 I<sup>2</sup>C subsystem includes hardware to simplify the software required to drive the I<sup>2</sup>C bus. This circuitry is the same as that on the 83C751. (See the 83C751 section for a detailed discussion of this subsystem).

---

**Pulse Width Modulation Output (P0.4)**

The PWM outputs pulses of programmable length and interval. The repetition frequency is defined by an 8-bit prescaler which generates the clock for the counter. The prescaler register is PWMP. The prescaler and counter are not associated with any other timer. The 8-bit counter counts modulo 255, that is from 0 to 254 inclusive. The value of the 8-bit counter is compared to the contents of a compare register, PWM. When the counter value matches the contents of this register, the output of the PWM is set high. When the counter reaches zero, the output of the PWM is set low. The pulse width ratio (duty cycle) is defined by the contents of the compare register and is in the range of 0 to 1 programmed in increments of 1/255. The PWM output can be set to be continuously high by loading the compare register with 0 and the output can be set to be continuously low by loading the compare register with 255. The PWM output is enabled by a bit in a special function register, PWENA. When enabled, the pin output is driven with a fully active pull-up. That is, when the output is high, a strong pull-up is continuously applied. when disabled, the pin functions as a normal bidirectional I/O pin, however, the counter remains active.

The PWM function is disabled during RESET and remains disabled after reset is removed until re-enabled by software. The PWM output is high during power down and idle. The counter is disabled during idle. The repetition frequency of the PWM is given by:

$$f_{\text{PWM}} = f_{\text{OSC}} / 2 (1 + \text{PWMP}) / 255$$

The low/high ratio of the PWM signal is PWM / (255 - PWM) for PWM not equal to 255. For PWM = 255, the output is always low.

The repetition frequency range is 92Hz to 23.5kHz for an oscillator frequency of 12MHz.

An interrupt will be asserted upon PWM counter overflow if the interrupt is not masked off.

The PWM output is an alternative function of P0.4. In order to use this port as a bidirectional I/O port, the PWM output must be disabled by clearing the enable/disable bit in PWENA. In this case, the PWM subsystem can be used as an interval timer by enabling the PWM interrupt.

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

# CMOS single-chip 8-bit microcontroller

# 83C752/87C752

## Special Function Register Addresses

Special function registers for the 8XC752 are identical to those of the 80C51, except for the changes listed below:

80C51 special function registers not present in the 8XC752 are TMOD (89), P2 (A0) and IP (B8). The 80C51 registers TH1, TL1, SCON, and SBUF are replaced with the 8XC752 registers RTH, RTL, I2CON, and I2DAT, respectively. Additional special function registers are I2CFG (D8) and I2STA (FB), ADCON (A0), ADAT (84), PWM (8E), PWMP (8F), and PWENA (FE). See Table 2.

## A/D Converter

The analog input circuitry consists of a 5-input analog multiplexer and an A to D converter with 8-bit resolution. The conversion takes 40 machine cycles, i.e., 40µs at 12MHz oscillator frequency. The A/D converter is controlled using the ADCON control register. Input channels are selected by the analog multiplexer through ADCON register bits 0–2.

The 83C752 contains a five-channel multiplexed 8-bit A/D converter. The conversion requires 40 machine cycles (40µs at 12MHz oscillator frequency).

The A/D converter is controlled by the A/D control register, ADCON. Input channels are selected by the analog multiplexer by bits ADCON.0 through ADCON.2. The ADCON register is not bit addressable.

## ADCON Register

| MSB |   |       |      |      |       |       |       | LSB |  |
|-----|---|-------|------|------|-------|-------|-------|-----|--|

| 0                       | 1     | 1     | P1.3      |
| 1                       | 0     | 0     | P1.4      |

| Position | Symbol | Function                                                                                                                                                                                                                                                                                                                                             |
|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADCON.5  | ENADC  | Enable A/D function when ENADC = 1. Reset forces ENADC = 0.                                                                                                                                                                                                                                                                                          |
| ADCON.4  | ADCI   | ADC interrupt flag. This flag is set when an ADC conversion is complete. If IE.6 = 1, an interrupt is requested when ADCI = 1. The ADCI flag is cleared when conversion data is read. This flag is read only.                                                                                                                                        |
| ADCON.3  | ADCS   | ADC start. Setting this bit starts an A/D conversion. Once set, ADCS remains high throughout the conversion cycle. On completion of the conversion, it is reset just before the ADCI interrupt flag is cleared. ADCS cannot be reset by software. ADCS should not be used to monitor the A/D converter status. ADCI should be used for this purpose. |
| ADCON.2  | AADR2  | Analog input select.                                                                                                                                                                                                                                                                                                                                 |
| ADCON.1  | AADR1  | Analog input select.                                                                                                                                                                                                                                                                                                                                 |
| ADCON.0  | AADR0  | Analog input select. This binary coded address selects one of the five analog input port pins of P1 to be input to the converter. It can only be changed when ADCI and ADCS are both low. AADR2 is the most significant bit.                                                                                                                         |

The completion of the 8-bit ADC conversion is flagged by ADCI in the ADCON register, and the result is stored in the special function register ADAT.

An ADC conversion in progress is unaffected by an ADC start. The result of a completed conversion remains unaffected provided ADCI remains at a logic 1. While ADCS is a logic 1 or ADCI is a logic 1, a new ADC START will be blocked and consequently lost. An ADC conversion in progress is aborted when the idle or power-down mode is entered. The result of a completed conversion (ADCI = logic 1) remains unaffected when entering the idle mode. See Figure 2 for an A/D input equivalent circuit.

The analog input pins ADC0-ADC4 may be used as digital inputs and outputs when the A/D converter is disabled by a 0 in the ENADC bit in ADCON. When the A/D is enabled, the analog input channel that is selected by the ADDR2-ADDR0 bits in ADCON cannot be used as a digital input. Reading the selected A/D channel as a digital input will always return a 1. The unselected A/D inputs may always be used as digital inputs. Unselected analog inputs will be floating and may not be used as digital outputs.

The A/D reference inputs on the 8XC752 are tied together with the analog supply pins AV<sub>CC</sub> and AV<sub>SS</sub>. This means that the reference voltage on the A/D cannot be varied separately from the analog supply pins. AV<sub>SS</sub> must be connected to 0V and AV<sub>CC</sub> must be connected to a supply voltage between 4.5V and 5.5V. A/D measurements may be made in the range of 4.5V to 5.5V. Increasing the voltage on the A/D ground reference above 0V or reducing the voltage on the positive A/D reference below 4.5V is not permitted.

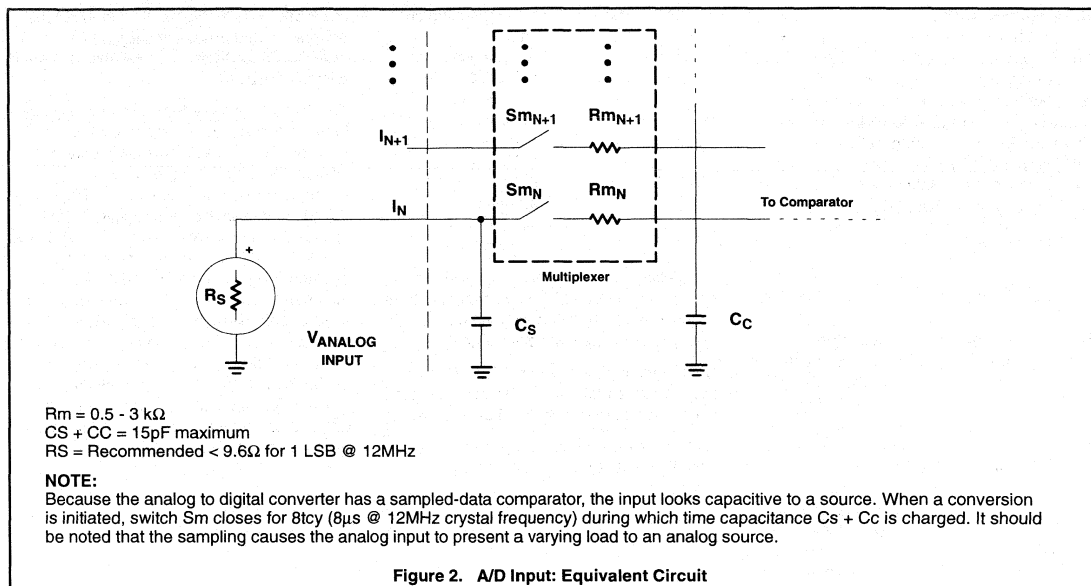

Figure 2. A/D Input: Equivalent Circuit

### A/D CONVERTER PARAMETER DEFINITIONS

The following definitions are included to clarify some specifications given and do not represent a complete set of A/D parameter definitions.

#### Absolute Accuracy Error

Absolute accuracy error of a given output is the difference between the theoretical analog input voltage to produce a given output and the actual analog input voltage required to produce the same code. Since the same output code is produced by a band of input voltages, the "required input voltage" is defined as the midpoint of the band of input voltage that will produce that code. Absolute accuracy error not specified with a code is the maximum over all codes.

#### Nonlinearity

If a straight line is drawn between the end points of the actual converter characteristics such that zero offset and full scale errors are removed, then non-linearity is the maximum deviation of the code transitions of the actual characteristics from that of the straight line so constructed. This is also referred to as relative accuracy and also integral non-linearity.

#### Differential Non-Linearity

Differential non-linearity is the maximum difference between the actual and ideal code widths of the converter. The code widths are the differences expressed in LSB between the code transition points, as the input voltage is varied through the range for the complete set of codes.

#### Gain Error

Gain error is the deviation between the ideal and actual analog input voltage required to cause the final code transition to a full-scale output code after the offset error has been removed. This may sometimes be referred to as full scale error.

#### Offset Error

Offset error is the difference between the actual input voltage that causes the first code transition and the ideal value to cause the first code transition. This ideal value is 1/2 LSB above  $V_{ref-}$ .

#### Channel to Channel Matching

Channel to channel matching is the maximum difference between the corresponding code transitions of the actual characteristics taken from different channels under the same

temperature, voltage and frequency conditions.

#### Crosstalk

Crosstalk is the measured level of a signal at the output of the converter resulting from a signal applied to one deselected channel.

#### Total Error

Maximum deviation of any step point from a line connecting the ideal first transition point to the ideal last transition point.

#### Relative Accuracy

Relative accuracy error is the deviation of the ADC's actual code transition points from the ideal code transition points on a straight line which connects the ideal first code transition point and the final code transition point, after nullifying offset error and gain error. It is generally expressed in LSBs or in percent of FSR.

CMOS single-chip 8-bit microcontroller

83C752/87C752

**COUNTER/TIMER**

The 8XC752 counter/timer is designated Timer 0 and is separate from Timer 1 of the I<sup>2</sup>C serial port and from the PWM. Its operation is similar to mode 2 of the 80C51 counter/timer, extended to 16 bits. When Timer 0 is used in the external counter mode, the T0 input (P1.7) is sampled every S4P1. The counter/timer function is controlled using the timer control register (TCON).

**TCON Register**

|      |     |    |    |     |     |     |     |     |  |  |
|------|-----|----|----|-----|-----|-----|-----|-----|--|--|

| GATE | C/T | TF | TR | IE0 | IT0 | IE1 | IT1 |     |  |  |

| Position | Symbol | Function                                                                                                    |
|----------|--------|-------------------------------------------------------------------------------------------------------------|
| TCON.7   | GATE   | 1 – Timer 0 is enabled only when INT0 pin is high and TR is 1.<br>0 – Timer 0 is enabled only when TR is 1. |
| TCON.6   | C/T    | 1 – Counter operation from T0 pin.<br>0 – Timer operation from internal clock.                              |
| TCON.5   | TF     | 1 – Set on overflow of T0.<br>0 – Cleared when processor vectors to interrupt routine and by reset.         |
| TCON.4   | TR     | 1 – Enable timer 0<br>0 – Disable timer 0                                                                   |

|        |     |                                                             |
|--------|-----|-------------------------------------------------------------|
| TCON.3 | IE0 | 1 – Edge detected on INT0                                   |
| TCON.2 | IT0 | 1 – INT0 is edge triggered.<br>0 – INT0 is level sensitive. |
| TCON.1 | IE1 | 1 – Edge detected on INT1                                   |
| TCON.0 | IT1 | 1 – INT1 is edge triggered.<br>0 – INT1 is level sensitive. |

These flags are functionally identical to the corresponding 80C51 flags except that there is only one of the 80C51 style timers, and the flags are combined into one register.

Note that the positions of the IE0/IT0 and IE1/IT1 bits are transposed from the positions used in the standard 80C51 TCON register.

A communications watchdog timer, Timer 1, is described in the I<sup>2</sup>C section. In I<sup>2</sup>C

applications, this timer is dedicated to time generation and bus monitoring for the I<sup>2</sup>C. In non-I<sup>2</sup>C applications, it is available for use as a fixed time base.

The 16-bit timer/counter's operation is similar to mode 2 operation on the 80C51, but is extended to 16 bits. The timer/counter is clocked by either 1/12 the oscillator frequency or by transitions on the T0 pin. The C/T pin in special function register TCON selects between these two modes. When the TCON TR bit is set, the timer/counter is enabled. Register pair TH and TL are incremented by the clock source. When the register pair overflows, the register pair is reloaded with the values in registers RTH and RTL. The value in the reload registers is left unchanged. The TF bit in special function register TCON is set on counter overflow and, if the interrupt is enabled, will generate an interrupt (see Figure 3).

| $C_t$                                                                  | Crosstalk                           | 0–100kHz                          |                     |                      | -60            | dB   |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
  - Maximum  $I_{OL}$  per port pin: 10mA (NOTE: This is 85°C spec.)
  - Maximum  $I_{OL}$  per 8-bit port: 26mA
  - Maximum total  $I_{OL}$  for all outputs: 67mA
 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.
- Power-down  $I_{CC}$  is measured with all output pins disconnected; port 0 =  $V_{CC}$ ; X2, X1 n.c.; RST =  $V_{SS}$ .
- $I_{CC}$  is measured with all output pins disconnected; X1 driven with  $t_{CLCH}$ ,  $t_{CHCL} = 5\text{ns}$ ,  $V_{IL} = V_{SS} + 0.5\text{V}$ ,  $V_{IH} = V_{CC} - 0.5\text{V}$ ; X2 n.c.; RST = port 0 =  $V_{CC}$ .  $I_{CC}$  will be slightly higher if a crystal oscillator is used.
- Idle  $I_{CC}$  is measured with all output pins disconnected; X1 driven with  $t_{CLCH}$ ,  $t_{CHCL} = 5\text{ns}$ ,  $V_{IL} = V_{SS} + 0.5\text{V}$ ,  $V_{IH} = V_{CC} - 0.5\text{V}$ ; X2 n.c.; port 0 =  $V_{CC}$ ; RST =  $V_{SS}$ .
- Load capacitance for ports = 80pF.
- The resistor ladder network is not disconnected in the power down or idle modes. Thus, to conserve power, the user may remove  $V_{CC}$ .
- If the A/D function is not required, or if the A/D function is only needed periodically,  $V_{CC}$  may be removed without affecting the operation of the digital circuitry. Contents of ADCON and ADAT are not guaranteed to be valid. If  $V_{CC}$  is removed, the A/D inputs must be lowered to less than 0.5V. Digital inputs on P1.0–P1.4 will not function normally.
- These parameters do not apply to P1.0–P1.4 if the A/D function is enabled.

**EXPLANATION OF THE AC SYMBOLS**

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:  
 C – Clock  
 D – Input data

H – Logic level high  
 L – Logic level low  
 Q – Output data  
 T – Time  
 V – Valid  
 X – No longer a valid logic level  
 Z – Float

Figure 5. AC Testing Input/Output

## CMOS single-chip 8-bit microcontroller

## 83C752/87C752

Figure 6.  $I_{CC}$  vs. FREQ

Maximum  $I_{CC}$  values taken at  $V_{CC} = 5.5V$  and worst case temperature.

Typical  $I_{CC}$  values taken at  $V_{CC} = 5.0V$  and  $25^{\circ}C$ .

Notes 6 and 7 refer to AC Electrical Characteristics.

## PROGRAMMING CONSIDERATIONS

### EPROM Characteristics

The 87C752 is programmed by using a modified Quick-Pulse Programming algorithm similar to that used for devices such as the 87C451 and 87C51. It differs from these devices in that a serial data stream is used to place the 87C752 in the programming mode.

Figure 7 shows a block diagram of the programming configuration for the 87C752. Port pin P0.2 is used as the programming voltage supply input ( $V_{PP}$  signal). Port pin P0.1 is used as the program (PGM) signal. This pin is used for the 25 programming pulses.

Port 3 is used as the address input for the byte to be programmed and accepts both the high and low components of the eleven bit address. Multiplexing of these address components is performed using the ASEL input. The user should drive the ASEL input high and then drive port 3 with the high order bits of the address. ASEL should remain high for at least 13 clock cycles. ASEL may then be driven low which latches the high order bits of the address internally. The high address should remain on port 3 for at least

two clock cycles after ASEL is driven low.

Port 3 may then be driven with the low byte of the address. The low address will be internally stable 13 clock cycles later. The address will remain stable provided that the low byte placed on port 3 is held stable and ASEL is kept low. **Note:** ASEL needs to be pulsed high only to change the high byte of the address.

Port 1 is used as a bidirectional data bus during programming and verify operations. During programming mode, it accepts the byte to be programmed. During verify mode, it provides the contents of the EPROM location specified by the address which has been supplied to Port 3.

The XTAL1 pin is the oscillator input and receives the master system clock. This clock should be between 1.2 and 6MHz.

The RESET pin is used to accept the serial data stream that places the 87C752 into various programming modes. This pattern consists of a 10-bit code with the LSB sent first. Each bit is synchronized to the clock input, X1.

### Programming Operation

Figures 8 and 9 show the timing diagrams for the program/verify cycle. RESET should initially be held high for at least two machine cycles. P0.1 (PGM) and P0.2 ( $V_{PP}$ ) will be at  $V_{OH}$  as a result of the RESET operation. At this point, these pins function as normal quasi-bidirectional I/O ports and the programming equipment may pull these lines low. However, prior to sending the 10-bit code on the RESET pin, the programming equipment should drive these pins high ( $V_{IH}$ ). The RESET pin may now be used as the serial data input for the data stream which places the 87C752 in the programming mode. Data bits are sampled during the clock high time and thus should only change during the time that the clock is low. Following transmission of the last data bit, the RESET pin should be held low.

Next the address information for the location to be programmed is placed on port 3 and ASEL is used to perform the address multiplexing, as previously described. At this time, port 1 functions as an output.

## CMOS single-chip 8-bit microcontroller

83C752/87C752

A high voltage  $V_{PP}$  level is then applied to the  $V_{PP}$  input (P0.2). (This sets Port 1 as an input port). The data to be programmed into the EPROM array is then placed on Port 1. This is followed by a series of programming pulses applied to the PGM/ pin (P0.1). These pulses are created by driving P0.1 low and then high. This pulse is repeated until a total of 25 programming pulses have occurred. At the conclusion of the last pulse, the PGM/ signal should remain high.

The  $V_{PP}$  signal may now be driven to the  $V_{OH}$  level, placing the 87C752 in the verify mode. (Port 1 is now used as an output port). After four machine cycles (48 clock periods), the contents of the addressed location in the EPROM array will appear on Port 1.

The next programming cycle may now be initiated by placing the address information at the inputs of the multiplexed buffers, driving the  $V_{PP}$  pin to the  $V_{PP}$  voltage level, providing the byte to be programmed to Port 1 and issuing the 26 programming pulses on the PGM/ pin, bringing  $V_{PP}$  back down to the  $V_C$  level and verifying the byte.

### Programming Modes

The 87C752 has four programming features incorporated within its EPROM array. These include the USER EPROM for storage of the application's code, a 16-byte encryption key array and two security bits. Programming and verification of these four elements are selected by a combination of the serial data stream applied to the RESET pin and the voltage levels applied to port pins P0.1 and P0.2. The various combinations are shown in Table 3.

### Encryption Key Table

The 87C752 includes a 16-byte EPROM array that is programmable by the end user. The contents of this array can then be used to encrypt the program memory contents during a program memory verify operation. When a program memory verify operation is performed, the contents of the program

memory location is XNOR'ed with one of the bytes in the 16-byte encryption table. The resulting data pattern is then provided to port 1 as the verify data. The encryption mechanism can be disabled, in essence, by leaving the bytes in the encryption table in their erased state (FFH) since the XNOR product of a bit with a logical one will result in the original bit. The encryption bytes are mapped with the code memory in 16-byte groups. The first byte in code memory will be encrypted with the first byte in the encryption table; the second byte in code memory will be encrypted with the second byte in the encryption table and so forth up to and including the 16th byte. The encryption repeats in 16-byte groups; the 17th byte in the code memory will be encrypted with the first byte in the encryption table, and so forth.

### Security Bits

Two security bits, security bit 1 and security bit 2, are provided to limit access to the USER EPROM and encryption key arrays. Security bit 1 is the program inhibit bit, and once programmed performs the following functions:

1. Additional programming of the USER EPROM is inhibited.
2. Additional programming of the encryption key is inhibited.
3. Verification of the encryption key is inhibited.
4. Verification of the USER EPROM and the security bit levels may still be performed.

(If the encryption key array is being used, this security bit should be programmed by the user to prevent unauthorized parties from reprogramming the encryption key to all logical zero bits. Such programming would provide data during a verify cycle that is the logical complement of the USER EPROM contents).

Security bit 2, the verify inhibit bit, prevents verification of both the USER EPROM array

and the encryption key arrays. The security bit levels may still be verified.

### Programming and Verifying Security Bits

Security bits are programmed employing the same techniques used to program the USER EPROM and KEY arrays using serial data streams and logic levels on port pins indicated in Table 3. When programming either security bit, it is not necessary to provide address or data information to the 87C752 on ports 1 and 3.

Verification occurs in a similar manner using the RESET serial stream shown in Table 3. Port 3 is not required to be driven and the results of the verify operation will appear on ports 1.6 and 1.7.

Ports 1.7 contains the security bit 1 data and is a logical one if programmed and a logical zero if erased. Likewise, P1.6 contains the security bit 2 data and is a logical one if programmed and a logical zero if erased.

### Erase Characteristics

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Flourless part number 2345-5 or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000uW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 3. Implementing Program/Verify Modes**

| OPERATION              | SERIAL CODE | P0.1 (PGM/) | P0.2 ( $V_{PP}$ ) |
|------------------------|-------------|-------------|-------------------|
| Program user EPROM     | 296H        | -*          | $V_{PP}$          |
| Verify user EPROM      | 296H        | $V_{IH}$    | $V_{IH}$          |
| Program key EPROM      | 292H        | -*          | $V_{PP}$          |
| Verify key EPROM       | 292H        | $V_{IH}$    | $V_{IH}$          |
| Program security bit 1 | 29AH        | -*          | $V_{PP}$          |
| Program security bit 2 | 298H        | -*          | $V_{PP}$          |
| Verify security bits   | 29AH        | $V_{IH}$    | $V_{IH}$          |

**NOTE:**

\* Pulsed from  $V_{IH}$  to  $V_{IL}$  and returned to  $V_{IH}$ .

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

## Low-voltage single-chip 8-bit microcontrollers

## 83CL781/83CL782

## GENERAL DESCRIPTION

The 83CL781 and 83CL782 are manufactured in an advanced CMOS technology. The instruction set of the 83CL781/83CL782 is based on that of the 8051. The 83CL781/83CL782 is an 8-bit general purpose microcontroller especially suited for cordless telephone applications. The device has low power consumption and a wide range of supply voltage. For emulation purposes, the 85CL782 (Piggy-back version) with 256 bytes of RAM is recommended. The 83CL781/83CL782 has two software selectable modes of reduced activity for further power reduction: Idle and Power-down. The 83CL781/83CL782 also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 46 two-byte, and 16 three-byte.

The 83CL782 is a faster version of the 83CL781 with a maximum speed of 12MHz at  $V_{DD} \geq 3.1V$ .

## FEATURES

- Full static 80C51 CPU
- 8-bit CPU, ROM, RAM, I/O in a single package
- 16K x 8 ROM, expandable externally to 64K bytes
- 256 bytes RAM, expandable externally to 64K bytes
- Four 8-bit ports, 32 I/O lines
- Three 16-bit timer/event counters
- External memory expandable up to 128K, external ROM up to 64K and/or RAM up to 64K
- On-chip oscillator suitable for RC, LC, quartz crystal or ceramic resonator
- Fifteen source, fifteen vector interrupt structure with two priority levels
- Full duplex serial UART
- I<sup>2</sup>C bus interface for serial transfer on two lines.
- Enhanced architecture with:
  - non-page oriented instructions
  - direct addressing
  - four eight-byte RAM register banks
  - stack depth limited only by available internal RAM (max. 256 bytes)
  - multiply, divide, subtract and compare instructions
- Power-down and IDLE instructions
- Wake-up via external interrupts at Port 1
- Single supply voltage of 1.8V to 6.0V
- Frequency range of DC to 12MHz
- 12MHz operation at 3.1V (8XCL782)
- Very low current consumption, typ 8mA at 12MHz/3.1V
- Operating temperature range:
  - 83CL781: -40 to +85°C
  - 83CL782: -25 to +55°C

## NOTES:

1. DIP = Dual In-line Package
2. QFP = Quad Flat Pack.

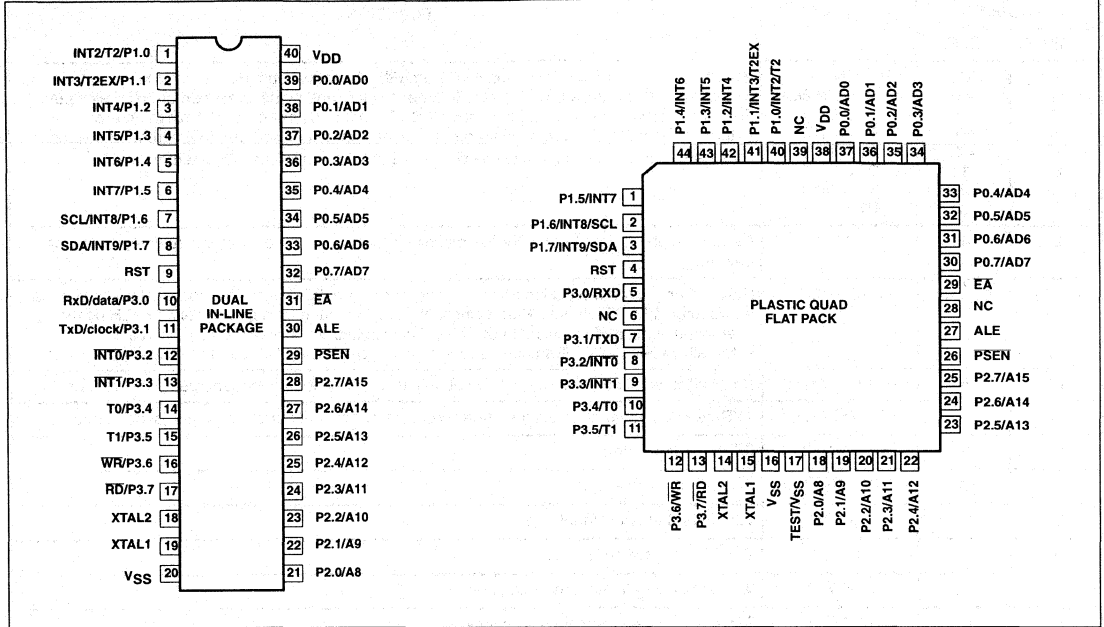

Two body sizes are available: SOT205 – 14mm x 14mm and SOT307 – 10mm x 10mm. See package dimension section for details.

3. Parts ordered by the Philips North America part number will be marked with the Philips part marking.

| 1          | 40      | P1.0/INT2/T2<br>P1.1/INT3T2EX<br>P1.2/INT4<br>P1.3/INT5<br>P1.4/INT6<br>P1.5/INT7<br>P1.6/INT8<br>P1.7/INT9 | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pullups. Port 1 pins that have 1s written to them are pulled HIGH by the internal pullups, and in that state can be used as inputs. The Port 1 output buffer can sink/source 4 LS TTL loads. As inputs, Port 1 pins that are externally pulled LOW will source current ( $I_{IL}$ in the characteristics) due to the internal pullups. Port 1 also serves the alternative functions INT2 to INT9, and Timer T2 external input. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 10–17      | 5, 7-13 | P3.0 - P3.7                                                                                                 | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. The Port 3 output buffers can sink/source 4 LS TTL inputs. Port 3 pins that have 1s written to them are pulled HIGH by the internal pull-ups, and in that state can be used as inputs; Port 3 pins that are externally pulled LOW will source current ( $I_{IL}$ in the characteristics) due to the internal pull-ups.                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 21–28      | 18-25   | P2.0 - P2.7                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled HIGH by the internal pull-ups, and in that state can be used as inputs. The Port 2 output buffer can sink/source 4 LS TTL loads.<br>Port 2 emits the high-order address byte during accesses to external memory that use 16-bit addresses (MOVX @DPTR). In this application it uses the strong internal pullups when emitting 1s. During accesses to external memory that use 8-bit addresses (MOVX @Ri). Port 2 emits the contents of the P2 Special Function Register. |
| 29         | 26      | PSEN                                                                                                        | <b>Program store enable output:</b> read strobe to external program memory. When executing code out of external program memory, PSEN is activated twice each machine cycle. However, during each access to external data memory two PSEN activations are skipped.                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 30         | 27      | ALE                                                                                                         | <b>Address Latch Enable:</b> output pulse for latching the low byte of the address during access to external memory. ALE is emitted at a constant rate of 1/6 of the oscillator frequency, and may be used for external timing or clocking purposes.                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 31         | 29      | EA                                                                                                          | <b>External Access:</b> When EA is held High the CPU executes out of internal program memory (unless the program counter exceeds 3FFFH). Holding EA LOW forces the CPU to execute out of external memory regardless of the value of the program counter.                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 32–39      | 37-30   | P0.0 - P0.7                                                                                                 | <b>Port 0:</b> Port 0 is an 8-bit open drain bidirectional I/O port. As an open drain output port it can sink 8 LS TTL loads. Port 0 pins that have 1s written to them float, and in that state will function as high impedance inputs. Port 0 is also the multiplexed low order address and data bus during access to external memory. In this application it uses strong internal pull-ups when emitting logic 1s.                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 40         | 38      | V <sub>DD</sub>                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Power supply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Low-voltage single-chip 8-bit microcontrollers

83CL781/83CL782

**BLOCK DIAGRAM**

## Low-voltage single-chip 8-bit microcontrollers

## 83CL781/83CL782

### 12.0 FUNCTIONAL DESCRIPTION

#### General

The 83CL781/83CL782 is a stand-alone high-performance CMOS microcontroller designed for use in real-time applications such as instrumentation, industrial control, intelligent computer peripherals and consumer products.

The device provides hardware features, architectural enhancements and new instructions to function as a controller for applications requiring up to 64K bytes of program memory and/or up to 64K bytes of data storage.

The 83CL781/83CL782 contains a non-volatile 16K byte x 8 read-only program memory; a static 256 byte x 8 read/write data memory; 32 I/O lines; three 16-bit timer/event counters; a fifteen-source two priority-level, nested interrupt structure and on-chip oscillator and timing circuit.

The device has two software selectable modes of reduced activity for power reduction; IDLE and Power-down. The Idle mode freezes the CPU while allowing the RAM, timers, serial I/O and interrupt system to continue functioning. The Power-down mode saves the RAM contents but freezes the oscillator causing all other chip functions to be inoperative.

In addition, the device provides an I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions, which allows communication

with the whole family of I<sup>2</sup>C-bus compatible ICs and a standard UART serial interface.

#### CPU timing

A machine cycle consists of a sequence of 6 states. Each state time lasts for two oscillator periods, thus a machine cycle takes 12 oscillator periods or 1 $\mu$ s if the oscillator frequency is 12MHz.

#### 12.1 Memory organization

The 83CL781/83CL782 has a 16K Program Memory (ROM) plus 256 bytes of Data Memory (RAM) on board. The device has separate address spaces for Program and Data Memory (see Figure 1). Using Ports P0 and P2, the 83CL781/83CL782 can address up to 64K bytes of external memory. The CPU generates both read and write signals (RD and WR) for external Data Memory accesses, and the read strobe (PSEN) for external Program Memory.

##### 12.1.1 Program Memory

The 83CL781/83CL782 contains 16K bytes of internal ROM. After reset the CPU begins execution at location 0000H. The lower 16K bytes of Program Memory can be implemented in either on-chip ROM or external Memory. If the EA pin is strapped to V<sub>DD</sub>, then program memory fetches from addresses 000H through 3FFFH are directed to the internal ROM. Fetches from addresses 4000H through FFFFH are directed to external ROM. Program counter values greater than 3FFFH are automatically addressed to external memory regardless of the state of the EA pin.

##### 12.1.2 Data Memory

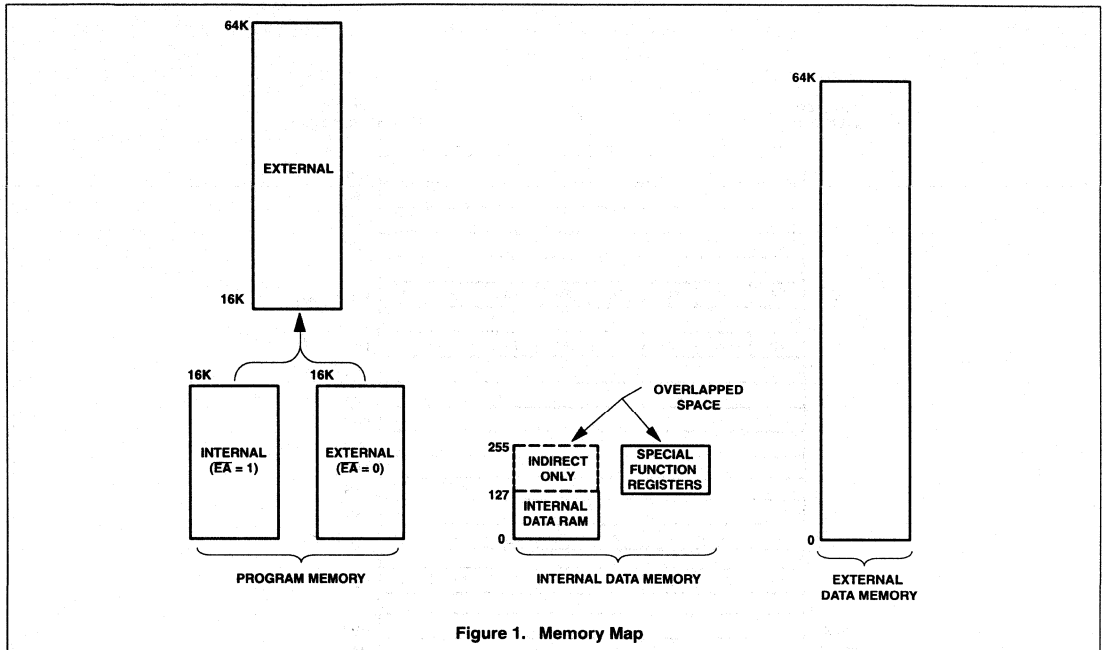

The 83CL781/83CL782 contains 256 bytes of internal RAM and 34 Special Function Registers (SFR). Figure 1 shows the internal Data Memory space divided into the Lower 128, the Upper 128, and the SFR space. Internal RAM locations 0-127 are directly and indirectly addressable. Internal RAM locations 128-255 are only indirectly addressable. The special function register locations 128-255 are only directly addressable.

##### 12.1.3 Special Function Registers

The upper 128 bytes are the address locations of the SFRs. Figure 3 shows the Special Function Register (SFR) space. SFRs include the port latches, timers, peripheral control, serial I/O registers, etc. These registers can only be accessed by direct addressing. There are 128 bit addressable locations in the SFR address space (SFRs with addresses divisible by eight).

## 12.1.4 Addressing

The 83CL781/83CL782 has five methods for addressing source operands:

- Register
- Direct
- Register-Indirect
- Immediate
- Base-Register-plus Index-Register-indirect

The first three methods can be used for addressing destination operands. Most instructions have a "destination/source" field that specifies data type, addressing methods and operands involved. For operations other than MOVs, the destination operand is also a source operand.

Access to memory addressing is as follows:

- Registers in one of the four register banks through register, direct or indirect.
- Internal RAM (256 bytes) through direct or register-indirect.
- Special Function Register through Direct.
- External data memory through Register-Indirect
- Program memory look-up tables through Base-Register-plus index-Register-indirect.

## 12.2 I/O facilities

### 12.2.1 Ports

The 83CL781/83CL782 has 32 I/O lines treated as 32 individually addressable bits or as four parallel 8-bit addressable ports. Port

0, 1, 2 and 3 perform the following alternate functions:

- Port 0: provides the multiplexed low-order address and data bus for expanding the device with standard memories and peripherals.
- Port 1:
  - (1) provides the inputs for the external interrupts INT2 / INT9;
  - (2) External counter/capture of Timer 2;
  - (3) I<sup>2</sup>C-bus
- Port 2: provides the high-order address when expanding the device with external program or data memory.
- Port 3: pins can be configured individually to provide:
  - (1) external interrupt request inputs;
  - (2) counter input;
  - (3) control signals to read and write to external memories; and
  - (4) UART input and output.

To enable a Port 3 pin alternate function, the Port 3 bit latch in its SFR must contain a logic 1.

Each port consists of a latch (Special Function Registers P0 to P3), an output driver and an input buffer. Ports 1,2,3 have internal pull-ups. Figure 4(a) shows that the strong transistor p1 is turned on for only 2 oscillator periods after a 0-to-1 transition in the port latch. When on, it turns on p3 (a weak pull-up) through the inverter. This inverter and p3 form a latch which hold the 1. In Port 0 the pull-up p1 is only on when emitting 1s for external memory access.

Writing a 1 to a Port 0 bit latch leaves both output transistors switched off so the pin can be used as a high-impedance input.

### 12.2.2 Port Options

Thirty of the 32 parallel port pins (excluding P1.6 and P1.7 with option '2S' only) may be individually configured with one of the following options (see Figure 4):

#### Option 1: Standard Port

Quasi-bidirectional I/O with pull-up. The strong booster pull-up p1 is turned on for two oscillator periods after a 0-to-1 transition in the port latch (see Figure 4(a)).

#### Option 2: Open drain

Quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull-up resistor (see Figure 4(c)).

#### Option 3: Push-Pull

Output with drive capability in both polarities. Under this option, pins can only be used as outputs (see Figure 4(b)).

The definition of port options for port 0 is slightly different. Two cases have to be examined. First, accesses to external memory (EA = 0 or access above the built-in memory boundary), second, I/O accesses.

Individual mask selection of the post-reset state is available on any of the above pins. Make your selection by appending "S" or "R" to option 1, 2, or 3 above.

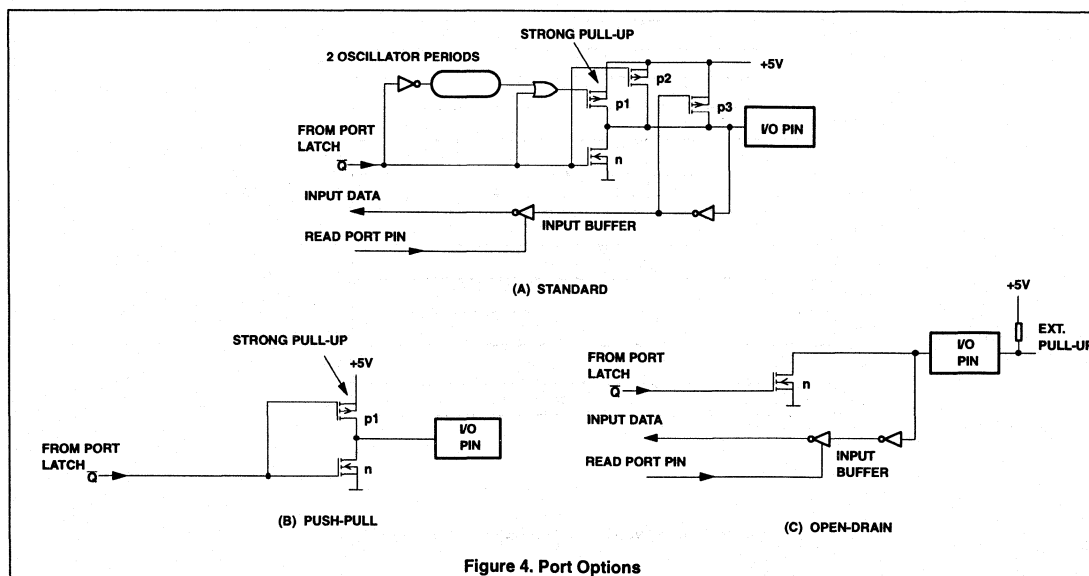

Figure 4. Port Options

Low-voltage single-chip 8-bit microcontrollers

83CL781/83CL782

**External Memory Accesses**

**Option 1:**  
True 0 and 1 are written as address to the external memory (strong pull-up is used).

**Option 2:**  
An external pull-up resistor is needed for external accesses.

**Option 3:**  
Not allowed for external memory accesses as the port can only be used as output.

**I/O Accesses**

**Option 1:**  
When writing a 1 to the port-latch, the strong pull-up p1 will be on for two oscillator periods. No weak pull-up exists. Without an external pull-up, this option can be used as a high-impedance input.

**Option 2:**  
Open drain; quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull-up resistor (see Figure 4(c)).

**Option 3:**  
Push-Pull; output with drive capability in both polarities. Under this option, pins can only be used as outputs.

Individual mask selection of the post-reset state is available on any of the above pins. Make your selection by appending "S" or "R" to option 1, 2, or 3 above.

**Option S:** SET;  
after reset this pin will be initialized HIGH.

**Option R:** RESET;  
after reset this pin will be initialized LOW.

**12.3 Timer/event counter**

The 83CL781/82CL782 contains three 16-bit Timer/Counter registers; Timer 0, Timer 1, and Timer 2 which can perform the following functions:

- Measure time intervals and pulse durations
- Count events
- Generate interrupts requests

Timer 0 and Timer 1 can be independently programmed to operate as follows:

- **Mode 0:**  
8-bit timer or counter with divide-by-32 prescaler
- **Mode 1:**  
16-bit time-interval or event counter
- **Mode 2:**  
8-bit time interval or event counter with automatic reload upon overflow
- **Mode 3:**  
Timer 0 establishes TL0 and TH0 as two separate counters.

In the "Timer" function, the register is incremented every machine cycle. Since a machine cycle consists of 12 oscillator periods, the count rate is 1/12 of the oscillator frequency.

In the "Counter" function, the register is incremented in response to a 1-to-0 transition. Since it takes two machine cycles (24 oscillator periods) to recognize a 1-to-0 transition, the maximum count rate is 1/24 of the oscillator frequency. To ensure a given level is sampled, it should be held for at least one full machine cycle.

**12.3.1 Timer 2**

Timer 2 is a 16-bit Timer/Counter. Like Timers 0 and 1, it can operate either as a timer or as an event counter. This is selected by bit C/T2 in the Special Function Register T2CON (Figure 5). It has three operating modes: "capture", "auto-load" and "baud rate generator", which are selected by bits in T2CON as shown in Table 1.

**Table 1. Timer 2 Operating Modes**

| RTCLK | CP/RL2 | TR2 | MODE                |
|-------|--------|-----|---------------------|
| 0     | 0      | 1   | 16-Bit Auto-reload  |
| 0     | 1      | 1   | 16-Bit Capture      |
| 1     | x      | 1   | Baud Rate Generator |
| x     | x      | 0   | (Off)               |

| (MSB)         |                 |     |                                                                                                                                                                                                                                                                                                                      | (LSB) |     |      |        |
|---------------|-----------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----|------|--------|
| TF2           | EXF2            | GF2 | RTCLK                                                                                                                                                                                                                                                                                                                | EXEN2 | TR2 | C/T2 | CP/RL2 |
| <b>Symbol</b> | <b>Position</b> |     | <b>Name and Significance</b>                                                                                                                                                                                                                                                                                         |       |     |      |        |
| TF2           | T2CON.7         |     | Timer 2 overflow flag set by a Timer 2 overflow and must be cleared by software. TF2 will not be set when RTCLK = 1.                                                                                                                                                                                                 |       |     |      |        |
| EXF2          | T2CON.6         |     | Timer 2 external flag set when either a capture or reload is caused by a negative transition of T2EX and EXEN2 = 1. When Timer 2 interrupt is enabled, EXF2 = 1 will cause the CPU to vector to the Timer 2 interrupt routine. EXF2 must be cleared by software.                                                     |       |     |      |        |
| GF2           | T2CON.5         |     | General purpose flag bit.                                                                                                                                                                                                                                                                                            |       |     |      |        |
| RTCLK         | T2CON.4         |     | Transmit clock flag. When set, causes the UART serial port to use Timer 2 overflow pulses for its receive and transmit clock in modes 1 and 3. TLCK = 0 causes Timer 1 overflows to be used for the receive and transmit clock.                                                                                      |       |     |      |        |
| EXEN2         | T2CON.3         |     | Timer 2 external enable flag. When set, allows a capture or reload to occur as a result of a negative transition on T2EX if Timer 2 is not being used to clock the UART serial port. EXEN2 = 0 causes Timer 2 to ignore events at T2EX.                                                                              |       |     |      |        |
| TR2           | T2CON.2         |     | Start/stop control for Timer 2. A logic 1 starts the timer.                                                                                                                                                                                                                                                          |       |     |      |        |
| C/T2          | T2CON.1         |     | Timer or counter select. (Timer 2)<br>0 = Internal timer (OSC/12)<br>1 = External event counter (falling edge triggered)                                                                                                                                                                                             |       |     |      |        |
| CP/RL2        | T2CON.0         |     | Capture/Reload flag. When set, captures will occur on negative transitions at T2EX if EXEN2 = 1. When cleaned, auto-reloads will occur either with Timer 2 overflows or negative transitions at T2EX when EXEN2 = 1. When RTCLK = 1, this bit is ignored and the timer is forced to auto-reload on Timer 2 overflow. |       |     |      |        |

# Low-voltage single-chip 8-bit microcontrollers

# 83CL781/83CL782

In the Capture Mode there are two options which are selected by bit EXEN2 in T2CON. If EXEN2=0, then Timer 2 is a 16-bit timer or counter which upon overflowing sets bit TF2, the Timer 2 overflow bit, which can be used to generate an interrupt. If EXEN2=1, then Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX causes the current value in the Timer 2 registers, TL2 and TH2, to be captured into registers RCAP2L and RCAP2H, respectively. In addition, the transition at T2EX causes bit EXF2 in T2CON to be set, and EXF2, like TF2, can generate an interrupt. The Capture Mode is illustrated in Figure 6.

In the auto-reload mode there are again two options, which are selected by bit EXEN2 in T2CON. If EXEN2=0, then when Timer 2 rolls

over, it not only sets TF2, but also causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2L and RCAP2H, which are preset by software. If EXEN2=1, the Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX will also trigger the 16-bit reload and set EXF2.

The auto-reload mode is illustrated in Figure 7.

The baud rate generator mode is selected by RTCLK=1. It will be described in conjunction with the UART serial port.

A conversion already in progress is aborted when the Power-down mode is entered. The result of a completed conversion (ADCI = logic 1) remains unaffected when entering the Idle mode.

## 12.4 Idle and Power-down Operation

Idle mode operation permits the interrupt, serial ports, timer blocks to continue functioning while the clock to the CPU is halted.

The following functions remain active during Idle mode. These functions may generate an interrupt or reset and thus end the Idle mode.

- Timer 0, Timer 1, Timer 2
- SIO, I<sup>2</sup>C
- External interrupt

The Power-down operation freezes the oscillator. The Power-down mode can only be activated by setting the PD bit in the PCON register.

## Low-voltage single-chip 8-bit microcontrollers

## 83CL781/83CL782

**12.4.1 Power control register (PCON)**

These special modes are activated by software via the Special Function Register PCON. Its hardware address is 87H. (PCON is not bit-addressable.)

|      |   |   |   |     |     |    |     |
|------|---|---|---|-----|-----|----|-----|

| SMOD | - | - | - | GF1 | GF0 | PD | IDL |
| MSB  |   |   |   | LSB |     |    |     |

| BIT    | SYMBOL | FUNCTION                                                                                                                       |
|--------|--------|--------------------------------------------------------------------------------------------------------------------------------|
| PCON.7 | SMOD   | Double Baud rate bit. When set to logic 1 the baud rate is doubled when the UART serial port SIO0 is being used in 1, 2, or 3. |
| PCON.6 | -      | (reserved)                                                                                                                     |
| PCON.5 | -      | (reserved)                                                                                                                     |
| PCON.4 | -      | (reserved)                                                                                                                     |
| PCON.3 | GF1    | General-purpose flag bit                                                                                                       |
| PCON.2 | GF0    | General-purpose flag bit                                                                                                       |
| PCON.1 | PD     | Power-down bit. Setting this bit activates Power-down mode.                                                                    |
| PCON.0 | IDL    | Idle mode bit. Setting this bit activates the Idle mode.                                                                       |

If logic 1s are written to PD and IDL at the same time, PD takes precedence. The reset value of PCON is (0XX00000).

**12.4.2 Power-down mode**

The instruction setting PCON.1 is the last executed prior to going into the Power-down mode. In Power-down mode the oscillator is stopped. The contents of the on-chip RAM

and SFRs are preserved. The port pins output the values held by their respective SFRs. ALE and PSEN are held LOW.

**12.4.3 Wake-up mode**

Setting the PD flag in the PCON register forces the controller into the Power-down mode. Setting this flag enables the controller to be awakened from the Power-down mode with either the external interrupts INT2/INT9, or a reset operation.

The wake-up operation after power-down in this controller has two basic approaches:

**12.4.3.1 Wake-up using INT2 to INT9**

If INT2 to INT9 are enabled, the 83CL781/83CL782 can be awakened from power-down mode with the external interrupts. To ensure that the oscillator is stable before the controller restarts, the internal clock will remain inactive for 1536 oscillator periods. This is controlled by an on-chip delay counter.

**12.4.3.2 Wake-up using RESET**

To wake-up the 83CL781/83CL782 the RESET pin has to be kept HIGH for a minimum of 24 periods. The on-chip delay counter is inactive. The user has to ensure that the oscillator is stable before any operation is attempted. Figure 8 illustrates the two possibilities for wake-up.

**12.4.4 Idle mode**

The instruction that sets PCON.0 is the last instruction executed in the normal operating mode before Idle mode is activated. Once in the Idle mode, the CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator, RAM and all other registers maintain their data during Idle mode. The status of the external pins during Idle mode is shown in Table 2.

There are two methods used to terminate the Idle mode. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, terminating Idle mode. The interrupt is serviced, and following the return-from-interrupt instruction RETI, the next instruction to be executed will be the one which follows the instruction that wrote a logic 1 to PCON.0.

Flag bits GF0 and GF1 may be used to determine whether the interrupt was received during normal execution or during Idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When Idle mode is terminated by an interrupt, the service routine can examine the status of the flag bits.

The second method of terminating the Idle mode is with an external hardware reset, or an internal reset caused by an overflow of Timer T3. Since the oscillator is still running, the hardware reset is required to be active for two machine cycles (24 oscillator periods) to complete the reset operation.

Reset redefines all SFRs, but does not affect the on-chip RAM.

In the Power-down mode,  $V_{DD}$  may be reduced to minimize power consumption. However, the supply voltage must not be reduced until Power-down mode is active, and must be held active until the oscillator has restarted and stabilized.

The status of the external pins during Idle and Power-down mode is shown in Table 2. If the Power-down mode is activated whilst accessing external memory, port data held in the Special Function Register P2 is restored to Port 2. If the data is a logic 1, the port pin is held HIGH during the Power-down mode by the strong pull-up transistor p1 (see Figure 4(a)).

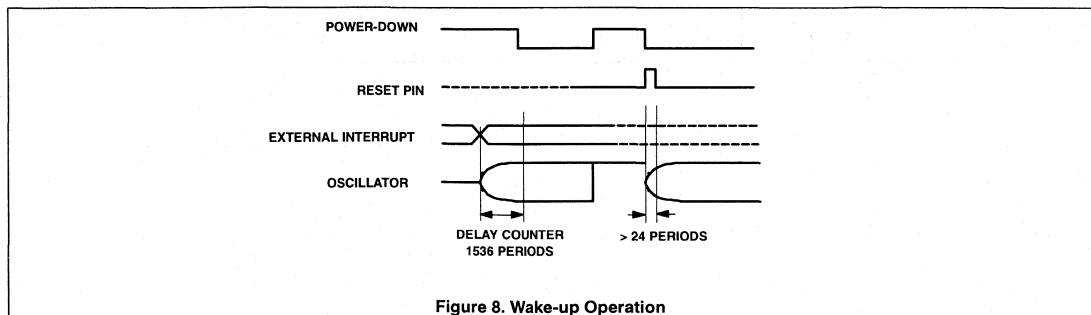

Figure 8. Wake-up Operation

Low-voltage single-chip 8-bit microcontrollers

83CL781/83CL782

**Table 2. Status of the External Pins during Idle and Power-down Modes**

| MODE       | MEMORY   | ALE | PSEN | PORT 0    | PORT 1    | PORT 2    | PORT 3    |
|------------|----------|-----|------|-----------|-----------|-----------|-----------|
| Idle (1)   | Internal | 1   | 1    | Port data | Port data | Port data | Port data |
| Idle (1)   | External | 1   | 1    | Floating  | Port data | Address   | Port data |
| Power-down | Internal | 0   | 0    | Port data | Port data | Port data | Port data |
| Power-down | External | 0   | 0    | Floating  | Port data | Port data | Port data |

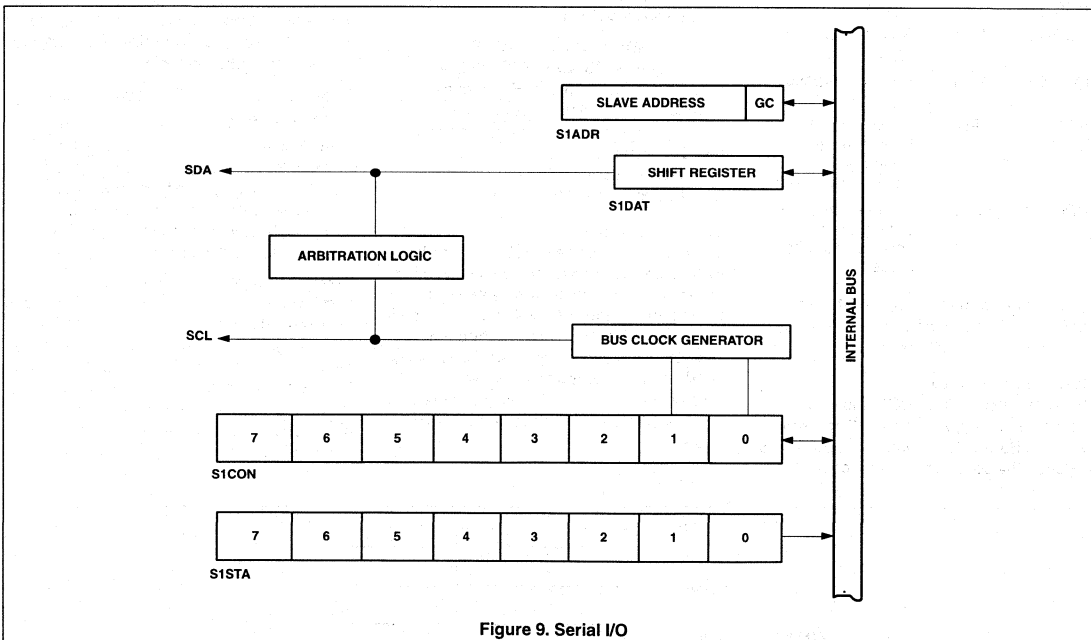

**12.5 I<sup>2</sup>C Bus Serial I/O**

The serial port supports the twin line I<sup>2</sup>C-bus. The I<sup>2</sup>C bus consists of a data line (SDA) and a clock line (SCL). These lines also function as I/O port lines P1.7 and P1.6 respectively. The system is unique because data transport, clock generation, address recognition and bus control arbitration are all

controlled by hardware. The I<sup>2</sup>C bus serial I/O has complete autonomy in byte handling and operates in four modes:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

These functions are controlled by the S1CON register. S1STA is the status register whose contents may also be used as a vector to various service routines. S1DAT is the data shift register and S1ADR the slave address register. Slave address recognition is performed by hardware.

**Figure 9. Serial I/O**

|-----|------|-----|-----|----|----|-----|-----|
|-----|------|-----|-----|----|----|-----|-----|

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CR0, CR1, CR2</b> | These three bits determine the serial clock frequency when SIO is in a master mode. See Table 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AA</b>            | Assert Acknowledge bit. When the AA flag is set, an acknowledge (low level SDA) will be returned during the acknowledge clock pulse on the SCL line when: <ul style="list-style-type: none"> <li>• own slave address is received</li> <li>• general call address is received (S1ADR.0=1)</li> <li>• data byte received while device is programmed as master</li> <li>• data byte received while device is a selected slave</li> </ul> With AA=0, no acknowledge will be returned. Consequently, no interrupt is requested when the "own slave address" or general call address is received. |
| <b>SI</b>            | SIO interrupt flag. When the SI flag is set, an acknowledge is returned after any one of the following conditions: <ul style="list-style-type: none"> <li>• a start condition is generated in master mode</li> <li>• own slave address received during AA=1</li> <li>• general call address received while S1ADR.0 and AA=1</li> <li>• data byte received or transmitted in master mode (even if arbitration is lost)</li> <li>• data byte received or transmitted as selected slave</li> <li>• stop or start condition received as selected slave receiver or transmitter</li> </ul>       |
| <b>STO</b>           | STOP flag. With this bit set while in master mode a STOP condition is generated. When a STOP condition is detected on the bus, the SIO hardware clears the STO flag. In the slave mode, the STO flag may also be set to recover from an error condition. In this case, no STOP condition is transmitted to the I <sup>2</sup> C bus. However, the SIO hardware behaves as if a STOP condition has been received and releases SDA and SCL. The SIO then switches to the "not addressed" receiver mode. The STO flag is automatically cleared by hardware.                                    |
| <b>STA</b>           | START flag. When the STA bit is set in slave mode, the SIO hardware checks the status of the I <sup>2</sup> C bus and generates a START condition if the bus is free. If STA is set while the SIO is in master mode, SIO transmits a repeated START condition.                                                                                                                                                                                                                                                                                                                              |
| <b>ENS1</b>          | When ENS1=0, the SIO is disabled. The SDA and SCL outputs are in a high-impedance state; P1.6 and P1.7 function as open drain ports. When ENS1=1, the SIO is enabled. The P1.6 and P1.7 port latches must be set to logic 1.                                                                                                                                                                                                                                                                                                                                                                |

# Low-voltage single-chip 8-bit microcontrollers

# 83CL781/83CL782

### Status Register S1STA (D9H)

|     |     |     |     |     |   |   |   |
|-----|-----|-----|-----|-----|---|---|---|
| SC4 | SC3 | SC2 | SC1 | SC0 | 0 | 0 | 0 |
|-----|-----|-----|-----|-----|---|---|---|

S1STA is an 8-bit read-only special function register. S1STA.3-S1STA.7 hold a status code. S1STA.0-S1STA.2 are held LOW. The contents of S1STA may be used as a vector to a service routine. This optimizes response time of the software and consequently that of the I<sup>2</sup>C bus.

The following is a list of the status code:

#### Abbreviations used:

- SLA: 7-bit slave address
- R: Read bit
- W: Write bit
- ACK: Acknowledgement (acknowledge bit = 0)
- ACKNOT: Not Acknowledge (acknowledge bit = 1)
- DATA: 8-bit byte to or from the I<sup>2</sup>C bus
- MST: Master
- SLV: Slave
- TRX: Transmitter
- REC: Receiver

#### MST/TRX Mode

|             |                                                     |
|-------------|-----------------------------------------------------|
| S1STA Value |                                                     |
| 08H         | A START condition has been transmitted              |
| 10H         | A repeated START condition has been transmitted     |
| 18H         | SLA and W have been transmitted, ACKNOT received    |
| 28H         | DATA of S1DAT has been transmitted, ACK received    |
| 30H         | DATA of S1DAT has been transmitted, ACKNOT received |
| 38H         | Arbitration lost in SLA, R/W or DATA                |

#### MST/REC Mode

|             |                                                  |
|-------------|--------------------------------------------------|
| S1STA Value |                                                  |
| 38H         | Arbitration lost while returning ACKNOT          |
| 40H         | SLA and R have been transmitted, ACK received    |
| 48H         | SLA and R have been transmitted, ACKNOT received |
| 50H         | DATA has been received, ACK returned             |
| 58H         | DATA has been received, ACKNOT returned          |

#### SLV/REC Mode

|             |                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------|
| S1STA Value |                                                                                                             |
| 60H         | Own SLA and W have been received, ACK returned                                                              |
| 68H         | Arbitration lost in SLA, RW as MST. Own SLA and W have been received, ACK returned.                         |
| 70H         | General Call has been received, ACK returned                                                                |
| 78H         | Arbitration lost in SLA, RW as MST. General Call has been received.                                         |

### Data Shift Register S1DAT (DAH)

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

This register contains the serial data to be transmitted or data that has just been received. Bit 7 is transmitted or received first; i.e., data is shifted from left to right.

### Own Address Register S1ADR (DBH)

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

This 8-bit register may be loaded with the 7-bit address to which the controller will respond when programmed as a slave receiver/transmitter. The LSB bit (GC) is used to determine whether the general CALL address is recognized.

- S1ADR.0, GC: 0 = general CALL address is not recognized.
- 1 = general CALL is recognized.
- S1ADR.7 - 1: own slave address

Low-voltage single-chip 8-bit microcontrollers

83CL781/83CL782

**12.6 Standard Serial Interface SIO0: UART**

This serial port is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the register. (However, if the first byte still hasn't been read by the time reception of the second byte is complete, one of the bytes will be lost). The serial port receive and transmit registers are both accessed at Special Function Register S0BUF. Writing to S0BUF loads the transmit register, and reading S0BUF loads the transmit register, and reading S0BUF accesses a physically separate receive register.

The serial port can operate in 4 modes:

**Mode 0:** Serial data enters and exits through RxD. TxD outputs the shift clock. 8 bits are transmitted/received (LSB first). The baud is fixed at 1/12 the oscillator frequency.

**Mode 1:** 10 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in Special Function Register SC0N. The baud rate is variable.

**Mode 2:** 11 bits are transmitted (through TxD) or received (through RxD): start bit (0), 8 data bits (LSB first), a programmable 9th

data bit, and a stop bit (1). On Transmit, the 9th data bit (TB8 in SC0N) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in Special Function Register SC0N, while the stop bit is ignored. The baud rate is programmable to either 1/32 or 1/64 the oscillator frequency.

**Mode 3:** 11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is variable.

In all four modes, transmission is initiated by any instruction that uses S0BUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

**12.6.1 Multiprocessor Communications**

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SC0N. A

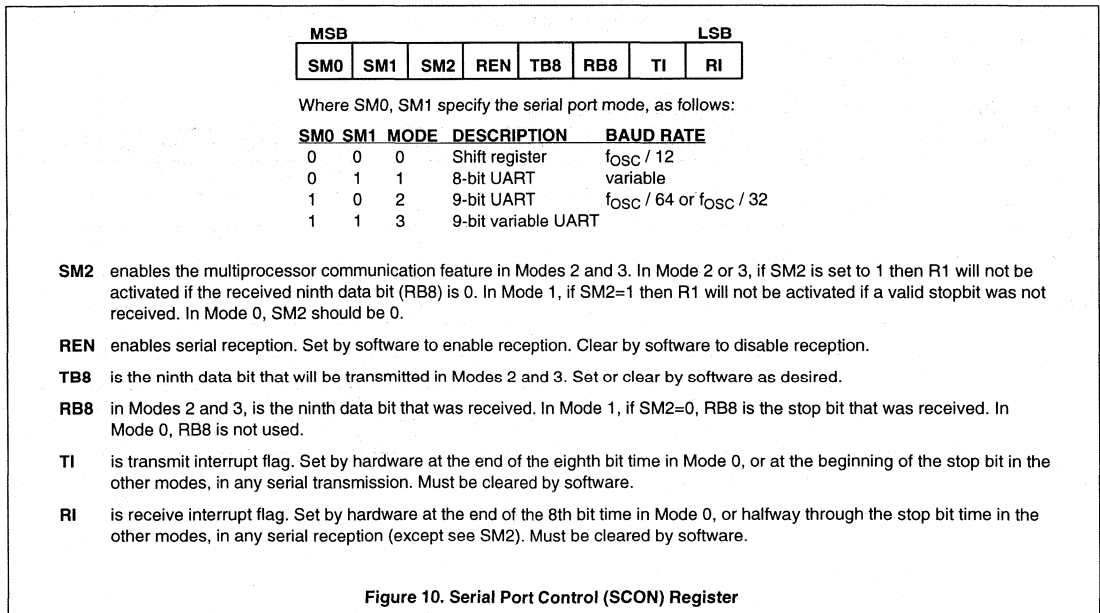

way to use this feature in multiprocessor systems is as follows:

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that weren't being addressed leave their SM2s set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. In a Mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

**12.6.2 Serial port control register**

The serial port control and status register is the Special Function Register S0CON, shown in Figure 10. The register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (TI and RI).

## Low-voltage single-chip 8-bit microcontrollers

## 83CL781/83CL782

**Baud Rates**

The baud rate in Mode 0 is fixed: Mode 0 Baud Rate = Oscillator Frequency / 12. The baud rate in Mode 2 depends on the value of bit SMOD in Special Function Register PCON. If SMOD = 0 (which is the value on reset), the baud rate is 1/64 the oscillator frequency. If SMOD = 1, the baud rate is 1/32 the oscillator frequency.

Mode 2 Baud Rate =  $(2^{\text{SMOD}} / 64) \times (\text{Oscillator Frequency})$

The baud rates in Modes 1 and 3 are determined by the Timer 1 or Timer 2 overflow rate.

**Using Timer 1 to Generate Baud Rates**

When Timer 1 is used as the baud rate generator, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate and the value of SMOD as follows:

Modes 1,3 Baud Rate =  $(2^{\text{SMOD}} / 32) \times (\text{Timer 1 Overflow Rate})$

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either "timer" or "counter" operation, and in any of its 3 running modes. In most typical applications, it is configured for "timer" operation, in the auto-reload mode (high nibble of TMOD = 0010B). In that case the baud rate is given by the formula:

Mode 1, 3 Baud Rate =  $\{(2^{\text{SMOD}} / 32) \times (\text{Oscillator Frequency})\} / \{12 \times (256 - (\text{TH1}))\}$

One can achieve very low baud rates with Timer 1 by leaving the Timer 1 interrupt

enabled, and configuring the Timer to run as a 16-bit timer (high nibble of TMOD = 0001B), and using the Timer 1 interrupt to do a 16-bit software reload. Table 4 lists various commonly used baud rates and how they can be obtained from Timer 1.

**Using Timer 2 to Generate Baud Rates**

Timer 2 is selected as the baud rate generator by setting RTCLK in T2CON (Figure 11). Setting RTCLK puts Timer 2 into its baud rate generator mode, as shown in Figure 11.

The baud rate generator mode is similar to the auto-reload mode, in that a rollover in TH2 causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2H and RCAP2L, which are preset by software.

Now, the baud rates in Modes 1 and 3 are determined by Timer 2's overflow rate as follows:

Modes 1,3 Baud Rate =  $(\text{Timer 2 Overflow Rate}) / 16$

The Timer can be configured for either "timer" or "counter" operation. In the most typical applications, it is configured for "timer" operation (C/T2 = 0). "Timer" operation is a little different for Timer 2 when it's being used as a baud rate generator. Normally, as a timer it would increment every machine cycle (thus at 1/12 the oscillator frequency). As a baud rate generator, however, it increments every state time (thus at 1/2 the oscillator

frequency). In that case the baud rate is given by the formula:

Modes 1,3 Baud Rate =  $(\text{Oscillator Frequency}) / \{32 \times (65536 - (\text{RCAP2H}, \text{RCAP2L}))\}$

where (RCAP2H, RCAP2L) is the content of RCAP2H and RCAP2L taken as a 16-bit unsigned integer.

Timer 2 as a baud rate generator is shown in Figure 11. This Figure is valid only if RTCLK = 1 in T2CON. Note that a rollover in TH2 does not set TF2, and will not generate an interrupt. Therefore, the Timer 2 interrupt does not have to be disabled when Timer 2 is in the baud rate generator mode. Note too, that if EXEN2 is set, a 1-to-0 transition in T2EX will set EXF2 but will not cause a reload from (RCAP2H, RCAP2L) to (TH2, TL2). Thus when Timer 2 is in use as a baud rate generator, T2EX can be used as an extra external interrupt, if desired.

It should be noted that when Timer 2 is running (TR2 = 1) in "timer" function in the baud rate generator mode, one should not try to read or write TH2 or TL2. Under these conditions the Timer is being incremented every state time, and the results of a read or write may not be accurate. The RCAP registers may be read, but shouldn't be written to, because a write might overlap a reload and cause write and/or reload errors. Turn the Timer off (clear TR2) before accessing the Timer 2 or RCAP register, in this case.

**Table 4. Timer 1 Generated Commonly Used Baud Rates**

| BAUD RATE        | f <sub>OSC</sub> (MHz) | SMOD | C/T | TIMER 1 MODE | RELOAD VALUE |
|------------------|------------------------|------|-----|--------------|--------------|

## 12.7 Interrupt System

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronous to execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution, a multiple-source, two-priority-level, nested interrupt system is provided. The 83CL781/83CL782 acknowledges interrupt requests from fifteen sources as follows:

- INT0 through INT9
- Timer 0, Timer 1, and Timer 2
- I<sup>2</sup>C bus serial I/O
- UART

Each interrupt vectors to a separate location in program memory for its service routine. Each source can be individually enabled or disabled by corresponding bits in the Interrupt Enable Registers (IEN0, IEN1). The priority level is selected via the Interrupt Priority register (IP0, IP1). All enabled sources can be globally disabled or enabled.

### 12.7.1 External Interrupts INT2/INT9

Port 1 lines serve an alternative purpose as seven additional interrupts INT2 to INT9.

When enabled, each of these lines may "wake-up" the device from Power-down mode. Using the IX1 register, each pin may

be initialized to either active HIGH or LOW. IRQ1 is the interrupt request flag register. Each flag, if the interrupt is enabled, will be set on an interrupt request but must be cleared by software, i.e., via the interrupt software or when the interrupt is disabled.

The port 1 interrupts are level sensitive. A port 1 interrupt will be recognized when a level (HIGH or LOW depending on Interrupt Polarity Register IX1) on P1x is held active for at least one machine cycle. The Interrupt Request is not served until the next machine cycle.

#### 12.7.2.1 Interrupt Priority

Each interrupt priority source can be set to either high or low priority. If both priorities are requested simultaneously, the controller will branch to the high priority vector.

A low priority interrupt can only be interrupted by a high priority interrupt. A high priority interrupt routine cannot be interrupted.

### 12.7.3 Related registers

The following registers are used in conjunction with the interrupt system:

| REGISTER | FUNCTION                                | SFR ADDRESS |
|----------|-----------------------------------------|-------------|
| IX1      | Interrupt polarity register             | E9H         |
| IRQ1     | Interrupt request flag register         | C0H         |
| IEN0     | Interrupt enable register               | A8H         |
| IEN1     | Interrupt enable register (INT2-INT9)   | E8H         |
| IP0      | Interrupt priority register             | B8H         |
| IP1      | Interrupt priority register (INT2-INT9) | F8H         |

### 12.8 Oscillator Circuitry

The on-chip oscillator circuitry of the 83CL781/83CL782 is a single-stage inverting amplifier biased by an internal feedback resistor (Figure 14). For operation as a standard quartz oscillator, no external components are needed (except at 32kHz). When using external capacitors, ceramic resonators, coils and RC networks to drive the oscillator, five different configurations are supported (see Figure 15 and oscillator options).

In the Power-down mode the oscillator is stopped and XTAL1 is pulled HIGH. The oscillator inverter is switched off to ensure no current will flow regardless of the voltage at XTAL1. To drive the device with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 to float, as shown in Figure 15(f). There are no requirements on the duty cycle of the external clock, since the input to the internal clocking circuitry is buffered by a flip-flop.

The following options are provided for optimum on-chip oscillator performance. Please state option when ordering.

#### 12.8.1 Oscillator options (see Figure 15)

- Osc.1: Figure 15(c). An option for 32kHz clock applications with external trimmer for frequency adjustment. A 4.7MΩ bias resistor is needed for use in parallel with the crystal.
- Osc.2: Figure 15(e). An option for low-power, low-frequency operations using LC components.
- Osc.3: An option for medium frequency range applications.
- Osc.4: An option for high frequency range applications.
- RC: Figure 15(g). An option for an RC oscillator.

**NOTE:**

1. The equivalent circuit data of internal oscillator compares with that of matched crystals.

**12.8.3 RC Oscillator**

The externally adjustable RC-oscillator has a frequency range from 100kHz to 500kHz.

## Low-voltage single-chip 8-bit microcontrollers

## 83CL781/83CL782

**12.9 Reset Circuitry**

To initialize the 83CL781/83CL782, a reset is performed by either of two methods:

- via the RST pin

- via a power-on-reset.

It leaves the internal registers as follows:

| Register      | Content   |
|---------------|-----------|
| ACC           | 0000 0000 |
| B             | 0000 0000 |

| PSW           | 0000 0000 |
| RCAP2L        | 0000 0000 |
| RCAP2H        | 0000 0000 |

The reset state of the port pins is mask-programmable and can therefore be defined by the user. The standard reset value for port P0-P3 is 1111 1111.

The reset input to the 83CL781/83CL782 is RST pin 15. A Schmitt trigger qualifies the input for noise rejection. The output of the Schmitt trigger is sampled by the reset circuitry every machine cycle.

A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods), while the oscillator is running. The CPU responds by generating an internal reset. Port pins adopt their reset state immediately after RST goes HIGH. During reset ALE and PSEN are held HIGH.

The external reset is asynchronous to the internal clock. The RST pin is sampled during State 5, Phase 2 of every machine cycle. After a HIGH is detected at the RST pin, an internal reset is repeated every cycle until RST goes LOW.

The internal RAM is not affected by reset. When  $V_{DD}$  is turned on the RAM contents are indeterminate.

**1.9.1 Power-on reset**

The 83CL781/83CL782 contains on-chip circuitry which switch the port pins to the

customer defined logic level as soon as  $V_{DD}$  exceeds 1.3V. As soon as the minimum supply voltage is reached, the oscillator will start up. However, to ensure that the oscillator is stable before the controller starts, the clock signals are gated away from the CPU for a further 1536 oscillator periods.

A hysteresis of approximately 50mV at a typical power-on switching level of 1.3V will ensure correct operation.

The on-chip Power-on reset circuitry can also be switched off via the mask option "OFF". This option reduces the Power-down current to typically 800nA and can be chosen if external reset circuitry is used.

An automatic reset can be obtained at power-on by connecting the RST pin to  $V_{DD}$  via a  $10\mu\text{F}$  capacitor. At power-on, the voltage on the RST pin is equal to  $V_{DD}$  minus the capacitor voltage, and decreases from  $V_{DD}$  as the capacitor discharges through the internal resistor  $R_{RST}$  to ground. The larger the capacitor, the more slowly  $V_{RST}$  decreases.  $V_{RST}$  must remain above the lower threshold of the Schmitt trigger long enough to effect a complete reset. The time required is the oscillator start-up time, plus 2 machine cycles.

## NOTES:

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10$ ns;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL2 not connected; EA = RST + Port 0 =  $V_{DD}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10$ ns;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL2 not connected; EA = Port 0 =  $V_{DD}$ .
- The power-down current is measured with all output pins disconnected; XTAL1 not connected; EA = Port 0 =  $V_{DD}$ ; RST =  $V_{SS}$ .
- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3 pins when these pins make a 1-to-0 transition during bus operations. In the most adverse conditions (capacitive loading > 100pF) the noise pulse on the ALE line may exceed 0.8V. In this event it may be required to qualify ALE with a Schmitt trigger, or use an address latch with a Schmitt trigger strobe input.
- Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE and PSEN to momentarily fall below the 0.9% of  $V_{DD}$  specification when the address bits are stabilizing.
- The input threshold voltage of P1.6/SCL and P1.7/SDA meet the I<sup>2</sup>C-bus specification, so an input voltage below  $0.3V_{DD}$  will be recognized as a logic 0, while an input voltage above  $0.7V_{DD}$  will be recognized as a logic 1.
- Circuits with Power-on Reset option "Off" are tested at  $V_{DD}$  minimum = 1.8V; with option "On" (typically 1.3V) are tested at  $V_{DD}$  minimum = 2.3V.

## Low-voltage single-chip 8-bit microcontrollers

## 83CL781/83CL782

**DC ELECTRICAL CHARACTERISTICS (83CL782)**

$V_{DD} = 1.8V$  to  $6V$ ;  $V_{SS} = 0V$ ;  $T_{amb} = -25^{\circ}C$  to  $+55^{\circ}C$ , all voltages with respect to  $V_{SS}$ ; unless otherwise specified.

**NOTES:**

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL2 not connected;  $\overline{EA} = RST + Port 0 = V_{DD}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL2 not connected;  $\overline{EA} = Port 0 = V_{DD}$ .
- The power-down current is measured with all output pins disconnected; XTAL1 not connected;  $\overline{EA} = Port 0 = V_{DD}$ ;  $RST = V_{SS}$ .
- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3 pins when these pins make a 1-to-0 transition during bus operations. In the most adverse conditions (capacitive loading >100 pF) the noise pulse on the ALE line may exceed 0.8V. In this event it may be required to qualify ALE with a Schmitt trigger, or use an address latch with a Schmitt trigger strobe input.
- Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE and PSEN to momentarily fall below the 0.9% of  $V_{DD}$  specification when the address bits are stabilizing.
- The input threshold voltage of P1.6/SCL and P1.7/SDA meet the I<sup>2</sup>C-bus specification, so an input voltage below  $0.3V_{DD}$  will be recognized as a logic 0, while an input voltage above  $0.7V_{DD}$  will be recognized as a logic 1.
- Circuits with Power-on Reset option "Off" are tested at  $V_{DD\text{minimum}} = 1.8V$ ; with option "On" (typically 1.3V), they are tested at  $V_{DD\text{minimum}} = 2.3V$ .

## NOTE TO THE AC CHARACTERISTICS:

- Interfacing the 83CL781 to devices with float times up to 75ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

## Low-voltage single-chip 8-bit microcontrollers

**NOTE TO THE AC CHARACTERISTICS:**

1. Interfacing the 83CL782 to devices with float times up to 75ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

# CMOS single-chip 8-bit microcontroller with on-chip EEPROM

## 80C851/83C851

### DESCRIPTION

The Philips 80C851/83C851 is a high-performance microcontroller fabricated with Philips high-density CMOS technology. The 80C851/83C851 has the same instruction set as the 80C51. The Philips CMOS technology combines the high speed and density characteristics of HMOS with the low power attributes of CMOS. The Philips epitaxial substrate minimizes latch-up sensitivity.

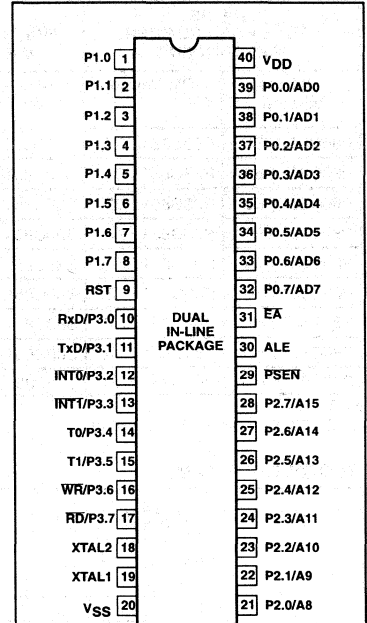

The 80C851/83C851 contains a 4k × 8 ROM with mask-programmable ROM code protection, a 128 × 8 RAM, 256 × 8 EEPROM, 32 I/O lines, two 16-bit counter/timers, a seven-source, five vector, two-priority level nested interrupt structure, a serial I/O port for either multi-processor communications, I/O expansion or full duplex UART, and on-chip oscillator and clock circuits.

In addition, the 80C851/83C851 has two software selectable modes of power reduction — idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM and EEPROM contents but freezes the oscillator, causing all other chip functions to be inoperative.

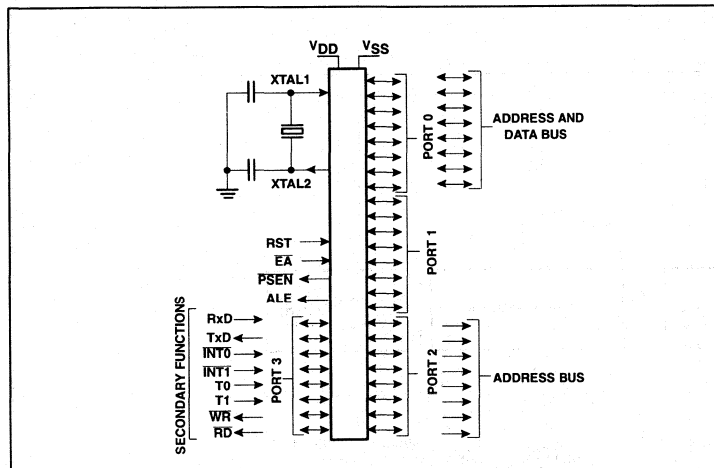

### FEATURES

- 80C51 based architecture
  - 4k × 8 ROM
  - 128 × 8 RAM
  - Two 16-bit counter/timers
  - Full duplex serial channel
  - Boolean processor
- Non-volatile 256 × 8-bit EEPROM (electrically erasable programmable read only memory)
  - On-chip voltage multiplier for erase/write
  - 50,000 erase/write cycles per byte
  - 10 years non-volatile data retention
  - Infinite number of read cycles
  - User selectable security mode
  - Block erase capability
- Mask-programmable ROM code protection
- Memory addressing capability
  - 64k ROM and 64k RAM
- Power control modes:
  - Idle mode
  - Power-down mode
- CMOS and TTL compatible
- 1.2 to 16MHz
- Three package styles
- Three temperature ranges
- ROM code protection

| P0.0–0.7        | 39–32   | 43–36        | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s.                                                                                                                                                                                                                                                                                                                                                                                                                |                                                     |
| P1.0–P1.7       | 1–8     | 2–9          | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ).                                                                                                                                                                                                                                                                                                                                                                                                   |                                                     |
| P2.0–P2.7       | 21–28   | 24–31        | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |                                                     |
| P3.0–P3.7       | 10–17   | 11,<br>13–19 | 5,<br>7–13    | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the SC80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                      |                                                     |

## 80C851/83C851

### EEPROM

Communications between the CPU and the EEPROM is accomplished via 5 special function registers; 2 address registers (high and low byte), 1 data register for read and write operations, 1 control register, and 1 timer register to adapt the erase/write time to the clock frequency. All registers can be read and written. Figure 1 shows a block diagram of the CPU, the EEPROM and the interface.

### Register and Functional Description

#### Address Register (EADRH, EADRL)

The lower byte contains the address of one of the 256 bytes. The higher byte (EADRH) is for future extensions and for addressing the security bits (see Security Facilities). The

EADRH register address is F3H. The EADRL register address is F2H.

#### Data Register (EDAT)

This register is required for read and write operations and also for row/block erase. In write mode, its contents are written to the addressed byte (for "row erase" and "block erase" the contents are don't care). The write pulse starts all operations, except read. In read mode, EDAT contains the data of the addressed byte. The EDAT register address is F4H.

#### Timer Register (ETIM)

The timer register is required to adapt the erase/write time to the oscillator frequency. The user has to ensure that the erase or write (program) time is neither too short or too long.

The ETIM register address is F5H. Table 2 contains the values which must be written to the ETIM register by software for various oscillator frequencies (the default value is 08H after RESET).

The general formula is:

2ms Write time:

$$\text{Value (decimal, to be rounded up)} = \frac{f_{\text{XTAL1}} [\text{kHz}]}{512} - 2$$

10ms Write time:

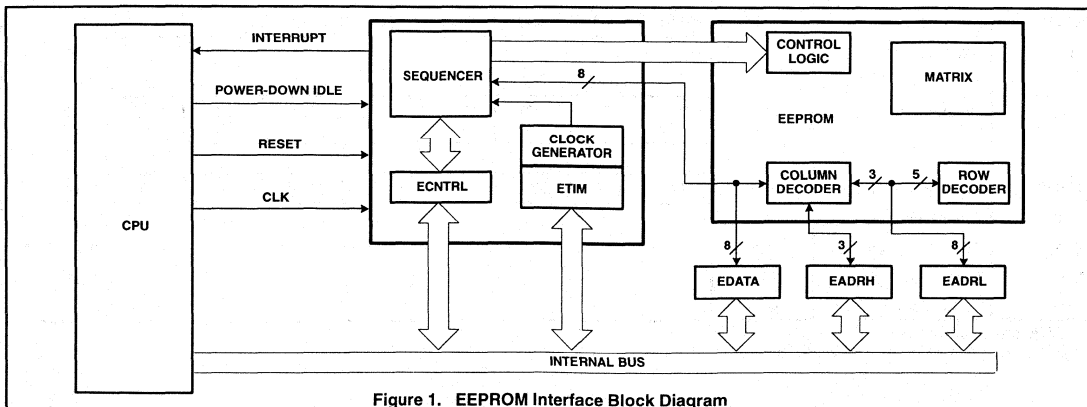

$$\text{Value (decimal)} = \frac{f_{\text{XTAL1}} [\text{kHz}]}{96} - 2$$

#### Control Register (ECNTRL)

See Figure 2 for a description of this register. The ECNTRL register address is F6H.

**Table 2. Values for the Timer Register (ETIM)**

| f <sub>XTAL1</sub> | VALUES FOR ETIM |     |                 |     |

\*Future products.

- Byte mode:** Normal EEPROM mode, default mode after reset. In this mode, data can be read and written to one byte at a time.
- Read mode:** This is the default mode when byte mode is selected. This means that the contents of the addressed byte are available in the data register.
- Write mode:** This mode is activated by writing to the data register. The address register must be loaded first. Since the old contents are read first (by default), this allows the sequencer to decide whether an erase/write or write cycle only (data = 00H) is required.
- Row erase:** In this mode, the addressed row is cleared. The three LSBs of EADR.L are not significant, i.e. the 8 bytes addressed by EADR.L are cleared in the same time normally needed to clear one byte ( $t_{\text{ROWERASE}} = t_{\text{E}} = t_{\text{W}}$ ). For the following write modes, only the write and not the erase/write cycle is required. For example, using the row erase mode, programming 8 bytes takes  $t_{\text{TOTAL}} = t_{\text{E}} + 8 \times t_{\text{W}}$  compared to  $t_{\text{TOTAL}} = 8 \times t_{\text{E}} + 8 \times t_{\text{W}}$  ( $t_{\text{E}} = t_{\text{ERASE}} \cdot t_{\text{W}} = t_{\text{WRITE}}$ ).
- Page write:** For future products.
- Page erase/write:** For future products.
- Block erase:** In this mode all 256 bytes are cleared. The byte containing the security bits is also cleared.  $t_{\text{BLOCKERASE}} = t_{\text{E}}$ . The contents of EADR.H, EADR.L and EDAT are insignificant.

### Program Sequences and Register Contents after Reset

The contents of the EEPROM registers after a Reset are the default values:

|        |            |                                                                       |
|--------|------------|-----------------------------------------------------------------------|
| EADR.H | = 1xxxxxxB | (security bit address)                                                |
| EADR.L | = 00H      | (security bit address)                                                |
| ETIM   | = 08H      | (minimum erase time with the lowest permissible oscillator frequency) |
| ECNTRL | = 00H      | (Byte mode, read)                                                     |
| EDAT   | = xxH      | (security bit)                                                        |

- Initialize:** MOV ETIM, ..  
MOV EADR.H, ..
- Read:** MOV EADR.L, ..  
MOV .., EDAT
- Write:** MOV EADR.L, ..  
MOV EDAT, ..
- Erase row:** MOV EADR.L, .. Row address, 3LSBs don't care  
MOV ECNTRL, #0CH Erase row mode  
MOV EDAT, .. (EDAT) don't care
- Erase block:** MOV ECNTRL, 0AH Erase block mode  
MOV EDAT, .. (EDAT) don't care

If the security bit is to be altered, the program generally starts as follows:

```
MOV EADR.H, #80H
MOV EADR.L, #00H
```

## Security Facilities

### EEPROM Protection

The EEPROM is protected using four security bits which are contained in an extra EEPROM byte at address 8000H (EADRH/EADRL). They can be set or cleared by software. To activate the EEPROM protection, the program sequence in byte mode must be as follows:

```
MOV EADRH, #80H
MOV EADRL, #00H
MOV EDAT, #FFH
```

If two or more of these bits are reset, SB = 0, the security mode is disabled and the EEPROM is not protected. If three or four bits are set, SB = 1 and the EA mode differs from the internal access mode.

In this case, access to the EEPROM is only possible in one mode regardless of how the external access mode is reached (by pulling

the EA pin low or by passing the 4K boundary). For SB = 1 and "external access" only, the "block erase" mode is enabled. The program sequence has to be as follows:

```
MOV EADRH, #80H (security byte address)
MOV EADRL, #00H (security byte address)
MOV ECNTL, #0AH (block erase mode)
MOV EDAT, #xxH (start block erase)
```

All 256 data bytes, the security bits, and SB will be cleared after completing this mode (EWP = 0). SB will also be affected in byte mode when writing to the security byte (not for SB = 1 and "external access"). Figure 3 illustrates the access to SB.

### ROM Code Protection

Since the external access mode can only be selected by pulling the EA pin low during reset, it is not possible to read the internal program memory using the MOVC instruction while executing external program memory. Furthermore, it is not possible to change this

mode to internal access within the MOVC cycle.

Additionally, a mask-programmable ROM code protection facility is available. When the program memory passes the 4K boundary using both the internal and external ROMs, it is not possible to access the internal ROM from the external program memory if the mask-programmable ROM security bit is set. An access to the lower 4K bytes of program memory using the MOVC instruction is only possible while executing internal program memory.

Also the verification mode (test-mode which writes the ROM contents to a port for comparison with a reference code) is not implemented for security reasons. A different test-mode is implemented for test purposes. This mode allows every bit to be tested. However, the internal code cannot be accessed via a port.

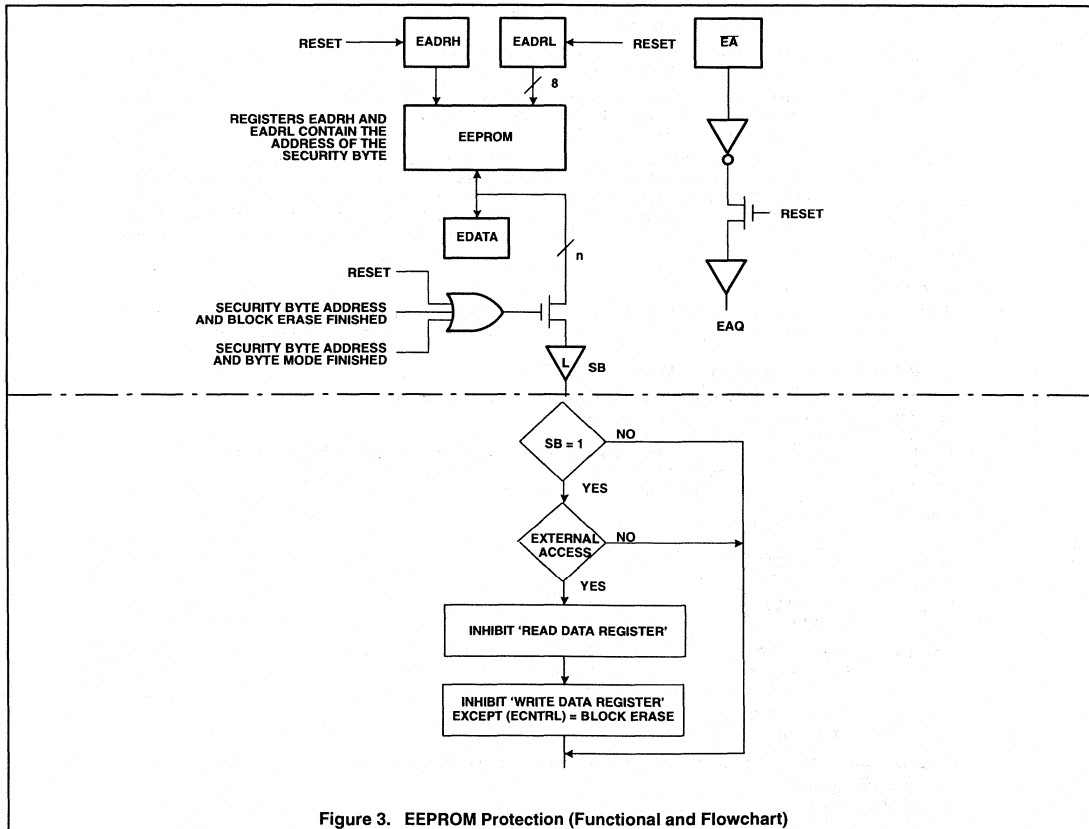

Figure 3. EEPROM Protection (Functional and Flowchart)

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol, page 1085.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-up, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

**Note:** Before entering the idle or power-down modes, the user has to ensure that there is no EEPROM erase/write cycle in progress

(i.e., the EWP bit has to be reset before activating the idle or power-down modes; otherwise EEPROM accesses will be aborted).

## IDLE MODE

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM and EEPROM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 3 shows the state of the I/O ports during low current operating modes.

## INTERRUPT SYSTEM

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronous to the execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution, a multiple-source, two-priority-level, nested interrupt system is provided. Interrupt response latency is from 3µs to 7µs when using a 12MHz crystal. The S83C851 acknowledges interrupt requests from 7 sources as follows:

- INT0 and INT1: externally via pins 12 and 13, respectively,
- Timer 0 and timer 1: from the two internal counters,
- Serial port: from the internal serial I/O port or EEPROM (1 vector).

Each interrupt vectors to a separate location in program memory for its service program. Each source can be individually enabled (the EEPROM interrupt can only be enabled when the serial port interrupt is enabled) or disabled and can be programmed to a high or low priority level. All enabled sources can also be globally disabled or enabled. Both external interrupts can be programmed to be level-activated and are active low to allow "wire-ORing" of several interrupt sources to one input pin.

**Note:** The serial port and EEPROM interrupt flags must be cleared by software; all other flags are cleared by hardware.

**Table 3. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |

| Storage temperature range                                                                    | –65 to +150  | °C   |
| Voltage on any other pin to V <sub>SS</sub>                                                  | –0.5 to +6.5 | V    |
| Input or output DC current on any single I/O pin                                             | ±5           | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.0          | W    |

### NOTES:

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
2. This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
3. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

# CMOS single-chip 8-bit microcontroller with on-chip EEPROM

### NOTES:

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\overline{EA} = \text{RST} = \text{Port 0} = V_{DD}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\overline{EA} = \text{Port 0} = V_{DD}$ ;  $\text{RST} = V_{SS}$ .
- The power-down current is measured with all output pins disconnected; XTAL2 not connected;  $\overline{EA} = \text{Port 0} = V_{DD}$ ;  $\text{RST} = \text{XTAL1} = V_{SS}$ .
- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make a 1-to-0 transition during bus operations. In the worst cases (capacitive loading  $> 100\text{pF}$ ), the noise pulse on the ALE line may exceed 0.8V. In such cases it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE and  $\overline{PSEN}$  to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
 

|                                             |       |
|---------------------------------------------|-------|
| Maximum $I_{OL}$ per Port pin:              | 10mA  |
| Maximum $I_{OL}$ per 8-bit port –           |       |
| Port 0:                                     | 26mA  |
| Ports 1, 2, and 3:                          | 15mA  |
| Maximum total $I_{OL}$ for all output pins: | 71mA. |

 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- See Figures 11 through 14 for  $I_{DD}$  test conditions.

### NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- The power-off fall-time of  $V_{DD}$  must be less than 1ms to prevent an overwrite pulse from being generated in the EEPROM which can cause spurious parasitic writing to EEPROM cells. If the  $V_{DD}$  power-off full-time is greater than 1ms, a power-off reset signal should be generated to prevent this condition from occurring.
- Test condition:  $T_{amb} = +55^{\circ}\text{C}$ .
- Number of erase/write cycles for each EEPROM byte.

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)

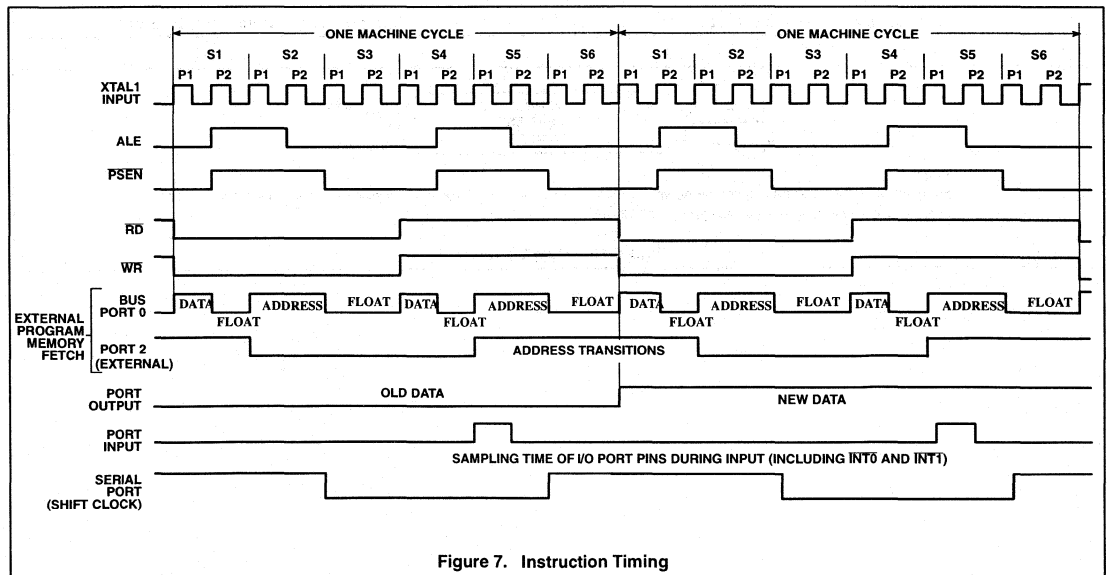

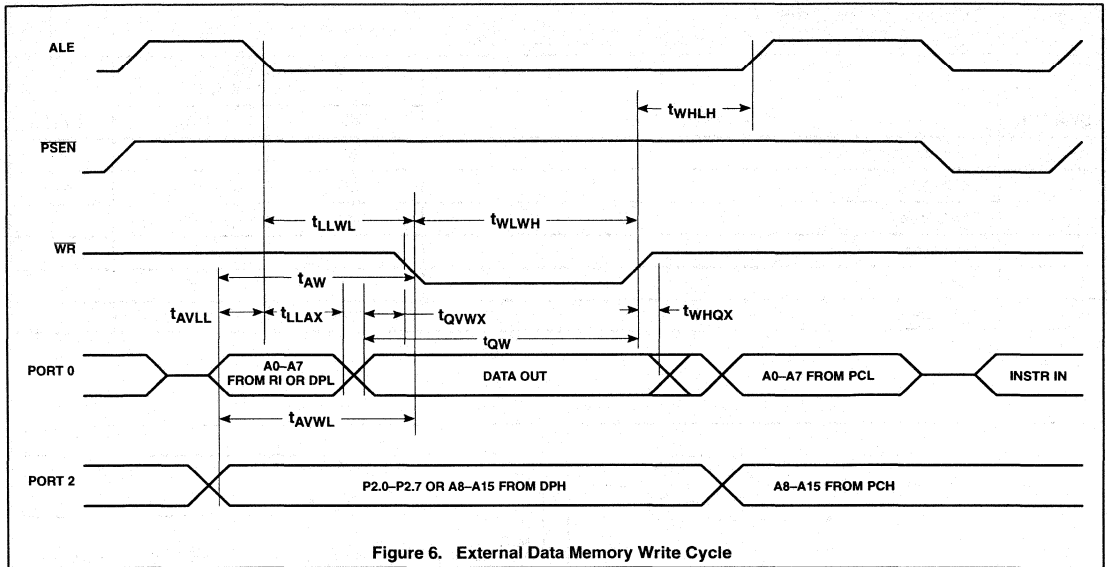

- L - Logic level low, or ALE
- P - PSEN
- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

| t <sub>r</sub>    | Rise time               | –                                 | 20                                    | ns   |
| t <sub>f</sub>    | Fall time               | –                                 | 20                                    | ns   |
| t <sub>CY</sub>   | Cycle time <sup>1</sup> | 0.75                              | 10                                    | ns   |

**NOTE:**

1. t<sub>CY</sub> = 12 t<sub>CLCL</sub>.

Figure 8. External Clock Drive

**NOTE:**  
AC inputs during testing are driven at 2.4V for a logic '1' and 0.45V for a logic '0'.  
Timing measurements are made at 2.0V min for a logic '1' and 0.8V for a logic '0'.

Figure 9. AC Testing Input/Output

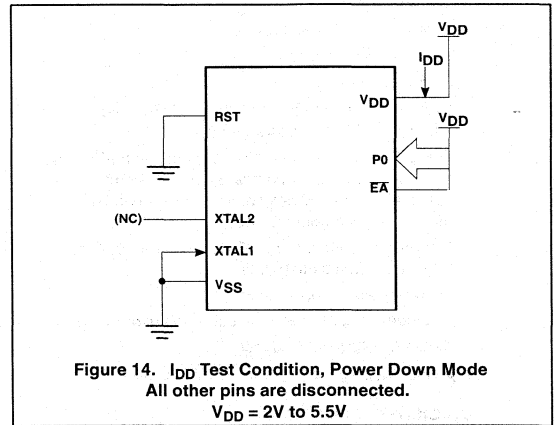

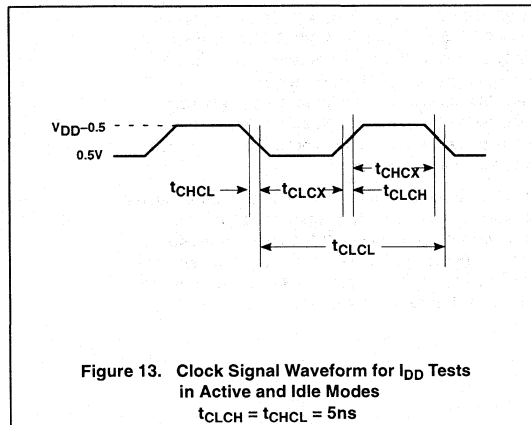

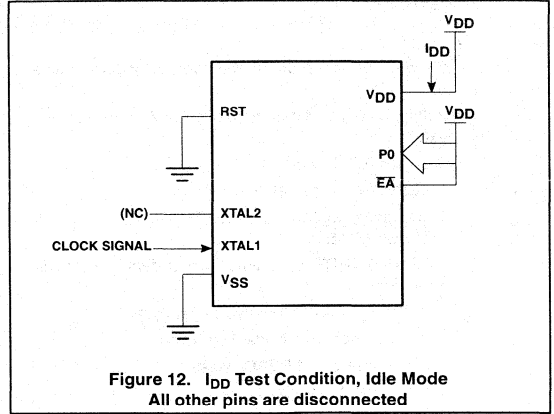

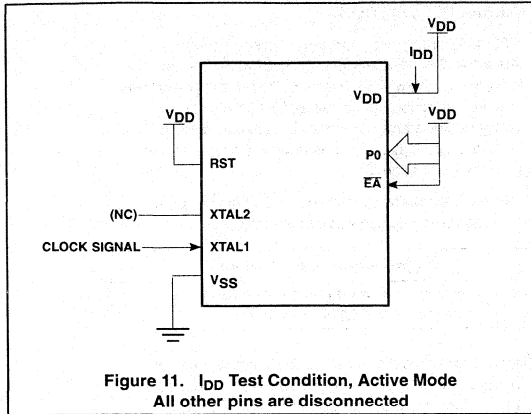

**NOTE:**  
For timing purposes, a port is no longer floating when a 100mV change from load voltage occurs, and begins to float when a 100mV change from the loaded V<sub>OH</sub>/V<sub>OL</sub> level occurs. I<sub>OH</sub>/I<sub>OL</sub> ≥ ± 20mA.

## Secured 8-bit microcontroller

83C852

## FEATURES

- 8-bit CPU
- 6K bytes of user program memory (ROM), no external extension
- 256 bytes of RAM data memory (RAM), no external extension
- 2K bytes EEPROM:
  - EEPROM stores data or program
  - on-chip voltage multiplier for EEPROM ERASE/WRITE
  - ERASE/WRITE cycle time independent of the clock frequency
  - 10000 ERASE/WRITE cycles per bytes
  - 10 years non-volatile data retention
  - infinite number of READ cycles
  - error code correction
- Calculation unit for cryptographic calculations
- Security features
- Power-ON/OFF reset circuit
- Low frequency detector
- Two 16-bit timers
- Clock frequency range 1 MHz to 6 MHz; 1  $\mu$ s cycle time with 6 MHz clock frequency
- Two I/O lines; only one I/O line is used in half-duplex, according to the ISO standards for the Smart Card applications; full-duplex communication can be performed with both I/O lines
- 5 interrupt sources from: I/O lines; Timer 0; Timer 1; EEPROM; Calculation unit
- Power-down and idle mode
- Two operating modes: test mode and user mode
- Single 5 volts power supply
- 6 pins:  $V_{DD}$ ,  $V_{SS}$ , I/O1, I/O2,  $\overline{RESET}$ , CLK

## QUICK REFERENCE DATA

| SYMBOL    | PARAMETER                           | CONDITION            | MIN. | MAX. | UNIT         |

## GENERAL DESCRIPTION

The 83C852 single chip secured microcontroller is manufactured in an advanced 1.2  $\mu$ CMOS process. It is a derivative of the 80C51 microcontroller family and has the same instruction set as the 80C51. It has been specially designed for conditional access in secure Smart Card applications and is implemented with the highest levels of security.

Its internal calculation unit speeds-up cryptographic calculations using Public Key Algorithms.

## Cryptographic calculations

|                                                                                                   |
|---------------------------------------------------------------------------------------------------|
| At $f_{CLK} = 6$ MHz: $X^e \text{ mod. } n$ is performed in 1.5 s typical, with 512 bit operands. |
|---------------------------------------------------------------------------------------------------|

External communications can be performed through a serial interface (I/O) according to ISO standards. The serial interface must be controlled by application software for access to the 83C852 internal memory.

The 83C852 contains a 6K bytes READ only memory (user ROM); a 256 bytes READ/WRITE data memory (RAM); 2K bytes electrically erasable programmable READ only memory (EEPROM); two I/O lines; two 16-bit timers; five vectorized interrupt sources; 33 Special Function Registers (SFRs) and a Calculation Unit to speed-up the execution time of public keys and secret keys cryptographic algorithms.

The 83C852 operates with a single 5 volts power supply and at a maximum clock frequency of 6 MHz. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With an input clock frequency of 6 MHz, 58% of the instructions are executed in 1  $\mu$ s and 40% in 2  $\mu$ s.

## Secured 8-bit microcontroller

83C852

**FUNCTIONAL DESCRIPTION****General**

The 83C852 is specially designed for secured applications such as conditional access and transactions in a Smart Card environment. It has a Calculation Unit which makes the microcontroller dedicated to asymmetric crypto systems. Special Function Registers (SFRs) are available to the user to manipulate memory transactions and calculation unit operations.

The address bus of the EEPROM is mixed to prevent fraudulent access and optical scanning. The EEPROM has an hardware error code correction which guarantees the data content integrity. The 83C852 is able to read and modify a part of the internal program memory contained in EEPROM.

The 83C852 has two software selectable modes of reduced activity for further power reduction, the idle mode and power-down mode:

- the idle mode freezes the CPU while allowing the RAM, the timers and the interrupt system to continue functioning.
- the power-down mode saves the RAM content and disables all other chip functions.

The 83C852 has 33 SFRs available for use by the user (see Table 23). The functional descriptions and usage of the SFRs as they co-relate to the RAM, EEPROM and the calculation unit activities, are described within the following sections.

**Memory organisation**

The central processing unit (CPU) manipulates operands in three memory spaces, (see Fig. 4) these are:

- 6K-byte internal program memory (ROM)
- 2K-byte program and data memory (EEPROM)
- 256-byte internal data memory (RAM).

The 256-byte internal RAM memory address space is sub-divided into:

- 128-byte internal data RAM locations 00 to 7FH. This address space is accessible with direct and indirect addressing
- 128-byte internal data RAM locations 80H to FFH. This address space is accessible with indirect addressing only

- 128-byte Special Function Register (SFR) address space 80H to FFH. This address space is parallel to the upper 128 byte RAM. It is accessible with direct addressing only. 33 SFRs reside inside this area, the remaining address space in between is unused.

**EEPROM**

The EEPROM has a capacity of 2K bytes (words) see Fig. 5. With its built-in error correction hardware the EEPROM is a very reliable non-volatile memory. In addition to each single stored data byte, 4 extra "parity" bits are stored in EEPROM. Single-bit errors per byte are automatically corrected when reading the memory. It can be accessed by both CPU and calculation unit (however, not at the same time).

Programming of the EEPROM is completely controlled by the EEPROM's sequencer. The EEPROM can be used either both as data memory and program memory for the CPU, or as data memory for the calculation unit.

**EEPROM AS DATA MEMORY:**

When the CPU executes opcodes from internal ROM (program address < 8000H), the EEPROM can be used as a data memory. The communication between CPU and EEPROM is performed via 6 SFRs (see Table 1), these comprise:

- 2 EEPROM (SFRs) address registers (HIGH and LOW address byte)
- 1 EEPROM (SFR) data register for READ and WRITE operations
- 2 EEPROM (SFRs) control registers to select the various operating and test modes
- 1 EEPROM (SFR) timer register to adapt the ERASE/WRITE time to the operating clock frequency.

**EEPROM AS PROGRAM MEMORY:**

When the program counter is higher than 7FFFH, the EEPROM is used as a program memory. The CPU fetches opcodes directly from the EEPROM. **EADRH, EADRL1 and EDAT registers cannot be written.** Their contents in this mode are irrelevant.

**Reading data from the EEPROM can still be done with the MOVC instruction, but EEPROM write operation is not possible.** The EEPROM can only be written by software executed from the ROM area (program address < 8000H).

# Secured 8-bit microcontroller

83C852

### EEPROM AS DATA MEMORY FOR THE CALCULATION UNIT:

Communication between calculation unit and EEPROM is performed via SFRs (see Table 1), these comprise:

- 2 EEPROM SFRs address registers (one HIGH and one of two alternate LOW address bytes)
- calculation unit SFRs.

The EEPROM data output is directly connected via a special bus to the data registers of the calculation unit. The calculation unit has direct READ access to the EEPROM.

During memory access, the EEPROM is addressed by one of two address pointers EADRL1 or EADRL2. Both

pointers are loaded by the CPU and decremented by the calculation unit's sequencer. EADRL1 or EADRL2 supply the LOW byte (LSB) of the EEPROM address. The HIGH byte (MSB) of the EEPROM address is taken directly from the EADRH register. The access to the EEPROM from the calculation unit, is controlled by the calculation unit SFRs.

When the access to EEPROM by the calculation unit is active, the EEPROM is not accessible by the CPU, neither as data memory nor as program memory. When the calculation unit is operating, but not accessing the EEPROM, the CPU can READ, WRITE and EXECUTE EEPROM.

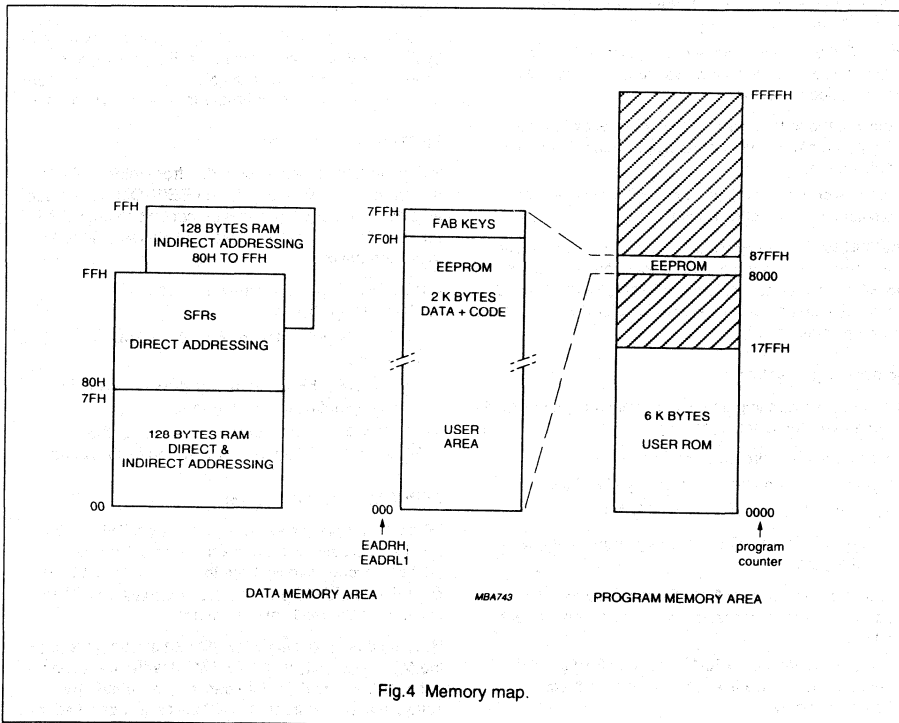

Fig.4 Memory map.

### EEPROM SFR descriptions

#### EADRH

EADRH is an 8-bit register (SFR), used as an address pointer, it is loaded from the CPU and contains the highest byte (MSB) of the EEPROM address. Only bits EADRH.7, 2, 1, 0 are relevant. Default value after reset is '10000000B'.

#### EADRL1, EADRL2

EADRL1 is an 8-bit register (SFR), used as an address pointer, it is loaded from the CPU. Its contents are transferred into an 8-bit down counter which provides the LOW byte (LSB) of the EEPROM address. The CPU has WRITE access to the EADRL1 register and READ access to the down counter.

Default value after reset of both the EADRL1 register and associated down counter are 00H. The transfer of EADRL1 to the down counter and the decrement are controlled by the calculation unit. The behaviour of EADRL1 depends on whether or not there is an access in progress from the calculation unit to the EEPROM.

No access from the calculation unit to the EEPROM:

- when there is no active access to the EEPROM from the calculation unit, the contents of the EADRL1 register are continuously loaded into its associated down counter. There is no hardware-decrement of the down counter. The combination of EADRL1 plus its down counter behaves therefore as a normal register. In this mode, the LOW address byte of the EEPROM is always supplied by EADRL1. EADRL2 behaves similar to EADRL1 but it is not used for EEPROM addressing. Its contents are irrelevant.

Calculation unit access to the EEPROM:

- EADRL1 is the EEPROM LOW address pointer used to address an operand (Ai) stored in the EEPROM. At the beginning of the calculation unit's computation cycle, the address content of the EADRL1 is loaded into its associated down counter. During the calculation, further EADRL1 address transfers to the down counter stop, whilst the down counter is decremented by the calculation unit's sequencer. During a calculation, the EADRL1 register can be reloaded from the CPU with a new address. This new address will then be used during the next calculation.

## Secured 8-bit microcontroller

83C852

- EADRL2 (SFR) is the second EEPROM LOW address pointer which is required for some operations of the calculation unit. It is used to address an operand (Xi) stored in the EEPROM. The function of EADRL2 is similar to EADRL1 function. EADRL2 cannot be used as a second address register for normal CPU access to the EEPROM.

**Data register EDAT**

This register (SFR) is used to read data from the currently addressed EEPROM byte. When EDAT is written during BYTE MODE, it's contents will be programmed into the addressed EEPROM byte. When EDAT is written during ROW ERASE or BLOCK ERASE mode, the ROW ERASE or BLOCK ERASE operation is

started. In this mode, the data written to EDAT is then irrelevant. The ECNTRL1 status bits EWP and IFE indicate whether the EEPROM ERASE/WRITE operation is still active. Whilst the EEPROM programming is in progress, rewriting data to EDAT is not allowed.

**Timer register ETIM**

The ETIM timer register (SFR) is required to adapt the ERASE/WRITE time to the clock frequency. ERASE ( $t_e$ ) and WRITE ( $t_w$ ) times of 5 ms each are required. The user has to ensure that the ERASE or WRITE time is neither too short nor too long. Table 2 gives values for ETIM register for given clock frequencies. ETIM has to be loaded by software in advance to the first ERASE/WRITE operation. ETIM's default value after reset is '08H'.

**Table 2** ETIM timer values

The general formula is: Value (decimal) =  $(f_{CLK} \text{ kHz}/102.4) - 2$

| OPERATING<br>$f_{CLK}$ MHz | VALUES FOR ETIM |      |             |         |

## Secured 8-bit microcontroller

83C852

**Control register ECNTRL1**

ECNTRL1 is the control register (SFR) for the several user operation modes of the EEPROM.

**Table 3** ECNTRL1 SFR

| IFE | EEINT | EWP           | – | OPERATION MODE SELECT |   |   |   |
|-----|-------|---------------|---|-----------------------|---|---|---|
| 7   | 6     | 5             | 4 | 3                     | 2 | 1 | 0 |
|     |       | BYTE MODE →   |   | 0                     | 0 | 0 | 0 |
|     |       | ROW ERASE →   |   | 1                     | 1 | 0 | 0 |
|     |       | BLOCK ERASE → |   | 1                     | 0 | 1 | 0 |
|     |       | TEST MODE →   |   | 1                     | 1 | 1 | 1 |

**Table 4** Description of the ECNTRL1 bits

| SYMBOL / PARAMETER                         | FUNCTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ECNTRL1.7</b>                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| IFE, interrupt flag EEPROM                 | set by the EEPROM sequencer after completion of an EEPROM WRITE access, or set and reset by software. When (IFE is set 1 and EEINT is set 1), an interrupt request is done. Interrupt vector 0023H will be forced if the bits EA and EE inside the interrupt Enable Register IE are also set 1.                                                                                                                                                                                                      |
| <b>ECNTRL1.6</b>                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| EEINT, enable EEPROM interrupt             | set and reset by software. Enables an EEPROM interrupt request when HIGH.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ECNTRL1.5</b>                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| EWP, ERASE/WRITE in progress               | set and reset by the EEPROM sequencer. EWP is active HIGH during EEPROM write operations. Consecutive write operations to EDAT are not allowed as long as EWP is set. EWP cannot be set or reset by software.                                                                                                                                                                                                                                                                                        |
| <b>ECNTRL1.4</b>                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| –                                          | reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ECNTRL1 bits 3, 2, 1, 0</b>             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| operation mode select:<br>BYTE MODE (0000) | normal EEPROM mode, default mode after reset. In this mode READ or WRITE access to one byte at a time is possible.                                                                                                                                                                                                                                                                                                                                                                                   |
| READ mode                                  | This is the default mode when BYTE MODE is selected. The contents of the addressed byte are available in the data register EDAT.                                                                                                                                                                                                                                                                                                                                                                     |
| WRITE mode                                 | This mode is activated after loading of the data register EDAT with the data byte to be written. Before writing EDAT, the address registers EADRL1 and EADRH must be loaded first. Depending on the previous contents of the addressed memory cells, the EEPROM sequencer decides whether to do a WRITE cycle ( $t_w$ ), or a combined ERASE/WRITE cycle ( $t_e + t_w$ ). A WRITE cycle is carried out when the previous memory content has been 00H. Otherwise an ERASE/WRITE cycle is carried out. |

## Secured 8-bit microcontroller

83C852

| SYMBOL / PARAMETER                           | FUNCTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| operation mode select:<br>ROW ERASE (1100)   | in this mode the contents of the addressed memory row will be erased. The three LSB's of EADRL1 are not significant, i.e. 8 bytes addressed by EADRL1 will be cleared in the same time normally needed to clear one single byte ( $t_{\text{ROW ERASE}} = t_b$ ). The ROW ERASE operation can be started by writing the EDAT register. The data that is written to EDAT is not significant. Writing of the erased 8 memory cells then takes only 8 WRITE cycles. This is much faster than writing 8 data bytes without a previous ROW ERASE. Such an operation would have taken a total = $8 t_e + 8 t_w$ . |
| operation mode select:<br>BLOCK ERASE (1010) | in this mode all memory cells of the EEPROM will be cleared. The BLOCK ERASE operation can be started by writing EDAT. The contents of the data and address registers EDAT, EADRL1, EADRH are don't care.                                                                                                                                                                                                                                                                                                                                                                                                   |
| operation mode select:<br>TEST MODE (1111)   | the selection of a specific EEPROM TEST MODE within the ECNTRL2 register is only possible when the ECNTRL1 register is switched in advance to TEST MODE.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Control register ECNTRL2

ECNTRL2 is the control register (SFR) for the several test modes of the EEPROM.

Table 6 Description of the ECNTRL2 bits

| SYMBOL / PARAMETER             | FUNCTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ECNTRL2 bits 7, 6, 5, 4</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| SP3, SP2, SP1, SP0             | this part of the ECNTRL2 register is READ only. The upper 4 bits of ECNTRL2 carry either the syndrome word which is generated by the EEPROM error correction logic or the parity bits stored in parallel to the data word in EEPROM memory. The syndrome word is always output during BYTE MODE READ (EWP = 0). A value of '0000B' means that no error has been detected/corrected. The parity bits are output during READ EEPROM WITHOUT ERRORCORRECTION TESTMODE or while EWP = 1. |
| <b>ECNTRL2 bits 3, 2, 1, 0</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| TM3, TM2, TM1, TM0             | this part of ECNTRL2 register is READ/WRITE. The lower 4 bits of ECNTRL2 are used to select one of the EEPROM test-modes. The selection of any test-mode is only possible if ECNTRL1 has been set to 'XXXX1111B' before. Otherwise TM3, TM2, TM1, TM0 are held at '0000B'.                                                                                                                                                                                                           |

Secured 8-bit microcontroller

83C852

## Secured 8-bit microcontroller

83C852

### RAM

The RAM has a capacity of 256 bytes. It can be accessed by both CPU and calculation unit (however, not at the same time). The CPU has full READ and WRITE access to the RAM only when the calculation unit is not operating.

When the calculation unit is operating, it reads and writes data from/to the RAM via a separate channel. In order to avoid possible access conflicts, the CPU cannot read or write the RAM at this time. This condition places some restrictions to the operations of the CPU:

- no subroutine calls possible while calculation unit is active
- register operations (e.g. MOV A,R0) are not possible
- stack pointer operations (PUSH, POP) are not possible
- interrupt requests are not granted while the calculation unit is active.

In the RAM address space, only the SFRs can be read and written by the CPU whilst the calculation unit is active.

### RAM address pointers

The calculation unit uses 4 RAM pointers to address the RAM during its direct memory access: AIPR, XIPR, AOPR and APR.

#### ADDRESS POINTERS AIPR, XIPR, AOPR

AIPR and XIPR pointers address the operand fields  $A_i$  resp.  $X_i$  inside RAM, while AOPR addresses a RAM area  $A_o$  where the calculation result is to be stored. Each pointer consists of an 8-bit register with associated 8-bit down counter. The counter provides a RAM address. It is parallel loaded from its register.

The CPU has WRITE access to the registers and READ access to the counters. Default values after reset for all registers and counters are 00H. The data transfer from the registers to their down counters and the counter decrement are controlled by the calculation unit.

#### ADDRESS POINTER APR

This is an 8-bit up counter which is used to address the A[3-0] operand field in RAM. It can be read and written by the CPU. Default value after reset is 00H. APR is incremented under the control of the calculation unit.

### RAM address pointer modes

The following RAM address pointer modes apply:

The calculation unit is at standby:

- there is no direct memory access from the calculation unit
- the down counters are continuously loaded from the AIPR, XIPR and AOPR registers
- because RAM is not addressed by any of the RAM pointers, their contents are irrelevant at this time. In advance to a calculation, the CPU has to load the RAM pointers with the start addresses of the operand and result fields. AIPR, XIPR and AOPR have to be loaded with the LSB's address, while APR has to be loaded with the MSB's address of the data field.

The calculation unit is active:

- there is direct RAM memory access from the calculation unit
- the data transfer from the registers to their associated down counters is stopped
- the address pointers AIPR, XIPR and APR address the operands  $A_i$ ,  $X_i$  and A[3-0] while AOPR addresses the  $A_o$  result area in RAM
- while the up and down counters are incremented/decremented under control of the calculation unit, the CPU can reload the registers with new addresses, ready for transfer to their down counters at the beginning of the next calculation cycle.

## Secured 8-bit microcontroller

83C852

**CALCULATION UNIT**

This unit computes, with its associated software, any exponential functions like  $x^n \text{ mod. } n$ . It has been designed to optimize the calculation time of exponent modulo N. It uses 196 bytes of RAM for 512-bit length operands.

**CALCULATION UNIT PERFORMANCE**

At  $f_{\text{CLK}} = 6 \text{ MHz}$ :  $X^n \text{ modulo } N$  is performed in 1.5  $\mu\text{s}$  typical, with 512 bit operands.

To reach this speed, the calculation unit's architecture provides:

- fast multiplication and addition
- fast carry handling
- fast data transfers to fetch operands from RAM or EEPROM and to store results in RAM
- simultaneous operation of both CPU and calculation unit.

The calculation unit does not carry out a complete exponentiation in one step. However, it provides a set of basic instructions, from which the complete exponentiation algorithm can be built by a dedicated software. All of these basic instructions operate on data-fields inside RAM and EEPROM. The width of these data-fields is variable. A typical operand width is 512 bits.

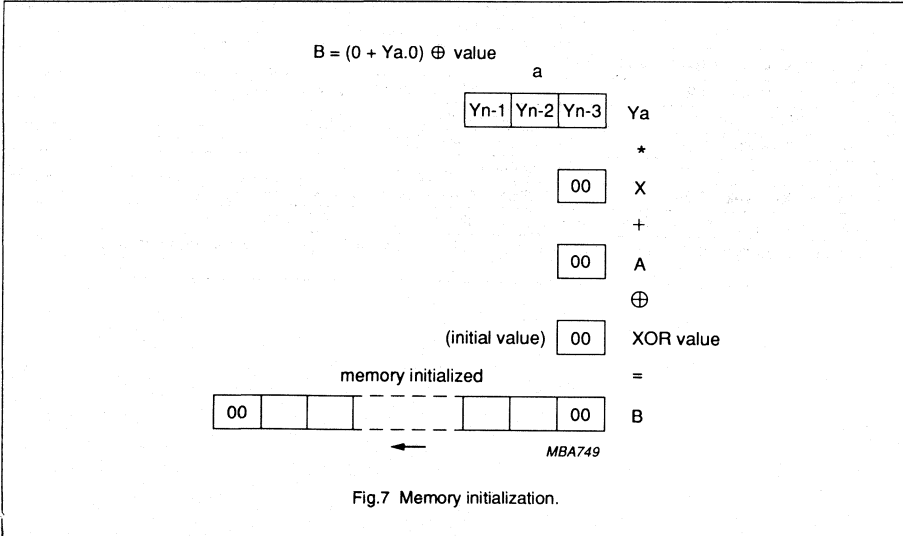

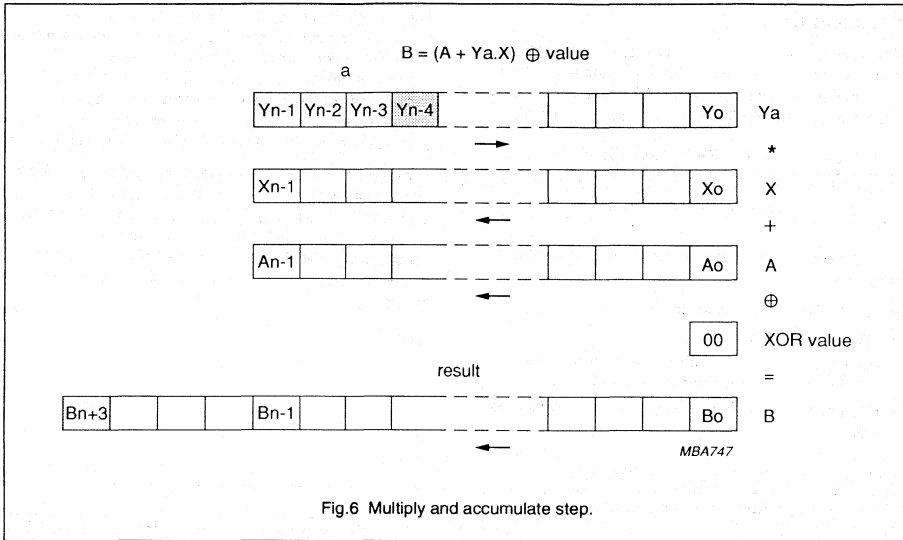

The basic operation of the calculation unit is to multiply either a 24-bit number or a 32-bit number with a long-word (e.g. 512-bit) and adding the result to another long-word. Further XOR and shift operations may be carried out to give the final result. With a 32-bit number this operation completes in typically 45  $\mu\text{s}$  at 6 MHz clock frequency.

**CALCULATION UNIT BASIC OPERATION**

|                                                                                                                              |                                                                                                                                                                                                                                                                        |

**Calculation unit related SFRs**

12 Special Function Registers (SFRs) are related to the calculation unit, see Table 7 and Figure 12.

**Memory access registers**

The calculation unit has direct READ and WRITE memory access to the RAM and READ-only access to the EEPROM. The unit uses four 8-bit wide RAM pointers to address operands and result inside RAM and two 8-bit pointers to address operands inside EEPROM. The MSB of the EEPROM address is supplied by the EADRH register. 5 out of the 6 pointers are pipelined. This allows the CPU to initialize these registers while a calculation is busy.

**Table 7** Calculation unit related SFRs

| SYMBOL  | ADDRESS | FUNCTION                                            |
|---------|---------|-----------------------------------------------------|
| AIPR    | A4H     | RAM address pointer for Ai input operand; note 1    |
| EADRL1  | F2H     | EEPROM address pointer for Ai input operand; note 1 |
| XIPR    | A5H     | RAM address pointer for Xi input operand; note 1    |
| EADRL2  | F1H     | EEPROM address pointer for Xi input operand; note 1 |
| APR     | A6H     | RAM address pointer for A[3-0] input operand        |
| AOPR    | A7H     | RAM address pointer for Ao result output            |
| CMD     | 99H     | command register                                    |
| CMDSTAT | 98H     | command and status register                         |
| CNTCYCL | F9H     | cycle counter                                       |
| CXOR    | A3H     | XOR operand register                                |
| WRLIM   | FBH     | WRITE operation limit register                      |
| RDLIM   | FAH     | limits register of the READ operands Xi and Ai.     |

**Note**

1. Ai operand and Xi operand can be stored in either the RAM or the EEPROM.

### Command and status registers CMD and CMDSTAT

The calculation unit has two 8 bit registers (SFRs) for commands and status. SFR CMD is used for commands only, SFR CMDSTAT is used for both commands and status (2 command bits and 3 status bits).

7 bits of the CMD register are pipelined (see Table 8). At the beginning of a calculation, the contents of these seven bits are transferred into an internal command register that controls the calculation unit's sequencer.

This allows the CPU to re-initialize the CMD register for the next calculation while the current calculation is still busy.

The CMDSTAT SFR (see Table 10) is not pipelined and may not be reloaded by the CPU whilst the calculation unit is active. Both CMD and CMDSTAT registers are cleared at reset. Tables 9 and 11 describe the function of single status and control bits within the CMD and CMDSTAT registers.

Table 8 CMD SFR

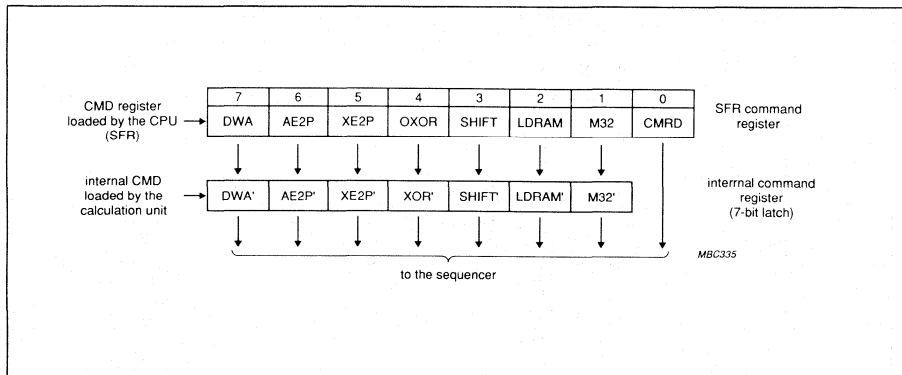

Table 9 Description of the CMD bits

| SYMBOL / PARAMETER                      | FUNCTION                                                                                                                                                                                                                                                                |

| CMRD = command ready                               | set by the CPU and cleared by the calculation unit (see Fig. 13).<br>To start a calculation, the CMRD bit is set 1 by the CPU. The CMRD bit will be reset 0 by hardware immediately after beginning the calculation. The CMD register is then ready to take the next command word from the CPU. When the CMRD bit is set 1 by the CPU while the calculation unit is still active, the calculation unit does not stop at the end of the current computation. The new calculation starts immediately with the new command parameters. In this case there will be no interrupt request. |

| CCY = carry                          | set and reset by the calculation unit.<br>When the contents of Ao3, Ao2, Ao1, Ao0 output pipeline registers are greater than 0 (zero), the CCY bit is set 1, otherwise CCY is reset 0.                                                                    |
| <b>CMDSTAT.0</b>                     |                                                                                                                                                                                                                                                           |
| DONE = end of the computation        | set by the calculation unit, reset by the CPU.<br>The DONE bit is set 1 by the calculation unit at the end of computation. When set 1, an interrupt request is generated. The DONE flag has to be reset 0 by the CPU during an interrupt service routine. |

**Cycle counter CNTCYCL**

This is an 8-bit register with associated down counter. It counts the number of bytes of the result which the calculation unit shall carry out. The first byte of the result is always zero.

The CPU has WRITE access to the register and READ access to the down counter. CNTCYCL is cleared to 00H during reset. As long as the calculation unit is in standby, the down counter is continuously loaded with the register contents. After start of calculation, the down counter becomes separated from the register and starts counting. The register can then be reloaded by the CPU for the next calculation cycle. As soon as the down counter reaches the state 00H, the calculation cycle is terminated.

**Limit registers**

The calculation unit has two 8-bit limit registers (SFRs) WRLIM and RDLIM. WRLIM controls the start of Ao result output to RAM, while RDLIM controls the length of Ai and Xi input operands. RDLIM is split into two 4-bit registers. RDLIM (7-4) carry the READ limit for the Xi operand and RDLIM (3-0) the READ limit for Ai.

The contents of WRLIM, RDLIM (7-4), RDLIM (3-0) are compared to the contents of the Cycle Counter CNTCYCL during calculation. As Xi and Ai limits are both only 4-bits wide, these values are expanded to 8-bits for comparison by adding four leading zeros.

**WRITE LIMIT REGISTER WRLIM:**

- as long as the CNTCYCL contents are greater than the WRLIM's contents, writing of the Ao output result to RAM is inhibited.

**READ LIMIT REGISTER RDLIM:**

- READ Xi limit (upper 4-bits): when the CNTCYCL contents has reached the Xi limit, the READ value of the Xi operand is 0.
- READ Ai limit (lower 4-bits): when CNTCYCL contents has reached the Ai limit, the READ value of the Ai operand is 0.

The limit registers can be read and written by the CPU. Because of their pipeline structure, they can be re-loaded whilst the calculation unit is active. Both registers are cleared to 00H during reset.

**CXOR register**

This is an 8-bit wide SFR that provides one operand for an exclusive-OR operation on the calculation result. It can be read and written by the CPU, the default value after reset is 0.

**Calculation unit interrupt**

At the end of a calculation cycle, an interrupt request is generated (DONE = 1). The DONE flag has to be reset by software during the interrupt service routine. The calculation unit's operation cannot be interrupted by any other interrupt. Interrupt requests are pending until the end of the calculation cycle. They will be acknowledged during the interrupt service routine.

**Parallel operation of CPU and calculation unit**

The performance of the calculation unit degrades if pointer and control register initializations are done in between two consecutive calculation cycles. The full calculation speed is reached when these initializations are carried out by the CPU in parallel to a computation

# Secured 8-bit microcontroller

83C852

cycle of the calculation unit (see Fig. 13). Thus with parallel initializations, when a current computation cycle is completed, all of the required initializations have already been done to enable the next computation cycle of the calculation unit to start immediately.

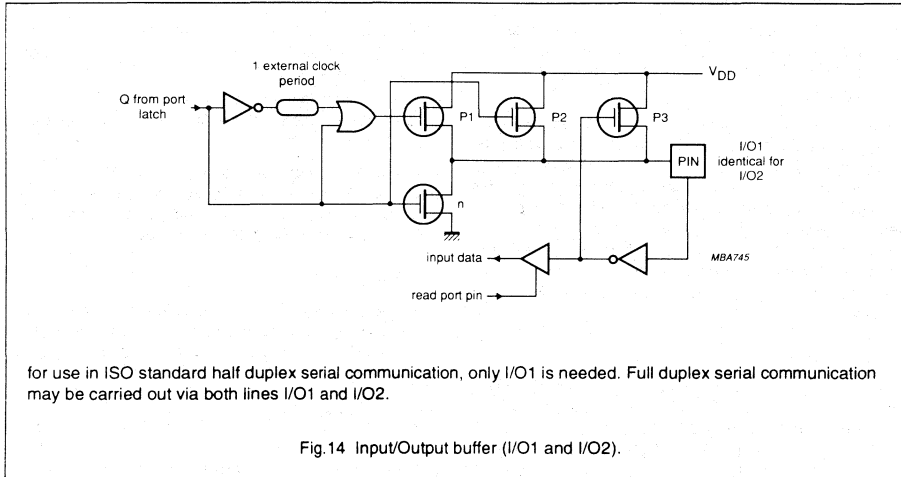

### IO register

The 83C852 has 2 I/O lines: I/O1 and I/O2. Line I/O1 is represented by IO1 (bit 0) and line I/O2 is represented by IO2 (bit 1) of the IO register (SFR). IO bits: 7, 6, 5, 4, 3 and 2 are don't care.

**Table 12** I/O SFR

|   |   |   |   |   |   |     |     |
|---|---|---|---|---|---|-----|-----|
| - | - | - | - | - | - | IO2 | IO1 |
| 7 | 6 | 5 | 4 | 3 | 2 | 1   | 0   |

Either I/O line can be used independently from the other as an input or as an output. For an I/O line to be used as an input, a set 1 must first be written to its port-latch. See Fig. 14. The strong output driver FET P1 is turned off after one external clock period. The pin is then pulled HIGH by the weak pull-up FETs P2 and P3. It can be pulled LOW by an external source. After a hardware reset, both port latches contain a set 1 and both lines I/O1 and I/O2 are in Input mode.

## Secured 8-bit microcontroller

83C852

**Timers**

The 83C852 has two 16-bit timer registers Timer 0 and Timer 1. The timer registers are incremented each machine cycle and are thus capable of counting each machine cycle and are thus capable of counting each machine cycle. Since a machine cycle consists of 6 external clock periods, the count rate is 1/6 of the clock frequency. Each timer has three operating modes:

- Mode 0 = 13-bit timer
- Mode 1 = 16-bit timer
- Mode 2 = 8-bit timer with auto-reload.

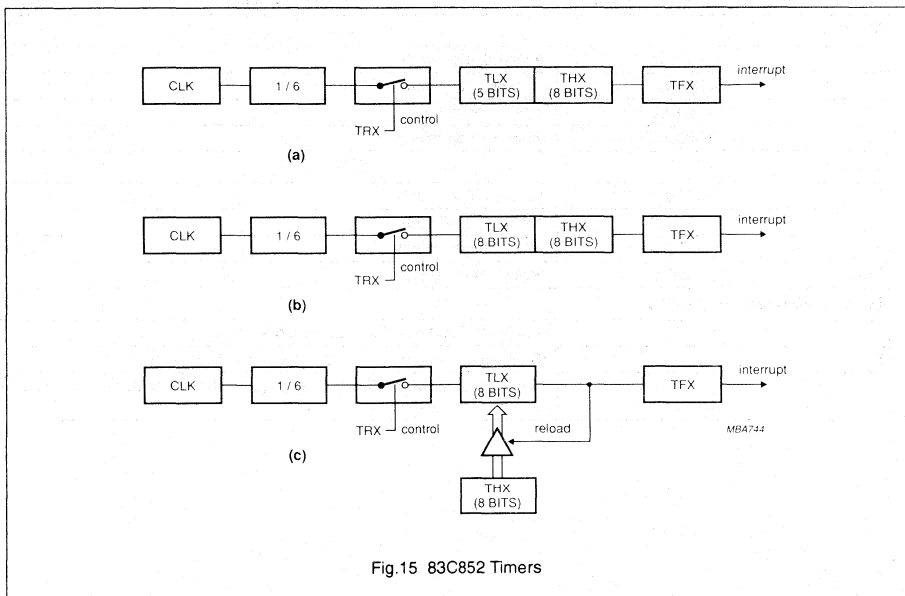

Fig.15 83C852 Timers

## Secured 8-bit microcontroller

83C852

Timers 0 and 1 are controlled via the two SFRs: Timer Mode Control (TMOD) and Timer Control/External Interrupt Control (TCON).

Table 13 TMOD SFR

| TIMER 1 |   |    |    | TIMER 2 |   |    |    |
|---------|---|----|----|---------|---|----|----|
| –       | – | M1 | M0 | –       | – | M1 | M0 |

| IE0                               | TCON.1    | is the external interrupt 0 edge flag. If IT0 is set 1, the IE0 bit is set 1 by hardware when the external interrupt source (either I/O1 pin or I/O2 pin) is detected to have made a 1 to 0 transition. The IE0 bit is cleared by hardware when the processor transfers control to the interrupt service routine. |
| IT0                               | TCON.0    | determines whether external interrupt is edge-triggered or level-triggered.<br>If IT0 is set 1: external interrupt 0 is edge-triggered.<br>If IT0 is reset 0, external interrupt 0 is triggered by a detected LOW at the external interrupt source.                                                               |

# Secured 8-bit microcontroller

83C852

### Interrupt system

The 83C852 has five interrupt sources, each can be programmed to one of two priority interrupt levels, either HIGH or LOW. The five interrupt sources are listed below:

1. I/O: external request from either I/O line
2. Timer 0: overflow from Timer 0
3. Cell: end of calculation
4. Timer 1: overflow from Timer 1
5. EEPROM: completion of EEPROM programming.

Each interrupt source can be individually enabled or disabled, all interrupt sources can also be globally enabled or disabled.

Each interrupt source can be programmed to either a HIGH or a LOW priority interrupt level. A LOW can be interrupted by a HIGH priority interrupt, but not by another LOW priority interrupt. A HIGH priority interrupt cannot be interrupted.

Only one of the I/O lines (either I/O1 or I/O2) can be used as an external interrupt source at a time. This selection is made by IOSW bit from TCON register.

### Interrupt vectors

The microcontroller acknowledges a request from an interrupt by a hardware subroutine call. It pushes the contents of the PC (program counter) into the stack, but it does not save the PSW (program status word). PC is reloaded with an address that depends on the source of the interrupt request, as shown below:

| Address | Source                            |
|---------|-----------------------------------|
| 0003H   | I/O1 or I/O2                      |
| 000BH   | Timer 0 Overflow                  |
| 0013H   | end of calculation                |
| 001BH   | Timer 1 Overflow                  |
| 0023H   | completion of EEPROM programming. |

### Interrupt registers IE and IP

#### INTERRUPT ENABLE REGISTER IE

Each source can be individually enabled or disabled by setting or clearing the corresponding bit inside the SFR Interrupt Enable register IE. All interrupt sources can also be globally enabled or disabled.

| PT1    | IP.3      | Timer 1 interrupt level          |
| PCU    | IP.2      | calculation unit interrupt level |
| PT0    | IP.1      | Timer 0 interrupt level          |
| PX0    | IP.0      | external 0 interrupt level       |

## INTERRUPT PRIORITY REGISTER IP

The interrupt level is selected within the SFR Interrupt Priority register IP. Setting a bit to '1' selects HIGH priority.

## Hardware security

## OPERATING MODE

The microcontroller has two operating modes:

- User mode
- Test mode

The test mode is permanently disabled once the test has been performed.

## Low frequency sensor

The low frequency detector circuit triggers a reset of the CPU when the clock frequency falls below  $f_{CLK}$  minimum (approximately 500 kHz). When the clock frequency rises above  $f_{CLK}$  minimum the reset is de-activated.

## Power ON/OFF reset

The power ON/OFF reset circuit triggers a reset of the CPU when the power supply falls below  $V_{DD}$  minimum (approximately 3.5 V). When the power supply rises above  $V_{DD}$  minimum, this reset is de-activated. When the power-down mode is active (PD is set 1) the power ON/OFF reset is de-activated.

## Idle mode and power-down mode

## IDLE MODE

The 83C852 provides two power saving operational modes, the idle mode and the power-down mode. In the idle mode, the CPU enters a sleep routine whilst some of the on-chip peripherals (timers and interrupt system) remain active. The contents of the RAM and SFRs remain unchanged during the duration of an idle mode. The idle mode can be terminated by an enabled interrupt or by a hardware reset. Besides stopping the CPU, the idle mode terminates EEPROM write operations and stops operation of the calculation unit.

## POWER-DOWN MODE

In the power-down mode, all on-chip internal clocks are frozen. The CPU and all on-chip peripherals stop working. The only exit from a power-down mode is by a hardware reset. The on-chip RAM and SFRs retain their values until the power-down mode is terminated. Reset redefines the SFRs, but does not change the RAM contents. The  $V_{DD}$  supply can be reduced to 2 V whilst the power-down mode is active. Both modes are activated by software via the SFR Power Control register PCON. PCON is not bit addressable.

## Secured 8-bit microcontroller

## Secured 8-bit microcontroller

83C852

**INSTRUCTION SET**

The instruction set consists of 49 single-byte, 46 two-byte and 16 three-byte instructions. When using a 6 MHz external clock, 64 instructions execute in 1 cycle (1  $\mu$ s) and 45 instructions execute in 2 cycles (2  $\mu$ s). Multiply and divide instructions execute in 4 cycles (4  $\mu$ s).

**INSTRUCTION SET DESCRIPTION**

For data addressing modes, Hexadecimal opcode cross-reference and invalid instructions, see Table notes.

## HANDLING

Inputs and outputs are protected against electrostatic discharge in normal handling. However, to be totally safe, it is desirable to take precautions appropriate to handling MOS devices (see 'Handling MOS Devices').

## Secured 8-bit microcontroller

83C852

## CHARACTERISTICS

 $V_{DD} = 5\text{ V}$  (+10 %);  $V_{SS} = 0\text{ V}$ ;  $T_{amb} = 0\text{ to }70\text{ }^{\circ}\text{C}$ ; all voltages with respect to  $V_{SS}$  unless otherwise specified.

## The I<sup>2</sup>C-bus and how to use it

# The I<sup>2</sup>C-bus and how to use it (including specification)

## 1.0 THE I<sup>2</sup>C-BUS BENEFITS DESIGNERS AND MANUFACTURERS

In consumer electronics, telecommunications and industrial electronics, there are often many similarities between seemingly unrelated designs. For example, nearly every system includes:

- Some intelligent control, usually a single-chip microcontroller
- General-purpose circuits like LCD drivers, remote I/O ports, RAM, EEPROM, or data converters
- Application-oriented circuits such as digital tuning and signal processing circuits for radio and video systems, or DTMF generators for telephones with tone dialling

To exploit these similarities to the benefit of both systems designers and equipment manufacturers, as well as to maximize hardware efficiency and circuit simplicity, Philips developed a simple bidirectional 2-wire bus for efficient inter-IC control. This bus is called the Inter IC or I<sup>2</sup>C-bus. At present, Philips' IC range includes more than 150 CMOS and bipolar I<sup>2</sup>C-bus compatible types for performing functions in all three of the previously mentioned categories. All I<sup>2</sup>C-bus compatible devices incorporate an on-chip interface which allows them to communicate directly with each other via the I<sup>2</sup>C-bus. This design concept solves the many interfacing problems encountered when designing digital control circuits.

Here are some of the features of the I<sup>2</sup>C-bus:

- Only two bus lines are required; a serial data line (SDA) and a serial clock line (SCL)
- Each device connected to the bus is software addressable by a unique address and simple master/slave relationships exist at all times; masters can operate as master-transmitters or as master-receivers
- It's a true multi-master bus including collision detection and arbitration to prevent data corruption if two or more masters simultaneously initiate data transfer
- Serial, 8-bit oriented, bidirectional data transfers can be made at up to 100 kbit/s in the standard mode or up to 400 kbit/s in the fast mode
- On-chip filtering rejects spikes on the bus

data line to preserve data integrity

- The number of ICs that can be connected to the same bus is limited only by a maximum bus capacitance of 400 pF

Figure 1 shows two examples of I<sup>2</sup>C-bus applications.

### 1.1 Designer Benefits

I<sup>2</sup>C-bus compatible ICs allow a system design to rapidly progress directly from a functional block diagram to a prototype. Moreover, since they 'clip' directly onto the I<sup>2</sup>C-bus without any additional external interfacing, they allow a prototype system to be modified or upgraded simply by 'clipping' or 'unclipping' ICs to or from the bus.

Here are some of the features of I<sup>2</sup>C-bus compatible ICs which are particularly attractive to designers:

- Functional blocks on the block diagram correspond with the actual ICs; designs proceed rapidly from block diagram to final schematic
- No need to design bus interfaces because the I<sup>2</sup>C-bus interface is already integrated on-chip
- Integrated addressing and data-transfer protocol allow systems to be completely software-defined
- The same IC types can often be used in many different applications
- Design-time reduces as designers quickly become familiar with the frequently used functional blocks represented by I<sup>2</sup>C-bus compatible ICs
- ICs can be added to or removed from a system without affecting any other circuits on the bus
- Fault diagnosis and debugging are simple; malfunctions can be immediately traced
- Software development time can be reduced by assembling a library of reusable software modules.

In addition to these advantages, the CMOS ICs in the I<sup>2</sup>C-bus compatible range offer designers special features which are particularly attractive for portable equipment and battery-backed systems.

They all have:

- Extremely low current consumption
- High noise immunity

- Wide supply voltage range
- Wide operating temperature range.

### 1.2 Manufacturer benefits

I<sup>2</sup>C-bus compatible ICs don't only assist designers, they also give a wide range of benefits to equipment manufacturers because:

- The simple 2-wire serial I<sup>2</sup>C-bus minimizes interconnections so ICs have fewer pins and there are not so many PCB tracks; result - smaller and less expensive PCBs
- The completely integrated I<sup>2</sup>C-bus protocol eliminates the need for address decoders and other 'glue logic'
- The multi-master capability of the I<sup>2</sup>C-bus allows rapid testing and alignment of end-user equipment via external connections to an assembly-line computer
- The availability of I<sup>2</sup>C-bus compatible ICs in SO (small outline), VSO (very small outline) as well as DIL packages reduces space requirements even more.

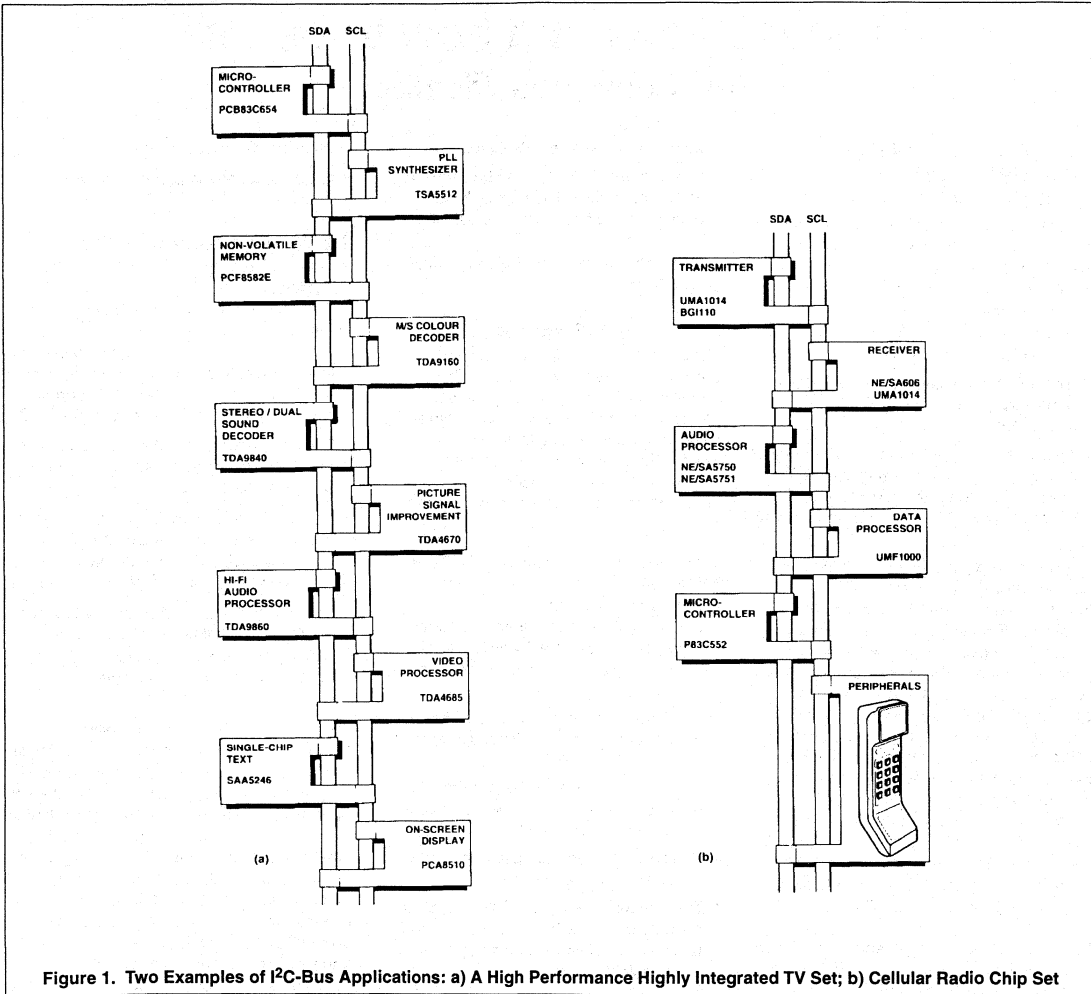

These are just some of the benefits.

In addition, I<sup>2</sup>C-bus compatible ICs increase system design flexibility by allowing simple construction of equipment variants and easy upgrading to keep designs up-to-date. In this way, an entire family of equipment can be developed around a basic model. Upgrades for new equipment, or enhanced-feature models (i.e. extended memory, remote control, etc.) can then be produced simply by clipping the appropriate ICs onto the bus. If a larger ROM is needed, it's simply a matter of selecting a microcontroller with a larger ROM from our comprehensive range. As new ICs supersede older ones, it's easy to add new features to equipment or to increase its performance by simply unclipping the outdated IC from the bus and clipping on its successor.

### 1.3 The ACCESS.bus

Another attractive feature of the I<sup>2</sup>C-bus for designers and manufacturers is that its simple 2-wire nature and capability of software addressing make it an ideal platform for the ACCESS.bus (Fig.2). This is a lower-cost alternative for an RS-232C interface for connecting peripherals to a host computer via a simple 4-pin connector (see Section 19).

# The I<sup>2</sup>C-bus and how to use it

**Table 1. Definition of I<sup>2</sup>C-Bus Terminology**

| Term            | Description                                                                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transmitter     | The device which sends the data to the bus                                                                                                               |
| Receiver        | The device which receives the data from the bus                                                                                                          |
| Master          | The device which initiates a transfer, generates clock signals and terminates a transfer                                                                 |
| Slave           | The device addressed by a master                                                                                                                         |
| Multi-master    | More than one master can attempt to control the bus at the same time without corrupting the message                                                      |

## The I<sup>2</sup>C-bus and how to use it

Figure 2. The ACCESS.bus - A Low-Cost Alternative to an RS-232C Interface

Figure 3. Examples of an I<sup>2</sup>C-Bus Configuration Using Two Microcontrollers

### 2.0 INTRODUCTION TO THE I<sup>2</sup>C-BUS SPECIFICATION

For 8-bit digital control applications, such as those requiring microcontrollers, certain design criteria can be established:

- A complete system usually consists of at least one microcontroller and other peripheral devices such as memories and I/O expanders
- The cost of connecting the various devices within the system must be minimized
- A system that performs a control function doesn't require high-speed data transfer
- Overall efficiency depends on the devices chosen and the nature of the interconnecting bus structure.

In order to produce a system to satisfy these criteria, a serial bus structure is needed. Although serial buses don't have the throughput capability of parallel buses, they do require less wiring and fewer IC connecting pins. However, a bus is not merely an interconnecting wire, it embodies all the formats and procedures for communication within the system.

Devices communicating with each other on a serial bus must have some form of protocol which avoids all possibilities of confusion, data loss and blockage of information. Fast devices must be able to communicate with slow devices. The system must not be dependent on the devices connected to it,

otherwise modifications or improvements would be impossible. A procedure has also to be devised to decide which device will be in control of the bus and when. And, if different devices with different clock speeds are connected to the bus, the bus clock source must be defined. All these criteria are involved in the specification of the I<sup>2</sup>C-bus.

### 3.0 THE I<sup>2</sup>C-BUS CONCEPT

The I<sup>2</sup>C-bus supports any IC fabrication process (NMOS, CMOS, bipolar). Two wires, serial data (SDA) and serial clock (SCL), carry information between the devices connected to the bus. Each device is recognised by a unique address – whether it's a microcontroller, LCD driver, memory or keyboard interface – and can operate as either a transmitter or receiver, depending on the function of the device. Obviously an LCD driver is only a receiver, whereas a memory can both receive and transmit data. In addition to transmitters and receivers, devices can also be considered as masters or slaves when performing data transfers (see Table 1). A master is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

The I<sup>2</sup>C-bus is a multi-master bus. This means that more than one device capable of

controlling the bus can be connected to it. As masters are usually micro-controllers, let's consider the case of a data transfer between two microcontrollers connected to the I<sup>2</sup>C-bus (Fig.3). This highlights the master-slave and receiver-transmitter relationships to be found on the I<sup>2</sup>C-bus. It should be noted that these relationships are

not permanent, but only depend on the direction of data transfer at that time. The transfer of data would proceed as follows:

1. Suppose microcontroller A wants to send information to microcontroller B:
  - microcontroller A (master), addresses microcontroller B (slave)
  - microcontroller A (master-transmitter), sends data to microcontroller B (slave-receiver)
  - microcontroller A terminates the transfer.
2. If microcontroller A wants to receive information from microcontroller B:
  - microcontroller A (master) addresses microcontroller B (slave)
  - microcontroller A (master-receiver) receives data from microcontroller B (slave-transmitter)
  - microcontroller A terminates the transfer.

Even in this case, the master (microcontroller A) generates the timing and terminates the transfer.

The possibility of connecting more than one microcontroller to the I<sup>2</sup>C-bus means that

# The I<sup>2</sup>C-bus and how to use it

more than one master could try to initiate a data transfer at the same time. To avoid the chaos that might ensue from such an event – an arbitration procedure has been developed. This procedure relies on the wired-AND connection of all I<sup>2</sup>C interfaces to the I<sup>2</sup>C-bus.

If two or more masters try to put information onto the bus, the first to produce a 'one' while the other produces a 'zero' will lose the arbitration. The clock signals during arbitration are a synchronized combination of the clocks generated by the masters using the wired-AND connection to the SCL line (for more detailed information concerning arbitration see Section 7.0).

Generation of clock signals on the I<sup>2</sup>C-bus is always the responsibility of master devices; each master generates its own clock signals when transferring data on the bus. Bus clock signals from a master can only be altered when they are stretched by a slow-slave device holding-down the clock line, or by another master when arbitration occurs.

## 4.0 GENERAL CHARACTERISTICS

Both SDA and SCL are bidirectional lines, connected to a positive supply voltage via a pull-up resistor (see Fig.4). When the bus is free, both lines are HIGH. The output stages of devices connected to the bus must have an open-drain or open-collector in order to perform the wired-AND function. Data on the I<sup>2</sup>C-bus can be transferred at a rate up to 100 kbit/s in the standard-mode, or up to 400 kbit/s in the fast-mode. The number of interfaces connected to the bus is solely dependent on the bus capacitance limit of 400 pF.

## 5.0 BIT TRANSFER

Due to the variety of different technology devices (CMOS, NMOS, bipolar) which can be connected to the I<sup>2</sup>C-bus, the levels of the logical '0' (LOW) and '1' (HIGH) are not fixed and depend on the associated level of V<sub>DD</sub> (see Section 15.0 for Electrical Specifications). One clock pulse is generated for each data bit transferred.

### 5.1 Data Validity

The data on the SDA line must be stable

during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW (see Fig.5).

### 5.2 START and STOP Conditions

Within the procedure of the I<sup>2</sup>C-bus, unique situations arise which are defined as START and STOP conditions (see Fig.6).

A HIGH to LOW transition on the SDA line while SCL is HIGH is one such unique case. This situation indicates a START condition.

A LOW to HIGH transition on the SDA line while SCL is HIGH defines a STOP condition.

START and STOP conditions are always generated by the master. The bus is considered to be busy after the START condition. The bus is considered to be free again a certain time after the STOP condition. This bus free situation is specified in Section 15.0.

Detection of START and STOP conditions by devices connected to the bus is easy if they incorporate the necessary interfacing hardware. However, microcontrollers with no such interface have to sample the SDA line at least twice per clock period in order to sense the transition.

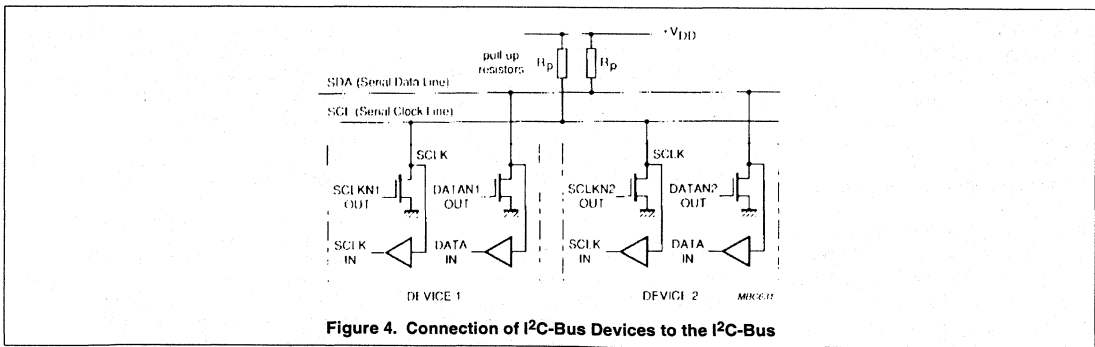

Figure 4. Connection of I<sup>2</sup>C-Bus Devices to the I<sup>2</sup>C-Bus

Figure 5. Bit Transfer on the I<sup>2</sup>C-Bus

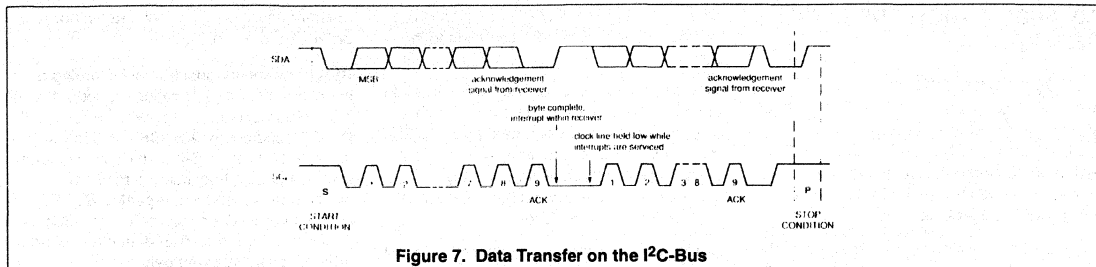

Figure 6. START and STOP Conditions

## The I<sup>2</sup>C-bus and how to use it

### 6.0 TRANSFERRING DATA

#### 6.1 Byte Format

Every byte put on the SDA line must be 8-bits long. The number of bytes that can be transmitted per transfer is unrestricted. Each byte has to be followed by an acknowledge bit. Data is transferred with the most significant bit (MSB) first (Fig.7). If a receiver can't receive another complete byte of data until it has performed some other function, for example servicing an internal interrupt, it can hold the clock line SCL LOW to force the transmitter into a wait state. Data transfer then continues when the receiver is ready for another byte of data and releases clock line SCL.

In some cases, it's permitted to use a different format from the I<sup>2</sup>C-bus format (for CBUS compatible devices for example). A message which starts with such an address can be terminated by generation of a STOP

condition, even during the transmission of a byte. In this case, no acknowledge is generated (see Section 9.1.3).

#### 6.2 Acknowledge

Data transfer with acknowledge is obligatory. The acknowledge-related clock pulse is generated by the master. The transmitter releases the SDA line (HIGH) during the acknowledge clock pulse.

The receiver must pull down the SDA line during the acknowledge clock pulse so that it remains stable LOW during the HIGH period of this clock pulse (Fig.8). Of course, set-up and hold times (specified in Section 15) must also be taken into account.

Usually, a receiver which has been addressed is obliged to generate an acknowledge after each byte has been received, except when the message starts with a CBUS address (see Section 9.1.3).

When a slave-receiver doesn't acknowledge the slave address (for example, it's unable to receive because it's performing some real-time function), the data line must be left HIGH by the slave. The master can then generate a STOP condition to abort the transfer.

If a slave-receiver does acknowledge the slave address but, some time later in the transfer cannot receive any more data bytes, the master must again abort the transfer. This is indicated by the slave generating the not acknowledge on the first byte to follow. The slave leaves the data line HIGH and the master generates the STOP condition.

If a master-receiver is involved in a transfer, it must signal the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter must release the data line to allow the master to generate the STOP condition.

## The I<sup>2</sup>C-bus and how to use it

### 7.0 ARBITRATION AND CLOCK GENERATION

#### 7.1 Synchronization

All masters generate their own clock on the SCL line to transfer messages on the I<sup>2</sup>C-bus. Data is only valid during the HIGH period of the clock. A defined clock is therefore needed for the bit-by-bit arbitration procedure to take place.

Clock synchronization is performed using the wired-AND connection of I<sup>2</sup>C interfaces to the SCL line. This means that a HIGH to LOW transition on the SCL line will cause the devices concerned to start counting off their LOW period and, once a device clock has gone LOW, it will hold the SCL line in that state until the clock HIGH state is reached (Fig.9). However, the LOW to HIGH transition of this clock may not change the state of the SCL line if another clock is still within its LOW period. The SCL line will therefore be held LOW by the device with the longest LOW period. Devices with shorter LOW periods enter a HIGH wait-state during this time.

When all devices concerned have counted off their LOW period, the clock line will be released and go HIGH. There will then be no difference between the device clocks and the state of the SCL line, and all the devices will start counting their HIGH periods. The first device to complete its HIGH period will again pull the SCL line LOW.

In this way, a synchronized SCL clock is generated with its LOW period determined by the device with the longest clock LOW period, and its HIGH period determined by the one with the shortest clock HIGH period.

#### 7.2 Arbitration

A master may start a transfer only if the bus is free. Two or more masters may generate a START condition within the minimum hold

time ( $t_{HD;STA}$ ) of the START condition which results in a defined START condition to the bus.

Arbitration takes place on the SDA line, while the SCL line is at the HIGH level, in such a way that the master which transmits a HIGH level, while another master is transmitting a LOW level will switch off its DATA output stage because the level on the bus doesn't correspond to its own level.

Arbitration can continue for many bits. Its first stage is comparison of the address bits (addressing information is in Sections 9.0 and 13.0). If the masters are each trying to address the same device, arbitration continues with comparison of the data. Because address and data information on the I<sup>2</sup>C-bus is used for arbitration, no information is lost during this process.

A master which loses the arbitration can generate clock pulses until the end of the byte in which it loses the arbitration.

If a master also incorporates a slave function and it loses

arbitration during the addressing stage, it's possible that the winning master is trying to address it. The losing master must therefore switch over immediately to its slave-receiver mode.

Figure 10 shows the arbitration procedure for two masters. Of course, more may be involved (depending on how many masters are connected to the bus). The moment there is a difference between the internal data level of the master generating DATA 1 and the actual level on the SDA line, its data output is switched off, which means that a HIGH output level is then connected to the bus. This will not affect the data transfer initiated by the winning master.

Since control of the I<sup>2</sup>C-bus is decided solely on the address and data sent by competing

masters, there is no central master, nor any order of priority on the bus.

Special attention must be paid if, during a serial transfer, the arbitration procedure is still in progress at the moment when a repeated START condition or a STOP condition is transmitted to the I<sup>2</sup>C-bus. If it's possible for such a situation to occur, the masters involved must send this repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration isn't allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition.

#### 7.3 Use of the Clock Synchronising Mechanism as a Handshake

In addition to being used during the arbitration procedure, the clock synchronization mechanism can be used to enable receivers to cope with fast data transfers, on either a byte level or a bit level.

On the byte level, a device may be able to receive bytes of data at a fast rate, but needs more time to store a received byte or prepare another byte to be transmitted. Slaves can then hold the SCL line LOW after reception and acknowledgement of a byte to force the master into a wait state until the slave is ready for the next byte transfer in a type of handshake procedure.

On the bit level, a device such as a microcontroller without, or with only a limited hardware I<sup>2</sup>C interface on-chip can slow down the bus clock by extending each clock LOW period. The speed of any master is thereby adapted to the internal operating rate of this device.

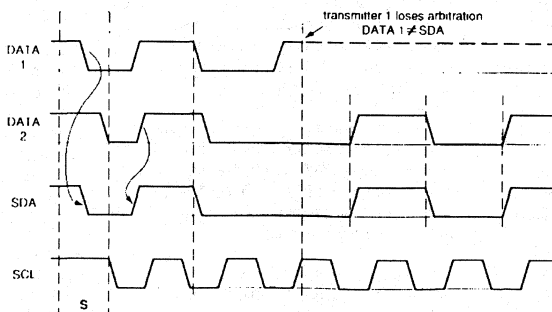

Figure 10. Arbitration Procedure of Two Masters

# The I<sup>2</sup>C-bus and how to use it

## 8.0 FORMATS WITH 7-BIT ADDRESSES

Data transfers follow the format shown in Fig.11. After the START condition (S), a slave address is sent. This address is 7 bits long followed by an eighth bit which is a data direction bit (R/W) – a 'zero' indicates a transmission (WRITE), a 'one' indicates a request for data (READ). A data transfer is always terminated by a STOP condition (P) generated by the master. However, if a master still wishes to communicate on the bus, it can generate a repeated START condition (Sr) and address another slave without first generating a STOP condition. Various combinations of read/write formats are then possible within such a transfer.

Possible data transfer formats are:

- Master-transmitter transmits to slave-receiver. The transfer direction is not changed (Fig.12)
- Master reads slave immediately after first byte (Fig.13). At the moment of the first acknowledge, the master-transmitter becomes a master-receiver and the slave-receiver becomes a slave-transmitter. This acknowledge is still generated by the slave. The STOP condition is generated by the master
- Combined format (Fig.14). During a change of direction within a transfer, the START condition and the slave address are both repeated, but with the R/W bit reversed.

NOTES:

1. Combined formats can be used, for example, to control a serial memory. During the first data byte, the internal memory location has to be written. After the START condition and slave address is repeated, data can be transferred.
2. All decisions on auto-increment or decrement of previously accessed memory locations etc. are taken by the designer of the device.
3. Each byte is followed by an acknowledgement bit as indicated by the A or  $\bar{A}$  blocks in the sequence.
4. I<sup>2</sup>C-bus compatible devices must reset their bus logic on receipt of a START or repeated START condition such that they all anticipate the sending of a slave address.

## The I<sup>2</sup>C-bus and how to use it

**Table 2. Definition of Bits in the First Byte**

| Slave address | R/ bit | Description                               |
|---------------|--------|-------------------------------------------|
| 0000 000      | 0      | General call address                      |
| 0000 000      | 1      | START byte                                |
| 0000 001      | X      | CBUS address                              |
| 0000 010      | X      | Address reserved for different bus format |
| 0000 011      | X      | Reserved for future purposes              |
| 0000 1XX      | X      | Reserved for future purposes              |
| 1111 1XX      | X      | Reserved for future purposes              |
| 1111 0XX      | X      | 10-bit slave addressing                   |

**NOTES:**

1. No device is allowed to acknowledge at the reception of the START byte.
2. The CBUS address has been reserved to enable the inter-mixing of CBUS compatible and I<sup>2</sup>C-bus compatible devices in the same system. I<sup>2</sup>C-bus compatible devices are not allowed to respond on reception of this address.
3. The address reserved for a different bus format is included to enable I<sup>2</sup>C and other protocols to be mixed. Only I<sup>2</sup>C-bus compatible devices that can work with such formats and protocols are allowed to respond to this address.

### 9.0 7-BIT ADDRESSING (see Section 13.0 for 10-Bit Addressing)

The addressing procedure for the I<sup>2</sup>C-bus is such that the first byte after the START condition usually determines which slave will be selected by the master. The exception is the 'general call' address which can address all devices. When this address is used, all devices should, in theory, respond with an acknowledge. However, devices can be made to ignore this address. The second byte of the general call address then defines the action to be taken. This procedure is explained in more detail in Section 9.1.1.

#### 9.1 Definition of Bits in the First Byte

The first seven bits of the first byte make up the slave address (Fig.15). The eighth bit is the LSB (least significant bit). It determines the direction of the message. A 'zero' in the least significant position of the first byte means that the master will write information to a selected slave. A 'one' in this position means that the master will read information from the slave.

When an address is sent, each device in a system compares the first seven bits after the START condition with its address. If they match, the device considers itself addressed by the master as a slave-receiver or slave-transmitter, depending on the R/W bit.

A slave address can be made-up of a fixed and a programmable part. Since it's likely that there will be several identical devices in a system, the programmable part of the slave address enables the maximum possible number of such devices to be connected to

the I<sup>2</sup>C-bus. The number of programmable address bits of a device depends on the number of pins available. For example, if a device has 4 fixed and 3 programmable address bits, a total of 8 identical devices can be connected to the same bus.

The I<sup>2</sup>C-bus committee coordinates allocation of I<sup>2</sup>C addresses. Further information can be obtained from the Philips representatives listed on the back cover. Two groups of eight addresses (0000XXX and 1111XXX) are reserved for the purposes shown in Table 2. The bit combination 11110XX of the slave address is reserved for 10-bit addressing (see Section 13).

#### 9.1.1 General Call Address

The general call address is for addressing every device connected to the I<sup>2</sup>C-bus. However, if a device doesn't need any of the data supplied within the general call structure, it can ignore this address by not issuing an acknowledgement. If a device does require data from a general call address, it will acknowledge this address and behave as a slave-receiver. The second and following bytes will be acknowledged by every slave-receiver capable of handling this data. A slave which cannot process one of these bytes must ignore it by not acknowledging. The meaning of the general call address is always specified in the second byte (Fig.16).

There are two cases to consider:

- When the least significant bit B is a 'zero'
- When the least significant bit B is a 'one'.

When bit B is a 'zero'; the second byte has the following definition:

- 00000110 (H'06'). Reset and write programmable part of slave address by hardware. On receiving this 2-byte sequence, all devices designed to respond to the general call address will reset and take in the programmable part of their address. Precautions have to be taken to ensure that a device is not pulling down the SDA or SCL line after applying the supply voltage, since these low levels would block the bus
- 00000100 (H'04'). Write programmable part of slave address by hardware. All devices which define the programmable part of their address by hardware (and which respond to the general call address) will latch this programmable part at the reception of this two byte sequence. The device will not reset.
- 00000000 (H'00'). This code is not allowed to be used as the second byte.

Sequences of programming procedure are published in the appropriate device data sheets.

The remaining codes have not been fixed and devices must ignore them.

When bit B is a 'one'; the 2-byte sequence is a 'hardware general call'. This means that the sequence is transmitted by a hardware master device, such as a keyboard scanner, which cannot be programmed to transmit a desired slave address. Since a hardware master doesn't know in advance to which device the message has to be transferred, it can only generate this hardware general call and its own address – identifying itself to the system (Fig.17).

The seven bits remaining in the second byte contain the address of the hardware master.

# The I<sup>2</sup>C-bus and how to use it

This address is recognised by an intelligent device (e.g. a microcontroller) connected to the bus which will then direct the information from the hardware master. If the hardware master can also act as a slave, the slave address is identical to the master address.

In some systems, an alternative could be that the hardware master transmitter is set in the slave-receiver mode after the system reset. In this way, a system configuring master can tell the hardware master-transmitter (which is

now in slave-receiver mode) to which address data must be sent (Fig. 18). After this programming procedure, the hardware master remains in the master-transmitter mode.

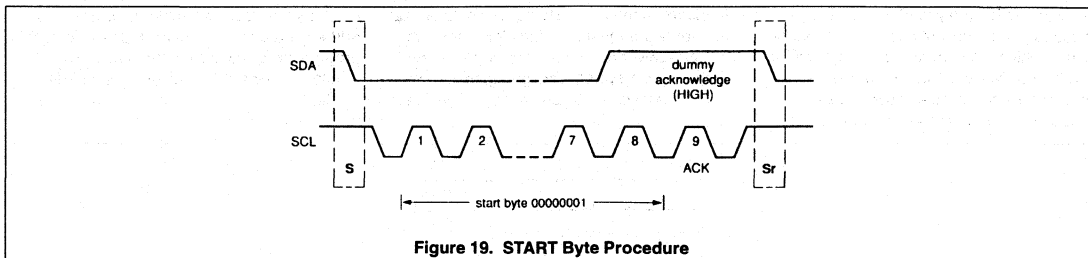

Figure 18. Data Transfer by a Hardware-Transmitter Capable of Dumping Data Directly to Slave Devices

## The I<sup>2</sup>C-bus and how to use it

### 9.1.2 START byte

Microcontrollers can be connected to the I<sup>2</sup>C-bus in two ways. A microcontroller with an on-chip hardware I<sup>2</sup>C-bus interface can be programmed to be only interrupted by requests from the bus. When the device doesn't have such an interface, it must constantly monitor the bus via software. Obviously, the more times the microcontroller monitors, or polls the bus, the less time it can spend carrying out its intended function.

There is therefore a speed difference between fast hardware devices and a relatively slow microcontroller which relies on software polling.

In this case, data transfer can be preceded by a start procedure which is much longer than normal (Fig.19). The start procedure consists of:

- A START condition (S)
- A START byte (00000001)
- An acknowledge clock pulse (ACK)
- A repeated START condition (Sr).

After the START condition S has been

transmitted by a master which requires bus access, the START byte (00000001) is transmitted. Another microcontroller can therefore sample the SDA line at a low sampling rate until one of the seven zeros in the START byte is detected. After detection of this LOW level on the SDA line, the microcontroller can switch to a higher sampling rate to find the repeated START condition Sr which is then used for synchronization.

A hardware receiver will reset on receipt of the repeated START condition Sr and will therefore ignore the START byte.

An acknowledge-related clock pulse is generated after the START byte. This is present only to conform with the byte handling format used on the bus. No device is allowed to acknowledge the START byte.

### 9.1.3 CBUS Compatibility

CBUS receivers can be connected to the I<sup>2</sup>C-bus. However, a third bus line called DLEN must then be connected and the

acknowledge bit omitted. Normally, I<sup>2</sup>C transmissions are sequences of 8-bit bytes; CBUS compatible devices have different formats.

In a mixed bus structure, I<sup>2</sup>C-bus devices must not respond to the CBUS message. For this reason, a special CBUS address (0000001X) to which no I<sup>2</sup>C-bus compatible device will respond, has been reserved. After transmission of the CBUS address, the DLEN line can be made active and a CBUS-format transmission (Fig.20) sent. After the STOP condition, all devices are again ready to accept data.

Master-transmitters can send CBUS formats after sending the CBUS address. The transmission is ended by a STOP condition, recognised by all devices.

**NOTE:** If the CBUS configuration is known, and expansion with CBUS compatible devices isn't foreseen, the designer is allowed to adapt the hold time to the specific requirements of the device(s) used.

# The I<sup>2</sup>C-bus and how to use it

## 10.0 ELECTRICAL CHARACTERISTICS FOR I<sup>2</sup>C-BUS DEVICES

The electrical specifications for the I/Os of I<sup>2</sup>C-bus devices and the characteristics of the bus lines connected to them are given in Tables 3 and 4 in Section-15.

I<sup>2</sup>C-bus devices with fixed input levels of 1.5 V and 3 V can each have their own appropriate supply voltage. Pull-up resistors

must be connected to a 5 V ± 10% supply (Fig.21). I<sup>2</sup>C-bus devices with input levels related to V<sub>DD</sub> must have one common supply line to which the pull-up resistor is also connected (Fig.22).

When devices with fixed input levels are mixed with devices with input levels related to V<sub>DD</sub>, the latter devices must be connected to one common supply line of 5 V ± 10% and must have pull-up resistors connected to their SDA and SCL pins as shown in Fig.23.

Input levels are defined in such a way that:

- The noise margin on the LOW level is 0.1 V<sub>DD</sub>
- The noise margin on the HIGH level is 0.2 V<sub>DD</sub>
- As shown in Fig.24, series resistors (R<sub>S</sub>) of e.g. 300 Ω can be used for protection against high-voltage spikes on the SDA and SCL lines (due to flash-over of a TV picture tube, for example).

# The I<sup>2</sup>C-bus and how to use it

## 10.1 Maximum and minimum values of resistors R<sub>p</sub> and R<sub>s</sub>

For standard-mode I<sup>2</sup>C-bus devices, the values of resistors R<sub>p</sub> and R<sub>s</sub> in Fig.24 depend on the following parameters:

- Supply voltage
- Bus capacitance
- Number of connected devices (input current + leakage current).

The supply voltage limits the minimum value of resistor R<sub>p</sub> due

to the specified minimum sink current of 3 mA at V<sub>OLmax</sub> = 0.4 V for the output stages. V<sub>DD</sub> as a function of R<sub>p min</sub> is shown in Fig.25. The desired noise margin of 0.1V<sub>DD</sub> for the LOW level, limits the maximum value of R<sub>s</sub>. R<sub>s max</sub> as a function of R<sub>p</sub> is shown in Fig.26.

The bus capacitance is the total capacitance of wire, connections and pins. This capacitance limits the maximum value of R<sub>p</sub> due to the specified rise time. Fig.27 shows

R<sub>p max</sub> as a function of bus capacitance.

The maximum HIGH level input current of each input/output connection has a specified maximum value of 10 μA. Due to the desired noise margin of 0.2V<sub>DD</sub> for the HIGH level, this input current limits the maximum value of R<sub>p</sub>. This limit depends on V<sub>DD</sub>. The total HIGH level input current is shown as a function of R<sub>p max</sub> in Fig.28.

- A **fast-mode** which allows a fourfold increase of the bit rate to 0 to 400 kbit/s
- **10-bit addressing** which allows the use of up to 1024 additional addresses.

There are two reasons for these extensions to the I<sup>2</sup>C-bus specification:

- New applications will need to transfer a larger amount of serial data and will therefore demand a higher bit rate than 100 kbit/s. Improved IC manufacturing technology now allows a fourfold speed increase without increasing the manufacturing cost of the interface circuitry
- Most of the 112 addresses available with the 7-bit addressing scheme have been issued more than once. To prevent problems with the allocation of slave addresses for new devices, it is desirable to have more address combinations. About a tenfold increase of the number of available addresses is obtained with the new 10-bit addressing.

## 11.0 EXTENSIONS TO THE I<sup>2</sup>C-BUS SPECIFICATION

The I<sup>2</sup>C-bus with a data transfer rate of up to 100 kbit/s and 7-bit addressing has now been in existence for more than ten years with an unchanged specification. The concept is accepted world-wide as a de facto standard and hundreds of different types of I<sup>2</sup>C-bus compatible ICs are available from Philips and other suppliers. The I<sup>2</sup>C-bus specification is now extended with the following two features:

Figure 25. Minimum Value of R<sub>p</sub> as a Function of Supply Voltage with the Value of R<sub>s</sub> as a Parameter

Figure 26. Maximum Value of R<sub>s</sub> as a Function of the Value of R<sub>p</sub> with Supply Voltage as a Parameter

Figure 27. Maximum Value of R<sub>p</sub> as a Function of Bus Capacitance for a Standard-Mode I<sup>2</sup>C-Bus

Figure 28. Total HIGH Level Input Current as a Function of the Maximum Value of R<sub>p</sub> with Supply Voltage as a Parameter

## The I<sup>2</sup>C-bus and how to use it

All new devices with an I<sup>2</sup>C-bus interface are provided with the fast-mode. Preferably, they should be able to receive and/or transmit at 400 kbit/s. The minimum requirement is that they can synchronize with a 400 kbit/s transfer; they can then prolong the LOW period of the SCL signal to slow down the transfer. Fast-mode devices must be downward-compatible which means that they must still be able to communicate with 0 to 100 kbit/s devices in a 0 to 100 kbit/s I<sup>2</sup>C-bus system.

Obviously, devices with a 0 to 100 kbit/s I<sup>2</sup>C-bus interface cannot be incorporated in a fast-mode I<sup>2</sup>C-bus system because, since they cannot follow the higher transfer rate, unpredictable states of these devices would occur.

Slave devices with a fast-mode I<sup>2</sup>C-bus interface can have a 7-bit or a 10-bit slave address. However, a 7-bit address is preferred because it is the cheapest solution in hardware and it results in the shortest message length. Devices with 7-bit and 10-bit addresses can be mixed in the same I<sup>2</sup>C-bus system regardless of whether it is a 0 to 100 kbit/s standard-mode system or a 0 to 400 kbit/s fast-mode system. Both existing and future masters can generate either 7-bit or 10-bit addresses.

### 12.0 FAST-MODE

In the fast-mode of the I<sup>2</sup>C-bus, the protocol, format, logic levels and maximum capacitive load for the SDA and SCL lines quoted in the previous I<sup>2</sup>C-bus specification are unchanged. Changes to the previous I<sup>2</sup>C-bus specification are:

- The maximum bit rate is increased to 400 kbit/s
- Timing of the serial data (SDA) and serial clock (SCL) signals has been adapted. There is no need for compatibility with other bus systems such as CBUS because they cannot operate at the increased bit rate
- The inputs of fast-mode devices must incorporate spike suppression and a Schmitt trigger at the SDA and SCL inputs
- The output buffers of fast-mode devices must incorporate slope control of the falling edges of the SDA and SCL signals
- If the power supply to a fast-mode device is switched off, the SDA and SCL I/O pins must be floating so that they don't obstruct the bus lines
- The external pull-up devices connected to the bus lines must be adapted to accommodate the shorter maximum

permissible rise time for the fast-mode I<sup>2</sup>C-bus. For bus loads up to 200 pF, the pull-up device for each bus line can be a resistor; for bus loads between 200 pF and 400 pF, the pull-up device can be a current source (3mA max.) or a switched resistor circuit as shown in Fig.37.

### 13.0 10-BIT ADDRESSING

The 10-bit addressing does not change the format in the I<sup>2</sup>C-bus specification. Using 10 bits for addressing exploits the reserved combination 1111XXX for the first seven bits of the first byte following a START (S) or repeated START (Sr) condition as explained in Section 9.1. The 10-bit addressing does not affect the existing 7-bit addressing. Devices with 7-bit and 10-bit addresses can be connected to the same I<sup>2</sup>C-bus, and both 7-bit and 10-bit addressing can be used in a standard-mode system (up to 100 kbit/s) or a fast-mode system (up to 400 kbit/s).

Although there are eight possible combinations of the reserved address bits 1111XXX, only the four combinations 11110XX are used for 10-bit addressing. The remaining four combinations 11111XX are reserved for future I<sup>2</sup>C-bus enhancements.

### 13.1 Definition of Bits in the First Two Bytes

The 10-bit slave address is formed from the first two bytes following a START condition (S) or a repeated START condition (Sr).

The first seven bits of the first byte are the combination 11110XX of which the last two bits (XX) are the two most-significant bits (MSBs) of the 10-bit address; the eighth bit of the first byte is the R/W bit that determines the direction of the message. A 'zero' in the least significant position of the first byte means that the master will write information to a selected slave. A 'one' in this position means that the master will read information from the slave.

If the R/W bit is 'zero', then the second byte contains the remaining 8 bits (XXXXXXXX) of the 10-bit address. If the R/W bit is 'one', then the next byte contains data transmitted from a slave to a master.

### 13.2 Formats with 10-bit Addresses

Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing. Possible data transfer formats are:

- **Master-transmitter transmits to slave-receiver with a 10-bit slave address. The transfer direction is not changed (Fig.29).** When a 10-bit

address follows a START condition, each slave compares the first seven bits of the first byte of the slave address (11110XX) with its own address and tests if the eighth bit (R/W direction bit) is 0. It is possible that more than one device will find a match and generate an acknowledge (A1). All slaves that found a match will compare the eight bits of the second byte of the slave address (XXXXXXXX) with their own addresses, but only one slave will find a match and generate an acknowledge (A2). The matching slave will remain addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address

#### NOTES:

1. Combined formats can be used, for example, to control a serial memory. During the first data byte, the internal memory location has to be written. After the START condition and slave address is repeated, data can be transferred.
2. All decisions on auto-increment or decrement of previously accessed memory locations etc. are taken by the designer of the device.
3. Each byte is followed by an acknowledgement bit as indicated by the A or  $\bar{A}$  blocks in the sequence.
4. I<sup>2</sup>C-bus compatible devices must reset their bus logic on receipt of a START or repeated START condition such that they all anticipate the sending of a slave address.
  - **Master-receiver reads slave-transmitter with a 10-bit slave address. The transfer direction is changed after the second R/W bit (Fig.30).** Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks if the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and tests if the eighth (R/W) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or until it receives another repeated START condition (Sr) followed by a different slave address. After a repeated START condition (Sr), all the other slave devices will also compare the first seven bits of the first byte of the slave address (11110XX) with their own addresses and

# The I<sup>2</sup>C-bus and how to use it

test the eighth (R/W) bit. However, none of them will be addressed because R/W = 1 (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match)

- **Combined format. A master transmits data to a slave and then reads data from the same slave (Fig.31).** The same master occupies the bus all the

time. The transfer direction is changed after the second R/W bit

- **Combined format. A master transmits data to one slave and then transmits data to another slave (Fig.32).** The same master occupies the bus all the time
- **Combined format. 10-bit and 7-bit addressing combined in one serial**

**transfer (Fig.33).** After each START condition (S), a 10-bit or 7-bit slave address can be transmitted. Figure 33 shows how a master-transmits data to a slave with a 7-bit address and then transmits data to a second slave with a 10-bit address. The same master occupies the bus all the time.

### NOTES:

n/a = not applicable

1. maximum V<sub>IH</sub> = V<sub>DD max.</sub> + 0.5 V

2. C<sub>b</sub> = capacitance of one bus line in pF. Note that the maximum t<sub>f</sub> for the SDA and SCL bus lines quoted in Table 4 (300 ns) is longer than the specified maximum t<sub>OF</sub> for the output stages (250 ns). This allows series protection resistors (R<sub>b</sub>) to be connected between the SDA/SCL pins and the SDA/SCL bus lines as shown in Fig.37 without exceeding the maximum specified t<sub>f</sub>.

3. I/O pins of fast-mode devices must not obstruct the SDA and SCL lines if V<sub>DD</sub> is switched off.

## The I<sup>2</sup>C-bus and how to use it

### 14.0 GENERAL CALL ADDRESS AND START BYTE

The 10-bit addressing procedure for the I<sup>2</sup>C-bus is such that the first two bytes after the START condition (S) usually determine which slave will be selected by the master. The exception is the 'general call' address 00000000 (H'00'). Slave devices with 10-bit addressing will react to a 'general call' in the same way as slave devices with 7-bit addressing (see Section 9.1.1).

Hardware masters can transmit their 10-bit address after a 'general call'. In this case, the 'general call' address byte is followed by two successive bytes containing the 10-bit address of the master-transmitter. The format is as shown in Fig.17 where the first DATA byte contains the eight least-significant bits of the master address.

The START byte 00000001 (H'01') can precede the 10-bit addressing in the same way as for 7-bit addressing (see Section 9.1.2).

### 15.0 ELECTRICAL SPECIFICATIONS

The I/O levels, I/O current, spike suppression, output slope control and pin capacitance for I<sup>2</sup>C-bus devices are given in Table 3. The I<sup>2</sup>C-bus timing is given in Table 4. Figure 34 shows the timing definitions for the I<sup>2</sup>C-bus.

The noise margin for HIGH and LOW levels on the bus lines for fast-mode devices are the same as those specified in Section 10.0 for standard-mode I<sup>2</sup>C-bus devices.

The minimum HIGH and LOW periods of the SCL clock specified in Table 4 determine the maximum bit transfer rates of 100 kbit/s for standard-mode devices and 400 kbit/s for fast mode devices. Standard-mode and fast-mode I<sup>2</sup>C-bus devices must be able to follow transfers at their own maximum bit rates, either by being able to transmit or receive at that speed or by applying the clock synchronization procedure described in Section 7 which will force the master into a wait state and stretch the LOW period of the SCL signal. Of course, in the latter case the bit transfer rate is reduced.

### 16.0 APPLICATION INFORMATION

#### 16.1 Slope-Controlled Output Stages of Fast-Mode I<sup>2</sup>C-Bus Devices

The electrical specifications for the I/Os of

I<sup>2</sup>C-bus devices and the characteristics of the bus lines connected to them are given in Tables 3 and 4 in Section 15.

Figures 35 and 36 show examples of output stages with slope control in CMOS and bipolar technology. The slope of the falling edge is defined by a Miller capacitor (C1) and a resistor (R1). The typical values for C1 and R1 are indicated on the diagrams. The wide tolerance for output fall time  $t_{OFF}$  given in Table 3 means that the design is not critical. The fall time is only slightly influenced by the external bus load (C<sub>b</sub>) and external pull-up resistor (R<sub>p</sub>). However, the rise time (t<sub>r</sub>) specified in Table 4 is mainly determined by the bus load capacitance and the value of the pull-up resistor.

#### 16.2 Switched Pull-Up Circuit for Fast-Mode I<sup>2</sup>C-Bus Devices

The supply voltage (V<sub>DD</sub>) and the maximum output LOW level determine the minimum value of pull-up resistor R<sub>p</sub> (see Section 10.1). For example, with a supply voltage of V<sub>DD</sub> = 5V ± 10% and V<sub>OL max.</sub> = 0.4 V at 3 mA,  $R_{p \min.} = (5.5 - 0.4)/0.003 = 1.7 \text{ k}\Omega$ . As shown in Fig.38, this value of R<sub>p</sub> limits the maximum bus capacitance to about 200 pF to meet the maximum t<sub>r</sub> requirement of 300 ns. If the bus has a higher capacitance than this, a switched pull-up circuit as shown in Fig.37 can be used.

The switched pull-up circuit in Fig.37 is for a supply voltage of V<sub>DD</sub> = 5 V ± 10 % and a maximum capacitive load of 400 pF. Since it is controlled by the bus levels, it needs no additional switching control signals. During the rising/falling edges, the bilateral switch in the HCT4066 switches pull-up resistor R<sub>p2</sub> on/off at bus levels between 0.8 V and 2.0 V. Combined resistors R<sub>p1</sub> and R<sub>p2</sub> can pull-up the bus line within the maximum specified rise time (t<sub>r</sub>) of 300 ns. The maximum sink current for the driving I<sup>2</sup>C-bus device will not exceed 6 mA at V<sub>OL2</sub> = 0.6 V, or 3 mA at V<sub>OL1</sub> = 0.4 V.

Series resistors R<sub>s</sub> are optional. They protect the I/O stages of the I<sup>2</sup>C-bus devices from high-voltage spikes on the bus lines, and minimize crosstalk and undershoot of the bus line signals. The maximum value of R<sub>s</sub> is determined by the maximum permitted voltage drop across this resistor when the bus line is switched to the LOW level in order to switch off R<sub>p2</sub>.

#### 16.3 Wiring Pattern of the Bus Lines

In general, the wiring must be so chosen that crosstalk and interference to/from the bus lines is minimized. The bus lines are most susceptible to crosstalk and interference at the HIGH level because of the relatively high impedance of the pull-up devices.

If the length of the bus lines on a PCB or ribbon cable exceeds 10 cm and includes the V<sub>DD</sub> and V<sub>SS</sub> lines, the wiring pattern must be:

SDA \_\_\_\_\_  
V<sub>DD</sub> \_\_\_\_\_  
V<sub>SS</sub> \_\_\_\_\_  
SCL \_\_\_\_\_

If only the V<sub>SS</sub> line is included, the wiring pattern must be:

SDA \_\_\_\_\_  
V<sub>SS</sub> \_\_\_\_\_  
SCL \_\_\_\_\_

These wiring patterns also result in identical capacitive loads for the SDA and SCL lines. The V<sub>SS</sub> and V<sub>DD</sub> lines can be omitted if a PCB with a V<sub>SS</sub> and/or V<sub>DD</sub> layer is used.

If the bus lines are twisted-pairs, each bus line must be twisted with a V<sub>SS</sub> return. Alternatively, the SCL line can be twisted with a V<sub>SS</sub> return, and the SDA line twisted with a V<sub>DD</sub> return. In the latter case, capacitors must be used to decouple the V<sub>DD</sub> line to the V<sub>SS</sub> line at both ends of the twisted pairs.

If the bus lines are shielded (shield connected to V<sub>SS</sub>), interference will be minimized. However, the shielded cable must have low capacitive coupling between the SDA and SCL lines to minimize crosstalk.

#### 16.4 Maximum and Minimum Values of Resistors R<sub>p</sub> and R<sub>s</sub> for Fast-Mode I<sup>2</sup>C-Bus Devices

The maximum and minimum values for resistors R<sub>p</sub> and R<sub>s</sub> connected to a fast-mode I<sup>2</sup>C-bus can be determined from Fig.25, 26 and 28 in Section 10.1. Because a fast-mode I<sup>2</sup>C-bus has faster rise times (t<sub>r</sub>) the maximum value of R<sub>p</sub> as a function of bus capacitance is less than that shown in Fig.27. The replacement graph for Fig.27 showing the maximum value of R<sub>p</sub> as a function of bus capacitance (C<sub>b</sub>) for a fast mode I<sup>2</sup>C-bus is given in Fig.38.

# The I<sup>2</sup>C-bus and how to use it

| Set-up time for STOP condition                                                                               | t <sub>SU;STO</sub> | 4.0                                | -      | 0.6                                  | -                      | μs       |
| Capacitive load for each bus line                                                                            | C <sub>b</sub>      | -                                  | 400    | -                                    | 400                    | pF       |

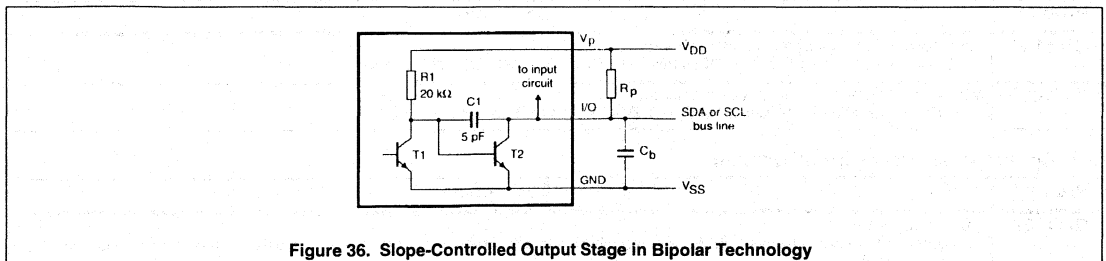

**NOTES:**

All values referred to V<sub>IH min.</sub> and V<sub>IL max.</sub> levels (see Table 3).

1. A device must internally provide a hold time of at least 300 ns for the SDA signal (referred to the V<sub>IH min.</sub> of the SCL signal) in order to bridge the undefined region of the falling edge of SCL.
2. The maximum t<sub>HD;DAT</sub> has only to be met if the device does not stretch the LOW period (t<sub>LOW</sub>) of the SCL signal.
3. A fast-mode I<sup>2</sup>C-bus device can be used in a standard-mode I<sup>2</sup>C-bus system, but the requirement t<sub>SU;DAT</sub> ≥ 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line t<sub>R max.</sub> + t<sub>SU;DAT</sub> = 1000 + 250 = 1250 ns (according to the standard-mode I<sup>2</sup>C-bus specification) before the SCL line is released.
4. C<sub>b</sub> = total capacitance of one bus line in pF.

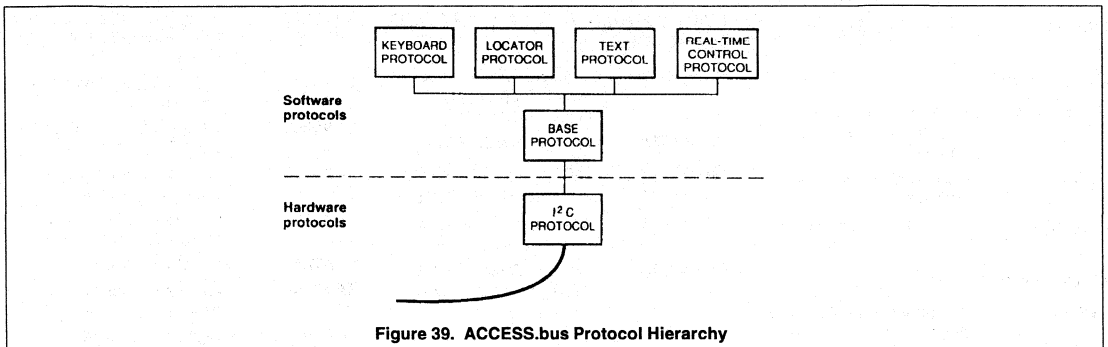

Figure 39. ACCESS.bus Protocol Hierarchy

## 19.0 APPLICATION OF THE I<sup>2</sup>C-BUS IN THE ACCESS.bus SYSTEM

The ACCESS.bus (bus for connecting ACCESSory devices to a host system) is an I<sup>2</sup>C-bus based open-standard serial interconnect system jointly developed and defined by Philips Semiconductors and Digital Equipment Corporation. It is a lower-cost alternative to an RS-232C interface for connecting up to 14 inputs/outputs from peripheral equipment to a desk-top computer or workstation over a distance of up to eight metres. The peripheral equipment can be relatively low speed items such as keyboards, hand-held image scanners, cursor positioners, bar-code readers, digitizing tablets, card readers or modems.

All that's required to implement an ACCESS.bus is an 8051-family

microcontroller with an I<sup>2</sup>C-bus interface, and a 4-wire cable carrying a serial data (SDA) line, a serial clock (SCL) line, a ground wire and a 12 V supply line (500 mA max.) for powering the peripherals.

Important features of the ACCESS.bus are that the bit rate is only about 20% less than the maximum bit rate of the I<sup>2</sup>C-bus, and the peripherals don't need separate device drivers. Also, the protocol allows the peripherals to be changed by 'hot-plugging' without re-booting.

As shown in Fig.39, the ACCESS.bus protocol comprises three levels: the I<sup>2</sup>C-bus protocol, the base protocol, and the application protocol.

The base protocol is common to all ACCESS.bus devices and defines the format of the ACCESS.bus message. Unlike the I<sup>2</sup>C-bus protocol, it restricts masters to sending and slaves to receiving data. One

item of appended information is a checksum for reliability control. The base protocol also specifies seven types of control and status messages which are used in the system configuration which assigns unique addresses to the peripherals without the need for setting jumpers or switches on the devices.

The application protocol defines the message semantics that are specific to the three categories of peripheral device (keyboards, cursor locators, and text devices which generate character streams e.g. card readers) which are at present envisaged.

Philips Semiconductors offers computer peripheral equipment manufacturers technical support, a wide range of I<sup>2</sup>C-bus devices and development kits for the ACCESS.bus. Hardware, software and marketing support is also offered by DEC.

## I<sup>2</sup>C peripheral selection guide

### GENERAL PURPOSE ICs

#### LCD Drivers

|                   |                                                                  |
|-------------------|------------------------------------------------------------------|
| <b>PCF8566</b>    | 96-segment LCD driver<br>1:1 – 1:4 Mux rates                     |
| <b>PCF8568</b>    | LCD row driver for dot matrix displays                           |
| <b>PCF8569</b>    | LCD Column driver for dot matrix displays                        |
| <b>PCF8576</b>    | 160-segment LCD driver<br>1:1 – 1:4 Mux rates                    |
| <b>PCF8577C</b>   | 64-segment LCD driver<br>1:1 – 1:2 Mux Rates                     |
| <b>PCF8578/79</b> | Row/column LCD dot-matrix driver/display<br>1:8 – 1:32 Mux rates |
| <b>SAA1064</b>    | 4-digit LED driver                                               |

#### I/O Expanders

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <b>PCF8574/A</b> | 8-bit remote I/O port (I <sup>2</sup> C-bus to parallel converter) |
| <b>PCD8584</b>   | 8-bit parallel to I <sup>2</sup> C converter                       |
| <b>SAA1300</b>   | 5-bit high-current driver                                          |

#### Data Converters

|                |                                    |
|----------------|------------------------------------|
| <b>PCF8591</b> | 4-channel, 8-bit Mux ADC + one DAC |
| <b>TDA8442</b> | Quad 6-bit DAC                     |
| <b>TDA8444</b> | Octal 6-bit DAC                    |

#### Memory

|                  |                             |
|------------------|-----------------------------|
| <b>PCF8570/C</b> | 256-byte static RAM         |
| <b>PCF8571</b>   | 128-byte static RAM         |
| <b>PCF8581</b>   | 128-byte EEPROM             |
| <b>PC.8582</b>   | 256-byte EEPROM             |
| <b>PCF8583</b>   | 256-byte RAM/clock/calendar |
| <b>PCF8594</b>   | 512-byte EEPROM             |
| <b>PCF8598</b>   | 1K-byte EEPROM              |

#### Clocks/Calendars

|                |                                 |
|----------------|---------------------------------|
| <b>PCF8573</b> | Clock/calendar                  |
| <b>PCF8583</b> | Clock/calendar/<br>256-byte RAM |

#### 68000-Based CMOS Microcontrollers

|               |                                          |

# I<sup>2</sup>C bus extender

**82B715**

## DESCRIPTION

The 82B715 is a bipolar integrated circuit intended for application in I<sup>2</sup>C bus systems.

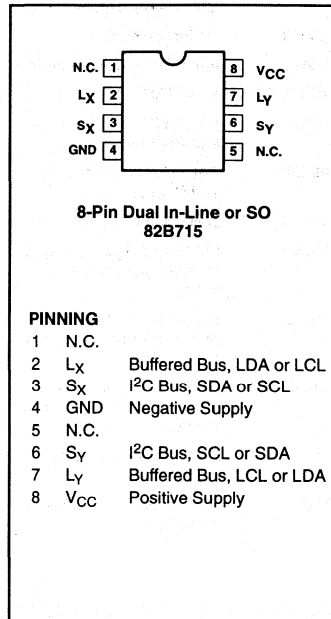

While retaining all the operating modes and features of the I<sup>2</sup>C system it permits extension of the practical separation distance between components on the I<sup>2</sup>C bus by buffering both the data (SDA) and the clock (SCL) lines.

The I<sup>2</sup>C bus capacitance limit of 400pF restricts practical communication distances to a few meters. Using one 82B715 at each end of longer cables reduces the cable loading capacitance on the I<sup>2</sup>C bus by a factor of 10 times and may allow the use of low cost general purpose wiring to extend bus lengths.

## FEATURES

- Dual, bi-directional, unity voltage gain buffer
- I<sup>2</sup>C bus compatible
- Logic signal levels may include both supply and ground
- X10 impedance transformation
- Wide supply voltage range

## PIN CONFIGURATIONS

## QUICK REFERENCE DATA

# I<sup>2</sup>C bus extender

# 82B715

### FUNCTIONAL DESCRIPTION

The 82B715 bipolar integrated circuit contains two identical buffer circuits which enable I<sup>2</sup>C and similar bus systems to be extended over long distances without degradation of system performance or requiring the use of special cables.

The buffer has an effective current gain of ten from I<sup>2</sup>C bus to Buffered bus. Whatever current is flowing out of the I<sup>2</sup>C bus side, ten times that current will be flowing into the Buffered bus side (see Figure 2).

As a consequence of this amplification the system is able to drive capacitive loads up to ten times the standard limit on the Buffered bus side. This current based buffering

approach preserves the bi-directional, open-collector/open-drain characteristic of the I<sup>2</sup>C SDA/SCL lines.

To minimize interference and ensure stability, current rise and fall rates are internally controlled.

### APPLICATION NOTES

By using two (or more) 82B715 ICs, a sub-system can be built which retains the interface characteristics of an I<sup>2</sup>C device so that it may be included in, or optionally added to, any I<sup>2</sup>C or related system.

The sub-system features a low impedance or "Buffered" bus, capable of driving large wiring capacities (see Figure 3).

### I<sup>2</sup>C Systems

As with the standard I<sup>2</sup>C system, pull-up resistors are required to provide the logic HIGH levels on the Buffered bus. (Standard open-collector configuration of the I<sup>2</sup>C bus). The size and number of these pull-up resistors depends on the system.

If the buffer is to be permanently connected into the system, the circuit should be configured with only one pull-up resistor on the Buffered bus and none on the I<sup>2</sup>C bus.

Alternatively a buffer may be connected to an existing I<sup>2</sup>C system. In this case the Buffered bus pull-up will act in parallel with the I<sup>2</sup>C bus pull-up.

## I<sup>2</sup>C bus extender

82B715

### Pull-Up Resistance Calculation

In calculating the pull-up resistance values, the gain of the buffer introduces scaling factors which must be applied to the system components. Viewing the system from the Buffered bus, all I<sup>2</sup>C bus capacitances have effectively 10 times their I<sup>2</sup>C bus value.

In practical systems the pull-up resistance is determined by the rise time limit for I<sup>2</sup>C systems. As an approximation this limit will be satisfied if the time constant (product of the net resistance and net capacitance) of the total system is set to 1 microsecond.

The total time constant may either be set by considering each bus node individually (i.e., the I<sup>2</sup>C nodes, and the Buffered bus node) and choosing pull-up resistors to give time constants of 1 microsecond for each node; or by combining the capacitances into an equivalent capacitive loading on the Buffered bus, and calculating the Buffered bus pull-up resistor required by this equivalent capacitance.

For each separate bus the pull-up resistor may be calculated as follows:

$$R = \frac{1 \mu \text{sec}}{C_{\text{device}} + C_{\text{wiring}}}$$

Where: C<sub>device</sub> = sum of device capacitances connected to each bus,

and C<sub>wiring</sub> = total wiring and stray capacitance on each bus.

If these capacitances are not known then a good approximation is to assume that each device presents 10pF of load capacitance and 10pF of wiring capacitance.

The capacitance figures for one or more individual I<sup>2</sup>C bus nodes should be multiplied by a factor of 10 times, and then added to the Buffered bus capacitance. Calculation of a new Buffered bus pull-up resistor will allow this single pull-up resistor to act for both the included I<sup>2</sup>C bus nodes and the Buffered bus. Thus it is possible to combine some or all of these separate pull-up resistors into a single resistor on the Buffered bus (the value of which is calculated from the sum of the scaled capacitances on the Buffered bus). If the buffer is to be permanently connected into the system then all the separate pull-up resistors should be combined. But if it is to be connected by adding it onto an existing system, then only those on the additional I<sup>2</sup>C bus system can be combined onto the Buffered bus if the original system is required to be able to still operate on a stand-alone basis.

A further restriction is that the maximum pull-up current, with the bus LOW, should not exceed the I<sup>2</sup>C bus specification maximum of

3mA, or 30mA on the Buffered bus. The following formula applies:

$$30\text{mA} > \frac{V_{\text{CC}} - 0.4}{R_{\text{P}}}$$

Where: R<sub>P</sub> = scaled parallel combination of all pull-up resistors.

If this condition is met, the fall time specifications will also be met.

Figure 4 shows typical loading calculations for the expanded I<sup>2</sup>C bus.

### Sx, Sy, I<sup>2</sup>C Bus, SDA or SCL

Because the two buffer circuits in the 82B715 are identical either input pin can be used as the I<sup>2</sup>C Bus SDA data line, or the SCL clock line.

### Lx, Ly, Buffered Bus, LDA or LCL

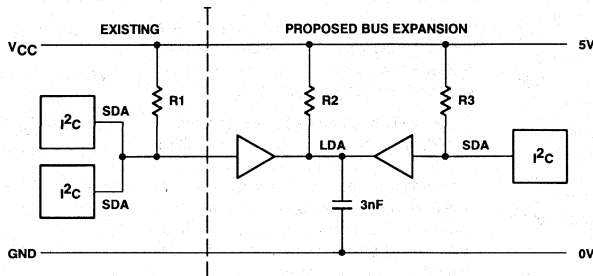

On the buffered low impedance line side, the corresponding output becomes LDA and LCL.

### V<sub>CC</sub>, GND — Positive and Negative Supply Pins

In normal use the power supply voltages at each end of the low impedance line should be comparable. If these differ by a significant amount, noise margin is sacrificed.

| 1 × I <sup>2</sup> C Devices | 10pF        |
| Strays                       | 10pF        |
| 82B715 Buffer                | 10pF        |
| <b>TOTAL CAP.</b>            | <b>30pF</b> |

I<sup>2</sup>C pull-up

$$R3 = \frac{1\mu\text{sec}}{30\text{pF}} = 33\text{K}\Omega$$

**AS AN ADDITION TO AN EXISTING SYSTEM \* :**

R1 = 20KΩ

$$R2' = \frac{R2 \times 0.1R3}{R2 + 0.1R3} = 300\Omega$$

R3 not required since buffer always connected

**FOR A PERMANENT SYSTEM \* :**

R1 not required since buffer always connected

$$R2' = \frac{0.1R1 \times R2 \times 0.1R3}{0.1R1 + R2 + 0.1R3} = 260\Omega$$

R3 not required since buffer always connected

**\* NOTE:**

R1, R2 and R3 are calculated from the capacitive loading and a 1μsec time constant on each bus node. For an addition to an existing system, R2' (the new value for R2) is shown as being calculated from the parallel combination of R2 and the scaled value of R3; while for a permanent system R2, and scaled values of R1 and R3 have been used. Note that this example has used scaled resistor values and combined the node and cable capacitances.

**CHECK FOR MAXIMUM PULL-UP CURRENT:**

$$\frac{(5 - 0.4)\text{V}}{260\Omega} = 17.6\text{mA} < 30\text{mA}$$

## ACCESS.bus™ technical overview

### INTRODUCTION

ACCESS.bus™ (a BUS for connecting ACCESSory devices to a host system) is a peripheral interconnect system defined and developed by Digital Equipment Corporation and offered to the computer industry as an open standard.

This overview aims to introduce the prospective developer of ACCESS.bus systems or peripherals to the essential technical features of this interconnect. It is meant to be a general technical overview of the ACCESS.bus architecture. Under no circumstances should it be used as the basis for designing any device or system. Developers wishing to design a host system or peripheral device that implements ACCESS.bus should refer to the *ACCESS.bus Hardware and Protocol Specifications Version 2.0*, July 1992, available from the ACCESS.bus Industry Group, Digital's TRI/ADD Program, or Philips. Addresses and other information on support may be found in Section 6.

### What is ACCESS.bus?

ACCESS.bus is a system for connecting a number of relatively low-speed I/O devices to a host computer, typically a desktop system, such as a workstation, personal computer, or terminal. Devices include both interactive

peripherals – keyboards, locators, hand-held scanners, bar code readers, and magnetic card readers – and non-interactive peripherals – printers, and in realtime control applications, signal transducers. Further, the ACCESS.bus protocol is general enough to accommodate a wide range of unusual peripheral types such as data gloves (see Figure 1).

ACCESS.bus has a bus topology architecture. That is, a single ACCESS.bus on a host can accommodate up to 125 peripheral devices. The total length of the cable connecting the devices on a common ACCESS.bus may be up to eight meters. The limiting factors are capacitance, which may not exceed 800pF, and the maximum voltage drop, which must allow maintenance of  $+5V \pm 10\%$ . Using an I<sup>2</sup>C bus extender that maximum distance may be lengthened. ACCESS.bus supports a maximum aggregate data throughput of approximately 80 Kbits/sec.

Digital has made the ACCESS.bus technology an open specification, enabling any vendor to implement it on host systems or in peripheral devices without fee or royalty.

ACCESS.BUS offers a number of advantages both to end users and to the developers of systems and peripheral

devices. A host computer needs only one hardware port to connect to a number of devices. The commonality in communication methods for a number of device types leads to economies in software and hardware development. As an open industry standard, ACCESS.bus will stimulate development of diverse peripheral devices, each usable with a number of different types of host systems.

ACCESS.bus incorporates more sophisticated technology and offers higher performance than any other bus-topology interconnect for desktop peripherals. Moreover, it is the first system of this kind to be offered as an open nonproprietary standard.

### ACCESS.bus Hardware

At the hardware level, ACCESS.bus is based on the well-established Inter-Integrated Circuit (I<sup>2</sup>C) serial bus developed and patented by Philips. The serial bus architecture, in which a single data line carries one bit of information at a time, entails lower costs for cabling, connectors and controller circuitry than parallel bus architectures.

Standard low-cost I<sup>2</sup>C components, available from Philips, handle the logical complications of the bit-level handshaking. More details on these components are given in section 5.

Figure 1. ACCESS.bus connects keyboards, locators, and text-type devices to a system.

## ACCESS.bus™ technical overview

Figure 2. A shielded connector with four pins for connecting the ACCESS.bus cable to a system

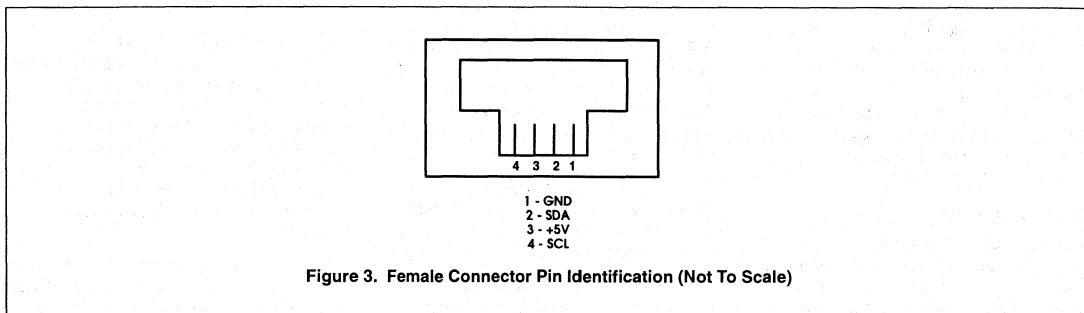

Figure 3. Female Connector Pin Identification (Not To Scale)

The physical medium for ACCESS.bus is a shielded cable containing four wires: serial data (SDA), serial clock (SCL), power (+5V), and ground (GND). It uses standard low-cost shielded modular connectors available from AMP and Molex (Figure 2 and 3). Shielding of the cables and connectors facilitates making ACCESS.bus-based systems conform to FCC radiation and ESD requirements. A typical ACCESS.bus device will have two connectors so that devices may be chained on the single bus; hand-held devices may have a captive cable joined to the bus trunk with a "T" connector.

The serial data (SDA) and serial clock (SCL) lines work together to define the information carried on the bus. That aspect of the technology is described in Section 2.3. The host computer drives the +5V power line with a minimum of 50mA to supply the peripheral devices. Devices may be supplied with power from an external source.

The I<sup>2</sup>C technology can support clock rates up to 100kHz. The maximum ACCESS.bus data transfer rate of approximately 80 Kbits/sec is derived from the top clock rate by subtracting the overhead imposed by the ACCESS.bus communication protocols for handshaking, addressing, and error control.

### ACCESS.bus Protocols

The ACCESS.bus communication protocol is composed of three levels: I<sup>2</sup>C Protocol, Base Protocol, and Application Protocol.

At the lowest level, nearest the hardware, the basic discipline of the ACCESS.bus is defined as a subset of the Philips Inter-Integrated Circuit (I<sup>2</sup>C) bus protocol. The simple and efficient I<sup>2</sup>C Protocol defines a symmetric multi-master bus on which arbitration among contending masters is effected without losing data. I<sup>2</sup>C provides for cooperative synchronization of the serial clock for exchange of data between bus partners with different maximum clock rates. The I<sup>2</sup>C Protocol defines a bus transaction scheme with addressing, framing of bits into bytes, and byte-acknowledgement by the receiver. More detail on the I<sup>2</sup>C Protocol level is given in Section 2.

The next ACCESS.bus protocol level is the Base Protocol. This level, common to all types of ACCESS.bus devices, establishes the nature of ACCESS.bus as an asymmetrical interconnect between a host computer and a number of peripheral devices. The host plays a special role as a manager of the ACCESS.bus. Data Communication is always between host and peripheral device and never between two

peripherals. While the I<sup>2</sup>C Protocol provides for mastership by either the sender or the receiver of a bus transaction, in the ACCESS.bus protocol masters are exclusively senders and slaves are exclusively receivers. Of course, the host and all the devices are both master/senders and slave/receivers at different times.

The ACCESS.bus Base Protocol defines the format of an ACCESS.bus message envelope, which is an I<sup>2</sup>C bus transaction with additional semantics, including checksum reliability control. Further, the Base Protocol defines a set of seven control and status message types which are used in the configuration process.

The eight required interface messages that ACCESS.bus protocol defines are listed below. Parameters defined within the body of the message are listed in parenthesis.

Computer-to-device Messages:

Reset()  
 Identification Request()  
 Assign Address(ID string, new addr)  
 Capabilities Request(offset)

Device-to-computer Messages:

Attention(status)  
 Identification Reply(ID string)  
 Capabilities Reply(offset, data frag)  
 Interface Error()

## ACCESS.bus™ technical overview

Two of the unique features of this configuration process are auto-addressing and hot plugging. Auto-addressing refers to the way that devices are assigned unique bus addresses in the configuration process, without the need for setting jumpers or switches on the devices. Hot plugging refers to the ability for attaching or detaching devices while the system is running, without the need for rebooting the host. The means by which the ACCESS.bus protocol provides these features is discussed in Section 2.

The highest level of the ACCESS.bus protocol, the Application Protocol, defines message semantics that are specific to particular functional types of devices. Different device types require different Application Protocols. Application Protocols have been defined so far for three device classes: keyboards, locators, and text devices. Each of these predefined classes is designed to be broad. The keyboard device protocol defines standard messages for reporting keystrokes and controlling keyboard peripherals. The protocol attempts to define the simplest set of functions from which common industry standard keyboard interfaces can be built. The locator device protocol defines a set of standard messages for reporting locator movement and key switch activation for mice, tablets, and other positioning devices. The protocol is designed to accommodate a range of basic locator devices such as a mouse or tablet. More complex devices can be modeled as a combination of basic devices or can provide their own device driver. The text device

protocol is intended to provide a simple way to transmit character or binary data to and from stream oriented devices such as a bar code reader, or modem. The sequential character stream model also serves as a common denominator for connecting RS-232 interface devices.

A major advantage in designing devices that conform to these general device-type semantics is that they may share device-specific software, both in the device-resident firmware and in the driver software needed in the host operating system to allow application programs to access the devices.

It is anticipated that further device-specific Application Protocols will be defined in the future, under the aegis of the ACCESS.bus Industry Group. Further, any device vendor may implement a special device protocol within the general message envelope defined by the Base Protocol.

Participation in all three of the protocol levels requires intelligence at the device level. The lower levels of this firmware are likely to be common to many devices. Higher levels of the firmware are expected to be more specific to the device and the application (Figure 4).

### HOW ACCESS.bus WORKS

#### Electrical

The host and devices are connected to both the serial data (SDA) and serial clock (SCL)

lines in a "wired-AND" logic configuration. The wired-AND may be implemented by connecting the data and clock output stages of each bus partner to the SDA and SCL lines respectively through open-collector or open-drain transistors. The standard I<sup>2</sup>C components include such output stages on-chip. The significance of the wired-AND logic is that any attached bus partner may force either of these lines to low (the ground level). When there is no output from any bus partner, the lines are held high by pull-up current sources in the host. Every bus partner can sense the level on both of these lines (Figure 5).

#### Bus Transactions

During a bus transaction, there is one clock pulse on SCL for each bit transferred on SDA. The SDA information is valid when SCL is high. During a transaction, the SDA must be stable between the rising and falling edges of the SCL pulse; SDA may change state only when SCL is low (Figure 6).

SDA transitions when the SCL is high are signals that delimit the bus transaction. When the ACCESS.bus is free, both SCL and SDA are high. A high-to-low SDA transition when SCL is high is a start condition; it signals the beginning of a bus transaction. A bus partner asserts mastership by pulling SDA low when the bus is free. A low-to-high SDA transition when SCL is high is a stop condition; it signals the end of a bus transaction. A master generates a stop condition when it relinquishes mastership (Figure 7).

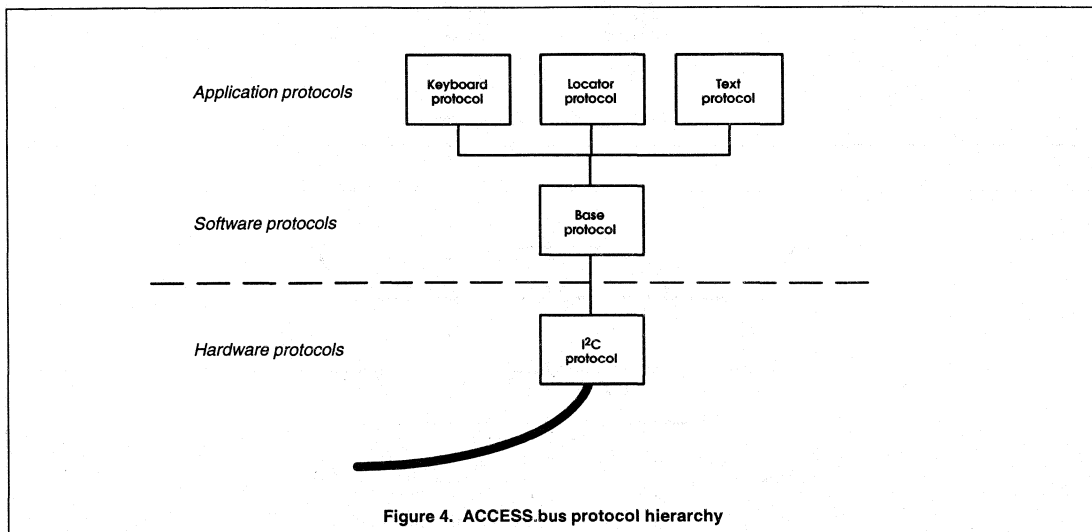

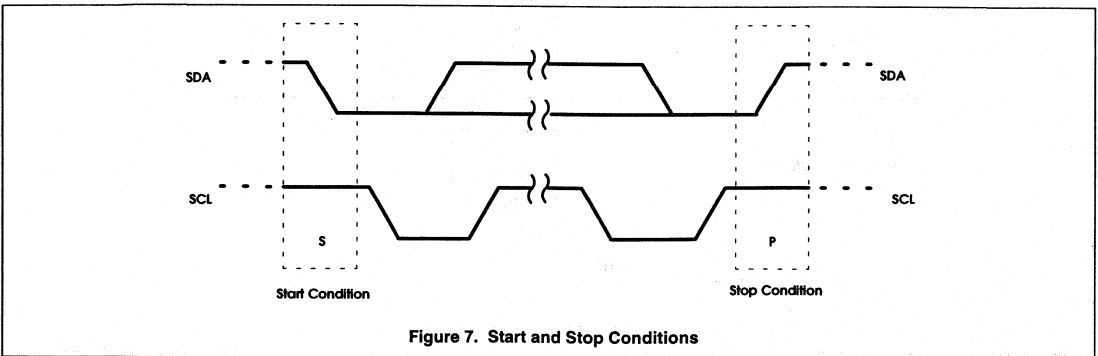

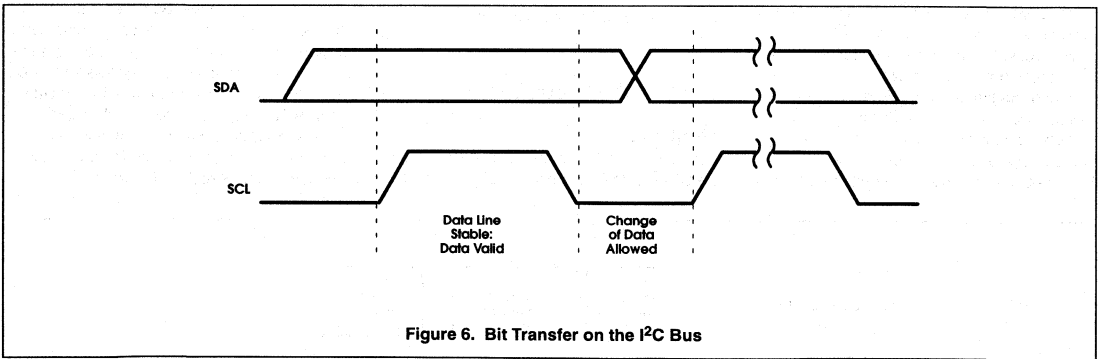

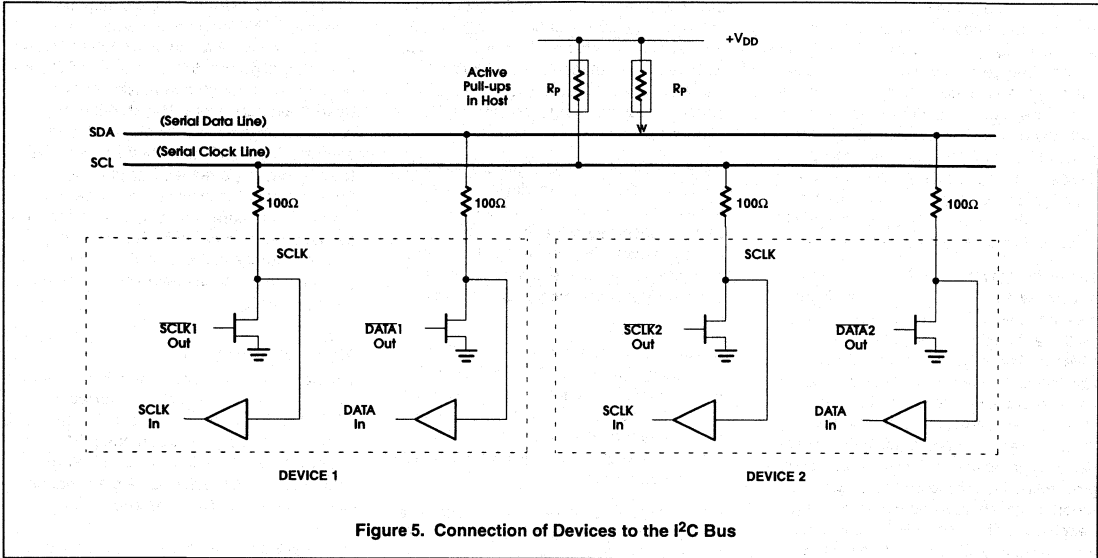

Figure 4. ACCESS.bus protocol hierarchy

# ACCESS.bus™ technical overview

## ACCESS.bus™ technical overview

### Synchronization

When a bus partner wishes to assert mastership of a free bus, it generates a start condition by pulling the SDA low. When SDA is low the new master begins the clock cycle, pulling the SCL low. All bus partners must be able to sense these events, and they respond by pulling all their SCL outputs low and beginning to count off their low periods. When each bus partner has reached the end of its low period, it lets its SCL output go high. Thus the SCL line will remain low for the duration of the longest low clock period among the bus partners.

When all the bus masters have reached the end of their low periods and let their SCL outputs go high, then the SCL goes high. All bus partners must be able to sense this event, and they begin counting their high period. The first bus master to reach the end of its high period pulls the SCL low again. In this way, all the bus partners simultaneously communicating on the bus are synchronized by a clock pulse whose low is as long as the longest of the low periods and whose high is as long as the shortest of the high periods. This synchronization persists until the master relinquishes the bus by generating a stop condition. The cooperative synchronization is a mechanism by which devices with slower clocks can regulate the operating rate of the bus. However, this mechanism, called "clock stretching", is not the normal means of data stream flow control. The ACCESS.bus protocol provides another mechanism for this purpose. (See Section 3.3.)

### Byte Framing and Acknowledgement

During this synchronized exchange the master/transmitter puts data on the SDA, one bit for each clock pulse. Eight successive bits comprise a byte, the most significant bit going first. The ACCESS bus is a Big Endian System.

As the new master puts the first byte on the bus, all the other bus partners participate in the synchronization. The first byte of the transaction contains the address of the intended slave/receiver of the transaction. Each non-master can check the address bits as they appear and cease participating in the synchronization as soon as the address bit on SDA fails to match the corresponding bit of its own address. The address check may also be done at the end of the address transmission.

At the end of the first byte, the master/transmitter lets its data output go high for the next clock pulse and the slave/receiver whose address matches the

transmitted address, is obliged to acknowledge receipt of the byte by pulling the SDA low for this pulse. This 1-bit Ack continues after each byte of the bus transaction; the master lets its SDA output go high and the receiver must pull the SCL low. Failure of the receiver to acknowledge a byte is an exception condition, which requires the master to terminate the transaction.

### Addressing

The slave/receiver of the bus transaction is determined by the address contained in the first byte. I<sup>2</sup>C uses the seven high-order bits of the first byte for addressing, and bit 0 to indicate whether the master is transmitting or receiving data. In ACCESS.bus, the master is always the transmitter, so bit 0 of the first byte of a transaction is always 0. Of the 128 7-bit addresses ACCESS.bus uses 15 addresses for general microcontrollers.

The host computer address is always 50h. In the configuration process to be described below, each peripheral device is assigned a unique address from the set of even numbers. 6Eh is used as a default address for devices before they have been assigned a unique address. A total of 125 addresses are available for devices on the bus.

### Arbitration

What happens when two devices simultaneously assert mastership? While putting data on the SDA, each transmitting master is, of course, independently sensing the state of SDA. Whenever a contending master detects that the state of the SDA is different from the data value it is putting out during a clock high, the contending master backs off, and waits for the stop condition before trying again. Thus, two contending masters will both put data on the bus as long as they are putting out the same data. The first bit where they differ will cause the contender that put out a 1 to back off.

Thus, under normal expected operation contending masters trying to send to different bus addresses will resolve the contention by the end of the first byte of the bus transaction. In the ACCESS.bus Base Protocol, the second byte of a transaction is the address of the transmitting master. Thus, as long as bus addresses are unique, the mastership of the bus will be resolved by the end of the second byte of the transaction. However, if two devices have the same address and are trying to send identical messages to a common address, then they will both send the entire message in unison. This situation can happen only during the configuration process before devices have all been assigned unique addresses; it is discussed further in Section 2.9 below.

Note that this arbitration mechanism never causes lost data or wasted transmissions, since the addresses of the receiver and transmitter are necessary overhead, in any case, for any sensible bus protocol. Note that bus priorities during arbitration are fixed by the device addresses, first by the address of the receiver, and then, for messages addressed to a common receiver, by the address of the transmitter. Lower addresses have priority over higher addresses. Lockouts of devices with high addresses are prevented by a rule of the Base Protocol that requires partners to wait a minimum time after relinquishing mastership before asserting it again.

### Message Format

An ACCESS.bus message comprises one I<sup>2</sup>C bus transaction. It consists of a string of bytes sent by a master/transmitter, each byte acknowledged by a one bit SCL-low Ack from the slave/receiver. The entire transaction is delimited by start and stop conditions generated by the master.

The first byte in the message is the receiver's unique address, as described above in Section 2.5. The second byte contains the transmitter's unique address.

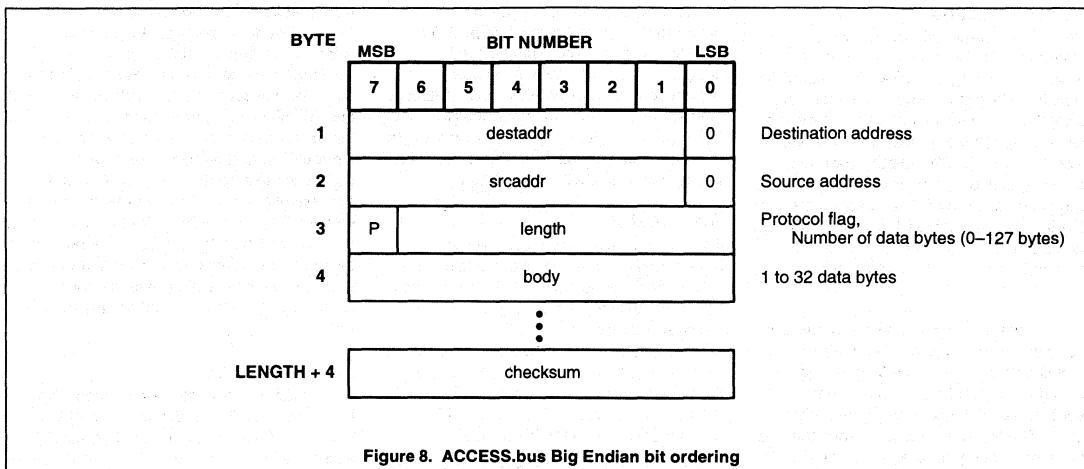

The third byte of an ACCESS.bus message comprises two fields. Bits 2-7 provide a byte count for the body of the message. Thus, a message body can have 0 to 127 bytes. The message body is followed by a checksum byte, for error control. The checksum is the bitwise XOR of all the preceding bytes of the message.

The high order bit of the third byte is a Protocol Flag (P) to distinguish between data stream messages (P=0) and control/status messages (P=1). The data stream messages carry the application information being exchanged between the device and the host. The control/status messages are used to manage the ACCESS.bus protocol (Figure 8).

### Control/Status Messages

The ACCESS.bus Base Protocol defines a number of control/status messages that pertain to the Interface Parts of devices. These control/status messages are used for the configuration process, in which devices are assigned unique bus addresses and connected with the appropriate drivers in the host. The configuration process is described in Section 2.9 to 2.11. In a control/status message, the message type is indicated by an operation code contained in the first byte of the message body. The various Interface Part control/status messages are shown in Table 1.

## ACCESS.bus™ technical overview

**Table 1. Interface Part Control/Status Messages**

**Computer-to-Device Messages Purpose**

**Reset()**

Force device to power-up state and default I<sup>2</sup>C address.

**Identification Request()**

Ask device for its "identification string."

**Assign Address(ID string, new addr)**

Ask device for its "identification string" to change its address to "new address."

**Capabilities Request(offset)**

Ask device to send the fragment of its capabilities information that starts at "offset."

**Attention(status)**

Inform computer that a device has finished its power-up/reset test and needs to be configured; "status" shall be the test result.

**Identification Reply(ID string)**

Reply to Identification Request with device's unique "identification string."

**Capabilities Reply(offset, data frag)**

Reply to Capabilities Request with "data fragment," a fragment of the device's capabilities string; the computer uses "offset" to reassemble fragments.

**Interface Error()**

Invalid checksum or premature end of message detected.

In addition, the Application Protocols define further control/status messages that are specific to particular device types. Some of these are discussed in Section 3 on the predefined device types.

**AppHardSiga**

Provision for a subdevice to generate an interrupt of the host system

**AppTest**

A message from the host to a peripheral device commanding it to test the Application Part subdevice

**AppTestReply**

A message by which a device replies to an AppTest command.

**Configuration**

The ACCESS.bus features auto-addressing and hot-plugging. These features are supported by the ACCESS.bus configuration process, which uses the seven types of control/status messages. Configuration consists of assigning unique bus addresses to the attached devices and connecting them with the appropriate drivers to provide host-resident application programs with access to the devices.

Configuration occurs when the device is powered-up or when it receives a Reset message. When the system is powered up, so are devices attached to the ACCESS.bus. Otherwise, devices are powered-up when they are hot-plugged into the bus. A device

may have a power source other than the +5V power line of the ACCESS.bus, but is must also be able to sense this line voltage and enter the power-up state when attached to the ACCESS.bus power source. When the system completes its boot up, the host sends a Reset message to all legal device addresses to put all devices in the power-up state.

Usually, when a device is powered up, it performs its specific self-testing. At the conclusion of self-test the device must assume the default address 6Eh and send an Attention message to announce its presence to the host. This message contains a single status byte to inform the host of the results of the power-up self-testing; zero indicates normal results and non-zero values indicate exception conditions that are specific to the device type.

On receiving an Attention message, the host sends an IDRequest message to the default address. Each device at this address replies with an IDReply message containing a unique 28-byte ID string described in the next section. The host is then able to assign unique ACCESS.bus addresses to each of the devices at the default address, by sending AssignAddress messages to the default address. Each AssignAddress message contains in its body the assigned address and the unique ID string of the corresponding device.

## ACCESS.bus™ technical overview

### Device Identifiers

During configuration, before address assignment, each device can be identified by a 28-byte unique ID string, which may be partly or entirely encoded in the device ROM. The first 24 bytes of the ID string are understood as ASCII-encoded information characterizing the device type:

- protocol revision 1 byte ("A")
- module revision 7 bytes (e.g., "V1.0 ")
- vendor name 8 bytes (e.g., "DEC ")
- module name 8 bytes (e.g., "LK501 ")
- device number 32-bit signed integer

The first 24 bytes characterize the device's firmware and are encoded in the device ROM.

The remaining 4 bytes of the device ID string are understood as a 32-bit two's complement integer that uniquely identifies the device among devices of the same type. This integer may be provided as a unique serial number contained in the device ROM. Or, in the absence of such a serial number, interactive devices may use a random or arbitrarily determined number for this part of the ID string. As an aid to the host software, the Base Protocol specifies that, in the IDReply message, unique serial numbers be sent as positive integers and randomly generated numbers be sent as negative integers, in the two's complement sense.

In the random number case, it is possible that different devices of the same type may come up with the same 32-bit discriminator. In this case, the different devices will be assigned the same bus address, an undesirable situation. The ACCESS.bus specification suggests a guideline to help avoid identical random identifiers: use the number of cycles of the device's own clock between power up and the time the IDRequest message is received. The natural dispersion of the frequencies of these oscillators is likely to provide unique numbers.

The Base Protocol includes a provision to ensure against the unlikely circumstance that different interactive devices of the same type and without unique serial numbers will generate the same random number. Namely, each such device must send a Reset message to its own assigned address. This self-addressed Reset is sent only once between power-ups or external Resets, just before the device sends the first message instigated by a user action. Of course, the transmitting device will ignore the self-addressed Reset, but other devices

possibly at the same address will be reset and will go through configuration again. The Base Protocol specifies that a device using a random number in its ID string shall change that random number after receiving a Reset message. In this way, all interactive devices are guaranteed assignment of unique addresses before sending their first data-carrying messages.

If several non-interactive devices of the same type are to be attached to a single ACCESS.bus, then they must have hardwired unique serial numbers.

During normal operation, the host periodically checks the configuration by sending IDRequest messages to inactive devices. The host also sends IDRequest messages to all assigned addresses whenever it receives an Attention message from a device seeking configuration. The purpose of these IDRequest messages is to verify the current state of the ACCESS.bus – what devices are still connected and which devices are no longer present.

### Device Capabilities Information

In order that a device be accessible to application programs running on the host, it must be connected to an appropriate software driver. Establishing this association is the last phase of configuration.

The appropriate driver will depend on the device type. There may be further parameters that characterize the device and which affect the choice of driver, or which at least must be furnished as arguments to the selected driver. Moreover, the application program may also need to be informed of these device parameters. The device Capabilities Information feature of the ACCESS.bus protocol allows a measure of device independence in the selection of drivers and provides for informing the host software of the device characteristics.

Device Capabilities Information is an explicit statement of a device's functional characteristics that are only implicit in the device type designation contained in the ID string, or that may even vary among individual devices of a given type. For example, the Capabilities Information about a keyboard might include the national alphabet used, or the Capabilities Information about a locator might include its resolution or units.

The Capabilities Information for each device is contained in a single human-readable ASCII-encoded text string stored on the device ROM. The ACCESS.bus Base Protocol defines a simple and compact grammar for building the capabilities string.

The semantics of the Capabilities Information is carried by keywords. The Base Protocol defines some keywords that can apply to all sorts of devices. Then each Application Protocol will define further keywords that are meaningful only for certain types of devices. To date, the ACCESS.bus Application Protocols define semantics for the Capabilities Information for generic keyboards, locators, and general text devices. The grammar allows for easy extension of the Capabilities Information specification.

An example of a simple mouse Capabilities string might be as follows:

```
(
 prot(locator)
 type(mouse)
 model(VSXXX)
 buttons(1(L)2(R)3(M)) dim(2) rel
 res(200 inch) range(-127 127)
 d0(dname(X))
 d1(dname(Y))
)
```

This would specify that the device uses the standard locator protocol; that it is a mouse, that it is model VSXXX; that it has three buttons designated left, middle and right corresponding with the respective bits in the keyswitch word; that it has two degrees of freedom, designated "X" and "Y", using inches as units with 200 counts per inch; that it reports relative values (displacement since last report) in the range -127 to 127 counts, and that its coordinate values correspond to X and Y.

After assigning a unique address to a device, the host sends it a CapRequest message to command it to send its Capabilities Information in a CapReply message. Of course, the device Capabilities string may well exceed the capacity of the message body of each CapRequest specifies where in the Capabilities Information string the fragment should start. The 'offset' value is repeated in the CapReply message, to be used as a check by the host in reassembling the Capabilities string. The offset is restricted to three values: send first (0), send again, and send next (offset from most recent string plus the number of bytes in the fragment).

The prot(), type(), and model() keywords must appear in that order and occur first in the Capabilities string. They must be within the first 128 bytes.

# ACCESS.bus™ technical overview

## APPLICATION DEVICE TYPES

The initial ACCESS.bus specification defines Application Protocols for three kinds of devices: keyboards, locators, and text devices. An important advantage of developing devices that conform to these defined protocols is the availability of pre-existing software to implement them, in particular, the drivers in the operating software of the host system through which application programs gain access to the devices.

### Keyboard Devices

A generic keyboard consists of an array of key stations assigned numbers between 8 and 255. When any key station transitions between open and closed, the entire list of key stations currently closed or depressed is transmitted to the host.

In addition to reporting key stations, the generic keyboard device can support simple feedback mechanisms such as keyclicks, bells, and light-emitting diodes. These mechanisms are controlled explicitly from the host so that minimal keyboard state modeling is required. The keyboard mapping table can also be stored in the keyboard itself as part of the capabilities string.

Each key is assigned a unique 8-bit number (8-255). The first 8 codes are reserved for other keyboard functions. On each key transition, up or down, the keyboard will report the complete state of the key array as a list of zero to ten key stations that are currently down.

Example: user enters the modified keystroke Alt-Shift-A

| Transition | Report       |
|------------|--------------|
| Alt down   | Alt          |
| Shift down | Alt Shift    |
| 'A' down   | Alt Shift A  |
| 'A' up     | Alt Shift    |
| Shift up   | Alt          |
| Alt up     | <empty list> |

This reporting scheme is functionally complete in that the host can detect every key transition and it provides the full state of the keyboard on each report. No special resynchronization reports are needed.

More detailed information can be found in the ACCESS.bus Keyboard Device Protocol Specification.

### Locator Devices

The *ACCESS.bus Locator Device Specification* provides for a device that has up to 15 degrees of freedom (with 16-bit precision) and up to 16 binary keys or buttons. Thus, in addition to such conventional pointer/locator devices as mouse, tablet, trackball. The ACCESS.bus locator protocol is suitable for valuator sets, such as dial boxes, and function key boxes with up to 16 function keys.

The locator capabilities information provides for specifying the number of switches and their designations (for example, "left", "right", "middle", etc.), whether the locator values are relative (like a mouse) or absolute (like a tablet or dial box), the resolution (counts per unit, and units), the dynamic range, and the names of the locator axes (for example, "x", "y", etc.).

The first 2-byte word of the event report message body contains a mask giving the state of the switches; the remaining words contain the value of each of the locator axes, either the absolute values or the change since the previous report in the case of relative devices. The locator report message is sent either on a regular sampling interval or on receipt of an AppPoll message from the host.

The locator-specific Application Protocol control/status messages are from the host to the device:

**AppPoll**  
Requests the device to report its state

**AppSamplingInterval**  
Sets the device sampling interval or instructs the device to report only when polled

More detailed information can be found in the ACCESS.bus Locator Device Protocol Specification.

### Text Devices

The text device protocol is intended to provide a simple way to transmit character or binary data to and from stream oriented devices such as a bar code reader, or character display. The sequential character stream model also serves as a common denominator for connecting RS-232 interfaced devices.

A generic text device transmits a stream of 8-bit bytes from a character set. Simple control messages are defined to support flow control and to select communication parameters that might be used to interface with a modem. The capabilities string

contains information that identifies the specific character set and communication parameters used.

More detailed information can be found in the ACCESS.bus Text Device Protocol Specification.

## TIMING RULES

To ensure good interactive response and to ensure that all devices will have access to the bus, the ACCESS.bus specifies rules on transaction timing. Further, specific timeouts are needed to avoid hanging up the interconnect when devices fail or are removed.

### Transaction Timing Rules

The ACCESS.bus is designed primarily for interactive devices. A basic objective of the definition of the ACCESS.bus specification is that every interactive device should be able to update the host on its state at least once in every display video frame time. To help meet this criterion, the Base Protocol imposes some rules on the timing of a device's interaction with the bus.

### Response Timeouts

In order that a dead or unplugged device will not hang up the system indefinitely, there must be time limits for responding to commands that require a response. The ACCESS.bus protocol specifies that devices shall complete the Reset command within 250ms. Further, a device shall respond to any command requiring a response within 40ms, or, in the case of commands that can be answered by several devices, within 40ms after the last device to respond.

## SOFTWARE ARCHITECTURE AND DEVELOPMENT

An ACCESS.bus peripheral requires software at both ends of the bus transaction for managing all levels of the peripheral interaction: the I<sup>2</sup>C interface, the ACCESS.bus Base Protocol, and the ACCESS.bus Application Protocol. Further, the peripheral device requires software to support communication between the device microcontroller and the application-specific I/O transducer circuitry. Finally, the host system operating software must provide interfaces by which application programs can access both the ACCESS.bus devices and the ACCESS.bus itself. An important advantage of the ACCESS.bus approach is that the lower levels of the interaction are common to diverse device types, so they can be supported by the same or similar software modules.

## ACCESS.bus™ technical overview

### Device Firmware Development

The microcontroller in the device provides the intelligence for managing the device's participation in all the levels of the ACCESS.bus protocol. Use of the components with hardware I<sup>2</sup>C interface functionality, described in "MICROCONTROLLERS", can simplify the development of the lowest level of this software. Moreover, because they concern only the bus communication methods that are common to all sorts of peripheral devices, the I<sup>2</sup>C interface and the ACCESS.bus Base Protocol may well be implemented by reusing software previously developed for some of these components. And devices conforming to the semantics of the predefined standard Application Protocols may also benefit from the availability of some off-the-shelf code at the top level.

Of course, each device vendor will have to develop substantial firmware specific to his or her device. Philips and several third party vendors offer a range of tools to support firmware development for the standard components of the 80C51 family. These tools include cross assemblers and cross compilers for C and PL/M, in-circuit emulators with symbolic debugging and real-time trace support, and EPROM programming equipment. Generally, these software and hardware tools are for use with PC-compatibles as the development platforms.

### Host Software Architecture

Vendors of host systems supporting ACCESS.bus will have to supply drivers and other kernel modules to provide access to the ACCESS.bus port, both for application program clients and for other system software, such as the interactive I/O handlers of the window system.

### DEVELOPMENT SUPPORT

Both Digital and Philips Semiconductors offer technical support and assistance to developers of ACCESS.bus devices and host systems.

### ACCESS.bus Industry Group

The ACCESS.bus Industry Group (ABIG) is an association of members interested in

promoting ACCESS.bus as an industry standard for the desktop connectivity of computer peripherals. As an association, ABIG is intended to maintain the ACCESS.bus specification as a simple, easy-to-implement, stable technology in the spirit of its design and contribute to the technical longevity of the ACCESS.bus architecture.

ABIG is an open industry group and anyone who has an interest in ACCESS.bus can be an ABIG member. An ABIG member is defined as a company including its divisions and subsidiaries, an organization, or a public or private institution.

There are two basic types of membership; General and Voting. General membership is open to everyone and Voting Membership is restricted to only those members who are actively developing a device or platform that incorporates the ACCESS.bus technology. ABIG is governed by an elected Steering committee of seven voting members.

ABIG Founding Members are those voting members who joined to form ABIG. They have the same voting privileges. The ABIG Founding Members are:

AMP, Inc.  
 Ceibo, Ltd.  
 Computer Access Technology Corp.  
 Digital Equipment Corp.  
 Discrete Time Systems Corp.  
 Honeywell Keyboard Division  
 Input Technologies, Inc.  
 ITAC Systems, Inc.  
 Kensington Microware Limited  
 Lexmark International, Inc.  
 Logitech, Inc.  
 Micro Computer Control Corp.  
 Molex Inc.  
 Mouse Systems Corp.

### Philips Semiconductors Support

An ACCESS.bus specification is available from Philips Semiconductors. This kit includes the complete specifications for the ACCESS.bus Base Protocol and pre-defined Application Protocols, as well as the Philips Data Handbook containing the detailed specification of the I<sup>2</sup>C bus, characteristics of the available integrated circuits which support it, application notes, and sample firmware code. The Data Handbooks also contain listing of development systems and third-party products supporting microcontroller firmware development, mentioned in the section entitled "Device Firmware Development".

Beside the 80C51-family microcontrollers, Philips and other manufacturers offer over 100 different components with built-in I<sup>2</sup>C support: memories, display controllers, data converters, clock/calendars, voice synthesizers, video processors, and others.

For technical questions on I<sup>2</sup>C call your local Philips Semiconductors sales office, or contact the Philips' Headquarters Application Group at [1]408-991-3518.

**Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.**

## **ACCESS.bus Development Kit**

## **A.b-DEV-KIT**

ACCESS.bus is an open industry standard providing a simple and uniform way to connect up to 125 devices to a single port on a computer. ACCESS.bus features 100,000 bits per second data rate, hardware arbitration, dynamic reconfiguration, a comprehensive capabilities grammar to support generic software device drivers, and off-the-shelf, low-cost I2C Microcontroller technology.

The A.b-DEV-KIT is an ACCESS.bus product development support package. It includes CATC's PC/AT A.b-125I ACCESS.bus controller board, an ACCESS.bus mouse, expansion box and cables and an 87C751 Microcontroller. The kit also includes a comprehensive software package, a user's manual and Hotline telephone support.

The software package includes on-board microcode, an ACCESS.bus Manager that runs as a TSR under DOS and an ACCESS.bus Monitor and Control program. In addition the A.b-DEV-KIT software includes source code of ACCESS.bus generic software drivers for the host and ACCESS.bus devices software modules.

### **Features**

- Complies fully with the ACCESS.bus standard
- ACCESS.bus hardware package including -
  - The A.b-125I PC/AT ACCESS.bus Controller
  - An A.b Mouse
  - An A.b expansion box
  - A.b cables (2 ft and 4 ft)
  - A Philips 87C751 Microcontroller
- A comprehensive software package including -
  - On-board ACCESS.bus Main Controller (MC) microcode
  - An ACCESS.bus Manager that runs as a TSR under DOS
  - An ACCESS.bus Monitor and Control program
  - Source code of an ACCESS.bus host generic software driver
  - Source code of a generic ACCESS.bus application layer software
  - Source code of ACCESS.bus devices software modules
- A comprehensive A.b user's manual
- Hotline telephone support

**The A.b-DEV-KIT includes ACCESS.bus accessories  
and comprehensive software**

## A.b-125I ACCESS.bus Controller Board

### **ACCESS.bus Interface**

Controls a standard ACCESS.bus network. Provides two industry standard ACCESS.bus connectors, supplying 5V @ 0.75 A.

### **ACCESS.bus Network Size**

Supports up to 125 ACCESS.bus devices. Physical distance up to 25 feet. With an external ACCESS.bus Buffer (optional) up to 250 feet.

### **System Interface**

IBM PC/AT and compatibles. Uses the PC/AT 16-bit programmable input / output mechanism:

User selectable I/O addresses -

0x250 to 0x25F

0x260 to 0x26F

0x350 to 0x35F

User selectable interrupt -

IRQ10, IRQ11 or IRQ12

### **Physical**

Power: +5V DC, 10 W max.

Temp. Range: +0 to +50 degree C

Board Size: 4.2" H x 6.5" W.

### **Warranty**

90-day. Return to factory for repair or replacement at manufacturers option

## A.b-DEV-KIT Software

### **On-board MC microcode**

A real-time package that controls the operation of physical ACCESS.bus devices.

### **ACCESS.bus Manager**

Runs as a TSR under DOS, communicates with the MC microcode and with the various device drivers. It routes control and application messages between the physical devices and their respective software drivers.

### **ACCESS.bus Monitor**

A user-friendly, menu-driven program, displays user-selected ACCESS.bus messages and allows the user to control specific devices.

### **Source Code License**

Source code of a generic ACCESS.bus software driver for the host. Source code of a generic ACCESS.bus application layer software. Source code of ACCESS.bus physical devices software modules.

### **Diagnostics**

A comprehensive self test is performed on the board on power up. Diagnostics are run under control of the ACCESS.bus Monitor.

## **ACCESS.bus PC/AT Controller Board**

**A.b-125I**

### **Description**

ACCESS.bus is an open industry standard providing a simple and uniform way to connect up to 125 devices to a single computer port. ACCESS.bus features data rate of 100,000 bits per second, hardware arbitration, dynamic reconfiguration, a comprehensive capabilities grammar to support generic software device drivers, and off-the-shelf, low-cost I2C microcontroller technology.

The A.b-125I is a PC/AT adapter board that serves as an ACCESS.bus master. It allows the connection of multiple devices to a single port on the PC. The board can be used in Desktop connectivity as well as in Control and Instrumentation applications. The board is based on a Philips 8xC654 microcontroller with I2C interface.

The A.b-125I is offered with a comprehensive software package including on-board microcode and an ACCESS.bus Manager that runs as a TSR under DOS.

### **Features**

- A highly integrated, half board design, uses a single 16-bit AT/ISA slot
- Full compliance with the ACCESS.bus standard
- On-board 8K bytes SRAM buffer memory
- A comprehensive software package including -
  - An on-board ACCESS.bus Main Controller (MC) microcode
  - An ACCESS.bus Manager that runs as a TSR under DOS

**The A.b-125 allows the connection of multiple devices  
to a single port on the PC**

## ACCESS.bus Interface

Controls a standard ACCESS.bus network. Provides two industry standard ACCESS.bus connectors, supplying 5V @ 0.75 A.

## ACCESS.bus Network Size

Supports up to 125 ACCESS.bus devices. Physical distance up to 25 feet. With an external ACCESS.bus Buffer (optional) up to 250 feet.

## Buffer Memory

8K x 8 bits (8K bytes) static RAM,

## System Interface

IBM PC/AT and compatibles. Uses the PC/AT 16-bit programmable input / output mechanism:

User selectable I/O addresses -

0x250 to 0x25F  
0x260 to 0x26F  
0x350 to 0x35F

User selectable interrupt -

IRQ10, IRQ11 or IRQ12

## Software

A comprehensive software package is provided with the board. The software includes the on-board ACCESS.bus Main Controller (MC) microcode and the ACCESS.bus Manager that runs as a TSR under DOS.

CATC has additional ACCESS.bus software available including a Windows 3.1 version of the ACCESS.bus Manager, software device drivers, bus monitoring and control program and development tools. Call CATC for additional information.

## Diagnostics

A comprehensive self test is performed on the board on power up.

## Physical

Power: +5V DC, 10 W max.

Temp. Range: +15 to +50 degree C

Board Size: 4.2" H x 6.5" W.

## Warranty

90-day. Return to factory for repair or replacement at manufacturers option

Product specifications are subject to change without notice

## Control Area Network (CAN) overview

---

### CAN OVERVIEW

The Control Area Network (CAN) is a multiplexed wiring protocol developed by Bosch for use in automotive applications. As products supporting CAN have been made available by Philips Semiconductors and other semiconductor manufacturers, the protocol has become used in other industries including: industrial automation, machine tools, medical equipment, and building environmental control, to name a few. The CAN protocol is attractive for use in a wide

range of applications because it has powerful error detection capabilities and features differential drive, and can be used comfortably in critical high noise environments. CAN is also very flexible in terms of the transmission media and the connection scheme, and is generally easy to adapt to most applications.

Philips offers a wide range of parts that support the CAN protocol, including

stand-alone parts as well as microcontrollers with integrated CAN interfaces. Datasheets for the 82C200 (Stand-alone CAN controller), 82C150 (CAN serial Linked I/O device), and 82C250 (CAN transceiver) are included in this section of this databook. Datasheets for the microcontrollers that have an integrated CAN interface (8XC592 and 8XC598) are included with Philips' 80C51 family products in Section 3 of this databook.

## CAN serial linked I/O device with digital and analog port functions

82C150

### 1. FEATURES

- Single-chip I/O device with CAN protocol controller
- Meets CAN protocol specification version 2.0 A and B (passive) with restricted bit timing
- Fully integrated clock oscillator (no crystal required)
- 16 configurable digital or analog I/O port pins
- Each of the port pins individually configurable via CAN-bus: port direction, port mode and event capture facilities for inputs (event driven or polling)
- Up to 16 digital inputs: automatic transmission of a CAN message on a change on inputs individually selectable
- Up to 16 3-state outputs
- Up to two quasi-analog outputs with 10-bit accuracy
- 10-bit analog-to-digital converter with up to six multiplexed analog input channels
- Two general purpose comparators
- Bit rate from 20 kbit/s up to 125 kbit/s using internal oscillator (extension by external clock possible)
- Automatic bit rate detection and calibration
- Up to 16 P82C150 nodes for one CAN-bus system
- Four identifier bits programmable
- Automatic recovery from bus wiring failures supported
- SLIO functions controlled by a single intelligent node ("host")
- Sleep-mode with wake-up via CAN-bus
- Differential CAN-bus input comparator and CAN-bus output driver
- 5V  $\pm$ 4 % supply voltage range
- Operating temperature range from  $-40$  to  $+125$  °C

### 2. GENERAL DESCRIPTION

The P82C150 is a single-chip 16-bit I/O device including a controller area network (CAN) protocol controller with automatic bit rate detection and calibration. It features 16 configurable I/O port pins with programmable direction, digital and analog modes.

The P82C150 provides a configurable event capture facility supporting automatic transmission caused by a change on the port input pins.

The clock oscillator requires no external components, thus, the cost of the CAN link is reduced significantly.

The P82C150 is a very cost-effective way to increase the I/O capability of a microcontroller as well as to reduce the amount and complexity of wiring. Advanced safety is provided by the CAN protocol.

#### Applications:

- body electronics and instrumentation in automotive applications
- sensor/actuator interface in automotive and general industrial applications
- extension of I/O capabilities of microcontrollers.

**PIN CONFIGURATION**

# CAN serial linked I/O device with digital and analog port functions

82C150

## 6. FUNCTIONAL DESCRIPTION

### 6.1. I/O functions

The PC82C150 provides 16 port pins (P15 to P0) which are individually configurable via CAN-bus. Besides the digital I/O functions some of these port pins provide analog I/O functions.

#### DIGITAL INPUT FUNCTIONS:

Input levels HIGH and LOW on the port pins (P15 to P0) can be read in two ways by the host node:

- polling: a Remote Frame is sent to the P82C150 to be answered by a Data Frame containing the Data Input Register contents
- event capture: in case of edge-triggered mode, the P82C150 sends the same Data Frame caused by the event of a rising and/or falling edge on the corresponding port pins (Table 2).

#### DIGITAL OUTPUT FUNCTIONS:

The Data Output Register is set via a CAN message. Its content is only output when the corresponding bits of the Output Enable Register are set to "1".

#### ANALOG INPUT/OUTPUT FUNCTIONS:

- up to six multiplexed analog input signals for A/D conversion or general purpose
- up to two quasi-analog output channels (DPM)
- two input comparators, for example for window comparator applications
- a separate A/D input comparator with feedback output (10-bit  $\pm 2$  LSB A/D conversion)

A/D converted digital results are obtained by reading the A/D register. Analog functions of each port pin are

individually controlled by the Analog Configuration Register. Writing the I/O registers is done serially via CAN-bus by Data Frames. The first data byte contains the register address, and the second and third data bytes represent the register contents. If a read-only register is addressed, the contents of the second and third data bytes are ignored. It is recommended to set unused port pins defined HIGH (100 k $\Omega$  resistor to V<sub>DD</sub>).

#### 6.1.1. Data Input Register (address 0; read only)

This register contains the states of port pins P15 to P0 which are transmitted on request, or automatically by change of one of the input levels, provided that the respective input is configured to event capture mode (Table 2). When an edge is detected, the port state is loaded after sending the Control Field of the triggered message. Thereby a delay for input settling is provided. Additionally, the register content is sent automatically after a reset or bus mode change, once the bit time has been calibrated.

#### 6.1.2. Positive Edge Register (address 1; write only)

This register contains configuration information per port pin for the event capture facility. The corresponding PE-bit (Table 2) has to be set to "1" to enable capturing of the rising edge.

#### 6.1.3. Negative Edge Register (address 2; write only)

This register contains configuration information per port pin for the event capture facility. The corresponding NE-bit (Table 2) has to be set to "1" to enable capturing of the falling edge.

The combination of PE and NE functions is possible.

Table 1 I/O Register map

| REGISTER             | ADDRESS | MSB  |      |      |      |      |      |     |     |     |     |     | LSB |     |     |     |     |

| Negative edge                                  | NE   | X                      | 0                               | 1       | 1                             | X                  |
| Output enable                                  | OE   | X                      | X                               | X       | X                             | 1                  |

**6.1.4. Data Output Register (address 3; write only)**

This register contains the output data for the port pins. The output drivers are bitwise enabled by OE.

**6.1.5. Output Enable Register (address 4; write only)**

This register controls the output drivers of the port pins. The corresponding Output Enable Register bit has to be set to "1" to enable an output driver. If set to "0", the corresponding output driver is disabled (floating; Fig.4).

**6.1.6. Analog Configuration Register (address 5; read/write)**

This register contains the bits ADC, OC3 to OC1, M3 to M1 and SW3 to SW1 (Fig. 5).

ADC BIT (A/D conversion start bit; write-only bit):

The P82C150 starts an A/D conversion cycle at ADC = 1 ended with the transmission of a message containing the result. After that, the ADC bit is reset automatically.

OC3 to OC1 BITS (comparator output data; read-only bits):

The P82C150 sends back the logical output value of these comparators after having received a Data Frame (6.2.3.) addressing the Analog Configuration Register. Monitoring is also possible by using the event capture facility.

M3 to M1 BITS (multiplexer control bits; write-only bits):

The logical value of the comparators is monitored on port pins P8, P9 and P7 (Fig.5) by setting M3 to M1 to "1", provided that these pins are configured as outputs (OE = 1).

SW3 to SW1 (analog switch control bits; write-only bits):

One of the analog switches S1 to S6 can be closed by setting the switch bits to the corresponding value (Fig.5):

| SW3 | SW2 | SW1 |                       |
|-----|-----|-----|-----------------------|
| 0   | 0   | 0   | no switch closed (S0) |
| 0   | 0   | 1   | S1 closed             |
| 0   | 1   | 0   | S2 closed             |
| 0   | 1   | 1   | S3 closed             |
| 1   | 0   | 0   | S4 closed             |
| 1   | 0   | 1   | S5 closed             |
| 1   | 1   | 0   | S6 closed             |
| 1   | 1   | 1   | reserved              |

Evidently if P14 is driven, it may not be connected to any other driven pin via the internal analog switches (avoid short-circuit!).

**6.1.7. DPM1 Register (address 6; write only)**

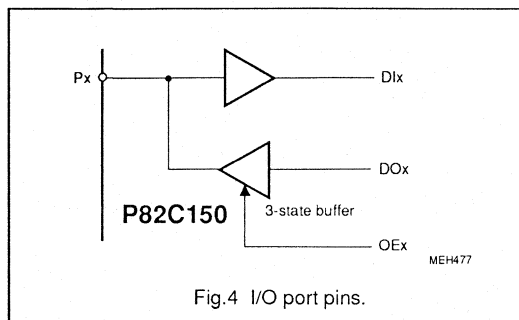

A quasi-analog output signal on port pin P10 is generated by distributed pulse modulation (DPM; Fig.8) if the Output Enable bit is set (OE10 = 1). The DPM1 output signal is inverted by setting DO10 = 1. The number of output pulses during a DPM period is given by the DPM1 Register value. These pulses have 4 x t<sub>CLK</sub> length and are distributed over the DPM period (Fig.8). An analog voltage is provided after smoothing the output signal by an external RC combination.

**6.1.8. DPM2 Register (address 7; write only)**

The function of the DPM2 output (P4) and the DPM2 Register correspond to the definition of DPM1.

**6.1.9. A/D Register (address 8; read only)**

This register contains the result of the A/D converted level of that I/O pin which was selected by the SW bits. The conversion is started by ADC-bit set to "1", or by transmitting a Data Frame addressing the A/D Register.

## CAN serial linked I/O device with digital and analog port functions

82C150

### 6.2. CAN functions

The P82C150 meets the CAN protocol specification version 2.0 A and B (passive) with restricted bit timing because of the on-chip RC-oscillator.

In a system with P82C150 nodes there must be at least one conventional crystal-operated CAN controller (host node), that is responsible to control P82C150 nodes. P82C150 nodes cannot control each other.

Each time a P82C150 node receives a Data Frame, it initiates the transmission of a Data Frame containing four bits status information, the register address (previously received) and the current contents of the addressed register. This enables the host node to verify that the addressed register has correctly been written in case of writable registers, and to read the contents in case of readable registers.

**Table 3** Message types and format

| FRAME          | TRANSMISSION             | RECEPTION                                                             |
|----------------|--------------------------|-----------------------------------------------------------------------|
| Data Frame     | yes (DLC = 3; DIR = 1)   | yes (DLC = 3; DIR = 0; calibration message with DLC = 2 to 8 allowed) |
| Remote Frame   | no                       | yes (DLC = 3; DIR = 1)                                                |
| Error Frame    | yes                      | yes                                                                   |
| Overload Frame | yes (only as a response) | yes                                                                   |

#### 6.2.1. CAN Identifier

Data and Remote Frames to be processed by the P82C150 are of Standard Format with 11 Identifier bits ID.10 to ID.0. Frames with extended Identifier (CAN specification version 2.0 B) are ignored.

| ID.10 | Identifier |    |   |   |    |    |    | ID.0 |   |     |     |
|-------|------------|----|---|---|----|----|----|------|---|-----|-----|
| 0     | 1          | P3 | 1 | 0 | P2 | P1 | P0 | 1    | 0 | DIR | RTR |

1 = recessive; 0 = dominant

P3 to P0 programmable identifier bits read from port pins P3 to P0 during reset.

DIR "1" for transmission of Data Frames to the host. It must be set to "1" in Remote Frames and to "0" in Data Frames received from the host.

RTR Remote Transmission Request bit.

The input levels on P3 to P0, for example set by resistors to  $V_{SS}$  or  $V_{DD}$ , are latched in the Identifier latch with the falling edge of the RST input signal. They represent the variable part of the Identifier, while the remaining bits are

fixed (mask-programmed). P3 to P0 can be used as I/O ports after reset.

The way of identifier programming is based on two facts:

- each P82C150 operates with only two Identifiers at which the higher priority Identifier is used for Data Frame reception (there is an extra Identifier for calibration purpose)
- there can be maximum sixteen P82C150 circuits in one network.

#### 6.2.2. Transmission of Data Frames

Data Frames transmitted by the P82C150 contain three data bytes (Fig.6). The first data byte contains the status information and the register address A3 to A0, the other two data bytes contain the content of the addressed I/O Register.

RSTD It is "1" in the first message after the successful detection of the bit rate (bit time calibrated).

EW "1", if the error warning limit (32) is reached

BM1, BM0 bus mode status bits

A3 to A0 register address bits

The EW status bit is set when the Receive Error Counter or the Transmit Error Counter have exceeded the Error Warning Limit of 32, also temporarily, since the last successful transmission of a message. After each successful message transmission, the P82C150 delays the transmission of a possibly further pending message for three bit times. The reason is to give other CAN controllers – with a lower identifier priority – the possibility to transmit a message in case of faulty contact at one of the edge-triggered port pins.

#### 6.2.3. Reception of Data Frames and Remote Frames

Received Data Frames have the same format as transmitted ones, only the DIR-bit (ID.0) in the Arbitration Field is different. The status bits RSTD, EW, BM1 and BM0 are ignored during reception.

The P82C150 confirms each reception of a Data Frame by transmitting a Data Frame containing the (new) contents of the addressed I/O Register.

# CAN serial linked I/O device with digital and analog port functions

82C150

Exceptions from this rule:

1. Analog Configuration Register:  
If a P82C150 receives a Data Frame addressing the Analog Configuration Register and the ADC bit is set to "1", it will respond with two messages. The first message returns the contents of the Analog Configuration Register. The control instructions are executed (e. g. next analog input channel selected), and an A/D conversion cycle is started after a set-up time. After finishing the A/D conversion cycle, the second message is transmitted containing the result (A/D Register).
2. A/D Register:  
On receiving a Data Frame addressing the A/D Register, the P82C150 starts an A/D conversion cycle. It automatically returns the result of the conversion (A/D Register) by transmitting a respective Data Frame after finishing the A/D conversion cycle.
3. At normal operation, the calibration messages are confirmed by returning a dominant bit in the acknowledge slot. There is no particular confirmation message returned by the P82C150. Only after entering the calibrated state (start-up), a Data Frame containing the Data Input Register contents is transmitted indicating to the host node, that the P82C150 is now ready for transmission.

Remote Frame:

Received Remote Frames must have the Data Length Code DLC = 3 (Remote Frames with DLC ≠ 3 are ignored). It is answered by a Data Frame containing the contents of the Data Input Register.

### 6.2.4. CAN-bus modes

The P82C150 can pass through four CAN-bus modes under certain conditions (Fig.7). In the bus modes 0 to 2 (Table 4) the P82C150 is operating with different input comparator configurations. Bus mode 3 is the power reduced Sleep Mode.

The bus modes support:

- communication on two balanced wires (differential system)
- communication on one wire in a two-wire differential system
- Sleep Mode with wake-up via either of the two RX inputs
- connection of a second transmission medium (redundancy)

There are two possibilities for condition 1 to switch to the next mode:

- overflow of the bit counter when 8192 is reached since the last calibration message or since end of reset

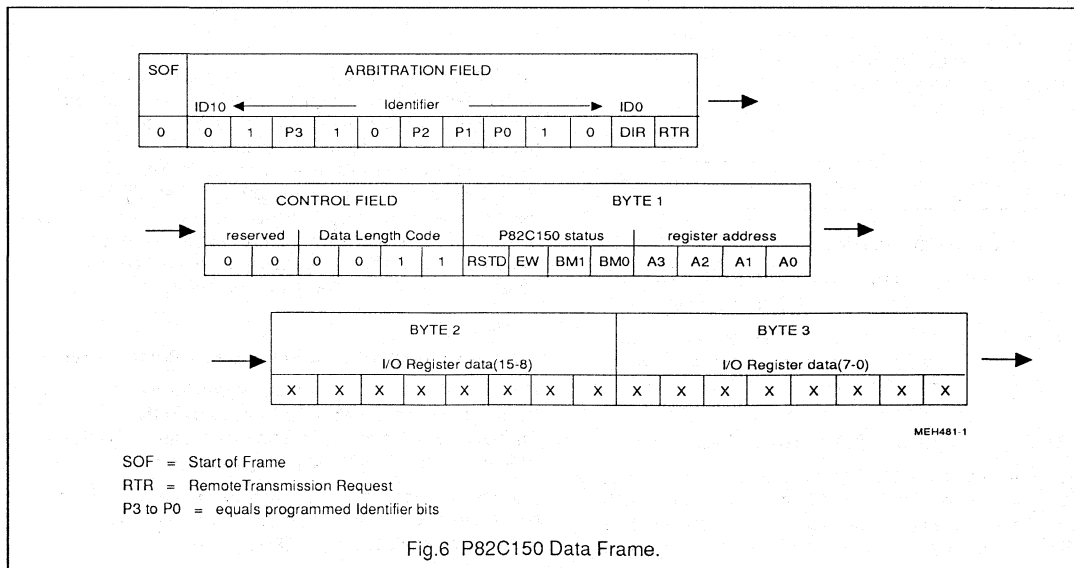

Fig.6 P82C150 Data Frame.

# CAN serial linked I/O device with digital and analog port functions

82C150

**Table 4** CAN-bus modes

| BUS MODE       | BITS<br>BM1, BM0 | RECEPTION LEVEL            |                           | TRANSMISSION |          |
|----------------|------------------|----------------------------|---------------------------|--------------|----------|
|                |                  | RECESSIVE                  | DOMINANT                  | TX1          | TX0      |
| 0 Differential | 00               | RX0 > RX1                  | RX0 < RX1                 | enabled      | enabled  |
| 1 One-wire RX1 | 01               | RX1 < REF                  | RX1 > REF                 | enabled      | enabled  |
| 2 One-wire RX0 | 10               | RX0 > REF                  | RX0 < REF                 | disabled     | enabled  |
| 3 Sleep        | 11               | RX0 > REF<br>and RX1 < REF | RX0 < REF<br>or RX1 > REF | disabled     | disabled |

**Note to Table 4**

Output TX1 is disabled in bus mode 2 to tolerate short-circuit between the CAN-bus wires CAN\_H and CAN\_L.

overflow of the Transmit Error Counter  
(>255; bus-off limit reached).

The P82C150 is in mode 0 after reset. All I/O Registers are cleared (outputs floating) when bus mode changes (e.g. by bus-off or Sleep Mode); the status bits are set additionally:

RSTD = 1  
EW = 0  
BM<sub>new</sub> = BM<sub>old</sub> + 1

The programmed Identifier bits remain unchanged.

During Sleep Mode, the internal RC oscillator is stopped, and all the output drivers are disabled (I/O Register contents cleared). A P82C150 in Sleep Mode can only be awoken via CAN-bus (dominant level on RX0 or RX1) or by a reset condition.

**6.2.5. Bit timing**

The Nominal Bit Time of the P82C150 is subdivided into 10 Time Quanta. The Synchronization Time Segment (SYNC\_SEG) and the Propagation Time Segment (PROP\_SEG) are each one Time Quantum long. The Phase Buffer Segment 1 (PHASE\_SEG1) and the Phase Buffer Segment 2 (PHASE\_SEG2) are each four Time Quanta long. The Resynchronization Jump Width (SJW) is four Time Quanta long. The sample point is located at the end of the Phase Buffer Segment 1. The Nominal Bit Time is internally adjusted to that bit timing which is provided by the crystal driven host (calibration message).

| 1 BIT TIME |          |            |     |     |     |            |     |     |      |
|------------|----------|------------|-----|-----|-----|------------|-----|-----|------|
| BT1        | BT2      | BT3        | BT4 | BT5 | BT6 | BT7        | BT8 | BT9 | BT10 |
| SYNC SEG   | PROP SEG | PHASE_SEG1 |     |     |     | PHASE_SEG2 |     |     |      |

The usable bus length at a given bit rate is reduced in comparison to other CAN controllers with programmable bit timing because the Propagation Time Segment is fixed to 1/10 length of the Nominal Bit Time.

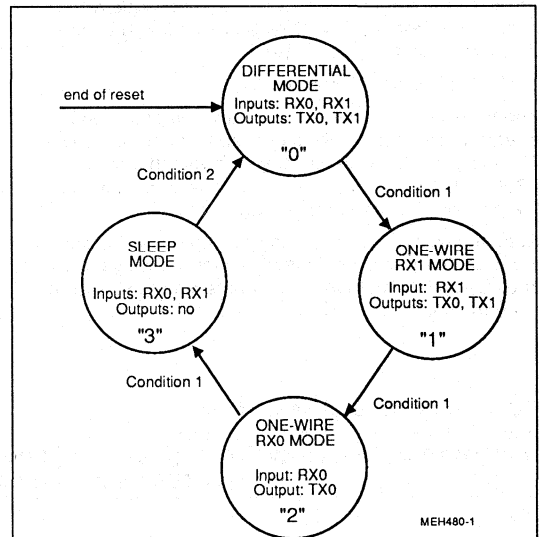

Fig.7 CAN-bus modes and switch-over conditions.

Condition 1:  
bit counter overflow (>8191) or Transmit Error Counter overflow (>255).

Condition 2:  
dominant bit detected on RX0 or RX1

# CAN serial linked I/O device with digital and analog port functions

82C150

## 6.2.6. CAN-bus transceiver

The transceiver of the P82C150 consists of the configurable input comparator and of complementary open-drain driver outputs. The reference voltage REF is an additional output.

### CAN-BUS INPUT COMPARATOR (RX0, RX1):

The input comparator monitors the transient voltage on RX1 and RX0.

The result of the input comparator is "1" if the voltage levels of the CAN-bus lines are regarded as recessive, and "0" if they are regarded as dominant.

The recessive state and the dominant state are not equivalent and may not be mixed-up.

The input comparator is configurable depending on the four CAN-bus modes (Table 4), supporting battery-powered applications (Sleep Mode) and tolerance against bus wiring failures.

### CAN-BUS OUTPUT DRIVERS (TX0, TX1)

The output driver function is shown in Table 5. The output driver TX1 is disabled in bus mode 2 to tolerate a short-circuit between the CAN-bus lines in a two-wire differential CAN physical layer.

## 6.2.7. Transmit and receive logic

The transmit and receive logic stores the destuffed bit stream which was received or is about to be transmitted. The incoming Identifier is compared with that of the P82C150. The content of the message is transferred to the port logic in case of matching.

At transmission, the message about to be sent is put together: the Identifier, the status information, the register address and the content of the addressed register from the port logic.

## 6.2.8. Bit Stream Processor and Error Management Logic

The Bit Stream Processor (BSP) is a sequencer to control the data stream between the transmit/receive logic (parallel data) and the on-chip CAN transceiver (serial data). Reception/transmission, bit stuffing/destuffing, arbitration and error detection, according to CAN protocol specification version 2.0 A and B (passive), are performed. Further, automatic re-transmission of corrupted messages is handled by means of continuously comparing the output bit stream with the input bit stream. Moreover, the Bit Stream Processor provides control information to calibrate the internal bit time.

The Error Management Logic is responsible for the complete CAN-inherent error management.

## 6.2.9. Oscillator and calibration

The P82C150 contains an on-chip RC-oscillator. The bit time is automatically calibrated by messages being received via CAN-bus. During start-up (after wake-up or reset) any message is used to calibrate the bit time until the calibration is sufficient to receive messages correctly. From this time on, the bit time is calibrated and fine-tuned by calibration messages with a special Identifier transmitted by the crystal-operated host.

Only P82C150 nodes being calibrated by calibration messages can transmit messages. The first message is transmitted directly after entering the calibrated state. Since the P82C150 is not able to transmit as long as the bit time is not calibrated, it cannot wake-up other CAN nodes via the bus line. Hence to keep the network alive, the calibration message must be transmitted regularly by a crystal-operated (host) node with a maximum repetition period of 8192 bit. It is recommended to transmit two calibration messages within a period of 8192 bit.

Table 5 CAN-bus driver output function

| CAN OUTPUT | RECESSIVE | DOMINANT (MODES 0 AND 1) | DOMINANT (MODE2) | RESET STATE, BUS-OFF AND SLEEP MODE (MODE 3) |
|------------|-----------|--------------------------|------------------|----------------------------------------------|
| TX0        | floating  | LOW                      | LOW              | floating                                     |
| TX1        | floating  | HIGH                     | floating         | floating                                     |

Table 6 Example of a suitable calibration message. The two important I/O transitions are marked (1).

| SOF | ARBITRATION FIELD | CONTROL FIELD | DATA BYTE 1 | DATA BYTE 2 | CRC FIELD            |
|-----|-------------------|---------------|-------------|-------------|----------------------|
| 0   | 000 1010 1010 0   | 0001010       | 1010 1010   | 00001 0100  | 00010 1011 1000 0010 |

I = stuff bit (recessive); (1) the total length is 67 bit from start-of -frame to end-of-intermission.

82C150

### 6.2.10. Calibration message

The calibration message has to meet the following requirements

- transmitted by a crystal-operated node (host node)
- identifier: 000 1010 1010 (1 = recessive; 0 = dominant)
- RTR bit: 0
- allowed control field: DLC = 2 to 8
- the first recessive to dominant transition after the control field must be followed by another recessive to dominant transition in a distance of exactly 32 bit (stuff bits included).

Example of a suitable calibration message (there are others using different data bytes; Table 6):

```
data length code: 0010
1st data byte 1010 1010 (AAh)
2nd data byte 0000 0100 (04h)
```

### 6.3. Initialization

#### 6.3.1. Identifier programming

Most of the P82C150 identifier bits are fixed. Four bits are programmable via port pins P3 to P0. All output drivers are disabled at reset, also P3 to P0. Thus the outputs are floating unless the input level is defined by external components to define identifier bits. They are latched at the end of reset, and P3 to P0 can be used as port pins. It is not allowed, according to the CAN protocol specification, that multiple bus nodes transmit the same identifier bit combination. Therefore a P82C150 must have one of the 16 possible identifier bit combinations, one that is not yet occupied.

#### 6.3.2. Reset function

RST = HIGH disables all output drivers P16 to P0, TX0 and TX1. All I/O Registers are automatically cleared and set to "0". The bit time is set greater than 50  $\mu$ s.

| After reset: | status bits | identifier bits |
|--------------|-------------|-----------------|
|              | RSTD = 1    | ID.8 equals P3  |
|              | EW = 0      | ID.5 equals P2  |
|              | BM1 = 0     | ID.4 equals P1  |
|              | BMO = 0     | ID.3 equals P0  |

If a particular clock period is necessary, e. g. for a dedicated DPM output frequency, this can be achieved by feeding an external clock signal into P0. RST and TEST must be permanently HIGH for this special mode. A reset is then performed as usual (RST = HIGH; TEST = LOW).

### 6.3.3. Bit time calibration

The P82C150 must receive at least two messages to calibrate its bit time after reset or change of bus mode. The first message is used to detect the bit time length between two consecutive falling edges at the output of the CAN input comparator. Therefore the bit stream should contain a sequence of "1010".

If this measurement is not disturbed, the P82C150 is able to receive messages correctly and to execute the respective commands. The P82C150 is fully calibrated and transmits its first bit (acknowledge) after a successful reception of a calibration message. Thus the P82C150 is enabled to transmit messages.

Sign-on message:

This special Data Frame is transmitted once by the P82C150 after entering the calibrated state. It indicates to the host node that the P82C150 is ready for transmission.

The sign-on message returns the contents of the Data Input Register, and can be recognized by the host node by checking the RSTD status bit.

Sign-on message RSTD = 1;  
other Data Frames RSTD = 0.

82C150

## 9. APPLICATION INFORMATION

### Maximum bus length

**Table 7** Maximum bus line length for CAN-bus systems with P82C150 nodes. The bit timing parameters refer to using a P8xCE598 or P8xC592 microcontroller with on-chip CAN interface as a host node (Fig.12).

Assumptions:

- the total in/out delay of external transceiver circuit is 120 ns (e. g. PCA82C250 CAN transceiver; Fig.13)
- the propagation delay on the transmission medium is 5.5 ns/m.

| BIT RATE<br>(kbit/s) | $t_{prop} / 2$ (note1)<br>( $\mu$ s) | MAXIMUM<br>BUS LENGTH | BIT TIMING (P8x CE 598/P8xC592) |               |               |
|----------------------|--------------------------------------|-----------------------|---------------------------------|---------------|---------------|

### Notes to Table 7

1.  $t_{prop} / 2$  is the maximum propagation delay between two CAN-bus nodes (delays of on- and off-chip transceiver circuits included)
2. BTR0 and BTR1 (hex values) are particular configuration registers referring to bit timing.

## Stand-alone CAN-controller

82C200

**1 FEATURES**

- Multi-master architecture
- Interfaces with a large variety of microcontrollers
- Bus access priority (determined by the message identifier)
- 2032 message identifiers
- Guaranteed latency time for high priority messages
- Powerful error handling capability
- Data length from 0 to 8 bytes
- Configurable bus interface
- Programmable clock output
- Multicast and Broadcast message facility
- Non destructive bit-wise arbitration
- Non-return-to-zero (NRZ) coding/decoding with bit-stuffing
- Programmable transfer rate (up to 1 Mbit/s)
- Programmable output driver configuration
- Suitable for use in a wide range of networks including the SAE networks Class A, B and C
- 16 MHz clock frequency
- -40 to +85/125 °C operating temperature.

**2 GENERAL DESCRIPTION**

The PCA82C200; PCF82C200 (hereafter generically referred to as PCX82C200) is a highly integrated stand-alone controller for the controller area network (CAN) used within automotive and general industrial environments. The temperature range includes an automotive temperature range version (PCA82C200) of -40 to +125 °C and a -40 to +85 °C version (PCF82C200) for general applications.

The PCX82C200 contains all necessary features required to implement a high performance communication protocol. The PCX82C200 with a simple bus line connection performs all the functions of the physical and data-link layers. The application layer of an Electronic Control Unit (ECU) is provided by a microcontroller, to which the PCX82C200 provides a versatile interface. The use of the PCX82C200 in an automotive or general industrial environment, results in a reduced wiring harness and an enhanced diagnostic and supervisory capability.

| $\overline{CS}$   | 4           | Chip select input, LOW level allows access to the PCX82C200.                                                                                                                                                                                                                                                                                                                                    |
| $\overline{RD}$   | 5           | $\overline{RD}$ signal (Intel mode) or E enable signal (Motorola mode) from the microcontroller.                                                                                                                                                                                                                                                                                                |
| $\overline{WR}$   | 6           | $\overline{WR}$ signal (Intel mode) or $\overline{RD}/\overline{WR}$ signal (Motorola mode) from the microcontroller.                                                                                                                                                                                                                                                                           |
| CLK OUT           | 7           | Clock output signal produced by the PCX82C200 for the microcontroller. The clock signal is derived from the built-in oscillator, via the programmable divider (see section 6.5). This output is capable of driving one CMOS or NMOS load.                                                                                                                                                       |
| $V_{SS1}$         | 8           | Ground potential for the logic circuits.                                                                                                                                                                                                                                                                                                                                                        |
| XTAL1<br>(note 1) | 9           | Input to the oscillator's amplifier. External oscillator signal is input via this pin.                                                                                                                                                                                                                                                                                                          |
| XTAL2<br>(note 1) | 10          | Output from the oscillator's amplifier. Output must be left open when an external oscillator signal is used.                                                                                                                                                                                                                                                                                    |
| MODE              | 11          | Mode select input: connected to $V_{DD}$ selects Intel mode; connected to $V_{SS}$ selects Motorola mode.                                                                                                                                                                                                                                                                                       |
| $V_{DD3}$         | 12          | 5 V power supply for the output driver.                                                                                                                                                                                                                                                                                                                                                         |
| TX0               | 13          | Output from the output-driver 0 to the physical bus-line.                                                                                                                                                                                                                                                                                                                                       |
| TX1               | 14          | Output from the output-driver 1 to the physical bus-line.                                                                                                                                                                                                                                                                                                                                       |
| $V_{SS3}$         | 15          | Ground potential for the output driver.                                                                                                                                                                                                                                                                                                                                                         |
| $\overline{INT}$  | 16          | Interrupt output, used to interrupt the microcontroller (see section 6.2.4). $\overline{INT}$ is active if the Interrupt Register contains a logic HIGH bit (present). $\overline{INT}$ is an open drain output and is designed to be a wired-OR with other $\overline{INT}$ outputs within the system. A LOW level on this pin will reactivate the IC from the sleep mode (see section 6.2.2). |
| $\overline{RST}$  | 17          | Reset input, used to reset the CAN interface (LOW level). Automatic power-ON reset can be obtained by connecting $\overline{RST}$ via a capacitor to $V_{SS}$ and via a resistor to $V_{DD}$ (e.g. C = 1 $\mu$ F; R = 50 k $\Omega$ ).                                                                                                                                                          |
| $V_{DD2}$         | 18          | 5 V power supply for the input comparator.                                                                                                                                                                                                                                                                                                                                                      |
| RX0-RX1           | 19, 20      | Input from the physical bus-line to the input comparator of the PCX82C200. A dominant level will wake-up the PCX82C200. A recessive level is read if RX0 is higher than RX1 and vice versa for the dominant level.                                                                                                                                                                              |
| $V_{SS2}$         | 21          | Ground potential for the input comparator.                                                                                                                                                                                                                                                                                                                                                      |
| $V_{DD1}$         | 22          | 5 V power supply for the logic circuits.                                                                                                                                                                                                                                                                                                                                                        |

**Note**

1. XTAL1 and XTAL2 pins should be connected to  $V_{SS}$  via 15 pF capacitors.

# Stand-alone CAN-controller

# 82C200

## 5 FUNCTIONAL DESCRIPTION

The PCX82C200 contains all necessary hardware for a high performance serial network communication (see Fig.1). The PCX82C200 controls the communication flow through the area network using the CAN-protocol. The PCX82C200 meets the following automotive requirements:

- short message length
- guaranteed latency time for urgent messages
- bus access priority, determined by the message identifier
- powerful error handling capability
- configuration flexibility to allow area network expansion.

The latency time defines the period between the initiation (Transmission Request) and the start of the transmission on the bus. Latency time is dependent on a variety of bus related conditions. In the case of a message being transmitted on the bus and one distortion the latency time can be up to 149 bit times (worst case). For more information see section 7.

### 5.1 Interface Management Logic (IML)

The IML interprets commands from the microcontroller, allocates the message buffers (TBF, RBF0 and RBF1) and provides interrupts and status information to the microcontroller.

### 5.2 Transmit Buffer (TBF)

The TBF is a 10 byte memory into which the microcontroller writes messages which are to be transmitted over the CAN network.

### 5.3 Receive Buffers (RBF0 AND RBF1)

The RBF0 and RBF1 are each 10 byte memories which are alternatively used to store messages received from the CAN network. The CPU can process one message while another is being received.

### 5.4 Bit Stream Processor (BSP)

The BSP is a sequencer, controlling the data stream between the Transmit Buffer, the Receive Buffer (parallel data) and the CAN-bus (serial data).

### 5.5 Bit Timing Logic (BTL)

The BTL synchronizes the PCX82C200 to the bitstream on the CAN-bus.

### 5.6 Transceiver Control Logic (TCL)

The TCL controls the output driver.

### 5.7 Error Management Logic (EML)

The EML performs the error confinement according to the CAN-protocol.

### 5.8 Controller Interface Logic (CIL)

The CIL is the interface to the external microcontroller. The PCX82C200 can directly interface with a variety of microcontrollers.

## 6 CONTROL SEGMENT AND MESSAGE BUFFER DESCRIPTION

The PCX82C200 appears to a microcontroller as a memory-mapped I/O device due to the on-chip RAM, guaranteeing the independent operation of both devices.

### 6.1 Address allocation

The address area of the PCX82C200 consists of the Control Segment and the message buffers. The Control Segment is programmed during an initialization download in order to configure communication parameters (e.g. bit timing). Communication over the CAN-bus is also controlled via this segment by the CPU. During initialization the CLOCK OUT signal may be programmed to a value determined by the microcontroller (see Fig.1). A message which is to be transmitted, must be written to the Transmit Buffer. After a successful reception the microcontroller may read the message from the Receive Buffer and then release it for further use.

### 6.2 Control Segment layout

The exchange of status, control and command signals between the microcontroller and the PCX82C200 is performed in the control segment. The layout of this segment is shown in Fig.3. After an initial down-load, the contents of the registers Acceptance Code, Acceptance Mask, Bus Timing Registers 0 and 1, and Output Control should not be changed. These registers may only be accessed when the Reset Request bit in the Control Register, is set HIGH (see section 6.2.1).

**Notes**

1. The Test Register is used for production testing only.
2. Register 30 is not implemented.

## Stand-alone CAN-controller

82C200

## 6.2.1 CONTROL REGISTER (CR)

The contents of the Control Register are used to change the behaviour of the PCX82C200. Control bits may be set or reset by the attached microcontroller which uses the Control Register as a read/write memory.

Table 2 Description of the Control Register bits

| CR   | ADDRESS 0 |                              |                                  |                                                                                                                                                                                                                                                                                                                  |

| CR.0 | RR        | Reset Request<br>(note 3)    | HIGH (present)<br>LOW (absent)   | Detection of a Reset Request results in the PCX82C200 aborting the current transmission or reception of a message and entering the reset state.<br>On the HIGH-to-LOW transition of the Reset Request bit, the PCX82C200 returns to its normal operating state.                                                  |

## Notes

- The Test Mode is intended for factory testing and not for customer use.
- The Sync bit should only be modified if the Reset Request bit is set HIGH (present), otherwise it is ignored. It is possible to set the Sync bit while the Reset Request bit is changed from HIGH to LOW.
- During an external reset ( $\overline{\text{RST}} = \text{LOW}$ ) or when the Bus Status bit is set HIGH (Bus-Off), the IML forces the Reset Request HIGH (present). During an external reset the microcontroller cannot set the Reset Request bit LOW (absent). Therefore, after having set the Reset Request bit LOW (absent), the microcontroller must check this bit to ensure that the external reset pin is not being held HIGH (present). After the Reset Request bit is set LOW (absent) the PCX82C200 will wait for:
  - one occurrence of the Bus-Free signal (11 recessive bits, see section 8.9.6), if the preceding reset (Reset Request = HIGH) was due to an external reset or a microcontroller initiated reset
  - 128 occurrences of Bus-Free, if the preceding reset (Reset Request = HIGH) was due to a PCX82C200 initiated Bus-Off, before re-entering the Bus-On mode (see section 8.9).
 When Reset Request is set HIGH (present), for whatever reason, the control, command, status and interrupt bits are affected, see Table 3. When Reset Request is set HIGH (present) the registers at addresses 4 to 8 are accessible but the TBF is not.

## Stand-alone CAN-controller

82C200

**Table 3** Effects of setting the Reset Request bit HIGH (present)

| TYPE      | BIT   | FUNCTION                     | EFFECT                  |
|-----------|-------|------------------------------|-------------------------|
| Control   | CR.7  | Test Mode                    | LOW (disabled)          |
| Command   | CMR.4 | Goto Sleep                   | LOW (wake-up)           |

|           | IR.0  | Receive Interrupt            | LOW (reset)             |

**Note**

1. Only after an external reset; see note 1 to Table 5 "Description of the Status Register bits".

## Stand-alone CAN-controller

82C200

## 6.2.2 COMMAND REGISTER (CMR)

A command bit initiates an action within the transfer layer of the PCX82C200. The Command Register appears to the microcontroller as a write only memory. If a read access is performed to this address the byte 11111111 (binary) is returned.

Table 4 Description of the Command Register bits

| CMR   | ADDRESS 1 |                                    |                 |                                                                                                                                                                                                                |           |

## Notes

1. The PCX82C200 will enter sleep mode, if Goto Sleep is set HIGH (sleep), there is no bus activity and  $\overline{\text{INT}} = \text{HIGH}$  (inactive). After sleep mode is set, the CLK OUT signal continues until at least 15 bit times have passed. The PCX82C200 will wake up when one of the three previously mentioned conditions is negated: after Goto Sleep is set LOW (wake up), there is bus activity or  $\overline{\text{INT}}$  is driven LOW (active). On wake up, the oscillator is started and a Wake-Up Interrupt (see section 6.2.4) is generated. A PCX82C200 which is sleeping and then awakened by bus activity will not be able to receive this message until it detects a Bus-Free signal (see section 8.9.6).
2. This command bit is used to acknowledge the Data Overrun condition signalled by the Data Overrun status bit. It may be given or set at the same time as a Release Receive Buffer command bit.
3. After reading the contents of the Receive Buffer (RBF0 or RBF1) the microcontroller must release this buffer by setting the Release Receive Buffer bit HIGH (released). This may result in another message becoming immediately available.
4. The Abort Transmission bit is used when the microcontroller requires the suspension of the previously requested transmission, for example to transmit an urgent message. A transmission already in progress is not stopped. In order to determine if the original message had been transmitted successfully, or aborted, the Transmission Complete status bit should be checked after the Transmit Buffer Access bit has been set HIGH (released) or a Transmit Interrupt has been generated (see section 6.2.4).
5. If the Transmission Request bit was set HIGH in a previous command, it cannot be cancelled by setting the Transmission Request bit LOW (absent). Cancellation of the requested transmission may be performed by setting the Abort Transmission bit HIGH (present).

| BIT  | SYMBOL    | NAME                                     | VALUE                                   | FUNCTION                                                                                                                                                                                                |
| SR.7 | BS        | Bus Status<br>(note 1)                   | HIGH (Bus-Off)<br>LOW (Bus-On)          | The PCX82C200 is not involved in bus activities.<br>The PCX82C200 is involved in bus activities.                                                                                                        |
| SR.6 | ES        | Error Status                             | HIGH (error)<br><br>LOW (ok)            | At least one of the Error Counters (see section 8.10.3) has reached the microcontroller Warning Limit.<br>Both Error Counters have not reached the Warning Limit.                                       |
| SR.5 | TS        | Transmit Status<br>(note 2)              | HIGH (transmit)<br>LOW (idle)           | The PCX82C200 is transmitting a message.<br>No message is transmitted.                                                                                                                                  |
| SR.4 | RS        | Receive Status<br>(note 2)               | HIGH (receive)<br>LOW (idle)            | The PCX82C200 is receiving a message.<br>No message is received.                                                                                                                                        |
| SR.3 | TCS       | Transmission Complete Status<br>(note 3) | HIGH (complete)<br><br>LOW (incomplete) | Last requested transmission has been successfully completed.<br>Previously requested transmission is not yet completed.                                                                                 |
| SR.2 | TBS       | Transmit Buffer Access<br>(note 3)       | HIGH (released)<br>LOW (locked)         | The microcontroller may write a message into the TBF.<br>The microcontroller cannot access the Transmit Buffer. A message is either waiting for transmission or is in the process of being transmitted. |
| SR.1 | DO        | Data Overrun<br>(note 4)                 | HIGH (overrun)<br><br>LOW (absent)      | This bit is set HIGH (Overrun), when both Receive Buffers are full and the first byte of another message should be stored.<br>No data overrun has occurred since the Clear Overrun command was given.   |
| SR.0 | RBS       | Receive Buffer Status<br>(note 5)        | HIGH (full)<br>LOW (empty)              | This bit is set when a new message is available.<br>No message has become available since the last Release Receive Buffer command bit was set.                                                          |

#### Notes

- When the Bus Status bit is set HIGH (Bus-Off), the PCX82C200 will set the Reset Request bit HIGH (present). It will stay in this state until the microcontroller sets the Reset Request bit LOW (absent). Once this is completed the PCX82C200 will wait the minimum protocol-defined time (128 occurrences of the Bus-Free signal) before setting the Bus Status bit LOW (Bus-On), the Error Status bit LOW (ok) and resetting the Error Counters.
- If both the Receive Status and Transmit Status bits are LOW (idle) the CAN-bus is idle.
- If the microcontroller tries to write to the Transmit Buffer when the Transmit Buffer Access bit is LOW (locked), the written bytes will not be accepted and will be lost without this being signalled. The Transmission Complete Status bit is set LOW (incomplete) whenever the Transmission Request bit is set HIGH (present). If an Abort Transmission command is issued, the Transmit Buffer will be released. If the message, which was requested and then aborted, was not transmitted, the Transmission Complete Status bit will remain LOW.
- If Data Overrun = HIGH (Overrun) is detected, the currently received message is dropped. A transmitted message, granted acceptance, is also stored in a Receive Buffer. This occurs because it is not known if the PCX82C200 will lose arbitration and so become a receiver of the message. If no Receive Buffer is available, Data Overrun is signalled.
- If the command bit Release Receive Buffer is set HIGH (released) by the microcontroller, the Receive Buffer Status bit is set LOW (empty) by IML. When a new message is stored in any of the receive buffers, the Receive Buffer Status bit is set HIGH (full) again.

## Stand-alone CAN-controller

82C200

## 6.2.4 INTERRUPT REGISTER (IR)

The Interrupt Register allows the identification of an interrupt source. When one or more bits of this register are set, the INT pin is activated. All bits are reset by the PCX82C200 after this register is read by the microcontroller. This register appears to the microcontroller as a read only memory.

**Table 6** Description of the Interrupt Register bits

| IR   | ADDRESS 3 |                            |                           |                                                                                                                                                                                                                                                                                                  |

| IR.4 | WUI       | Wake-Up Interrupt          | HIGH (set)<br>LOW (reset) | The Wake-Up Interrupt bit is set HIGH, when the sleep mode is left (see section 6.2.2).<br>Wake-Up Interrupt bit is reset by a read access of Interrupt Register by the microcontroller.                                                                                                         |
| IR.3 | OI        | Overrun Interrupt (note 1) | HIGH (set)<br>LOW (reset) | This bit is set HIGH, if both Receive Buffers contain a message and the first byte of another message should be stored (passed acceptance), and the Overrun Interrupt Enable is HIGH (enabled).<br>Overrun Interrupt bit is reset by a read access of Interrupt Register by the microcontroller. |
| IR.2 | EI        | Error Interrupt            | HIGH (set)<br>LOW (reset) | This bit is set on a change of either the Error Status or Bus Status bits (see section 6.2.3) if the Error Interrupt Enable is HIGH (enabled).<br>The Error Interrupt bit is reset by a read access of the Interrupt Register by the microcontroller.                                            |
| IR.1 | TI        | Transmit Interrupt         | HIGH (set)<br>LOW (reset) | This bit is set on a change of the Transmit Buffer Access bit from LOW to HIGH (released) and Transmit Interrupt Enable is HIGH (enabled).<br>Transmit Interrupt bit will be reset after a read access of the Interrupt Register by the microcontroller.                                         |
| IR.0 | RI        | Receive Interrupt (note 2) | HIGH (set)<br>LOW (reset) | This bit is set when a new message is available in the Receive Buffer and the Receive Interrupt Enable bit is HIGH (enabled).<br>Receive Interrupt bit is automatically reset by a read access of Interrupt Register by the microcontroller.                                                     |

**Notes**

1. Overrun Interrupt bit (if enabled) and Data Overrun bit (see section 6.2.3) are set at the same time.
2. Receive Interrupt bit (if enabled) and Receive Buffer Status bit (see section 6.2.3) are set at the same time.

## Stand-alone CAN-controller

## 82C200

## 6.2.5 ACCEPTANCE CODE REGISTER (ACR)

The Acceptance Code Register is part of the acceptance filter of the PCX82C200. This register can be accessed (read/write), if the Reset Request bit is set HIGH (present). When a message is received which passes the acceptance test and if there is an empty Receive Buffer, then the respective Descriptor and Data Field (see Fig.4) are sequentially stored in this empty buffer. In the case that there is no empty Receive Buffer, the Data Overrun bit is set HIGH (overrun), see sections 6.2.3 and 6.2.4. When the complete message has been correctly received the following occurs:

- the Receive Buffer Status bit is set HIGH (full)
- if the Receive Interrupt Enable bit is set HIGH (enabled), the Receive Interrupt is set HIGH (set).

The Acceptance Code bits (AC.7-AC.0) and the eight most significant bits of the message's Identifier (ID.10-ID.3) must be equal to those bit positions which are marked relevant by the Acceptance Mask bits (AM.7-AM.0). If the following equation is satisfied, acceptance is given:

$$[(ID.10 .. ID.3) = (AC.7 .. AC.0)] \text{ or } (AM.7 .. AM.0) = 1111 \text{ 1111 binary}$$

During transmission of a message which passes the acceptance test, the message is also written to its own Receive Buffer. If no Receiver Buffer is available, Data Overrun is signalled because it is not known at the start of a message whether the PCX82C200 will lose arbitration and so become a receiver of the message.

Table 7 Acceptance Code Register bits

| ACR  | ADDRESS 4 |      |      |      |      |      |      |
|------|-----------|------|------|------|------|------|------|
| 7    | 6         | 5    | 4    | 3    | 2    | 1    | 0    |
| AC.7 | AC.6      | AC.5 | AC.4 | AC.3 | AC.2 | AC.1 | AC.0 |

## 6.2.6 ACCEPTANCE MASK REGISTER (AMR)

The Acceptance Mask Register is part of the acceptance filter of the PCX82C200. This register can be accessed (read/write) if the Reset Request bit is set HIGH (present). The Acceptance Mask Register qualifies which of the corresponding bits of the acceptance code are "relevant" or "don't care" for acceptance filtering.

Table 8 Acceptance Mask Register bits

| AMR  | ADDRESS 5 |      |      |      |      |      |      |
|------|-----------|------|------|------|------|------|------|
| 7    | 6         | 5    | 4    | 3    | 2    | 1    | 0    |
| AM.7 | AM.6      | AM.5 | AM.4 | AM.3 | AM.2 | AM.1 | AM.0 |

Table 9 Description of the Acceptance Mask Register bits

| ACCEPTANCE MASK BIT | VALUE             | COMMENTS                                                           |
|---------------------|-------------------|--------------------------------------------------------------------|
| AM.7 to AM.0        | HIGH (don't care) | This bit position is "don't care" for the acceptance of a message. |
|                     | LOW (relevant)    | This bit position is "relevant" for acceptance filtering.          |

## Stand-alone CAN-controller

82C200

## 6.2.7 BUS TIMING REGISTER 0 (BTR0)

The contents of Bus Timing Register 0 defines the values of Baud Rate Prescaler (BRP) and the Synchronization Jump Width (SJW). This register can be accessed (read/write) if the Reset Request bit is set HIGH (present).

Table 10 Bus Timing Register 0 bits

| BTR0  | ADDRESS 6 |       |       |       |       |       |       |
|-------|-----------|-------|-------|-------|-------|-------|-------|
| 7     | 6         | 5     | 4     | 3     | 2     | 1     | 0     |
| SJW.1 | SJW.0     | BRP.5 | BRP.4 | BRP.3 | BRP.2 | BRP.1 | BRP.0 |

*Baud Rate Prescaler (BRP)*

The period of the system clock  $t_{SCL}$  is programmable and determines the individual bit timing. The system clock is calculated using the following equation:

$$t_{SCL} = 2t_{CLK} (32BRP.5 + 16BRP.4 + 8BRP.3 + 4BRP.2 + 2BRP.1 + BRP.0 + 1)$$

$t_{CLK}$  = time period of the PCX82C200 oscillator.

*Synchronization Jump Width (SJW)*

To compensate for phase shifts between clock oscillators of different bus controllers, any bus controller must resynchronize on any relevant signal edge of the current transmission. The synchronization jump width defines the maximum number of clock cycles a bit period may be shortened or lengthened by one resynchronization:

$$t_{SJW} = t_{SCL} (2SJW.1 + SJW.0 + 1)$$

For further information on bus timing see sections 6.2.8 and 7.

## 6.2.8 BUS TIMING REGISTER 1 (BTR1)

The contents of Bus Timing Register 1 defines the length of the bit period, the location of the sample point and the number of samples to be taken at each sample point. This register may be accessed (read/write) if the Reset Request bit is set HIGH (present).

Table 11 Bus Timing Register 1 bits

| BTR1 | ADDRESS 7 |         |         |         |         |         |         |
|------|-----------|---------|---------|---------|---------|---------|---------|
| 7    | 6         | 5       | 4       | 3       | 2       | 1       | 0       |
| SAM  | TSEG2.2   | TSEG2.1 | TSEG2.0 | TSEG1.3 | TSEG1.2 | TSEG1.1 | TSEG1.0 |

*Sampling (SAM)*

Table 12 Selection of sampling

| BIT | VALUE            | COMMENTS                 |
|-----|------------------|--------------------------|
| SAM | HIGH (3 samples) | Three samples are taken. |
|     | LOW (1 sample)   | The bus is sampled once. |

SAM = LOW (logic 0) is recommended for high speed buses (SAE class C), while SAM = HIGH (logic 1) is recommended for slow/medium speed buses (class A and B) where filtering of spikes on the bus-line is beneficial (see section 7.1.6).

# Stand-alone CAN-controller

82C200

### Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2)

TSEG1 and TSEG2 determine the number of clock cycles per bit period and the location of the sample point:

$$t_{TSEG1} = t_{SCL} (8TSEG1.3 + 4TSEG1.2 + 2TSEG1.1 + TSEG1.0 + 1)$$

$$t_{TSEG2} = t_{SCL} (4TSEG2.2 + 2TSEG2.1 + TSEG2.0 + 1)$$

For further information on bus timing see sections 6.2.7 and 7.

### 6.2.9 OUTPUT CONTROL REGISTER (OCR)

The Output Control Register allows, under software control, the set-up of different output driver configurations. This register may be accessed (read/write) if the Reset Request bit is set HIGH (present).

**Table 13** Output Control Register bits

| OCR   | ADDRESS 8 |        |       |       |        |         |         |
|-------|-----------|--------|-------|-------|--------|---------|---------|
| 7     | 6         | 5      | 4     | 3     | 2      | 1       | 0       |
| OCTP1 | OCTN1     | OCPOL1 | OCTP0 | OCTN0 | OCPOL0 | OCMODE1 | OCMODE0 |

If the PCX82C200 is in the sleep mode (Goto Sleep = HIGH) a recessive level is output on the TX0 and TX1 pins. If the PCX82C200 is in the reset state (Reset Request = HIGH) the output drivers are floating.

### Normal Output Mode

In Normal Output Mode the bit sequence (TXD) is sent via TX0 and TX1. The voltage levels on the output driver pins TX1 and TX0 depend on both the driver characteristic programmed by OCTPx, OCTNx (float, pull-up, pull-down, push-pull) and the output polarity programmed by OCPOLx (see Fig.4).

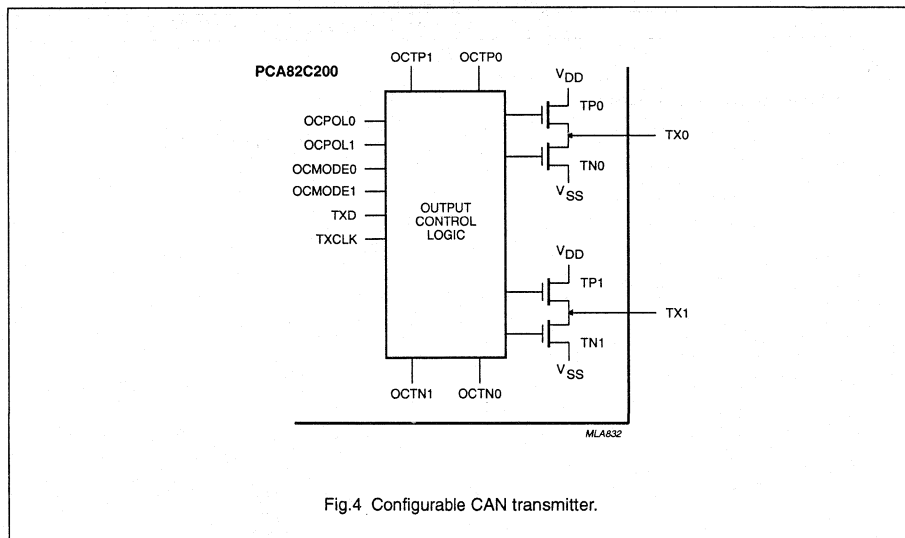

Fig.4 Configurable CAN transmitter.

## Stand-alone CAN-controller

82C200

*Clock Output Mode*

For the TX0 pin this is the same as in Normal Output Mode. However, the data stream to TX1 is replaced by the transmit clock (TXCLK). The rising edge of the transmit clock (non inverted) marks the beginning of a bit period. The clock pulse width is  $t_{SCL}$ .

*Bi-phase Output Mode*

In contrast to Normal Output Mode the bit representation is time variant and toggled. If the bus controllers are galvanically decoupled from the bus-line by a transformer, the bit stream is not allowed to contain a DC component. This is achieved by the following scheme. During recessive bits all outputs are deactivated (3-state). Dominant bits are sent alternately on TX0 and TX1, i.e. the first dominant bit is sent on TX0, the second is sent on TX1, and the third one is sent on TX0 again, etc.

*Test Output Mode*

For the TX0 pin this is the same as in Normal Output Mode. To measure the delay time of the transmitter and receiver this mode connects the output of the input comparator (COMP OUT) with the input of the output driver TX1. This mode is used for production testing only.

The following two tables, Table 14 and Table 15, show the relationship between the bits of the Output Control Register and the two serial output pins TX0 and TX1 of the PCX82C200, connected to the serial bus (see Fig.1).

**Table 14** Description of the Output Mode bits

| OCMODE1 | OCMODE0 | DESCRIPTION                                                   |
|---------|---------|---------------------------------------------------------------|
| 1       | 0       | Normal Output Mode; TX0, TX1: bit sequence (TXD; note 1).     |
| 1       | 1       | Clock Output Mode; TX0: bit sequence, TX1: bus clock (TXCLK). |
| 0       | 0       | Bi-phase Output Mode.                                         |
| 0       | 1       | Test Output Mode; TX0: bit sequence, TX1: COMP OUT.           |

**Note**

1. TXD is the data bit to be transmitted.

|           | 0                 | 1                 | 1                  | 1   | OFF                         | ON                          | LOW                         |
| Pull-up   | 1                 | 0                 | 0                  | 0   | OFF                         | OFF                         | float                       |
|           | 1                 | 0                 | 0                  | 1   | ON                          | OFF                         | HIGH                        |
|           | 1                 | 0                 | 1                  | 0   | ON                          | OFF                         | HIGH                        |
|           | 1                 | 0                 | 1                  | 1   | OFF                         | OFF                         | float                       |
| Push/Pull | 1                 | 1                 | 0                  | 0   | OFF                         | ON                          | LOW                         |
|           | 1                 | 1                 | 0                  | 1   | ON                          | OFF                         | HIGH                        |
|           | 1                 | 1                 | 1                  | 0   | ON                          | OFF                         | HIGH                        |
|           | 1                 | 1                 | 1                  | 1   | OFF                         | ON                          | LOW                         |

**Notes**

1. TP<sub>x</sub> is the on-chip output transistor x, connected to V<sub>DD</sub>; x = 0 or 1.
2. TN<sub>x</sub> is the on-chip output transistor x, connected to V<sub>SS</sub>; x = 0 or 1.
3. TX<sub>x</sub> is the serial output level on pin TX0 or TX1. It is required that the output level on the CAN-bus is dominant with TXD = 0 and recessive with TXD = 1 (see section 8.1.1).

## 6.2.10 TEST REGISTER (TR)

The Test Register is used for production testing only.

## Stand-alone CAN-controller

82C200

**6.3 Transmit Buffer layout**

The global layout of the Transmit Buffer is shown in Fig.3. This buffer serves to store a message from the microcontroller to be transmitted by the PCX82C200. It is subdivided into Descriptor and Data Field. The Transmit Buffer can be written to and read from by the microcontroller (see note 3 to Table 2).

## 6.3.1 DESCRIPTOR

**Table 16** Descriptor Byte 1 (DSCR1)

| DSCR1 |      | ADDRESS 10 |      |      |      |      |      |
|-------|------|------------|------|------|------|------|------|
| 7     | 6    | 5          | 4    | 3    | 2    | 1    | 0    |
| ID.10 | ID.9 | ID.8       | ID.7 | ID.6 | ID.5 | ID.4 | ID.3 |

**Table 17** Descriptor Byte 2 (DSCR2)

| DSCR2 |      | ADDRESS 11 |     |       |       |       |       |
|-------|------|------------|-----|-------|-------|-------|-------|
| 7     | 6    | 5          | 4   | 3     | 2     | 1     | 0     |
| ID.2  | ID.1 | ID.0       | RTR | DLC.3 | DLC.2 | DLC.1 | DLC.0 |

*Identifier (ID)*

The Identifier consists of 11 bits (ID.10 to ID.0). ID.10 is the most significant bit, which is transmitted first on the bus during the arbitration process. The Identifier acts as the message's name, used in a receiver for acceptance filtering and also determines the bus access priority during the arbitration process. The lower the binary value of the Identifier the higher the priority. This is due to the larger number of leading dominant bits during arbitration (see section 8.7 "Bus organization").

*Remote Transmission Request bit (RTR)***Table 18** Description of the RTR bit

| BIT | VALUE         | COMMENTS                                           |
|-----|---------------|----------------------------------------------------|
| RTR | HIGH (remote) | Remote Frame will be transmitted by the PCX82C200. |
|     | LOW (data)    | Data Frame will be transmitted by the PCX82C200.   |

*Data Length Code (DLC)*

The number of bytes (Data Byte Count) in the Data Field of a message is coded by the Data Length Code. At the start of a Remote Frame transmission the Data Length Code is not considered due to the RTR bit being HIGH (remote). This forces the number of transmitted/received data bytes to be 0. Nevertheless, the Data Length Code must be specified correctly to avoid bus errors, if two CAN-controllers start a Remote Frame transmission simultaneously.

The range of the Data Byte Count is 0 to 8 bytes and coded as follows:

$$\text{Data Byte Count} = 8\text{DLC.3} + 4\text{DLC.2} + 2\text{DLC.1} + \text{DLC.0}$$

For reasons of compatibility no Data Byte Counts other than 0 to 8 should be used.

## 6.3.2 DATA FIELD

The number of transferred data bytes is determined by the Data Length Code. The first bit transmitted is the most significant bit of data byte 1 at address 12.

## Stand-alone CAN-controller

82C200

**6.4 Receive Buffer layout**

The layout of the Receive Buffer and the individual bytes correspond to the definitions given for the Transmit Buffer layout, except that the addresses start at 20 instead of 10 (see Fig.3).

**6.5 Clock Divider Register (CDR)**

The Clock Divider Register controls the CLK OUT frequency for the microcontroller (see Fig.1). It can be written to or read by the microcontroller. The default state of the register is divide by 12 for Motorola mode and divide by 2 for Intel mode. Values from 0 to 7 may be written into this register and will result in the CLK OUT frequencies shown in Table 20.

**Table 19** Clock Divider Register bits

| CDR | ADDRESS 31 |   |   |   |      |      |      |
|-----|------------|---|---|---|------|------|------|
| 7   | 6          | 5 | 4 | 3 | 2    | 1    | 0    |
| –   | –          | – | – | – | CD.2 | CD.1 | CD.0 |

**Note**

Bits CDR.7 to CDR.3 are reserved.

**Table 20** CLK OUT frequency selection

| CD.2 | CD.1 | CD.0 | CLK OUT FREQUENCY |
|------|------|------|-------------------|
| 0    | 0    | 0    | $f_{CLK}/2$       |
| 0    | 0    | 1    | $f_{CLK}/4$       |
| 1    | 1    | 0    | $f_{CLK}/6$       |
| 0    | 1    | 1    | $f_{CLK}/8$       |
| 1    | 0    | 0    | $f_{CLK}/10$      |
| 1    | 0    | 1    | $f_{CLK}/12$      |
| 1    | 1    | 0    | $f_{CLK}/14$      |
| 1    | 1    | 1    | $f_{CLK}$         |

**Note**

1.  $f_{CLK}$  is the frequency of the oscillator.

# Stand-alone CAN-controller

82C200

## 7 BUS TIMING/SYNCHRONIZATION

The Bus Timing Logic (BTL) monitors the serial bus-line via the on-chip input comparator and performs the following functions (see section 5):

- monitors the serial bus-line level
- adjusts the sample point, within a bit period (programmable)
- samples the bus-line level using majority logic (programmable, 1 or 3 samples)
- synchronization to the bit stream:
  - hard synchronization at the start of a message
  - resynchronization during transfer of a message.

The configuration of the BTL is performed during the initialization of the PCX82C200. The BTL uses the following three registers:

- Control register (Sync)
- Bus Timing Register 0
- Bus Timing Register 1.

### 7.1 Bit timing

A bit period is built up from a number of system clock cycles ( $t_{scl}$ ), see section 6.2.7. One bit period is the result of the addition of the programmable segments TSEG1 and TSEG2 and the general segment SYNCSEG (see sections 6.2.7 to 6.2.8).

#### 7.1.1 SYNCHRONIZATION SEGMENT (SYNCSEG)

The incoming edge of a bit is expected during this state; this state corresponds to one system clock cycle ( $1 \times t_{scl}$ ).

#### 7.1.2 TIME SEGMENT 1 (TSEG1)

This segment determines the location of the sampling point within a bit period, which is at the end of TSEG1. TSEG1 is programmable from 1 to 16 system clock cycles (see section 6.2.8).

The correct location of the sample point is essential for the correct functioning of a transmission. The following points must be taken into consideration:

- a Start-Of-Frame (see section 8.2.1) causes all PCX82C200's to perform a 'hard synchronization' (see section 7.2.1) on the first recessive-to-dominant edge. During arbitration, however, several PCX82C200's may simultaneously transmit. Therefore it may require twice the sum of bus-line, input comparator and the output driver delay times until the bus is stable. This is the propagation delay time.
- to avoid sampling at an incorrect position, it is necessary to include an additional synchronization buffer on both sides of the sample point. The main reasons for incorrect sampling are:
  - incorrect resynchronization due to spikes on the bus-line
  - slight variations in the oscillator frequency of each PCX82C200 in the network, which results in a phase error.

Time Segment 1 consists of the segment for compensation of propagation delays and the synchronization buffer directly before the sample point (see Fig.5).

#### 7.1.3 TIME SEGMENT 2 (TSEG2)

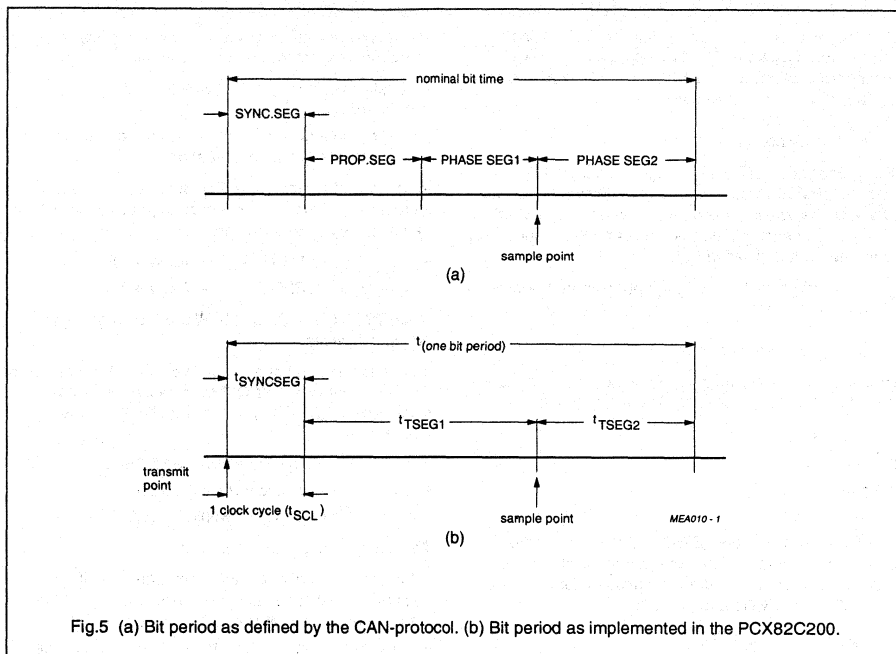

This time segment provides:

- additional time at the sample point for calculation of the subsequent bit levels (e.g. arbitration)
- synchronization buffer segment directly after the sample point (see section 7.1.2).

TSEG2 is programmable from 1 to 8 system clock cycles (see section 6.2.8).

Stand-alone CAN-controller

82C200

## Stand-alone CAN-controller

82C200

### 7.1.4 SYNCHRONIZATION JUMP WIDTH (SJW)

SJW defines the maximum number of clock cycles ( $t_{SCL}$ ) a bit period may be reduced or increased by one resynchronization. SJW is programmable from 1 to 4 system clock cycles (see section 6.2.7).

### 7.1.5 PROPAGATION DELAY TIME

The propagation delay time ( $t_{prop}$ ) is calculated by summing the maximum propagation delay times of the physical bus, the input comparator and the output driver. The resulting sum is multiplied by 2 and then rounded up to the nearest multiple of  $t_{SCL}$ .

$t_{prop} = 2 \times (\text{physical bus delay} + \text{input comparator delay} + \text{output driver delay})$

### 7.1.6 BIT TIMING RESTRICTIONS

Restrictions on the configuration of the bit timing are based on internal processing. The restrictions are:

- $t_{TSEG2} \geq 2t_{SCL}$
- $t_{TSEG2} \geq t_{SJW}$
- $t_{TSEG1} \geq t_{TSEG2}$
- $t_{TSEG1} \geq t_{SJW} + t_{prop}$

The three sample mode (SAM = 1) has the effect of introducing a delay of one system clock cycle on the bus-line. This must be taken into account for the correct calculation of TSEG1 and TSEG2:

- $t_{TSEG1} \geq t_{SJW} + t_{prop} + 2t_{SCL}$
- $t_{TSEG2} \geq 3t_{SCL}$

## 7.2 Synchronization

Synchronization is performed by a state machine which compares the incoming edge with its actual bit timing and adapts the bit timing by hard synchronization or resynchronization.

### 7.2.1 HARD SYNCHRONIZATION

This type of synchronization occurs only at the beginning of a message. The PCX82C200 synchronizes on the first incoming recessive-to-dominant edge of a message (being the leading edge of a message's Start-Of-Frame bit; see section 7.1).

### 7.2.2 RESYNCHRONIZATION

Resynchronization occurs during the transmission of a message's bit stream to compensate for:

- variations in individual PCX82C200 oscillator frequencies
- changes introduced by switching from one transmitter to another (e.g. during arbitration).

As a result of resynchronization either  $t_{TSEG1}$  may be increased by up to a maximum of  $t_{SJW}$  or  $t_{TSEG2}$  may be decreased by up to a maximum of  $t_{SJW}$ :

- $t_{TSEG1} \leq t_{SCL} ((TSEG1 + 1) + (SJW + 1))$
- $t_{TSEG2} \geq t_{SCL} ((TSEG2 + 1) - (SJW + 1))$

Note: TSEG1, TSEG2 and SJW are the programmed numerical values.

The phase error ( $e$ ) of an edge is given by the position of the edge relative to SYNCSEG, measured in system clock cycles ( $t_{SCL}$ ). The value of the phase error is defined as:

- $e = 0$ , if the edge occurs within SYNCSEG
- $e > 0$ , if the edge occurs within TSEG1
- $e < 0$ , if the edge occurs within TSEG2.

The effect of resynchronization is:

- the same as that of a hard synchronization, if the magnitude of the phase error ( $e$ ) is less or equal to the programmed value of  $t_{SJW}$  (see section 6.2.7)
- to increase a bit period by the amount of  $t_{SJW}$ , if the phase error is positive and the magnitude of the phase error is larger than  $t_{SJW}$
- to decrease a bit period by the amount of  $t_{SJW}$ , if the phase error is negative and the magnitude of the phase error is larger than  $t_{SJW}$ .

### 7.2.3 SYNCHRONIZATION RULES

The synchronization rules are as follows:

- only one synchronization within one bit time is used
- an edge is used for synchronization only if the value detected at the previous sample point differs from the bus value immediately after the edge
- hard synchronization is performed whenever there is a recessive-to-dominant edge during Bus-Idle (see section 7)

# Stand-alone CAN-controller

# 82C200

- all other edges (recessive-to-dominant and optionally dominant-to-recessive edges if the Sync bit is set HIGH; see section 6.2.1) which are candidates for resynchronization will be used with the following exception:
  - a transmitting PCX82C200 will not perform a resynchronization as a result of a recessive-to-dominant edge with positive phase error, if only these edges are used for resynchronization. This ensures that the delay times of the output driver and input comparator do not cause a permanent increase in the bit time.

## 8 COMMUNICATION PROTOCOL

### 8.1 Frame types

The PCX82C200 bus controller supports the four different CAN-protocol frame types for communication:

- Data Frame, to transfer data
- Remote Frame, request for data
- Error Frame, globally signal a (locally) detected error condition
- Overload Frame, to extend delay time of subsequent frames (an Overload Frame is not initiated by the PCX82C200).

### 8.1.1 BIT REPRESENTATION

There are two logical bit representations used in the CAN-protocol:

- a recessive bit on the bus-line appears only if all connected PCX82C200's send a recessive bit at that moment
- dominant bits always overwrite recessive bits i.e. the resulting bit level on the bus-line is dominant.

### 8.2 Data Frame

A Data Frame carries data from a transmitting PCX82C200 to one or more receiving PCX82C200's. A Data Frame is composed of seven different bit-fields:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field (may have a length of zero)
- CRC Field
- Acknowledge Field
- End-Of-Frame.

Fig.6 Data Frame.

## Stand-alone CAN-controller

## 82C200

### 8.2.1 START-OF-FRAME BIT

Signals the start of a Data Frame or Remote Frame. It consists of a single dominant bit used for hard synchronization of a PCX82C200 in receive mode.

### 8.2.2 ARBITRATION FIELD

Consists of the message Identifier and the RTR bit (see section 6.3.1). In the event of simultaneous message transmissions by two or more PCX82C200's the bus access conflict is solved by bit-wise arbitration, which is active during the transmission of the Arbitration Field.

#### *Identifier*

This 11-bit field is used to provide information about the message, as well as the bus access priority. It is transmitted in the order ID.10 to ID.0 (LSB). The situation that the seven most significant bits (ID.10 to ID.4) are all recessive must not occur.

An Identifier does not define which particular PCX82C200 will receive the frame, because a CAN based communication network does not discriminate between a point-to-point, multicast or broadcast communication.

#### *Remote Transmission Request bit (RTR)*

A PCX82C200, acting as a receiver for certain information may initiate the transmission of the respective data by transmitting a Remote Frame to the network, addressing the data source via the Identifier and setting the RTR bit HIGH (remote; recessive bus level). If the data source simultaneously transmits a Data Frame containing the requested data, it uses the same Identifier. No bus access conflict occurs due to the RTR bit being set LOW (data; dominant bus level) in the Data Frame.

### 8.2.3 CONTROL FIELD

This field consists of six bits. It includes two reserved bits (for future expansions of the CAN-protocol), transmitted with a dominant bus level, and is followed by the Data Length Code (4 bits). The number of bytes in the (destuffed; number of data bytes to be transmitted/received) Data Field is indicated by the Data Length Code. Admissible values of the Data Length Code and hence the number of bytes in the (destuffed) Data Field, are 0 to 8. A logic 0 (logic 1) in the Data Length Code is transmitted as a dominant (recessive) bus level, respectively.

### 8.2.4 DATA FIELD

The data, stored within the Data Field of the Transmit Buffer, are transmitted according to the Data Length Code. Conversely, data of a received Data Frame will be stored in the Data Field of a Receive Buffer. Data is stored byte-wise both for transmission by the microcontroller and on reception by the PCX82C200. The most significant bit of the first data byte (lowest address) is transmitted/received first.

### 8.2.5 CYCLIC REDUNDANCY CODE FIELD (CRC)

The CRC Field consists of the CRC Sequence (15 bits) and the CRC Delimiter (1 recessive bit). The Cyclic Redundancy Code (CRC) encloses the destuffed bit stream of the Start-Of-Frame, Arbitration Field, Control Field, Data Field and CRC Sequence. The most significant bit of the CRC Sequence is transmitted/received first. This frame check sequence, implemented in the PCX82C200, is derived from a cyclic redundancy code best suited for frames with a total bit count of less than 127 bits, see section 8.8.3 With Start-Of-Frame (dominant bit) included in the code word, any rotation of the code word can be detected by the absence of the CRC Delimiter (recessive bit).

### 8.2.6 ACKNOWLEDGE FIELD (ACK)

The Acknowledge Field consists of two bits, the Acknowledge Slot and the Acknowledge Delimiter, which are transmitted with a recessive level by the transmitter of the Data Frame. All PCX82C200's having received the matching CRC Sequence, report this by overwriting the transmitter's recessive bit in the Acknowledge Slot with a dominant bit (see section 8.9.2). Thereby a transmitter, still monitoring the bus level recognizes that at least one receiver within the network has received a complete and correct message (i.e. no error was found). The Acknowledge Delimiter (recessive bit) is the second bit of the Acknowledge Field. As a result, the Acknowledge Slot is surrounded by two recessive bits: the CRC Delimiter and the Acknowledge Delimiter.

All nodes within a CAN network may use all the information coming to the network by the PCX82C200's (shared memory concept). Therefore, acknowledgement and error handling are defined to provide all information in a consistent way throughout this shared memory. Hence, there is no reason to discriminate different receivers of a message in the acknowledge field. If a

## Stand-alone CAN-controller

82C200

node is disconnected from the network due to bus failure, this particular node is no longer part of the shared memory. To identify a 'lost node' additional and application specific precautions are required.

### 8.2.7 END-OF-FRAME

Each Data Frame or Remote Frame is delimited by the End-Of-Frame bit sequence which consists of seven recessive bits (exceeds the bit stuff width by two bits). Using this method a receiver detects the end of a frame independent of a previous transmission error because the receiver expects all bits up to the end of the CRC sequence to be coded by the method of bit-stuffing (see section 8.7.3). The bit-stuffing logic is deactivated during the End-Of-Frame sequence.

### 8.3 Remote Frame

A PCX82C200, acting as a receiver for certain information may initiate the transmission of the respective data by transmitting a Remote Frame to the network, addressing the data source via the Identifier and setting the RTR bit HIGH (remote; recessive bus level). The Remote Frame is similar to the Data Frame with the following exceptions:

- RTR bit is set HIGH
- Data Length Code is ignored
- no Data Field contained.

Note that the Data Length Code value should be the same as for the corresponding Data Frame (although this is ignored for a Remote Frame).

A Remote Frame is composed of six different bit fields:

- Start-Of-Frame
- Arbitration Field
- Control Field
- CRC-Field
- Acknowledge Field
- End-Of-Frame.

See section 8.2 for a more detailed explanation of the Remote Frame bit fields.

### 8.4 Error Frame

The Error Frame consists of two different fields. The first field is accomplished by the superimposing of Error Flags contributed from different PCX82C200s. The second field is the Error Delimiter (see Fig.7).

#### 8.4.1 ERROR FLAG

There are two forms of an Error Flag:

- Active Error Flag, consists of six consecutive dominant bits
- Passive Error Flag, consists of six consecutive recessive bits unless it is overwritten by dominant bits from other PCX82C200's.

An error-active PCX82C200 (see section 8.9) detecting an error condition signals this by transmission of an Active Error Flag. This Error Flag's form violates the bit-stuffing law (see section 8.7.3) applied to all fields, from Start-Of-Frame to CRC Delimiter, or destroys the fixed form of the fields Acknowledge Field or End-Of-Frame (see Fig.6). Consequently, all other PCX82C200's detect an error condition and start transmission of an Error Flag. Therefore the sequence of dominant bits, which can be monitored on the bus, results from a superposition of different Error Flags transmitted by individual PCX82C200's. The total length of this sequence varies between six (minimum) and twelve (maximum) bits.

An error-passive PCX82C200 (see section 8.9) detecting an error condition tries to signal this by transmission of a Passive Error Flag. The error-passive PCX82C200 waits for six consecutive bits with identical polarity, beginning at the start of the Passive Error Flag. The Passive Error Flag is complete when these six identical bits have been detected.

#### 8.4.2 ERROR DELIMITER

The Error Delimiter consists of eight recessive bits and has the same format as the Overload Delimiter. After transmission of an Error Flag, each PCX82C200 monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every PCX82C200 has finished sending its Error Flag and all PCX82C200's start transmission of seven recessive bits (plus the recessive bit at dominant-to-recessive transition, results in a total of eight recessive bits). After this event and an Intermission Field all error-active PCX82C200's within the network can start a transmission simultaneously.

If a detected error is signalled during transmission of a Data Frame or Remote Frame, the current message is spoiled and a retransmission of the message is initiated.

## Stand-alone CAN-controller

82C200

Fig.7 Error Frame.

If a PCX82C200 monitors any deviation of the Error Frame, a new Error Frame will be transmitted. Several consecutive Error Frame's may result in the PCX82C200 becoming error-passive and leaving the network unblocked.

In order to terminate an Error Flag correctly, an error-passive CAN-bus controller requires the bus to be Bus-Idle (see section 8.6.2) for at least three bit periods (if there is a local error at an error-passive receiver). Therefore a CAN-bus should not be 100% permanently loaded.

### 8.5 Overload Frame

The Overload Frame consists of two fields, the Overload Flag and the Overload Delimiter. There are two conditions in the CAN-protocol which lead to the transmission of an Overload Flag:

- condition 1; receiver circuitry requires more time to process the current data before receiving the next frame (receiver not ready)
- condition 2; detection of a dominant bit during Intermission Field (see section 8.6.1).

The transmission of an Overload Frame may only start:

- condition 1; during the first bit period of an expected Intermission Field

- condition 2; one bit period after detecting the dominant bit during Intermission Field.

The PCX82C200 will never initiate transmission of a condition 1 Overload Frame and will only react on a transmitted condition 2 Overload Frame, according to the CAN-protocol. No more than two Overload Frames are generated to delay a Data Frame or a Remote Frame. Although the overall form of the Overload Frame corresponds to that of the Error Frame, an Overload Frame does not initiate or require the retransmission of the preceding frame.

#### 8.5.1 OVERLOAD FLAG

The Overload Flag consists of six dominant bits and has a similar format to the Error Flag.

The Overload Flag's form corrupts the fixed form of the Intermission Field. All other PCX82C200's detecting the overload condition also transmit an Overload Flag (condition 2).

#### 8.5.2 OVERLOAD DELIMITER

The Overload Delimiter consists of eight recessive bits and takes the same form as the Error Delimiter. After transmission of an Overload Flag, each PCX82C200 monitors the bus-line until it detects a transition from a

## Stand-alone CAN-controller

82C200

dominant-to-recessive bit level. At this point in time, every PCX82C200 has finished sending its Overload Flag and all PCX82C200's start simultaneously transmitting seven more recessive bits.

### 8.6 Inter-Frame Space

Data Frames and Remote Frames are separated from preceding frames (all types) by an Inter-Frame Space, consisting of an Intermission Field and a Bus-Idle. Error-passive PCX82C200's also send a Suspend Transmission (see section 8.9.5) after transmission of a message. Overload Frames and Error Frames are not preceded by an Inter-Frame Space.

#### 8.6.1 INTERMISSION FIELD

The Intermission Field consists of three recessive bits. During an Intermission period, no frame transmissions will be started by any PCX82C200. An Intermission is required to have a fixed time period to allow a CAN-controller to execute internal processes prior to the next receive or transmit task.

#### 8.6.2 BUS-IDLE

The Bus-Idle time may be of arbitrary length (minimum 0 bit). The bus is recognized to be free and a CAN-controller having information to transmit may access the bus. The detection of a dominant bit level during Bus-Idle on the bus is interpreted as the Start-Of-Frame.

### 8.7 Bus organization

Bus organization is based on five basic rules described in the following paragraphs.

#### 8.7.1 BUS ACCESS

PCX82C200's only start transmission during the Bus-Idle state. All PCX82C200's synchronize on the leading edge of the Start-Of-Frame (hard synchronization).

#### 8.7.2 ARBITRATION

If two or more PCX82C200's simultaneously start transmitting, the bus access conflict is solved by a bit-wise arbitration process during transmission of the Arbitration Field.

During arbitration every transmitting PCX82C200 compares its transmitted bit level with the monitored bus level. Any PCX82C200 which transmits a recessive bit and monitors a dominant bus level immediately becomes

the receiver of the higher priority message on the bus without corrupting any information on the bus. Each message contains an unique Identifier and a RTR bit describing the type of data within the message.

The Identifier together with the RTR bit implicitly define the message's bus access priority. During arbitration the most significant bit of the Identifier is transmitted first and the RTR bit last. The message with the lowest binary value of the Identifier and RTR bit has the highest priority. A Data Frame has higher priority than a Remote Frame due to its RTR bit having a dominant level.

For every Data Frame there is an unique transmitter. For reasons of compatibility with other CAN-bus controllers, use of the Identifier binary bit pattern ID = 1111111XXXX (X being bits of arbitrary level) is forbidden. The number of available different Identifiers is 2032 ( $2^{11} - 2^4$ ).

#### 8.7.3 CODING/DECODING

The following bit fields are coded using the bit-stuffing technique:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field
- CRC Sequence.

When a transmitting PCX82C200 detects five consecutive bits of identical polarity to be transmitted, a complementary (stuff) bit is inserted into the transmitted bit-stream.

When a receiving PCX82C200 has monitored five consecutive bits with identical polarity in the received bit streams of the above described bit fields, it automatically deletes the next received (stuff) bit. The level of the deleted stuff bit has to be the complement of the previous bits; otherwise a Stuff Error will be detected and signalled (see section 8.8.2).

The remaining bit fields or frames are of fixed form and are not coded or decoded by the method of bit-stuffing.

The bit-stream in a message is coded according to the Non-Return-to-Zero (NRZ) method, i.e. during a bit period, the bit level is held constant, either recessive or dominant.

## Stand-alone CAN-controller

82C200

### 8.7.4 ERROR SIGNALLING

A PCX82C200 which detects an error condition, transmits an Error Flag. Whenever a Bit Error, Stuff Error, Form Error or an Acknowledgement Error is detected, transmission of an Error Flag is started at the next bit. Whenever a CRC Error is detected, transmission of an Error Flag starts at the bit following the Acknowledge Delimiter, unless an Error Flag for another error condition has already started. An Error Flag violates the bit-stuffing law or corrupts the fixed form bit fields. A violation of the bit-stuffing law affects any PCX82C200 which detects the error condition. These devices will also transmit an Error Flag.

An error-passive PCX82C200 (see section 8.9) which detects an error condition, transmits a Passive Error Flag. A Passive Error Flag is not able to interrupt a current message at different PCX82C200's, but this type of Error Flag may be cancelled by other PCX82C200's. After having detected an error condition, an error-passive PCX82C200 will wait for six consecutive bits with identical polarity and when monitoring them, interpret them as an Error Flag.

After transmission of an Error Flag, each PCX82C200 monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every PCX82C200 has finished transmitting its Error Flag and all PCX82C200's start transmitting seven additional recessive bits (Error Delimiter, see section 8.4.2).

The message format of a Data Frame or Remote Frame is defined in such a way, that all detectable errors can be signalled within the message transmission time and therefore, it is very simple for a PCX82C200 to associate an Error Frame to the corresponding message and to initiate retransmission of the corrupted message.

If a PCX82C200 monitors any deviation of the fixed form of an Error Frame, it transmits a new Error Frame.

### 8.7.5 OVERLOAD SIGNALLING

Some CAN-controllers (but not the PCX82C200) require to delay the transmission of the next Data Frame or Remote Frame by transmitting one or more Overload Frames. The transmission of an Overload Frame must start during the first bit of an expected Intermission. Transmission of Overload Frames which are reactions on a dominant bit during an expected Intermission Field, start one bit after this event.

Though the format of Overload Frame and Error Frame are identical, they are treated differently. Transmission of an Overload Frame during Intermission Field does not initiate the retransmission of any previous Data Frame or Remote Frame.

If a CAN-controller which transmitted an Overload Frame monitors any deviation of its fixed form, it transmits an Error Frame.

### 8.8 Error detection

The processes described in the following paragraphs are implemented in the PCX82C200 for error detection.

#### 8.8.1 BIT ERROR

A transmitting PCX82C200 monitors the bus on a bit-by-bit basis. If the bit level monitored is different from the transmitted one, a Bit Error is signalled. The exceptions being:

- during the Arbitration Field, a recessive bit can be overwritten by a dominant bit. In this case, the PCX82C200 interprets this as a loss of arbitration
- during the Acknowledge Slot, only the receiving PCX82C200's are able to recognize a Bit Error.

#### 8.8.2 STUFF ERROR

The following bit fields are coded using the bit-stuffing technique:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field
- CRC Sequence.

There are two possible ways of generating a Stuff Error:

- the disturbance generates more than the allowed five consecutive bits with identical polarity. These errors are detected by all PCX82C200's
- a disturbance falsifies one or more of the five bits preceding the stuff bit. This error situation is not recognized as a Stuff Error by the receivers. Therefore, other error detection processes may detect this error condition such as: CRC check, format violation at the receiving PCX82C200's or Bit Error detection by the transmitting PCX82C200.

## Stand-alone CAN-controller

82C200

### 8.8.3 CRC ERROR

To ensure the validity of a transmitted message all receivers perform a CRC check. Therefore, in addition to the (destuffed) information digits (Start-Of-Frame up to Data Field), every message includes some control digits (CRC Sequence; generated by the transmitting PCX82C200 of the respective message) used for error detection.

The code used for the PCX82C200 bus controller is a (shortened) BCH code, extended by a parity check and has the following attributes:

- 127 bits as maximum length of the code
- 112 bits as maximum number of information digits (maximum 83 bits are used by PCX82C200)
- length of the CRC Sequence amounts to 15 bits
- Hamming distance  $d = 6$ .

As a result,  $(d-1)$  random errors are detectable (some exceptions exist).

The CRC Sequence is calculated by the following procedure:

1. the destuffed bit stream consisting of Start-Of-Frame up to the Data Field (if present) is interpreted as a polynomial with coefficients of 0 or 1
2. this polynomial is divided (modulo-2) by the following generator polynomial:

$$f(X) = (X^{14} + X^9 + X^8 + X^6 + X^5 + X^4 + X^2 + X + 1) (X + 1) = 1100010110011001 \text{ binary.}$$

The remainder of this polynomial division is the CRC Sequence which includes a parity check. Burst errors are detected up to a length of 15 [degree of  $f(X)$ ]. Multiple errors (number of disturbed bits at least  $d = 6$ ) are not detected with a residual error probability of  $2^{-15}$  ( $\approx 3 \times 10^{-5}$ ) by CRC check only.

### 8.8.4 FORM ERROR

Form Errors result from violation of the fixed form of the following bit fields:

- End-Of-Frame
- Intermission
- Acknowledge Delimiter
- CRC Delimiter.

During the transmission of these bit fields an error condition is recognized if a dominant bit level instead of a recessive one is detected.

### 8.8.5 ACKNOWLEDGEMENT ERROR

This is detected by a transmitter whenever it does not monitor a dominant bit during the Acknowledge Slot.

### 8.8.6 ERROR DETECTION BY AN ERROR FLAG OF ANOTHER PCX82C200

The detection of an error is signalled by transmitting an Error Flag. An Active Error Flag causes a Stuff Error, a Bit Error or a Form Error at all other PCX82C200's.

### 8.8.7 ERROR DETECTION CAPABILITIES

Errors which occur at all PCX82C200's (global errors) are 100% detected. For local errors, i.e. for errors occurring at some PCX82C200's only, the shortened BCH code, extended by a parity check, has the following error detection capabilities:

- up to five single bit errors are 100% detected, even if they are distributed randomly within the code
- all single bit errors are detected if their total number (within the code) is odd
- the residual error probability of the CRC check amounts to  $3 \times 10^{-5}$ . As an error may be detected not only by CRC check but also by other detection processes described in sections 8.8.1 to 8.8.5, the residual error probability is several magnitudes less than  $3 \times 10^{-5}$  for undetected errors.

## 8.9 Error confinement (definitions)

### 8.9.1 BUS-OFF

A PCX82C200 which has too many unsuccessful transmissions, relative to the number of successful transmissions, will enter the Bus-Off state. It remains in this state, neither receiving nor transmitting messages until the Reset Request bit is set LOW (absent) and both Error Counters are set to '0' (see note 1 to Table 5 and section 8.10.3).

### 8.9.2 ACKNOWLEDGE (ACK)

A PCX82C200 which has received a valid message correctly, indicates this to the transmitter by transmitting a dominant bit level on the bus during the Acknowledge Slot, independent of accepting or rejecting the message.

## Stand-alone CAN-controller

## 82C200

### 8.9.3 ERROR-ACTIVE

An error-active PCX82C200 is in its normal operating state able to receive and to transmit normally and also to transmit an active Error Flag (see section 8.10.3).

### 8.9.4 ERROR-PASSIVE

An error-passive PCX82C200 may transmit or receive messages normally. In the case of a detected error condition it transmits a Passive Error Flag, instead of an Active Error Flag. Hence the influence on bus activities by an error-passive PCX82C200 (e.g. due to a malfunction) is reduced.

### 8.9.5 SUSPEND TRANSMISSION

After an error-passive PCX82C200 has transmitted a message, it sends eight recessive bits after the Intermission Field and then checks for Bus-Idle. If during Suspend Transmission another PCX82C200 starts transmitting a message the suspended PCX82C200 will become the receiver of this message; otherwise being in Bus-Idle it may start to transmit a further message.

### 8.9.6 START-UP

A PCX82C200 which was either switched off or is in the Bus-Off state, must run a start-up routine in order to:

- synchronize with other available PCX82C200's, before starting to transmit. Synchronizing is achieved, when 11 recessive bits, equivalent to Acknowledge Delimiter, End-Of-Frame and Intermission Field, have been detected (Bus-Free)
- wait for other PCX82C200s without passing into the Bus-Off state (due to a missing acknowledge), if there is no other PCX82C200 currently available.

## 8.10 Aims of error confinement

### 8.10.1 DISTINCTION OF SHORT AND LONG-LASTING DISTURBANCES

The microcontroller must be informed when there are long-lasting disturbances and when bus activities have returned to normal operation. During long-lasting disturbances, a PCX82C200 enters the Bus-Off state and the microcontroller may use default values.

Minor disturbances of bus activities will not affect a PCX82C200. In particular, a PCX82C200 does not enter the Bus-Off state or inform the microcontroller of a short-lasting bus disturbance.

### 8.10.2 DETECTION AND LOCALIZATION OF HARDWARE DISTURBANCES AND DEFECTS

The rules for error confinement are defined by the CAN-protocol specification (and implemented in the PCX82C200), in that the PCX82C200, being nearest to the error-locus, reacts with a high probability, the quickest (i.e. becomes error-passive or Bus-Off), hence errors can be localized and their influence on normal bus activities is minimized.

### 8.10.3 ERROR CONFINEMENT

All PCX82C200's contain a Transmit Error Counter and a Receive Error Counter, which registers errors during the transmission and the reception of messages, respectively.

If a message is transmitted or received correctly, the count is decreased. In the event of an error, the count is increased. The Error Counters have a non-proportional method of counting: an error causes a larger counter increase than a correctly transmitted/received message causes the count to decrease. Over a period of time this may result in an increase in error counts, even if there are fewer corrupted messages than uncorrupted ones. The level of the Error Counters reflect the relative frequency of disturbances. The ratio of increase/decrease depends on the acceptable ratio of invalid/valid messages on the bus and is hardware implemented to eight.

If one of the Error Counters exceeds the Warning Limit of 96 error points, indicating a significant accumulation of error conditions, this is signalled by the PCX82C200 (Error Status, Error Interrupt).

A PCX82C200 operates in the error-active mode until it exceeds 127 error points on one of its Error Counters. At this point it will enter the error-passive state.

A transmit error which exceeds 255 error points results in the PCX82C200 entering the Bus-Off state.

## Stand-alone CAN-controller

82C200

**9 LIMITING VALUES**

Limiting values in accordance with the Absolute Maximum Rating System (IEC134)

| SYMBOL           | PARAMETER                                               | MIN. | MAX. | UNIT |
|------------------|---------------------------------------------------------|------|------|------|
| V <sub>DD</sub>  | supply voltage range                                    | 4.5  | 5.5  | V    |
| I <sub>I</sub>   | input/output current on any pin except from TX0 and TX1 | –    | ±10  | mA   |
| I <sub>OT</sub>  | sink current of TX0 and TX1 together (note 1)           | –    | 28   | mA   |
| I <sub>OT</sub>  | source current of TX0 and TX1 together (note 1)         | –    | –20  | mA   |
| T <sub>amb</sub> | operating ambient temperature range:                    |      |      |      |
|                  | PCA82C200                                               | –40  | +125 | °C   |
|                  | PCF82C200                                               | –40  | +85  | °C   |
| T <sub>stg</sub> | storage temperature range                               | –65  | +150 | °C   |
| P <sub>tot</sub> | total power dissipation (note 2)                        | –    | 1    | W    |

**Notes**

- I<sub>OT</sub> is allowed in case of a bus failure condition because then the TX-outputs are switched off automatically after a short time (Bus-Off state). During normal operation I<sub>OT</sub> is a peak current, permitted for t < 100 ms. The average output current must not exceed 10 mA for each TX-output.
- The value is based on the maximum allowable die temperature and the thermal resistance of the package, not on device power consumption.

**10 DC CHARACTERISTICS**

V<sub>DD</sub> ≤ 5 V ±10%; V<sub>SS</sub> = 0 V; T<sub>amb</sub> = –40 to +125 °C for the PCA82C200 and T<sub>amb</sub> = –40 to +85 °C for the PCF82C200. All voltages measured with respect to V<sub>ss</sub> unless otherwise specified

**12 DEVELOPMENT SUPPORT AND TOOLS****12.1 The PCX82C200 Evaluation Board**

Philips offers powerful support during the design and test stages of CAN networks, working closely with customers to develop their systems. The 'Philips Stand-alone CAN-Controller (PSCC) Evaluation Board' is a versatile tool being a ready-to-use hardware and software module, very similar to a real CAN module. Since a 5 V power supply is provided, the board can be used in any vehicle without modification. An RS232 interface allows a terminal or a PC with terminal-emulation software to be connected to the board. The board comprises:

- a PCX82C200 CAN-bus controller
- a PCA80C552 microcontroller with up to 32K x 8 bits external RAM and EPROM

- a 5 V power supply with protection against car battery disturbances
- two different physical CAN-bus interfaces (selectable)
- an RS232 interface
- demonstration hardware
- a wrap field for customer-specific circuitry.

The software provided with the board supports "learning about CAN" and assists in prototype (e.g. in-vehicle) networks. It provides:

- demonstration software (automatically-initiated)
- the menu-driven software comprises:
  - a facility to alter the contents of the PCX82C200 registers
  - a bus monitor to receive messages from the CAN-bus and to display them on a terminal
  - a download facility for the user's application software.

With these facilities the board is a basis for prototype modules; when using entirely your own software, the board can be used as a custom, debugged and proven hardware module.

**12.2 Advanced support**

For further development support, Philips subcontractor I+ME offers a complete set of development tools including:

- a CAN simulator; CAN/Net Sim
- an emulator; CAN/Net Emu
- a network analyzer; CAN/Net Anal.

I+ME can be contacted through the following address:

I+ME GmbH  
Ferdinandstrasse 15 A  
D-3340 Wolfenbuettel  
West Germany.

Phone: ++49-5331-72066  
Fax: ++49-5331-32455

**CAN controller interface****PCA82C250****FEATURES**

- Fully compatible with the ISO/DIS 11898 standard
- High speed (up to 1 Mbaud)
- Bus lines protected against transients in an automotive environment
- Slope control to reduce radio frequency interference (RFI)
- Thermally protected
- Short-circuit proof to battery and ground
- Low current standby mode
- An unpowered node does not disturb the bus lines
- At least 110 nodes can be connected.

**GENERAL DESCRIPTION**

The PCA82C250 is the interface between the CAN protocol controller and the physical bus. It is primarily intended for high-speed applications (up to 1 Mbaud) in cars. The device provides differential transmit capability to the bus and differential receive capability to the CAN controller

## CAN controller interface

## PCA82C250

## FUNCTIONAL DESCRIPTION

The PCA82C250 is the interface between the CAN protocol controller and the physical bus. It is primarily intended for high-speed applications (up to 1 Mbaud) in cars. The device provides differential transmit capability to the bus and differential receive capability to the CAN controller. It is fully compatible with the ISO/DIS 11898 standard.

A current limiting circuit protects the transmitter output stage against short-circuit to positive and negative battery voltage. Although the power dissipation is increased during this fault condition, this feature will prevent destruction of the transmitter output stage.

If the junction temperature exceeds a value of approximately 160 °C, the limiting current of both transmitter outputs is decreased. Because the transmitter is responsible for the major part of the power dissipation, this will result in a reduced power dissipation and hence a lower chip temperature. All other parts of the IC will remain in operation. The thermal protection is particularly needed when a bus line is short-circuited.

The CANH and CANL lines are also protected against electrical transients which may occur in an automotive environment.

Pin 8 (Rs) allows three different modes of operation to be selected: high-speed, slope control or standby.

For high-speed operation, the transmitter output transistors are simply switched on and off as fast as possible. In this mode, no measures are taken to limit the rise and fall slope. Use of a shielded cable is recommended to avoid RFI problems. The high-speed mode is selected by connecting pin 8 to ground.

For lower speeds or shorter bus length, an unshielded twisted pair or a parallel pair of wires can be used for the bus. To reduce RFI, the rise and fall slope should be limited. The rise and fall slope can be programmed with a resistor connected from pin 8 to ground. The slope is proportional to the current output at pin 8.

If a HIGH level is applied, the circuit enters a low current standby mode. In this mode, the transmitter is switched off and the receiver is switched to a low current. If dominant bits are detected (differential bus voltage > 0.9 V), RxD will be switched to a LOW level. The microcontroller should react to this condition by switching the transceiver back to normal operation (via pin 8). Because the receiver is slow in standby mode, the first message will be lost.

Table 1 Truth table of CAN transceiver.

| SUPPLY                 | TxD             | CANH                                 | CANL                                 | BUS STATE | RxD |
|------------------------|-----------------|--------------------------------------|--------------------------------------|-----------|-----|
| 4.5 to 5.5 V           | 0               | HIGH                                 | LOW                                  | dominant  | 0   |
| 4.5 to 5.5 V           | 1 (or floating) | floating                             | floating                             | recessive | 1   |

| $T_{stg}$ | storage temperature               |                                           | -55  | +150           | °C   |
| $T_{amb}$ | operating ambient temperature     |                                           | -40  | +125           | °C   |
| $T_{vj}$  | virtual junction temperature      | note 1                                    | -40  | +150           | °C   |

**Note**

- In accordance with IEC 747-1.

An alternative definition of virtual junction temperature  $T_{vj}$  is;

$$T_{vj} = T_{amb} + P_d \times R_{th\ vj-amb}$$

where  $R_{th\ vj-amb}$  is a fixed value to be used for the calculation of  $T_{vj}$ .

The rating for  $T_{vj}$  limits the allowable combinations of power dissipation ( $P_d$ ) and ambient temperature ( $T_{amb}$ )

**HANDLING**

Classification A: human body model; C = 100 pF; R = 1500  $\Omega$ ; V =  $\pm 2000$  V.

Classification B: machine model; C = 200 pF; R = 0  $\Omega$ ; V =  $\pm 200$  V.

**THERMAL RESISTANCE**

| SYMBOL        | PARAMETER                            | THERMAL RESISTANCE |
|---------------|--------------------------------------|--------------------|
| $R_{th\ j-a}$ | from junction to ambient in free air |                    |
|               | PCA82C250                            | 100 K/W            |
|               | PCA82C250T                           | 160 K/W            |

## CAN controller interface

## PCA82C250

## CHARACTERISTICS

$V_{CC} = 4.5$  to  $5.5$  V;  $T_{amb} = -40$  to  $+125$  °C;  $R_L = 60$   $\Omega$ ;  $I_B = > -10$   $\mu$ A; unless otherwise specified. All voltages referenced to ground (pin 2); positive input current; all parameters are guaranteed over the ambient temperature range by design, but only 100% tested at  $+25$  °C.

# Single-chip 8-bit microcontroller

# 8031AH/8051AH

## DESCRIPTION

The Philips 8031AH/8051AH is a high-performance microcontroller fabricated with Philips high-density highly reliable +5V, depletion-load, N-channel, silicon-gate, N500 MOS process technology. It provides the hardware features, architectural enhancements and instructions that are necessary to make it a powerful and cost-effective controller for applications requiring up to 64k bytes of program memory and/or up to 64k bytes of data storage.

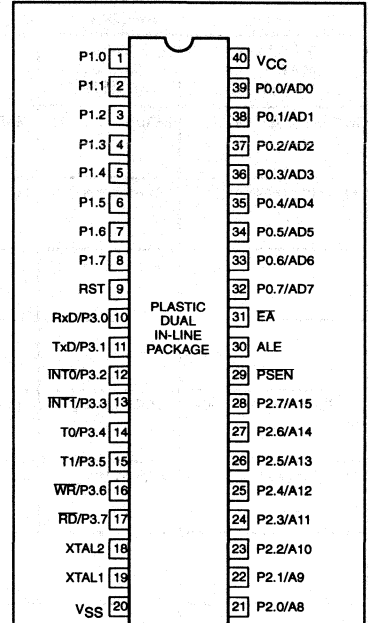

The 8051AH contains a 4k x 8 read-only program memory, a 128 x 8 read-only data memory, 32 I/O lines, two 16-bit counter/timers, a five-source, two-priority level nested interrupt structure, a serial I/O port for either multi-processor communications, I/O expansion or full duplex UART, and on-chip oscillator and clock circuits. The 8031AH is identical, except that it lacks the program memory. For systems that require extra capability, the 8051AH can be expanded using standard TTL compatible memories and byte oriented peripheral controllers.

The 8051AH microcontroller, like its 8048 predecessor, is efficient both as a controller and as an arithmetic processor. It has extensive facilities for binary and BCD arithmetic and excels in bit-handling capabilities. Efficient use of program memory results from an instruction set consisting of 44% one-byte, 41% two-byte, and 15% three-byte instructions. With a 12MHz crystal, 58% of the instructions execute in 1µs, 40% in 2µs and multiply and divide require only 4µs.

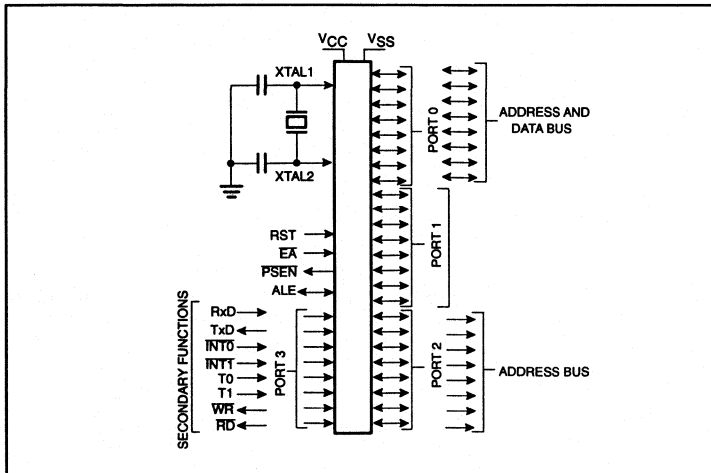

## FEATURES

- Reduced supply current
- 4k x 8 ROM (8051AH)
- 128 x 8 RAM
- Four 8-bit ports, 32 I/O lines
- Two 16-bit timer/event counters
- High-performance full-duplex serial channel
- External memory expandable to 128k
- Boolean processor
- Industry standard 8051 architecture:
  - Non-paged jumps
  - Direct addressing
  - Four 8-register banks
  - Stack depth up to 128-bytes
  - Multiply, divide, subtract, compare
- Most instructions execute in 1µs
- 4µs multiply and divide

## PIN CONFIGURATIONS

| V <sub>CC</sub> | 40                                                 | 44           | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| P0.0–P0.7       | 39–32                                              | 43–36        | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s.                                                                                                                                                                                                                                                                                                                                                                                                                |
| P1.0–P1.7       | 1–8                                                | 2–9          | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ).                                                                                                                                                                                                                                                                                                                                                                                                   |
| P2.0–P2.7       | 21–28                                              | 24–31        | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |
| P3.0–P3.7       | 10–17                                              | 11,<br>13–19 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                        |
|                 |                                                    |              | I    | <b>RxD (P3.0):</b> Serial input port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol.

To drive the device from an external clock source, XTAL2 should be driven while XTAL1 is connected to ground. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum

high and low times specified in the data sheet must be observed.

## DESIGN CONSIDERATIONS

At power-on, the voltage on V<sub>CC</sub> and RST should come up at the same time for a proper start-up.

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- For operating at elevated temperatures, the device must be derated based on +150°C maximum junction temperature.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.
- All voltage measurements are referenced to ground. For testing, all input signals swing between 0.45V and 2.4V with a transition time of 20ns maximum. All time measurements are referenced at input voltages of 0.8V and 2.0V and at output voltages of 0.8V and 2.0V as appropriate.
- V<sub>OL</sub> is derated when the device rapidly discharges external capacitance. This AC noise is most pronounced during emission of address data. When using external memory, locate the latch or buffer as close as possible to the device.

| Datum      | Emitting Ports | Degraded I/O Lines | V <sub>OL</sub> (Peak Max) |
|------------|----------------|--------------------|----------------------------|
| Address    | P2, P0         | P1, P3             | 0.8V                       |
| Write Data | P0             | P1, p3, ALE        | 0.8V                       |

- C<sub>L</sub> = 100pF for port 0, ALE and PSEN outputs; C<sub>L</sub> = 80pF for all other ports.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.

# Single-chip 8-bit microcontroller

# 8031AH/8051AH

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## Single-chip 8-bit microcontroller

## 8032AH/8052AH

## DESCRIPTION

The Philips 8032AH/8052AH is a high-performance microcontroller fabricated using the Philips high-density highly reliable +5V, depletion-load, N-channel, silicon-gate, N500 MOS process technology. It provides the hardware features, architectural enhancements and instructions that are necessary to make it a powerful and cost-effective controller for applications requiring up to 64k bytes of program memory and/or up to 64k bytes of data storage.

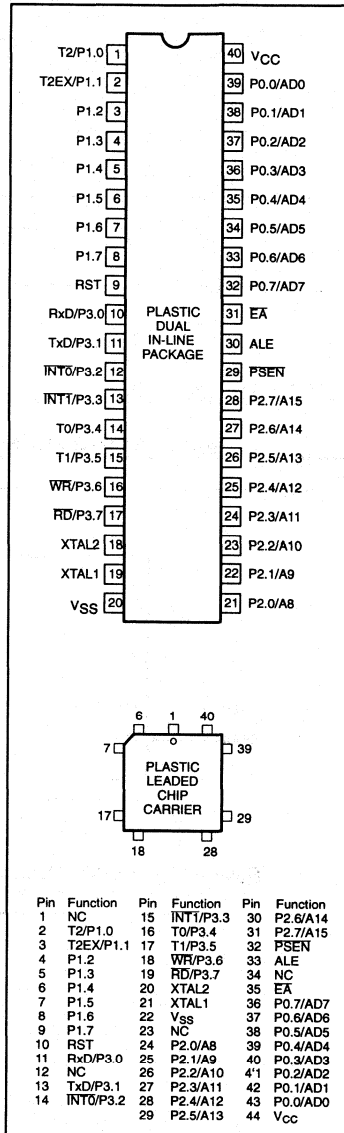

The 8032AH/8052AH contains 256 bytes of read/write data memory, 32 I/O lines configured as four 8-bit ports, three 16-bit counter/timers, a six-source, two-priority-level nested interrupt structure, a programmable serial I/O port and on-chip oscillator and clock circuitry. The 8052AH has all of these features plus 8k bytes of non-volatile read-only program memory. Both microcontrollers have memory expansion capabilities of up to 64k bytes of data storage and 64k bytes of program memory that can be attained with standard TTL compatible memories.

Because of its extensive BCD/binary arithmetic and bit-handling facilities, the 8032AH/8052AH microcontroller is efficient at both computational and control-oriented tasks. Efficient use of program memory is also achieved by using the familiar compact instruction set of the 8031AH/8051AH. Forty-four percent of the instructions are one-byte, 41% two-byte, and 15% three-byte instructions. With a 12MHz crystal, the majority of the instructions execute in just 1.0µs. The longest instructions, multiply and divide, require only 4µs at 12MHz.

## FEATURES

- 8032AH — control-oriented CPU with RAM and I/O
- 8052AH — an 8032AH with factory mask-programmable ROM
- 8k X 8 ROM (8052AH only)
- 256 X 8 RAM
- Four 8-bit ports, 32 I/O lines
- Three 16-bit timer/counters
- Programmable full-duplex serial channel
  - Variable transmit/receive baud rate capability
- Timer 2 capture capability
- External memory
  - 64k ROM and 64k RAM
- Boolean processor
- 128 user bit-addressable locations
- Upward compatible with 8031AH/8051AH

| V <sub>SS</sub> | 20      | 22        | I    | <b>Ground:</b> 0V reference.                                                                                                                                                                                                                                                                                                                                                                              |    |    |                                                           |
| V <sub>CC</sub> | 40      | 44        | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                         |    |    |                                                           |
| P0.0–P0.7       | 39–32   | 43–36     | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s.                                                       |    |    |                                                           |
| P1.0–P1.7       | 1–8     | 2–9       | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Pins P1.0 and P1.1 also correspond to the special functions T2, timer 2 counter trigger input, and T2EX, external input to timer 2. The output latch on these two special functions must be programmed to one for that function to operate. Port 1 also receives the low-order address byte during program verification. |    |    |                                                           |
|                 |         |           |      | 1                                                                                                                                                                                                                                                                                                                                                                                                         | 2  | I  | <b>T2 (P1.0):</b> Timer/counter 2 trigger input.          |
|                 |         |           |      | 2                                                                                                                                                                                                                                                                                                                                                                                                         | 3  | I  | <b>T2EX (P1.1):</b> Timer/counter 2 external count input. |
| P2.0–P2.7       | 21–28   | 24–31     | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register.      |    |    |                                                           |
| P3.0–P3.7       | 10–17   | 11, 13–19 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 also serves the special features of the SC80C51 family, as listed below:                                                                                                                                                                                                                                          |    |    |                                                           |
|                 |         |           |      | 10                                                                                                                                                                                                                                                                                                                                                                                                        | 11 | I  | <b>RxD (P3.0):</b> Serial input port                      |

### OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol.

To drive the device from an external clock source, XTAL2 should be driven while XTAL1

is connected to ground. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running.

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- For operating at elevated temperatures, the device must be derated based on +150°C maximum junction temperature.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.
- All voltage measurements are referenced to ground. For testing, all input signals swing between 0.45V and 2.4V with a transition time of 20ns maximum. All time measurements are referenced at input voltages of 0.8V and 2.0V and at output voltages of 0.8V and 2.0V as appropriate.
- V<sub>OL</sub> is derated when the device rapidly discharges external capacitance. This AC noise is most pronounced during emission of address data. When using external memory, locate the latch or buffer as close as possible to the device.

| Datum      | Ports  | Degraded I/O Lines | V <sub>OL</sub> (Peak Max) |
|------------|--------|--------------------|----------------------------|
| Address    | P2, P0 | P1, P3             | 0.8V                       |
| Write Data | P0     | P1, p3, ALE        | 0.8V                       |

- C<sub>L</sub> = 100pF for port 0, ALE and PSEN outputs: C<sub>L</sub> = 80pF for all other ports.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.

Single-chip 8-bit microcontroller

8032AH/8052AH

**EXPLANATION OF THE AC SYMBOLS**

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

8032AH/8052AH

Single-chip 8-bit microcontroller

8032AH/8052AH

Figure 5. External Clock Drive

NOTE:  
AC inputs during testing are driven at 2.4V for a logic '1' and 0.45V for a logic '0'.  
Timing measurements are made at 2.0V min for a logic '1' and 0.8V for a logic '0'.

Figure 6. AC Testing Input/Output

NOTE:  
For timing purposes, the float state is defined as the point at which a P0 pin sinks 2.4mA or sources 400µA at the voltage test levels.

## Development support tools

### DEVELOPMENT SUPPORT TOOLS

Philips Semiconductors manufactures support tools and also works closely with many "third-party" vendors who provide support tools for our wide variety of 80C51-based microcontroller derivatives.

### Development Systems

In most cases, development systems are available in two versions for ROM and ROMless applications. The ROM emulation products are capable of supporting all versions of a given device type, including EPROM, ROM, and ROMless devices. In contrast, a ROMless emulator can only support applications designed for a ROMless microcontroller. Most development systems are designed to connect to an IBM-PC or compatible personal computer.

### EPROM Programming Support

Philips Semiconductors works closely with major suppliers of EPROM programming equipment to support our family of EPROM microcontrollers. As a result, EPROM programming support is available within the programming facilities of many major distributors.

The following is a list of vendors that offer support for Philips Semiconductors 80C51 microcontroller family.

### DEVELOPMENT SYSTEM CONTACTS

| COMPANY                      | ADDRESS                                                                                                                      | TELEPHONE                           |

## MICROCONTROLLER DEVELOPMENT SYSTEMS

| PRODUCT                  | DEVICES SUPPORTED                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>NOHAU CORPORATION</b> |                                                                                                               |
| EMUL51-PC/E32            | 12MHz Emulator, 32k emulation memory                                                                          |
| EMUL51-PC/E128           | 12MHz Emulator, 128k emulation memory                                                                         |
| EMUL51-PC/E32-16         | 16MHz Emulator, 32k emulation memory                                                                          |
| EMUL51-PC/E128-16        | 16MHz Emulator, 128k emulation memory                                                                         |
| EMUL51-PC/E128-20        | 20MHz Emulator, 128k emulation memory                                                                         |
| EMUL51-PC/E128-24        | 24MHz Emulator, 128k emulation memory                                                                         |
| EMUL51-PC/E128-30        | 30MHz Emulator, 128k emulation memory                                                                         |
| EMUL51-PC/E128-33        | 33MHz Emulator, 128k emulation memory                                                                         |
| EMUL51-PC/E128-BSW       | 12MHz Emulator, 128k bankswitched CODE memory                                                                 |
| EMUL51-PC/E128-BSW-16    | 16MHz Emulator, 128k bankswitched CODE memory                                                                 |
| EMUL51-PC/E128-BSW-24    | 24MHz Emulator, 128k bankswitched CODE memory                                                                 |
| EMUL51-PC/E256-BSW       | 12MHz Emulator, 256k bankswitched CODE memory                                                                 |
| EMUL51-PC/E256-BSW-16    | 16MHz Emulator, 256k bankswitched CODE memory                                                                 |
| EMUL51-PC/E256-BSW-24    | 24MHz Emulator, 256k bankswitched CODE memory                                                                 |
| POD-C054                 | 12MHz 83C053, 83C054, 87C054, 87C055 pod                                                                      |
| POD-31                   | 12MHz 8031 pod                                                                                                |
| POD-C31                  | 12MHz 80C31 pod                                                                                               |
| POD-C31-1                | 16MHz 80C31 pod                                                                                               |
| POD-C31-20               | 20MHz 80C31 pod                                                                                               |
| POD-C31-24               | 24MHz 80C31 pod                                                                                               |
| POD-C31-30               | 30MHz 80C31 pod                                                                                               |
| POD-C31-33               | 33MHz 80C31 pod                                                                                               |
| POD-32                   | 12MHz 8032 pod                                                                                                |
| POD-C32                  | 12MHz 80C32 pod                                                                                               |
| POD-C32-16               | 16MHz 80C32 pod                                                                                               |
| POD-C652                 | 12MHz 80C652 pod                                                                                              |
| POD-C652-16              | 16MHz 80C652 pod                                                                                              |
| POD-C51B                 | 12MHz bondout pod for 8051, 80C51, 83C552, 83C652, 83C654, 83C851, and EPROM or ROMless versions of the above |
| POD-C51B-16              | 16MHz bondout pod for 8051, 80C51, 83C552, 83C652, 83C654, 83C851, and EPROM or ROMless versions of the above |
| POD-C51B-24              | 24MHz version of the above                                                                                    |
| POD-C52                  | 12MHz 80C32, 80C52, 87C52                                                                                     |
| POD-C52-16               | 16MHz 80C32, 80C52, 87C52                                                                                     |
| POD-CL410                | 12MHz 80CL31, 80CL51, 83CL410, 83CL610                                                                        |
| POD-C451-DIP             | 12MHz 80C451 DIP pod                                                                                          |
| POD-C451-DIP-16          | 16MHz 80C451 DIP pod                                                                                          |
| POD-C451-PGA             | 12MHz 80C451 PLCC pod (PGA from pod)                                                                          |
| POD-C451-PGA-16          | 16MHz 80C451 PLCC pod (PGA from pod)                                                                          |
| POD-C451B-PGA            | 12MHz bondout pod for 83C451, 87C451, 80C451 PLCC (PGA from pod)                                              |

# DB-51

## CEIBO Development Board

DB-51 is a high-performance system design board dedicated to the Philips 80C51 family of microcontrollers. It provides an easy-to-use flexible instrument which enables the user to build a primary prototype, analyze and debug it, make changes, and continue debugging. And you can improve your design decisions by using the DB-51 to check and test the advantages of several different microcontrollers. The DB-51 is also a great training and tutorial aid for becoming familiar with designs using the 80C51 architecture. Note that the DB-51 is not intended to replace a full emulator system in complex microcontroller designs.

- Supports most of the Philips 80C51 derivative microcontrollers
- Serially linked to IBM PC or compatible hosts
- 32K of user code memory
- Software breakpoints
- Examine and alter chip registers, RAM, and ports
- Symbolic debugger compatible with linker object files
- Source Level Debugger for Assembler, PLM and C.
- Software Trace and Performance Analyzer
- Upload and download of object and hex files
- Special wire-wrap area for prototyping
- User's manual with examples and applications designed to familiarize the user with 8XC51 architecture and programming as well as the use of the DB-51 itself

# SPECIFICATIONS

## System Memory

DB-51 provides 32K of user code memory. This RAM memory permits downloading and modifying of users' programs.

## Breakpoints

Breakpoints allow real-time program execution until an opcode is executed at a specified address.

## Symbolic Debugger

DB-51 allows symbolic debugging of assembler or high-level languages. The symbolic debugger uses symbols contained in the absolute file generated by the most commonly used relocater and linker programs.

## Supported Microcontrollers

8X31/51, 8X32/52, 8XC31/51, 8XC32/52, 8XC652, 8XC654, 8XC851, 8XC550, 8XC552, 8XC562, 8XC451, 8XC528, and others with external memory addressing and a UART are fully supported. 8XCL410, 8XC751 and 8XC752 have very limited support.

## Limitations

"Fully supported" microcontrollers are self-debugging on the DB-51. Thus, some of the chip resources are used by the board: the monitor program uses the bottom 32K of program memory; chips are always operated in the external memory mode; the UART is used to communicate to the PC and is thus not normally available to the user program; interrupt response is slowed slightly by re-vectoring from the monitor

program to the user program; use of watchdog timers and power-down and idle modes of operation are limited due to interaction with the monitor program.

"Limited support" microcontrollers do not have on-chip UARTs and most do not support external program memory. Thus, download of programs to these parts is not supported on the DB-51. The 87C751 provided with the board is pre-programmed with a "micro" monitor program and some predefined experiments described in the user manual. All these parts use the I<sup>2</sup>C bus to communicate to the PC, limiting the use of I<sup>2</sup>C for other purposes.

## User Software

The board is provided with a very easy-to-use menu-driven software program as well as command oriented user interface software. On-line assembler and disassembler: provided together with upload and download capabilities hexadecimal and object files.

## Command Set

ASM - BIT - BYTE - BREAKPOINT [enable, disable, reset] - CHIP [type] - CLS - CODE - DATA - DASM - DEFAULT - DIR - EVALUATE - EXIT - GO [from, till] - HALT - HISTORY - LINES - LIST [file] - LOAD [code, symbols] - LOCALS - MODULES - PORTS - PROCEDURES - PUBLICS - RBIT - RBYTE - REGISTERS - RESET - SAVE - SOUND - STATUS - STEP [n] - TIME

## Host Characteristics

IBM PC/XT/AT or compatible system with 512 kbyte of RAM, one floppy disk drive, one RS-232 interface board for the board and cable, PC-DOS 2.0 or later.

## Input Power

7.5 VDC to 12.0 VDC (9 VDC wall transformer supplied).

## Mechanical Dimensions

20 cm x 25 cm

## Items Supplied as Standard

DB-51 board, 80C552 and 87C751 microcontrollers, monitor EPROM, power supply, RS-232 cable.

User software including symbolic debugger, on-line assembler and disassembler.

User's manual and operating instructions.

## ORDERING INFORMATION

Order part number P8051DBSD from your local Philips Semiconductors Distributor.

# DS-51 CEIBO In-Circuit Emulator

*In-Circuit Emulator for 8051 Family of Microcontrollers*

## FEATURES

- Real-time and transparent in-circuit emulator
- Supports most of the 8051 derivatives
- Emulates 1.5V to 6V microcontrollers
- Maximum frequency of 42MHz
- 128K of internal memory
- 32K trace memory and logic analyzer
- 64K hardware and conditional breakpoints
- Source Level Debug for Assembler, PLM and C
- Serially linked to IBM PC at 115 KBaud

**CEIBO TEL: 314-830-4084 FAX: 314-830-4083**

## **DS-51 CEIBO In-Circuit Emulator**

### **DESCRIPTION**

DS-51 is a real-time in-circuit emulator dedicated to the 8051 family off microcontroller. It is serially linked to a PC/XT/At or compatible host and carries out a transparent emulation on the target microcontroller.

The system emulates almost every 8051 derivative in the complete voltage and frequency range specified by the microcontroller manufacturer.

DS-51 also supports the new low-power and low-voltage 8051 microcontrollers and derivatives and can emulate the microcontrollers using either the built-in 5V power supply or any voltage applied to the target circuitry. This selection is done by means of software control. The permitted voltage range is from 1.5V to 6V or higher.

The software includes Source Level Debugger for PLM and C, a unique Assembler Debugger, Performance analyzer, On-line Assembler and Disassembler, Conditional Breakpoints and may other features.

Files generated by the most common 8051 Assemblers and High-Level Language Compilers are accepted by the DS-51.

Standard systems are supplied with 128 KBytes of internal memory, 64K hardware breakpoints, 32K real-time trace memory and logic analyzer with external test points, and personality probe C51 supporting most of the 40-pin DIP or 44-pin PLCC/QFP microcontrollers.

### **SUPPORTED DEVICES**

Consult Ceibo for other microcontrollers support.

## **DS-51 CEIBO In-Circuit Emulator**

### **SPECIFICATIONS**

#### **Emulation Memory**

DS-51 provides 128 KBytes of code memory with software mapping and banking capabilities.

#### **Hardware Breakpoints**

Up to 65536 hardware breakpoints allow real-time program execution until an opcode is executed at a specified address line of your source code, data contents and read/write operation.

#### **Conditional Breakpoints**

A complete set of conditional breakpoints permit halting program emulation on code addresses, source code lines, access to external data, and on-chip memory, port and register contents.

#### **Performance Analyzer**

This useful function checks the software trace buffer and provides time statistics on modules and procedures as a percentage of the total execution time.

#### **Languages and File Formats**

DS-51 accepts files with Intel OMF51 object or hex format. Other assemblers and high-level languages such as C with OMF51 format (Franklin, Archimedes, IAR, MCC, BSO/Tasking, etc.) are also supported.

#### **Source Level Debugger**

The DS-51 Software includes a high-level language Source Level Debugger. This program may be used to debug code written Assembler, PLM and C. The Source Level Debugger includes commands which allow the user to get all the information needed for testing the programs and hardware in real-time. The commands permit setting breakpoints on high-level language lines, adding a watch window with the symbols and variables of interest, modifying variables, displaying floating point values, showing the trace buffer, executing assembly steps and many more useful functions.

#### **Personality Probes**

DS-51 uses standard and bond-out microcontrollers for hardware and software emulation. The selection of a different microcontroller is made by replacing the microcontroller on the probe or changing the probe. The personality probes run at a frequency of the crystal on them or from the clock source supplied by the user hardware. Therefore, the same probe may be adapted to you frequency requirements. The minimum and maximum frequencies are determined by the emulated chip characteristics, while the emulator maximum frequency for standard probes is 42MHz.

#### **Trace and Logic Analyzer**

The trace memory is 32 KByte deep and is used to record the microprocessor activities. Eight lines are user selectable test points. Trigger inputs and conditions are available for starting and stopping the trace recording. The trace buffer can be viewed in disassembled symbolics, frames or high level language source code.

#### **Host Characteristics**

IBM PC/XT/AT or compatible systems with 640 KBytes of RAM, one hard disk, one RS-232C interface card for the PC, PC-DOS 5.0 or later.

#### **Items Supplied As Standard**

In-circuit emulator with 64 KByte breakpoints, 128 KByte Internal Code Memory. Personality probe C51 for 8051 microcontrollers. User software including source level debugger, on-line assembler and disassembler. User's Manual and Operating Instructions. RS-232 Interface Cable. Power Supply and Power Cord.

#### **Options**

Personality probes for the different microcontrollers. Adapter for 44-pin PLCC devices.

## TRACE CAPABILITIES

### External Trace Start/Stop Triggers

DS-51 has two External Trigger signals that allow starting and stopping of the trace recording upon external events.

### Stop Trace when Full or Continuous Recoding Mode

There are two trace recoding modes: Cyclic and Trace Full. In the Cyclic Mode the trace is continuously filled with recorded data. In the Full Mode recoding stops when trace is full.

### Selectable Trace Trigger Levels

The trigger state permits selecting the way trigger signals behave. The active mode may be either level or edge for the external start and stop trigger signals.

### Trace Status on the Fly

Trace Status allows viewing information without stopping emulation. The Trace Status includes buffer full, buffer empty, length, etc.

### Trace Filtering on Address Ranges

Up to 10 different ranges are allowed to filter the recorded data into the trace memory. The start and stop addresses of modules and procedures can be entered using special prefixes.

```

## DS-51 CEIBO In-Circuit Emulator

### BREAKPOINT OPTIONS

#### Breakpoint on Data Read/Write and Address

Real-time Hardware Breakpoints can be set on Data Read, Data Write, Data Read or Write and Opcode Fetch in any address range.

#### Stop Emulation on Pass Count

Pass Count on any event including opcode may be specified by the number of occurrences.

#### Breakpoint on External Events

Trace Testpoints may be used as external Breakpoints on Hardware events if enabled. The External Breakpoint triggers may also be the Trace Full condition, then program execution will stop once it is full. The Logic Operator commands allow selection of AND/OR combinations of the two external breakpoints. The options are both low, any one is low, both are high, only one is high, both are leading edge, etc.

```

## ***DS-51 CEIBO In-Circuit Emulator***

### **ABOUT THE DEBUGGER**

#### **Environment**

C51D is a menu-driven program supplied with DS-51. This debugger runs either under DOS or Windows. C51D Debugger is used to load a program, execute it in real-time or simulate the software environment and many other functions.

#### **Tracing**

A program may be executed one line at a time. You can trace a program using high-level language lines or assembly instructions.

#### **Stepping**

This is like tracing but program execution steps over CALL instructions without leaving the current procedure.

#### **Viewing**

C51D Debugger allows special windows to be opened showing your program state from various perspectives: variables and their values, breakpoints, a text file, a source file, CPU registers, memory, peripheral registers, etc.

#### **Inspecting**

The debugger can delve deeper into your program and show you the variable contents.

#### **Changing**

The current value of a variable can be replaced with your specified value.

#### **Watching**

Program variables can be isolated and their values kept track of while the program runs.

#### **Global Menus**

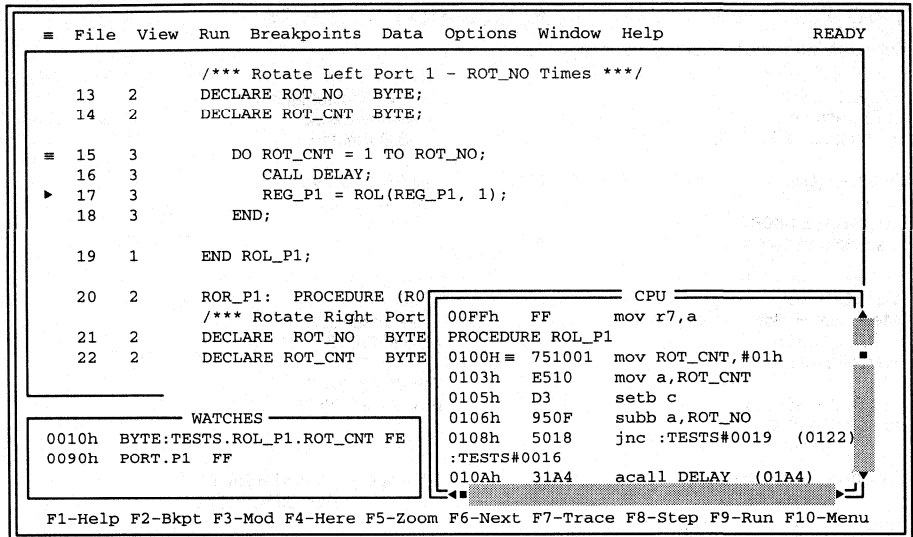

A Global Menu is the list of commands easily accessible from a bar which runs along the top of the screen. A pull-down menu is available for each item on the menu bar and allows the following:

- Execute a command
- Open a pop-up menu. Pop-up menus appear when a menu item is chosen followed by a menu icon (➤).
- Open a dialog box. Dialog boxes appear when a menu item is chosen followed by a dialog box icon (...).

Global menus are accessed by pressing F10 and using the arrow keys or typing the first letter of the menu name. Their contents never change.

Some of the menu commands have hot key shortcuts that are available from any part of the C51D Debugger.

ABOUT THE DEBUGGER

**Local Menus**

C51D Debugger is context-sensitive and uses Local Menus specifying different windows. Local menus are tailored to the particular window you are in. It is important not to confuse them with global menus. To prompt a local menu press Alt-F10 or click the right button of your mouse. Menu placement and contents depends on which window or pane you are in and where your cursor is. Contents may vary from one local menu to another. Many local commands appear in almost all local menus. The results of these similarly-named commands may differ, depending on the context. Every command on a local menu has a hot key shortcut consisting of Ctrl plus the highlighted letter in the command. Because of this setup, a hot key, like Ctrl-S might mean one thing in one context but something quite different in another. The core commands are still consistent across local menus. For example, the Goto command and the Search command always do the same thing, even when they are invoked from different windows.

**Input Boxes**

Many of the C51D Debugger command options are available in input boxes. An input box prompts you to type in a string, i.e., the name of a file.

**Windows**

C51D Debugger displays all information and data in both global and local menus, dialog boxes (where options are set and information entered) and windows. There are many window types depending on the kind of information it holds. Windows may be opened and closed using menu commands (or hot key shortcuts for those commands). Most of the Debugger windows come from the View menu. After a window has been opened, you can move, resize, close, and otherwise manage them with commands from the Window and System menus (=).

# DS-750 Microcontroller CEIBO Development Tool

Part Number: P750EM SD

*Development Tool for 83/87C750 Microcontrollers*

## FEATURES

- Emulates 87C750 and 83C750 microcontrollers in real-time
- Programmable clock up to 40MHz
- Built-in programmer for 87C750/1/2
- Simulator debug mode
- Source-level debugger for C, PLM and Assembler
- DOS and Windows Software
- 24-pin DIP emulation header
- Serially linked to IBM PC at 115K baud

DS-750 is a development tool that supports Philips 87C750 microcontrollers at any frequency allowed by the devices. It is serially linked to a PC/XT/AT or compatible system and can emulate the microcontroller using either the built-in clock oscillator or any other clock source connected to the microcontroller. The clock oscillator generates 40MHz, 20MHz, 16MHz, 10MHz and 5MHz. Emulation is carried out by programming an 87C752 microcontroller with the user software and an embedded monitor program. DS-750 provides the on-board programming capabilities and locates the monitor in the upper 1K that is not available for the 87C750. Two working modes are available: real-time and simulator debugger mode. In the real-time mode the user software is executed transparently and without interfering with the microcontroller speed. Breakpoints can be added to stop program execution at a specific address. In the simulator debug mode, an additional microcontroller is used to take control of the 87C750 lines and to simulate its operation but not real-time. This operating mode allows access to all the microcontroller functions (I/O, timers, interrupts, etc.) and interacts with the hardware according to the user software execution or directly by means of emulator commands sent from the host computer. The combination of the two available working modes allows an easy way to debug hardware and software functions. The software includes C and PLM and Assembler Source Level Debugger, On-line Assembler and Disassembler, Software Trace, Conditional Breakpoints and many other features. Two versions of the software are available: DOC and Windows. The system is supplied with a User's Manual, microcontroller documentation, two samples of the 87C752 and one of the 87C750 (all windowed EPROM microcontrollers) and a power supply.

## SPECIFICATIONS

### Monitor Program

The Monitor Program links the microcontroller to the host computer and is used to control the emulation of the application software in real-time. The monitor code is transparent for the 87C750 and does not reduce the 1K Byte of available code for the application.

### Breakpoints

Breakpoints allow real-time program execution until an opcode is executed at a specified address. Breakpoints are inserted into the application program and then the Emulation EPROM Device is programmed with the application code. The breakpoints can be disabled by results in adding a few cycles to the program execution.

### User Software

DS-750 program has two software environments: DOS and Windows 3.X. The DOS program is based on pull-down menus. The additional Windows program carries out the same functions of the DOS program with all the features and benefits of the new operating system.

### Symbolic Debugger

DS-750 allows symbolic debugging of assembler or high-level languages. The symbolic debugger uses symbols contained in the absolute file generated by the most commonly used Assemblers and High Level Language Compilers.

### Source Level Debugger

The DS-750 software includes a source level debugger for Assembler and High-Level Languages (PLM, C and others) with the capability of executing lines of the program while displaying the state of any variable.

## Software Trace

Program execution can be recorded in a 64K buffer. Conditional breakpoints may be defined to stop program execution. The user can define events and variables to be added to the software trace. The software trace is not a real-time function and is performed by slowing down the emulation speed.

## Frequency

The system includes a crystal oscillator able to support clock frequencies of 5MHz, 10MHz, 16MHz, 20MHz, and 40MHz. Additionally, the user may select any other frequency by connecting an external clock source through the application hardware. Frequency selection is done by means of jumpers.

## Simulator Debug Mode

The simulator allows breakpoints to be set at any address and condition even though the user software is actually programmed in the 87C752 EPROM. The simulator debug mode will be automatically activated in case a breakpoint is enabled and not programmed in the device.

## Built-in Programmer

The built-in programmer may be used to program the following devices: 87C750, 87C751, and 87C752. All the programming features like security and encryption are fully supported.

## Emulation Restrictions

The following restrictions are valid for DS-750:

1. The system uses some of the microcontroller resources to emulate it: one interrupt (either INTO or INT1 according to software selection) and 5 bytes of the internal stack.
2. If you specify a breakpoint not programmed in the device, program execution will be slowed down by the simulator.
3. Disabling a programmed breakpoint will add a few cycles to the program execution. This only happens while reaching the specified condition, otherwise the real-time is not affected.

## Host Characteristics

IBM PC/XT/AT or compatible systems with 640K Bytes of RAM, one floppy disk drive, one RS-232 interface card for the PC, PC-DOS 5.0 or later.

## Input Power

120 VAC to 15 VDC wall transformer supplied.

## Mechanical Dimensions

10cm x 10cm.

## Items Supplied as Standard

Development Systems with built-in programmer. 24-pin emulation header. User software including source level debugger, on-line assembler and disassembler. User's Manual and Operating Instruction. RS-232 interface cable. Power supply.

## Warranty

Six months limited warranty, parts and labor.

# DS-752

## CEIBO Emulator

DS-752 is a real-time, high performance microcontroller development system dedicated to the 8XC751/8XC752 single-chip microcontrollers. It provides an easy-to-use and flexible instrument which reduces the development and debugging cycle and enables the user to solve hardware and software problems quickly and efficiently. It operates with an IBM PC or compatible computer and carries out complete real-time and transparent emulation of the target CPU.

- Real time and transparent in-circuit emulator
- Supports Philips 83C751/83C752 and 87C751/87C752 microcontrollers
- Symbolic Debugger compatible with Intel object files
- Source Level Debug for C and PLM
- Source Level Assembler Debugger
- 2K hardware breakpoints and conditional breakpoints
- 2K of internal memory
- 64K Software Trace
- Performance Analyzer
- Serially linked to IBM PC or compatible hosts
- On-line Assembler and Disassembler
- Easy to follow pull-down menus and windows

PC-DOS, PC/XT/AT are trademarks of IBM.  
IBM is a registered trademark of IBM Corporation.  
Intel is a registered trademark of Intel Corporation.

# SPECIFICATIONS

## Emulation Memory

DS-752 provides 2KBytes of code memory.

## Hardware Breakpoints

Up to 2,048 hardware breakpoints allow real-time program execution until an opcode is executed at a specified address or line of your source code.

## Conditional Breakpoints

A complete set of conditional breakpoints permits halting program emulation on code addresses, source code lines, access to on-chip memory, port and register contents.

## Software Analyzer

A 64 KByte buffer is used to record any software and hardware events of your program, such as executed code, memory accesses, port and internal register states, on-chip data memory and others. The trace buffer can be viewed in disassembled symbolics, or high level language source code. Trace recording is not carried out in real-time.

## Symbolic Debugger

DS-752 allow symbolic debugging of assembler or high-level languages. The symbolic debugger uses predefined port and register names, and the symbols contained in your software, like labels, variable names, line numbers and others.

## Source Level Debugger

DS-752 gives full support for debugging directly in assembler, PLM and C source code. From your source code screen you can specify a breakpoint, execute a line step or an assembly instruction, open a flexible-in-size watch window to display any variable, use the function keys to display the trace memory, registers and data, redefine the Program Counter, and reset the microprocessor.

## Languages and File Formats

DS-752 accepts files generated by Intel software (Assembler, PLM) or compatibles in hex or object format. Other assemblers and high-level languages such as C with Intel compatible format (Franklin, Archimedes, IAR, etc.) are also supported.

## Personality Adapters

DS-752 uses standard microcontrollers for hardware and software emulation. The selection of a different microcontroller is made by software commands and using a supplied socket adapter. The systems run at the frequency of the crystal on them or from the clock source supplied by the user hardware. Therefore, the same system may be adapted to your frequency requirements.

The minimum frequency is determined by the emulated chip characteristics, while maximum frequency for standard probes is 16MHz.

## Supported Devices

83C751, 87C751, 83C752, 87C752.

## Command Set

The available functions include: FILE (load, save), DEBUG (go, halt, reset, source level debugger, breakpoints), MODIFY (code, byte, registers, ports, assembler, disassembler), VIEW (watch window, publics, modules, procedures, lines, symbols, file, dir), ANALYZER (conditional breakpoints, software trace, event watch), SETUP (default, chip, base, rs-232 port).

## Host Characteristics

IBM PC/XT/AT or compatible system with 640 KBytes of RAM, one floppy disk drive, one RS-232C interface card for the PC, PC-DOS 2.0 or later.

## Input Power

7.5VDC to 12VDC or 5VDC/500mA from the user circuit.

## Mechanical Dimensions

1" × 5" × 6" (2.4 cm × 13 cm × 15 cm).

## Items Supplied as Standard

In-circuit emulator with 2 KByte breakpoints, 2 KByte Internal Code Memory. Personality adapter for 24-pin DIP microcontrollers. User Software including source level debugger, on-line assembler and disassembler. User's Manual and Operating Instructions. RS-232 Interface Cable. 9 VDC wall transformer.

## Warranty

Six months limited warranty; parts and labor.

# MP-51

## CEIBO Programmer

MP-51 is an EPROM, PLD and Microcontroller Programmer dedicated to standard 24 to 32-pin EPROMs, all of the microcontrollers belonging to the 8051 family, and high density PLDs. Its modern design provides a powerful low-cost and high performance instrument, easy to use and conveniently sized.

MP-51 operates with an IBM PC/XT/AT or compatible personal computer, and carries out a set of powerful functions on the selected device. An RS-232 interface is used to link MP-51 to a PC.

The unit consists of the instrument and adaptors. The adaptors may be replaced to suit the user's requirements. Adapters are available for all the possible packages such as DIP, QFP, LCC and PLCC.

MP-51 software handles a PC Memory Buffer where code is loaded from a disk or filled with the contents of a device. Furthermore, this buffer may be saved on a disk file, parts of the buffer can be moved from one location to another, filled with a constant, or modified by the user. The Memory Buffer can be displayed, and finding values or strings in it is possible.

Before programming, MP-51 checks if the installed adapter is compatible with the device type selected by the user. This test is done before programming any device.

MP-51 has the capability to check if the device is totally erased, and can also compare if the contents of the plugged device are equal to the contents of the Memory Buffer. Address range can be specified for both operations.

MP-51 allows to enable or disable the PLD or Microcontroller security capabilities and handles the Lock Bit 1, Lock Bit 2, Lock Bit 3 and Encryption Table available in several Microcontrollers.

- High quality EPROM, PLD and Microcontroller Programmer
- Serially linked to IBM PC/XT/AT or other compatible host computers
- Loads/Saves Hex, Binary, Object and JEDEC files to and from disk
- Easy to follow windows and pull-down menus
- Supports 24 to 32-pin EPROMs, several PLDs and all Philips PSD devices, members of the 8051 and 80C51 family of Microcontrollers
- Programs Lock Bits, Encryption Tables and Security Bits

PC-DOS, PC/XT/AT are trademarks of IBM.  
IBM is a registered trademark of IBM Corporation.  
Intel is a registered trademark of Intel Corporation.

# SPECIFICATIONS

## Supported Devices

**EPROMs:** 2716, 2732, 2764, 27128, 27256, 27512, 27010, 27040, both NMOS and CMOS versions for all the available programming voltages.

**Microcontrollers:** 8751H, 8751BH, 87C51, 87C51FA/B/C, 87C52, 87C451, 87C528, 87C550, 87C552, 87C562, 87C575, 87C592, 87C652, 87C654, 87C751, 87C752, 87C054-MT and others.

**PLDs:** AT22V10, ATV750, ATV2500, ATV5000.

**PSD Devices:** PSD3XX

## File Formats

MP-51 loads different file formats:

- Intel Hex files and Motorola S-records
- Binary files
- Object files
- JEDEC files

It saves portions of memory in Intel Hex, Binary and JEDEC formats.

## Command Set

The available functions include: TYPE, BLANK CHECK, SECURITY, PROGRAM, LOAD, SAVE, READ, VIEW, COMPARE, CHECKSUM, FILL, MOVE, MODIFY, DIRECTORY, CHANGE DIR, TEXT FILE, DUMP, QUIT.

## Host Characteristics

IBM PC/XT/AT or compatible system with 512 KBytes of RAM, one floppy disk drive, one RS-232 interface card for the PC, PC-DOS 2.0 or later.

## Input Power

85VAC to 263VAC, 50Hz to 60Hz. That makes this unit suitable for any country outlet.

## Mechanical Dimensions

MP-51 is 155mm long, 60mm high, and 250mm wide.

## Adapters and Supported Devices

The following list partially shows which adapter should be used for the different supported devices:

|            |                   |                                                                      |

**In-Circuit Emulator**

**NOW**  
**8051, 8052,**  
**8xC51FX**  
**SUPPORT**

## PRODUCT DESCRIPTION

Unique **iceMASTER-PE** packs an advanced feature into a tiny, palm-sized package that any engineer can afford. Designed for demanding projects, **iceMASTER-PE** supports frequencies up to 42 MHz, a full complement of emulation memory, external memory, and a transparent trace buffer 16K words deep with advanced searching capabilities. The emulator plugs directly into the target application or operates in a stand-alone mode.

**iceMASTER-PE** is the world's most portable emulator because the emulator and probe electronics are integrated into a pocket-able package about the size of a PC mouse. To achieve this dramatic breakthrough in the size and cost of high-performance emulation, MetaLink invented a new emulation system architecture, Advanced Emulator Technology (AET, patent pending).

**iceMASTER-PE's** windowed user interface offers the highest development productivity and is easy to learn and easy to use, including a context-sensitive hypertext and hyperlinked help system. This powerful, productive interface gives the user total command flexibility in the configuration of the size, position, content, and color of each window.

**iceMASTER-PE** includes a full symbolic and source-level debugger for Assemblers and Compilers. The emulator supports all 9 of the most popular 8051 assemblers and Compilers.

**iceMASTER-PE** sets the new standard for excellence, portability and value in 8051 family emulation.

## KEY CHARACTERISTICS

- Supports 8051 family devices up to 42MHz
- Support for 8031, 8051, 8x32, 8x52, 8xC54, 8xC58, 8xC51FA, 8xC51FB, 8xC51FC, 8xC751, 8xC752, 8xC750, NMOS, CMOS, ROM, EPROM/OTP Devices.
- Full-Featured, Real-time & Transparent Emulator
- Emulator and Probe electronics integrated into a single package only 3" x 4" x 1"
- Plugs directly into target applications or operates in a stand-alone mode
- Patent-pending AET system architecture

## HARDWARE CAPABILITIES

- Up to 64K Program & 64K External Data Memory
- 16K frame trace buffer
- View trace while executing
- Up to 128K hardware breakpoints
- Up to 64K Trace ON & 64K Trace OFF triggers
- Integrated diagnostic self-test capability

## SYSTEM FEATURES

- PC-hosted via RS-232 serial link
- Efficient, powerful, easy to learn
- User control of window size, content & color
- Supports third party Assemblers & Compilers
- Full Symbolic & Source-Level debug
- Complete system includes Emulator, 8051 Macro Cross Assembler, RS-232 cable & power supply

**FLEXIBLE, EASY-TO-USE INTERFACE**

iceMASTER has an advanced, windowed user interface that emphasizes ease of use. Each window can be sized, moved, highlighted, scrolled, color-controlled, added, or removed completely. iceMASTER provides pull-down and pop-up menus, function keys, and context-sensitive help. The contents of any memory space may be perused and altered directly from the appropriate window using the keyboard or a mouse.

You have immediate access to the hypertext/hyperlinked, context-sensitive, on-line help system which clearly explains what your options are (at any detail level you choose), keeping you productive. There is even a HELP-FOR-HELP feature. Whether you are beginning your first design project, or are a veteran designer searching for the fastest possible debugging method, you will appreciate the EASE-OF-USE features designed into iceMASTER.

Novices can navigate smoothly through a debugging session by accessing the commands and menus as standard pull-downs. Experienced designers can instantaneously pop-up their menu of choice by using redefinable hot keys.

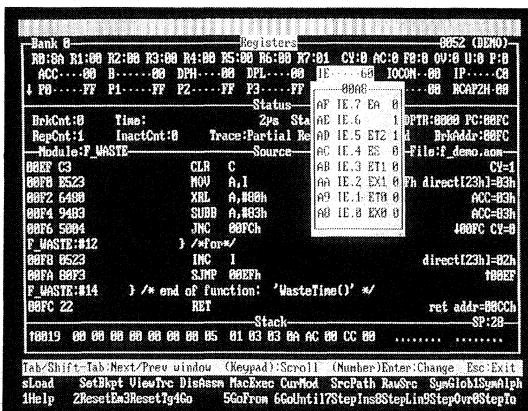

**DECREASED DEVELOPMENT TIME**

Your iceMASTER source window accelerates the debugging process with Dynamically Annotated Code. When single-stepping, instruction execution information is displayed and retained next to each instruction. You can clearly see the data behind your program's flow, including contents of all accessed (read or write) memory locations and registers, as well as flow-of-control direction change markers. A moving color bar indicates the current position in the program as it executes.

At your option, the iceMASTER source window allows operations on three different views of code memory: disassembled instructions, instructions mixed with High Level Language (HLL) source statements, or HLL source only.

HLL source statements and symbolic disassembly information are also displayed when you disassemble the program or view the trace buffer.

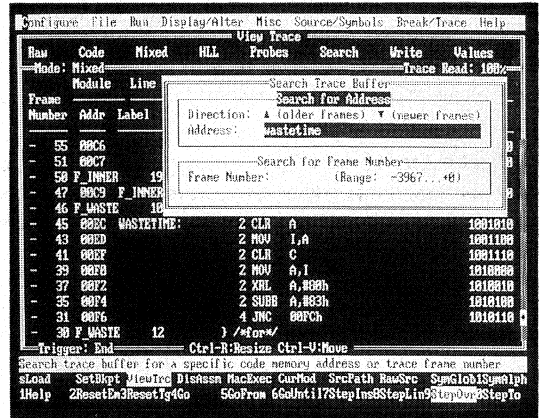

**THE COMPLETE DEBUGGER**

The trace buffer captures data in real-time. Trace information consists of address and data bus values and user-selectable probe clips. You can view the trace buffer data through several display filters: raw hex, disassembled instructions, instructions mixed with HLL source statements, or HLL source only. You can display the probe clip bit values in binary, hex, or digital waveform formats.

You can trigger the trace to begin capturing data on all instructions leading up to a breakpoint, around (before and after) a breakpoint, or following a breakpoint. Capture filtering allows you to focus attention only on areas of interest, eliminating clutter.

To further speed your design process, an integrated search mechanism allows you to locate any label, HLL source line number, or address in the trace buffer in either the backward or forward direction. The days of manually scanning or post-processing a large buffer of trace data are gone!

If you WRITE your program in a HLL, you should be able to DEBUG it that way – iceMASTER lets you do just that!

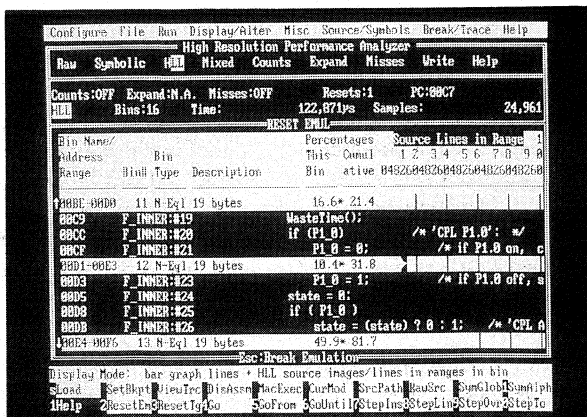

**IMPROVING THE QUALITY OF YOUR PRODUCT: FINDING THE HOT (OR NOT SO HOT) SPOTS**

iceMASTER emulators (Model 400 & PE) provide a PERFORMANCE ANALYZER that allows you to monitor the time spent executing specific portions of your program to find "hot spots" or "dead code." You can define and analyze memory areas based on code address, module, line number or label ranges.

You can view results dynamically during emulation or later for a more detailed analysis. You can toggle the display from bar graph format to actual frequency counts, and you can filter the level of detail in the displayed results to include raw data, code labels, and/or HLL source statements.

iceMASTER Model 400 provides an additional Performance Analyzer that is the absolute best in the industry for tuning and testing your code. It is very flexible and far more accurate than most other emulators, with a resolution of less than six microseconds. You can define and analyze up to 15 memory areas and each of these 15 memory areas can consist of non-contiguous, logically related subranges, (e.g. groupings of related functions which are not necessarily contiguous in memory).

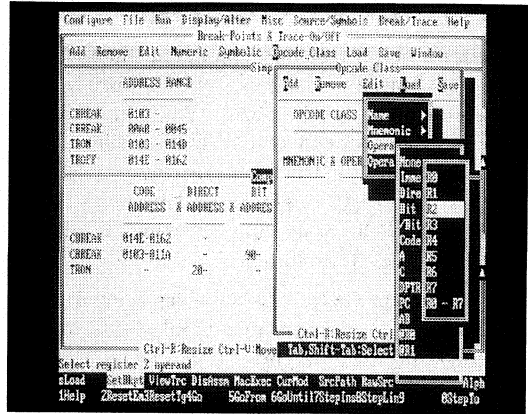

**FINDING THAT BUG**

You have access to as many as 128K breakpoints and 64K tracetriggers. These triggers can be enabled, disabled, set or cleared. Simple triggers are based on code or external data addresses or address ranges. Simple breakpoints can be set or cleared directly in the source window at disassembled instructions or HLL source statements.

Breakpoints can also be complex triggers, based on code address, direct address, bit address, opcode value, opcode class or immediate operand. Complex triggers can be ANDed and ORed together.

Finding that elusive bug is now much easier!

**SMALL AND POWERFUL**

Some companies design emulators that use one or two full size PC expansion board slots. These companies take it for granted that you have the "right" kind of PC, that you don't need the expansion slots for something else, and that you don't mind taking apart your computer to install their emulator!

At MetaLink, we don't take our customers for granted.

The iceMASTER family is the culmination of over 7 years of focused engineering by MetaLink to bring advanced semiconductor technologies to emulator design. Using state-of-the-art PALs (PEELs), LCAs, VLSI memories and microprocessors, MetaLink designed world-class emulation capability into the smallest emulator footprints in the industry, combining powerful and complex emulation features with all-around ease-of-use.

The high speed serial link connects easily to the back of your computer with a standard RS-232 cable. The emulators are smaller than the size of a VCR tape, fit neatly in crowded work spaces and are easy to move around on the bench or to other computers. **PORTABLE PRODUCTIVITY!**

# MASTER-PE Development System

MetaLink specializes in enhancing the emulation technology required by EMBEDDED SYSTEMS DESIGNERS. MetaLink has consistently led the industry in emulation technology: it PC-based 8051 emulator; the first 8052 emulator; the first to offer support for all the unique features of the 8051 family components, such as watchdog-timer, idle modes, power mode, DMA and A/D.

MetaLink is a full-service emulation company. We support our customers over the long term with services such as repair, discounted upgrades, rental units, 10-day trial purchase periods & technical support for applications problems. A network of world-wide sales and service representatives is augmented by a well-trained telemarketing staff at headquarters.

## HOST SPECIFICATIONS

IBM PC, XT, AT, 386, 486, PS/2, Laptop, notebook or compatible system. 640K bytes of RAM, Hard Disk Drive, Monochrome or Color Display, with a Standard RS-232 Serial Port. Operating System DOS 2.0 or greater.

## EMULATOR SOFTWARE SPECIFICATIONS

File Formats Supported with Symbolic or Source-Level Debugging:

2500AD, Archimedes, Avocet, BSO/Tasking, Franklin, IAR Systems, Intel OMF, Keil, MCC, Microtec Research, Motorola 'S' Record, Systronix and Intel HEX.

Source/Symbol Support:

Assembler, BASIC, C and PL/M Languages

Symbolic or Source-Level Debug:

Setting of Breakpoints  
Setting of Trace ON/OFF  
Viewing of Trace Buffer  
Viewing of Source Window Display  
Viewing of Performance Analyzer  
Assembly/Disassembly of Code

LL Structure/Content Display of:

Modules Line Numbers  
Scopes Program Variables

## EMULATOR HARDWARE SPECIFICATIONS

EMULATOR-PE MODELS:

- 8031: Supports 8031 and 80C31  
Operates up to 33MHz  
40-Lead DIP or optional 44-Lead PLCC
- 8032: Supports 8031, 80C31, 8032, 80C32 and C501  
Operates up to 42MHz  
40-Lead DIP or optional 44-Lead PLCC
- 83752: Supports 83C751, 87C751, 83C752, 87C752 and 87C750  
Operates up to 16MHz  
24- & 28-Lead DIP or optional 28-Lead PLCC
- 8351FX: Supports 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8052, 80C52, 8752, 87C52, 80C51FA, 83C51FA, 87C51FA, 83C51FB, 87C51FB, 83C51FC, 87C51FC, 80C54, 87C54, 80C58 and 87C58  
Operates up to 16MHz  
40-Lead DIP or optional 44-PLCC

## OPERATING CHARACTERISTICS

clock frequency user-selectable between external target crystal/clock or internal clock source  
real-time, Electrically and Operationally Transparent

## USER INTERFACE

Keyboard or Mouse Control

Full-down & Pop-up menus with fill-in boxes

Available Main Screen Windows:

- Registers and PSW bits
- Bit Memory
- Stack data displayed in HEX &/or ASCII
- Up to 5 Internal Data Memory displayed in HEX &/or ASCII
- Up to 5 External Data Memory displayed in HEX &/or ASCII
- Up to 5 Code Memory displayed in HEX &/or ASCII
- Source Program displayed in Code, HLL Source or Mixed
- Watch window for variable data
- System Status data

Main Screen Window Display Controls:

- Movable Selectable (On/Off)
- Resizable Color selection
- Scrollable Highlighting of key data

Function/Hot Key Access:

- User-assignable for commands
- User-displayable for quick reference

## MEMORY OPERATIONS

Emulation Memory:

iceMaster-PE Models: 8031 8032 8351FX 83752

Program Memory: 64K 64K 64K 2K

External Data Memory: 64K 64K 64K N/A

Mapping Resolution:

- Program: Down to 1-byte
- External Data: Down to 1-byte

Program Memory:

- Single Line Assembler (full instruction set support)
- Disassemble in Code or Source/Code mode
- Disassembly may be written to a disk file

Data Memory:

- Internal or External Memory
- Fill a block of memory with data
- Copy a block of data to another area
- Change a single address data content
- Compare any two blocks of addressed data
- Displayed data may be written to a file

Registers/SFRs/Bit Memory:

- Examine or Modify

Program Variables:

- Examine or Modify

## EMULATION CONTROLS

Reset from Emulator and Go

Reset from Target and Go

Reset Processor

Go from current Program Counter

Go From a new Program Counter

Go Until a Program Counter/Label

Slow Motion (Repetitive Step commands)

Step by machine instruction

Step by Line Number

Step Over calls

Step To next function or procedure

## HARDWARE BREAKPOINTS

Up to 64K real-time Program Addresses

Up to 64K real-time External Data Addresses

## TRIGGER CONDITIONS

Set directly in Source window or Pull-down menu

PC address & range of addresses

Opcode Value

Opcode Class

SFRs/Registers

Direct byte address & range of addresses

Direct bit address & range of addresses

Immediate operand value

Read/Write to bit address

Register address modes

Read/Write to Register address

Logical AND/OR of any of the above

External Data address & range of addresses

Break Count Overflow

External (CLIP) Break Input

External (CLIP) Trigger Output

## TRACE

Real-time trace with view while executing code

16K-Frame Trace Buffer

Start, Center, End and Variable Trace Trigger settings

Up to 64K Trace ON/OFF triggers for trace filtering

Trace Contents consist of:

16-bits Address Bus

8-bits Data Bus

7-bits External Clips

Trace Display Modes:

Raw Hex

Symbolic

HLL Source

Mixed

External Clips display format:

Binary data

HEX data

Digital waveform

Trace Buffer Operations:

Write trace buffer to a disk file

Search trace buffer for labels & addresses

## PERFORMANCE ANALYZER

Program profiling capability

7 year duration

Display options:

Bar Graph

Frequency Count

Display Modes:

Raw

HLL Source Lines

Symbolic

Mixed

Up to 999 Bin capacity

User-controlled Bin set-up:

By Address By Symbol

By Module By Line Number

Automatic

## HELP

On-Line

Context sensitive

Hypertext/Hyperlinked

## DIAGNOSTIC SELF-TEST

Determines Emulation Hardware Status

## MACRO

Repetitive routines

User-created and callable

## ELECTRICAL SPECIFICATIONS

Input Power (maximum):

0.75 A @ +5 VDC +/-5%

Power Source: Target system or power supply

## MECHANICAL SPECIFICATIONS

Emulator Dimensions:

4.4" x 3.25" x 0.9"

11.18cm x 8.25cm x 2.29cm

Emulator weight:

0.5lbs 0.3kg

## ANNUNCIATORS

# iceMASTER™ 8051 In-Circuit Emulators

## PRODUCT DESCRIPTION

The **iceMASTER-8051** Model 200/400 emulator represents a culmination of 7 years of focused engineering to create the world's most affordable and portable full-featured emulators.

The **iceMASTER-8051** emulators offer real-time and transparent emulation at up to 24MHz for a broad number of derivative devices through the use of interchangeable probe cards. Powerful breakpoint systems allow an engineer to stop a program at any time and examine all states and conditions. Trace memory provides a complete history of each event that has occurred, including source-level information, address, data, status, searching and external logic events. The best performance analyzer capability in the industry allows a thorough evaluation of the program to decide what areas are taking the most time and simplify those areas requiring improved performance.

The **iceMASTER-8051** emulators support symbolic and source-level debugging for the most popular 8051 Cross Assemblers, 'C' Compilers, and PL/M Compilers. These capabilities allow the designer to debug their system the way it was designed, at the symbolic or source-level. This methodology increases productivity while decreasing cost and time-to-market.

The **iceMASTER-8051** emulators provide pull-down and pop-up menus, mouse support, function/hot keys, and context-sensitive hyperlinked help. The advanced windowed user interface emphasizes ease of use. Each window can be sized, moved, scrolled, highlighted, color-controlled, added or removed completely. The contents of any memory space may be perused and altered directly from the appropriate window, with multiple memory spaces displayable simultaneously.

## KEY CHARACTERISTICS

- Full-Featured, Real-time & Transparent Emulator
- Supports 8051 family devices up to 24MHz
- Interchangeable Probe Cards
- Hosted on any PC or compatible, including Laptops, Notebooks, or Micro Channel
- 115K baud serial link using a standard comm port
- Unlimited user support

## HARDWARE CAPABILITIES

- 64K Program & 64K External Data Memory
- 4K frame trace buffer
- Advanced trace search ability
- 128K hardware breakpoints
- 64K Trace ON/OFF triggers
- Broad 8051 derivative device support (more than 65 devices)
- Dual Performance Analyzers

## SYSTEM FEATURES

- Efficient, powerful, easy to learn
- User control of window size, content & color
- Supports third party Assemblers & Compilers
- Full Symbolic & Source-Level debug
- Complete system - includes Emulator, 8051 Macro Cross Assembler, RS-232 cable & power supply

MetaLink Corporation

**FLEXIBLE, EASY-TO-USE INTERFACE**

iceMASTER has an advanced, windowed user interface that emphasizes ease of use. Each window can be sized, moved, highlighted, scrolled, color-controlled, added, or removed completely. iceMASTER provides pull-down and pop-up menus, function keys, and context-sensitive help. The contents of any memory space may be perused and altered directly from the appropriate window using the keyboard or a mouse.

You have immediate access to the hypertext/hyperlinked, context-sensitive, on-line help system which clearly explains what your options are (at any detail level you choose), keeping you productive. There is even a HELP-FOR-HELP feature. Whether you are beginning your first design project, or are a veteran designer searching for the fastest possible debugging method, you will appreciate the EASE-OF-USE features designed into iceMASTER.

Novices can navigate smoothly through a debugging session by accessing the commands and menus as standard pull-downs. Experienced designers can instantaneously pop-up their menu of choice by using redefinable hot keys.

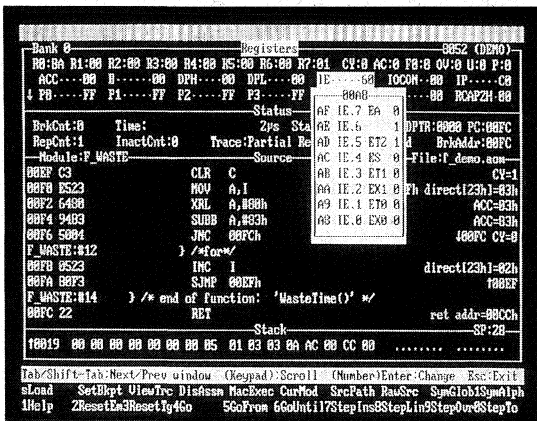

**DECREASED DEVELOPMENT TIME**

Your iceMASTER source window accelerates the debugging process with Dynamically Annotated Code. When single-stepping, instruction execution information is displayed and retained next to each instruction. You can clearly see the data behind your program's flow, including contents of all accessed (read or write) memory locations and registers, as well as flow-of-control direction change markers. A moving color bar indicates the current position in the program as it executes.

At your option, the iceMASTER source window allows operations on three different views of code memory: disassembled instructions, instructions mixed with High Level Language (HLL) source statements, or HLL source only.

HLL source statements and symbolic disassembly information are also displayed when you disassemble the program or view the trace buffer.

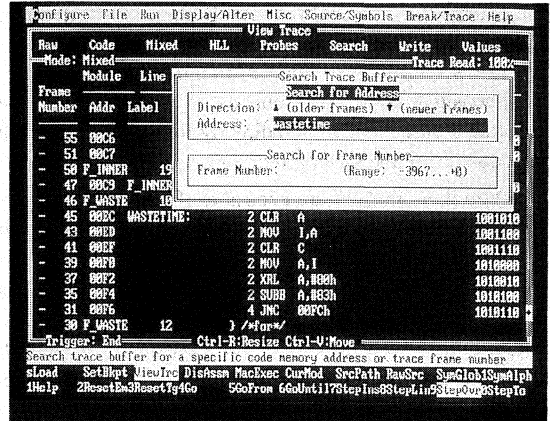

THE COMPLETE DEBUGGER

The trace buffer captures data in real-time. Trace information consists of address and data bus values and user-selectable probe clips. You can view the trace buffer data through several display filters: raw hex, disassembled instructions, instructions mixed with HLL source statements, or HLL source only. You can display the probe clip bit values in binary, hex, or digital waveform formats.

You can trigger the trace to begin capturing data on all instructions leading up to a breakpoint, around (before and after) a breakpoint, or following a breakpoint. Capture filtering allows you to focus attention only on areas of interest, eliminating clutter.

To further speed your design process, an integrated search mechanism allows you to locate any label, HLL source line number, or address in the trace buffer in either the backward or forward direction. The days of manually scanning or post-processing a large buffer of trace data are gone!

If you WRITE your program in a HLL, you should be able to DEBUG it that way - iceMASTER lets you do just that!

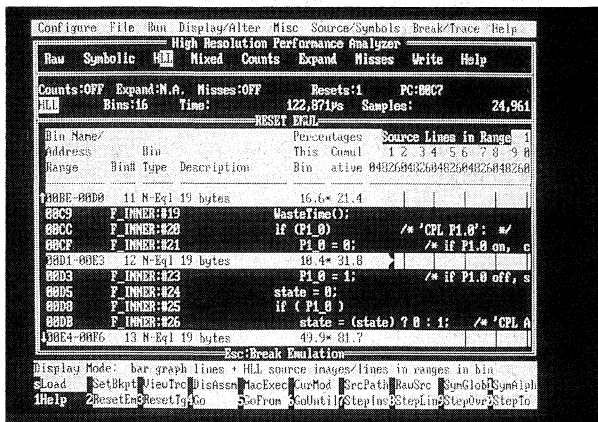

IMPROVING THE QUALITY OF YOUR PRODUCT: FINDING THE HOT (OR NOT SO HOT) SPOTS

iceMASTER emulators (Model 400 & PE) provide a PERFORMANCE ANALYZER that allows you to monitor the time spent executing specific portions of your program to find "hot spots" or "dead code." You can define and analyze memory areas based on code address, module, line number or label ranges.

You can view results dynamically during emulation or later for a more detailed analysis. You can toggle the display from bar graph format to actual frequency counts, and you can filter the level of detail in the displayed results to include raw data, code labels, and/or HLL source statements.

iceMASTER Model 400 provides an additional Performance Analyzer that is the absolute best in the industry for tuning and testing your code. It is very flexible and far more accurate than most other emulators, with a resolution of less than six microseconds. You can define and analyze up to 15 memory areas and each of these 15 memory areas can consist of non-contiguous, logically related subranges, (e.g. groupings of related functions which are not necessarily contiguous in memory).

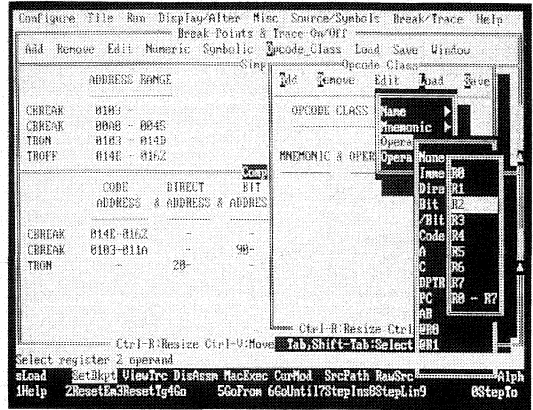

**FINDING THAT BUG**

You have access to as many as 128K breakpoints and 64K tracetriggers. These triggers can be enabled, disabled, set or cleared. Simple triggers are based on code or external data addresses or address ranges. Simple breakpoints can be set or cleared directly in the source window at disassembled instructions or HLL source statements.

Breakpoints can also be complex triggers, based on code address, direct address, bit address, opcode value, opcode class or immediate operand. Complex triggers can be ANDed and ORed together.

Finding that elusive bug is now much easier!

**SMALL AND POWERFUL**

Some companies design emulators that use one or two full size PC expansion board slots. These companies take it for granted that you have the "right" kind of PC, that you don't need the expansion slots for something else, and that you don't mind taking apart your computer to install their emulator!

At MetaLink, we don't take our customers for granted.

The iceMASTER family is the culmination of over 7 years of focused engineering by MetaLink to bring advanced semiconductor technologies to emulator design. Using state-of-the-art PALs (PEELs), LCAs, VLSI memories and microprocessors, MetaLink designed world-class emulation capability into the smallest emulator footprints in the industry, combining powerful and complex emulation features with all-around ease-of-use.

The high speed serial link connects easily to the back of your computer with a standard RS-232 cable. The emulators are smaller than the size of a VCR tape, fit neatly in crowded work spaces and are easy to move around on the bench or to other computers. **PORTABLE PRODUCTIVITY!**

# iceMASTER-8051 Model 200/400 Development Systems

MetaLink specializes in enhancing the emulation technology required by EMBEDDED SYSTEMS DESIGNERS. MetaLink has consistently led the industry in emulation technology. The first PC-based 8051 emulator; the first 8052 emulator; the first to offer support for all the unique features of the 8051 family components, such as watchdog-timer, idle modes, power down mode, DMA and A/D.

MetaLink is a full-service emulation company. We support our customers over the long term with services such as repair, discounted upgrades, rental units, 10-day trial purchase price and free technical support for applications problems. A network of world-wide sales and service representatives is augmented by a well-trained telemarketing staff at headquarters.

## ❑ HOST SPECIFICATIONS

Host IBM PC, XT, AT, 386, 486, PS/2, Laptop, Notebook or compatible system, 640K bytes of RAM, Hard Disk Drive, Monochrome or Color/Graphic Display, with a Standard RS-232 Serial Port. Operating System DOS 2.0 or greater.

## ❑ EMULATOR SOFTWARE SPECIFICATIONS

File Formats Supported with Symbolic or Source-Level Debugging:  
Archimedes, Avocet, BSO/Tasking, Franklin, IAR Systems, Intel OMF, Keil, MCC, Microtec Research, Motorola 'S' records and Intel HEX.  
Source/Symbol Support:  
Assembler, C and PL/M Languages  
Symbolic or Source-Level Debug:  
Setting of Breakpoints  
Setting of Trace ON/OFF  
Viewing the Trace Buffer  
Viewing of Source Window Display  
Viewing of Performance Analyzer  
Assembly/Disassembly of Code  
HLL Structure/Content Display of:  
Modules Line Numbers  
Scopes Program Variables

## ❑ EMULATOR HARDWARE SPECIFICATIONS

iceMASTER-8051 Models:  
200 Basic Emulator  
400 Enhanced Emulator with:  
4K Trace Buffer  
2 Performance Analyzers  
Full Watchdog Timer Support  
Operating Modes:  
Single-Chip ROM  
Romless  
Interchangeable Probe Card  
Used to support the functional derivatives of each micro controller family as well as the full range of NMOS, CMOS, EPROM, and OTP technology variations. Contact MetaLink for the latest information on any device supported.  
Device Unique Support  
A-to-D Converter  
FIFO  
Multiple-Divide Unit  
Multiple DPTRs

## ❑ OPERATING CHARACTERISTICS

Clock frequency user-selectable between external target crystal/clock or internal crystal source  
Electrically and Operationally Transparent  
Real-time: 0.5-24MHz

## ❑ USER INTERFACE

Keyboard or Mouse Control  
Pull-down & Pop-up menus with fill-in boxes  
Available Main Screen Windows:  
Registers and PSW bits  
Bit Memory  
Stack data displayed in HEX &/or ASCII  
Up to 5 Internal Data Memory displayed in HEX &/or ASCII  
Up to 5 External Data Memory displayed in HEX &/or ASCII  
Up to 5 Code Memory displayed in HEX &/or ASCII  
Source Program displayed in Code, HLL Source or Mixed

Watch window for variable data  
System Status data displayed in HEX  
Main Screen Window Display Controls:  
Movable Selectable (On/Off)  
Sizable Color selection  
Scrollable Highlighting of key data  
Function/Hot Key Access:  
User-assignable for commands  
User-displayable for quick reference

## ❑ MEMORY OPERATIONS

Emulation Memory:  
64K Program Memory  
64K External Data Memory  
Mapping Resolution:  
Program: 16-bytes/block  
External Data: 16-bytes/block  
Program Memory:  
Single Line Assembler (full instruction set support)  
Disassemble in Code or Source/Code mode  
Disassembly may be written to a disk file  
Data Memory:  
Internal or External Memory  
Fill of a block of memory with data  
Copy a block of data to another area  
Change a single address data content  
Compare any two blocks of addressed data  
Displayed data may be written to a file  
Registers/SFRs/Bit Memory:  
Examine or Modify  
Program Variables:  
Examine or Modify

## ❑ EMULATION CONTROLS

Reset from Emulator and Go  
Reset from Target and Go  
Reset Processor  
Go from current Program Counter  
Go From a new Program Counter  
Go Until a Program Counter/Label  
Slow Motion (Repetitive Step commands)  
Step by machine instruction  
Step by Line Number  
Step Over calls  
Step To next function or procedure

## ❑ HARDWARE BREAKPOINTS

64K real-time Program Addresses  
64K real-time External Data Addresses

## ❑ TRIGGER CONDITIONS

Set directly in Source window or Pull-down menu  
PC address & range of addresses  
Opcode Value  
Opcode Class  
SFRs/Registers  
Direct byte address & range of addresses  
Direct bit address & range of addresses  
Immediate operand value  
Read/Write to bit address  
Register address modes  
Read/Write to Register address  
Logical AND/OR of any of the above  
External Data address & range of addresses  
Break Count Overflow  
External (CLIP) Break Input  
External (CLIP) Trigger Output

## ❑ TRACE (Model 400)

4K-Frame Trace Buffer  
Start, Center, End & Variable Trace Trigger  
64K Trace ON/OFF triggers for trace filter  
Trace Contents consist of:  
16-bits Address Bus  
8-bits Data Bus  
7-bits External Clips  
DMA Activity  
Trace Display Modes:  
Raw Hex  
Symbolic  
HLL Source  
Mixed  
External Clips display format:  
Binary data  
HEX data  
Digital waveform  
Trace Buffer Operations:  
Write trace buffer to a disk file  
Search trace buffer for labels & add

## ❑ PERFORMANCE ANALYZERS (Model 400)

Real-time Program profiling capability  
5.4µ-sec sampling period  
7 year duration  
Display options:  
Bar Graph  
Frequency Count  
Display Modes:  
Raw Symbolic  
Mixed HLL Source Lines  
Up to 999 Bin capacity  
User-controlled Bin set-up:  
By Address By Symbol  
By Module By Line Number  
Automatic

## ❑ HELP

On-Line  
Context sensitive  
Hypertext/Hyperlinked

## ❑ MACRO

Repetitive routines  
User-created and callable

## ❑ ELECTRICAL SPECIFICATIONS

Input Power (maximum):  
1.5 A @ +5 VDC +/-5%

## ❑ MECHANICAL SPECIFICATIONS

Emulator Dimensions:  
7.0" x 5.5" x 1.0"  
17.8cm x 14cm x 2.54cm  
Emulator weight:  
2.0lbs 0.9kg

## ❑ ANNUNCIATORS

Power, Reset, Break, and Active LEDs  
Power ON/OFF, Reset, Break switches

## ❑ WARRANTY

One (1) year limited warranty, parts and

**Ordering Information****Philips Semiconductors 8051 Family Microcontroller Support****iceMASTER-PE Emulators**

The iceMASTER-PE emulators for the 8051 family are self-contained units, each dedicated to a particular member of the 8051 family. The emulator and probe card electronics are combined into a single, small package. Every iceMASTER-PE emulator comes with 64K of Code memory, 64K of External Data memory, a 16K frame Trace Buffer (which can be viewed without breaking emulation), power supply, RS-232 cable and an 8051 Macro Cross Assembler. All iceMASTER-PE emulators support an optional Break-Input signal clip, a Trigger-Output signal clip and seven user-placeable Trace-Capture-Input signal clips.

The following iceMASTER-PE emulators are currently available:

**PE-8031-33**

This emulator supports device operation from DC to 33MHz and has a 40-lead DIP footprint. This emulator supports the 8031 and 80C31 devices, regardless of process variation.

**PW-8032-30**

This emulator supports device operation from DC to 30MHz and has a 40-lead DIP footprint. This emulator supports the 8031, 80C31, 8032 and 80C32 devices, regardless of process variation.

**PE-83752-16**

This emulator supports device operation from DC to 16MHz and has a 28-lead DIP footprint. This emulator supports the 83C750, 87C750, 83C751, 87C751, 83C752 and 87C752 devices, regardless of process variation. This emulator is supplied with a 28-lead DIP to 24-lead DIP converter (CONV11) for 8xC751 support.

**PE-8351FX**

This emulator supports device operation from DC to 16MHz and has a 40-lead DIP footprint. This emulator supports the 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 8052, 80C52, 8752, 87C52, 8xC51FX, 80C54, 87C54, 80C58 and 87C58, regardless of process variation.

The following iceMASTER-PE emulators will be available in Q2'94.

**PE-87L51FB**

This emulator supports device operation from 3.5 to 16MHz and has a 40-lead DIP footprint. This emulator supports the 87L51FB device from 3.0 to 5.5 volts.

**PE-8XCL410**

This emulator supports device operation from 0.5 to 16MHz and has a 40-lead DIP footprint. This emulator supports the 83CL410 and 80CL410 devices from 1.8 to 6 volts.

**PE-80CL51**

This emulator supports device operation from 32kHz to 16MHz and has a 40-lead DIP footprint. This emulator supports the 80CL51 and 80CL31 devices from 1.8 to 6 volts.

**iceMASTER Model 200 & Model 400 Emulators**

All iceMASTER Model 200 & Model 400 emulators support full probe card interchangeability. To emulate several different devices, you need purchase only a single emulator base unit, the iceMASTER-8051, and then one probe card for each unique device to be emulated.

Both the iceMASTER-8051 Model 200 and the iceMASTER-8051 Model 400 emulators come with 64K of Code memory and 64K of External Data memory, power supply, RS-232 cable and an 8051 Macro Cross Assembler.

The IceMASTER Model 400 emulator has the following additional features/capabilities:

1. 4K-Frame Trace Buffer
2. Performance Analyzers
  - a. High Resolution
  - b. Hig Bin Count
3. Full Watchdog Timer (WDT) Support in all emulation modes

**Philips-Signetics 8051 Family Probe Cards**

All MetaLink probe cards include a Break-Input signal clip, a Trigger-Output signal clip and seven user-placeable Trace-Capture-Input signal clips. In addition, there is a user-selectable jumper for XTAL source. Most probe cards have other user-selectable jumpers to control/configure the unique capabilities of each particular device. Some probe cards also contain a user-selectable jumper for Vcc source. iceMASTER-8051 emulators fully supports:

All I/O ports, with no restrictions.

The CMOS Idle and Power Down modes of operation, in those devices having such capabilities.

The Watchdog Timer (WDT), in those devices having such a capability. (iceMASTER-8051 Model 400 only)

Correct device interconnection footprints.

Following is a list of all Philips-Signetics 8051 Family Probe Cards which MetaLink currently offers. Since MetaLink is constantly adding to its list of supported devices, please contact MetaLink for information on any device not listed below.

If support for a particular device is available at different maximum frequencies (MHz), the description of the Probe Card appears only once, with the speed variations noted in the Probe Card names above the description. Example: 8031-24 for a 24MHz 8031 Probe Card and 8031-20 for a 20MHz 8031 Probe Card.

**MHW-8031-20****MHW-8031-24**

The 8031 Probe Card supports device operation from 0.5 to 24MHz and has a 40-lead DIP package interface. This probe card supports 8031 and 80C31 devices, regardless of process variation.

**MHW-8032-20**

The 8032 Probe Card supports device operation from 0.5 to 20MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, 8032, 80C32 and 80C32 devices, regardless of process variation.

**MHW-80C51FA-16**

The 80C51FA Probe Card supports device operation from 0.5 to 16MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, 8032, 80C51FA and 80C32 devices, regardless of process variation.

**MHW-83C51FX-16**

The 83C51FC Probe Card supports device operation from 0.5 to 16MHz and has either a 40-lead DIP or a 44-lead PLCC package interface. This probe card supports 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8x51FA, 8x51FB, 8052, 80C52, 8752 and 87C52 devices, regardless of process variation.

**MHW-8052-16**

The 8052 Probe Card supports device operation from 0.5 to 16MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, 8032, 80C32, 8051, 80C51, 8052, 80C52, 8751, 87C51, 8752, and 87C52 devices, regardless of process variation.

**MHW-83C053-12**

The 83C053 Probe Card supports device operation from 6 to 12MHz and has a 42-lead Shrink DIP package interface. This probe card supports 83C053, 83C054, 87C054, 83C055 and 87C055 devices, regardless of process variation.

**MHW-80CL410-12**

The 80CL410 Probe Card supports device operation from 0.5 to 12MHz and has a 40-lead DIP package interface. This probe card supports the 80CL410 device (4.5V-5.5V only).

**MHW-80C451-16**

The 80C451 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C451 device, regardless of process variation. Converter #5 is available to convert the probe card to a 64-lead DIP footprint.

**MHW-83C451-12**

The 83C451 Probe Card supports device operation from 1.2 to 12MHz and has a 68-lead PLCC package interface. This probe card supports the 80C451, 83C451 and 87C451 devices, regardless of process variation. Converter #5 is available to convert the probe card to a 64-lead DIP footprint.

**MHW-80C528-16**

The 80C528 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports the 80C528 device.

**MHW-83C528-12****MHW-83C528-16**

The 83C528 Probe Card supports device operation from 1.2 to 16MHz and has either a 40-lead DIP or 44-lead PLCC package interface. This probe card supports 80C528, 83C528, 87C528, 83C524 and 87C524 devices, regardless of process variation.

**MHW-83C550-12**

The 83C550 Probe Card supports device operation from 1.2 to 12MHz and has a 44-lead PLCC package interface. This probe card supports the 83C550, 80C550 and 87C550 devices, regardless of process variation.

**MHW-80C552-16**

The 80C552 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C552 and 80C562 devices, regardless of process variation. Converter #7 is available to convert the probe card interface to a 40-lead DIP footprint for operation as an 8031, 8032, 80C31, 80C32 or 80C652.

**MHW-83C552-16**

The 83C552 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C552, 83C552, 87C552, 80C562, 83C562 and 87C562 devices, regardless of process variation. Converter #7 is available to convert the probe card interface to a 40-lead DIP footprint for operation as an 8031, 8032, 80C31, 80C32, 8x51, 8xC51, 8x52, 8xC52, 8xC652 or 8xC654.

**MHW-83C575-16**

The 83C575 Probe Card supports device operation from 0.5 to 16MHz and has either a 40-lead DIP or a 44-lead PLCC package interface. This Probe Card supports 80C575, 83C575 and 87C575 devices, regardless of process variation.

**MHW-83C592-16**

The 83C592 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C592, 83C592 and 87C592 devices, regardless of process variation.

**MHW-80C652-16**

The 80C652 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31 and 80C652 devices from any IC manufacturer, regardless of process variation.

**MHW-83C652-16**

The 83C652 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports 80C652, 83C652 and 87C652 devices from any IC manufacturer, regardless of process variation.

**MHW-83C654-16**

The 83C654 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports 80C652, 83C654 and 87C654 devices from any IC manufacturer, regardless of process variation.

**MHW-83C751-16**

The 83C751 Probe Card supports device operation from 0.5 to 16MHz and has 24-lead Skinny DIP package interface. This probe card supports 83C751 and 87C751 devices, regardless of process variation.

**MHW-83C752-12**

The 83C752 Probe Card supports device operation from 0.5 to 12MHz and has a 28-lead DIP package interface. This probe card supports 83C752 and 87C752 devices, regardless of process variation.

**MHW-80C851-12**

The 80C851 Probe Card supports device operation from 1.2 to 12MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, and 80C851 devices, regardless of process variation.

**MHW-83C851-12**

The 83C851 Probe Card supports device operation from 1.2 to 12MHz and has a 40-lead DIP package interface. This probe card supports 80C851, and 83C851 devices, regardless of process variation.

**iceMASTER Converters**

iceMASTER converters are used with the iceMASTER-8051 Probe Card to allow the user to change the device footprint supported by the Probe Card to a new device footprint or to allow the iceMASTER-8051 Probe Card to support a new device with the existing Probe Card.

**MHW-CONV5**

A 68-lead PLCC to 64-lead DIP converter for 83C451 or 80C451 Probe Cards to 80C451, 83C451 and 87C451 devices.

**MHW-CONV7**

A 68-lead PLCC to 40-lead DIP converter for 83C552 or 80C552 Probe Cards to 8031, 8032\*, 80C31, 80C32\*, 8051, 8751, 80C51, 87C51, 8052\*, 8752\*, 80C52\*, 80C652, 83C652, 87C652, 87C654, 83C654 and 87C52\* devices. \*Not all modes of Timer 2 supported.

**MHW-CONV11**

A 28-lead DIP to 24-lead DIP converter for the PE-83752 or 83C752 Probe Card to 83C751 and 87C751 devices.

**MHW-CONV12**

A 24-lead Skinny DIP to 28-lead PLCC converter for 83C751 Probe Card to 83C751 and 87C751 devices.

**MHW-CONV13**

A 28-lead DIP to 28-lead PLCC converter for PE-83752 and 83C752 Probe Card to 83C752 and 87C752 devices.

**MHW-CONV14**

A 40-lead DIP to 44-lead PLCC converter for PE-8031, 8031 Probe Card to 8031, 80C31, 8031 and 80C31 devices.

A 40-lead DIP to 44-lead PLCC converter for PE-8032, 8032 Probe Card to 8031, 80C31, 8031, 80C31, 80C32, 8032 and 80C32 devices.

A 40-lead DIP to 44-lead PLCC converter for 8052 Probe Card to 8031, 80C31, 8031, 80C31, 80C32, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8052, 80C52, 8752 and 87C52 devices.

A 40-lead DIP to 44-lead PLCC converter for 8351FB Probe Card to 8031, 80C31, 8031, 80C31, 80C32, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8052, 80C52, 8752, 87C52, 8XC51FA and 8XC51FB devices.

A 40-lead DIP to 44-lead PLCC converter for 80410 Probe Card to 80CL410 devices.

A 40-lead DIP to 44-lead PLCC converter for 80652 and 83652 Probe Cards to 80C652, 87C652, 83C652, 87C654 and 83C654 devices.

A 40-lead DIP to 44-lead PLCC converter for 80528 and 83528 Probe Cards to 80C528, 87C528, 83C528, 87C524 and 83C524 devices.

A 40-lead DIP to 44-lead PLCC converter for 80851 and 83851 Probe Cards to 80C851 and 83C851 devices.

**MHW-CONV19**

A 68-lead PLCC to 44-lead PLCC converter for 83552 and 80552 Probe Cards to 8031, 8032\*, 80C31, 80C32\*, 8051, 8751, 80C51, 87C51, 8052\*, 8752\*, 80C52\*, 80C652, 83C652, 87C652, 87C654, 83C654 and 87C52\* devices.

**MHW-CONV23**

A 44-lead PLCC to 40-lead DIP converter for 80550 Probe Card to 80C550, 87C550 and 83C550 devices.

**iceMASTER-8051 and PE Hardware Miscellaneous Products****MHW-EXT24DIP**

A 24 Lead Skinny DIP, 6 inch target interface extension cable for 83C751 and 87C751 devices.

**MHW-EXT28DIP**

A 28 Lead DIP, 6 inch target interface extension cable for 83C752 and 87C752 devices.

**MHW-EXT40DIP**

A 40 Lead DIP, 6 inch target interface extension cable for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

**MHW-EXT28PLCC**

A 28 Lead PLCC, 6 inch target interface extension cable for 83C751, 87C751, 83C752 and 87C752 devices.

**MHW-EXT44PLCC**

A 44 Lead PLCC, 6 inch target interface extension cable for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C550, 83C550, 87C550, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

**MHW-EXT68PLCC**

A 68 Lead PLCC 6 inch target interface extension cable for 83C552, 87C552, 83C562, 87C562, 80C552, 83C451, 87C451, 80C451, 87C592, 80C592 and 83C592 devices.

**MHW-DIPSE24/3**

A 24 Lead Skinny DIP pin isolator for 83C751 and 87C751 devices.

**MHW-DIPSE28/6**

A 28 Lead DIP pin isolator for 83C752 and 87C752 devices.

**MHW-DIPSE40/6**

A 40 Lead DIP pin isolator for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C550 83C550, 87C550, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

**MHW-DIPSE42S/6**

A 42 Lead Shrink DIP pin isolator for 87C054, 83C054 and 83C053 devices.

**MHW-PLCSE28**

A 28 Lead PLCC pin isolator for 83C751, 87C751, 83C752 and 87C752 devices.

**MHW-PLCSE44**

A 44 Lead PLCC pin isolator for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C550 83C550, 87C550, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

**MHW-PLCSE68**

A 68 Lead PLCC pin isolator for 83C552, 87C552, 83C562, 87C562, 80C552, 83C451, 87C451, 80C451, 87C592, 80C592 and 83C592 devices.

**NOHAU EMUL51-PC – PC-based in-circuit emulator**

**1.0 System Architecture**

Features of the Nohau EMUL51-PC in-circuit emulator include:

- Low-cost full real-time emulation
- IBM PC-bus plug-in boards or stand alone Box version with 115K baud RS232-C connection to IBM PC
- Easy-to-learn user interface with windows and pull-down menus
- Source-level debugging in C, PL/M or Pascal with full support for typed symbols
- 256k frames by 64 bit real-time trace option with time stamp
- Program Performance Analyzer

The Nohau EMUL51-PC consists of a board which plugs directly into the IBM PC/XT/AT bus for fast file transfer. An optional external box with a serial link is also available. The optional Trace board features an advanced trace function with many trigger capabilities.

The POD, which plugs into the target system, is connected with a 5 ft (1.5 m) ribbon cable to the Emulator board to provide a flexible operating range.

The EMUL51-PC uses no wait states and does not intrude on memory, stack, I/O or interrupt pins.

fig 1 EMUL51-PC plug-in board version

fig 2 External Box version

## **2.0 User Interface**

The user interface is based on MS-DOS software. It incorporates a variety of techniques. The user can select to operate either with short typed commands or using pull-down menus. On-screen features include windows to monitor or alter:

- Assembly or high level language source code
- CPU registers
- Internal data and Special Function Registers
- External data
- Watch variables in C, PL/M or assembly
- Trace setup and display

All commands are supported with context-sensitive help and full on-line manual.

## **3.0 Specific Features**

### **3.1 Source Level Debugging**

Using high level language for code generation is a way to cut development time. Therefore the EMUL51-PC gives full support for debugging directly in C or PL/M source code. This eliminates the need for paper listings. Breakpoints can be marked directly in the source code window. The user can single step through the program line by line and follow the program execution on the screen listing.

The trace permits the user to trace his source code in real-time.

All variables can be displayed and altered. This includes full support for typed symbols which permits the user to address such variables as floating-point, arrays and structures — both global and local.

### **3.2 Emulation Memory**

The EMUL51-PC features 64 K of code memory and 64 K of external data memory. The addressable memory can be mapped either to target or to the emulator in 4K pages.

The emulator can load all common file formats and the user can view and alter all registers and memory areas of the microcontroller.

### **3.3 Breakpoints**

The EMUL51-PC permits the user to generate program breakpoints in a number of ways:

- 64K program breakpoints
- 64K data read and 64K data write breakpoints
- Break on external signal
- Break on direct access to internal bit or byte memory
- Break on contents of internal register or memory
- Break on program access out-of-boundary

Using the Trace board it is possible to break on combinations of address, data, control signals, port signals and external signals.

### **3.4 Macros and debug session logging**

Test session automation is made possible using the Macro commands. This permits the user to define his own command sequences using structures like IF/ELSE and REPEAT/WHILE. Such command sequences can be stored to a file which can be loaded automatically when the emulator is invoked.

A complete debug session and all setups can also be recorded to a file.

### 3.5 Trace Memory

The optional trace board features a trace buffer capable of storing up to 256k frames of 64 bit data each. The 64 bits consist of address, data, control signals, port signals, external signals and a time stamp.

The trace memory can be displayed, reprogrammed and restarted during emulation.

#### 3.5.1 Trace Filter

The trace filter makes it possible to select what events are stored in the trace buffer. The qualifiers permit the user to define the criteria for which bus cycles are stored. The qualifiers can specify address, data, control signals, port signals and external signals.

#### 3.5.2 Trace Trigger

The trace works much like a logic analyzer. It is therefore possible to trigger the trace on an event and display what happened before or after that event.

The trigger event can be defined using any of the qualifiers in up to eight levels. It is possible to trigger on boolean combinations of the qualifiers, or sequential combinations including a loop counter.

The trigger point can be selected anywhere within the 256k trace buffer to give full choice of pre/post trigger alignment.

#### 3.5.3 Trace Display

The trace information can be displayed in high-level language statements, in disassembled form or in binary/hex form. It can also be stored to a file.

#### 3.5.4 Program Performance Analyzer

With the PPA, information can be generated showing which addresses the user program spends its time on. The information can be displayed as statistics or in histogram form.

## 4.0 General Specifications

- Host: IBM PC/XT/AT/386/486, PS/2 or compatible with 640K of RAM. Monochrome, color or enhanced graphics display.
- External Box: The emulator boards can be installed in an external box with serial communication to the PC.
- Processors supported: 8051, 8052, 8031, 8032, 80C51, 80CL51, 80C52, 80CL52, 80C31, 80CL31, 80C32, 8XC053/054/055, 83/80CL410/610, 83/80C451, 8XC524, 8XC528, 8XC550, 83/80C552, 8XCE558, 80C562, 8XC575, 80CL580, 8XC592, 8XC598, 83/80C652, 83/87C750, 83/87C751, 83/87C752, 8XCL781, 8XCL782, 83/80C851 (For more details, please refer to the following pages.)  
A switch from one microcontroller to another is made by changing the low cost POD.
- File formats supported: Intel HEX/OBJ/SYM/OMF, Avocet, Archimedes/IAR, BSO/Tasking, Franklin/Keil, Intermetrics/Whitesmiths/Comic, and many more.
- Clock speed: Allows operation up to 33 MHz in real-time.
- Power supply: The boards are powered from the PC-bus. The Emulator board requires 1.7A/5V and the Trace board 1.3A/5V.

## 5.0 Ordering information

### PHILIPS SEMICONDUCTORS Microcontroller Support

#### EMULATOR UNITS

Includes software and ribbon cable. Must be connected to a POD to operate. Each step up in frequency rating covers all lower frequency steps. Includes DIP isolator if ordered with 40-pin POD. Emulator software has high-level debug and all options.

| Order Number      | Description                                         |
|-------------------|-----------------------------------------------------|
| EMUL51-PC/E32     | 12 MHz Emulator, 32 kB (kiloByte) Emulation Memory. |
| EMUL51-PC/E32-16  | 16 MHz Emulator, 32 kB Emulation Memory.            |
| EMUL51-PC/E128    | 12 MHz Emulator, 128 kB Emulation Memory.           |
| EMUL51-PC/E128-16 | 16 MHz Emulator, 128 kB Emulation Memory.           |
| EMUL51-PC/E128-20 | 20 MHz Emulator, 128 kB Emulation Memory.           |
| EMUL51-PC/E128-24 | 24 MHz Emulator, 128 kB Emulation Memory.           |
| EMUL51-PC/E128-30 | 30 MHz Emulator, 128 kB Emulation Memory.           |
| EMUL51-PG/E128-33 | 33 MHz Emulator, 128 kB Emulation Memory.           |

#### TRACE BOARD OPTIONS

Optional second PC plug-in board. Emulator board contains no trace capability. Each frequency step covers all lower steps.

| Order Number      | Description                                    |
|-------------------|------------------------------------------------|
| EMUL51-PC/TR4     | 12 MHz 4 kiloframe (4096 frames) Trace Buffer. |
| EMUL51-PC/TR4-16  | 16 MHz 4 k Trace Buffer.                       |
| EMUL51-PC/TR16    | 12 MHz 16 k Trace Buffer.                      |
| EMUL51-PC/TR16-16 | 16 MHz 16 k Trace Buffer.                      |
| EMUL51-PC/TR16-20 | 20 MHz 16 k Trace Buffer.                      |
| EMUL51-PC/TR16-24 | 24 MHz 16 k Trace Buffer.                      |
| EMUL51-PC/TR16-30 | 30 MHz 16 k Trace Buffer.                      |
| EMUL51-PC/TR16-33 | 33 MHz 16 k Trace Buffer.                      |

**Advanced Trace Boards** feature 32-bit timestamping with 16-bit prescaler, eight-level triggers, state and counter functions, search.

| Order Number        | Description                                                         |
|---------------------|---------------------------------------------------------------------|
| EMUL51-PC/ATR64-16  | 16 MHz 64 k Advanced Trace Buffer.                                  |
| EMUL51-PC/ATR256-16 | 16 MHz 256 k Advanced Trace Buffer. Contact Nohau for availability. |
| EMUL51-PC/ATR64-24  | 24 MHz 64 k Advanced Trace Buffer.                                  |
| EMUL51-PC/ATR256-24 | 24 MHz 256 k Advanced Trace Buffer.                                 |
| EMUL51-PC/ATR64-33  | 33 MHz 64 k Advanced Trace Buffer.                                  |
| EMUL51-PC/ATR256-30 | 30 MHz 256 k Advanced Trace Buffer.                                 |

#### BONDOUT PODS, 24-PIN, 40-PIN, 68-PIN, 84-PIN

Allow full emulation of internal, external and mixed modes of bus or port input/output. On-board POD crystal is 12 MHz on all PODs of any frequency specification. Each step up in frequency rating covers all lower frequency steps.

| Order Number     | Description                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POD-C51B         | 12 MHz Bondout POD for 80C51, 8051, 87C51, 8751, 80C31, 8031, 80C/83C652, 83C654, 80C/83C662, 80C/83C851 single-chip or external mode.                                                                                                                         |
| POD-C51B-16      | 16 MHz Bondout POD for 80C/87C51-1, 80C/87C51, 80/8751, 80C31-1, 80C31, 8031, 80C/83C652, 83C654, 80C/83C662, 80C/83C851 single-chip or external mode.                                                                                                         |
| POD-C51B-24      | 24 MHz POD for 80C/87C51-24, 80/8751, 80C31-24, 80C/83C652/654, 80C/83C662, 80C/83C851 single-chip or external mode. <b>Special Requirement:</b> Due to bondout chip timing, this POD requires a 30 MHz emulator board and trace board must be 30 MHz if used. |
| POD-CL410        | POD for 83CL410, 83CL610, 80CL31, 80CL51. Target voltage range: 1.5–5.0V. Maximum frequency: 12 MHz at 5.0V. This POD is intended for emulating internal code. External bus operation is limited.                                                              |
| POD-C451B-PGA    | 12 MHz Bondout POD for 83C451, 87C451, 80C451 PLCC, single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.                                                                                                                          |
| POD-C451B-PGA-16 | 16 MHz Bondout POD for 83C451, 87C451, 80C451 PLCC, single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.                                                                                                                          |
| POD-C552B-PGA    | 12 MHz Bondout POD for 83C552, 87C552, 80C552 PLCC, single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.                                                                                                                          |
| POD-C552B-PGA-16 | 16 MHz Bondout POD for 83C552, 87C552, 80C552 16 MHz, 12 MHz single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.                                                                                                                 |

|                  |                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POD-C552B-PGA-24 | 24 MHz Bondout POD for 8XC552 or 8XC562 PLCC single-chip or external mode. PGA from POD. Use optional adapter (etc). <b>Special Requirement:</b> Due to bondout chip timing, this POD requires a 30MHz emulator board and trace board must be 30 MHz if used. |
| POD-CL580        | 12MHz Bondout POD for 83CL580.                                                                                                                                                                                                                                |
| POD-C652B        | Order as POD-C51B.                                                                                                                                                                                                                                            |
| POD-C751         | 12 MHz 83C750, 87C750, 83C751, 87C751, DIP POD. Includes EXT-DIP24.                                                                                                                                                                                           |
| POD-C751-16      | 16 MHz 83C750, 87C750, 83C751, 87C751, DIP POD. Includes EXT-DIP24.                                                                                                                                                                                           |
| POD-CL782        | 12 MHz POD for 83CL781, 83CL782, 83CL52                                                                                                                                                                                                                       |

### "HOOKS" MODE PODS, 28-PIN, 40-PIN, 42-PIN, 44-PIN, 68-PIN

Standard chip operated in special "hooks" emulation mode for single-chip or external modes. Some electrical characteristics are different from microcontroller's. On-board POD crystal is 12 MHz on all PODs of any frequency specification.

| Order Number    | Description                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| POD-C52         | 12 MHz POD for 80C31, 80C32, 80C51, 80C52, 87C51, 87C52.                                                                |
| POD-C52-16      | 16 MHz POD for 80C31, 80C32, 80C51, 80C52, 87C51, 87C52.                                                                |
| POD-C528        | 12 MHz POD for 80C528, 83C528, 87C528, 83C524, 83C528.                                                                  |
| POD-C528-16     | 16 MHz POD for 80C528, 83C528, 87C528, 83C524, 83C528.                                                                  |
| POD-C550-PGA    | 12 MHz POD for 80C550, 83C550, 87C550. PGA from POD. Use optional adapter for PLCC target.                              |
| POD-C550-PGA-16 | 16 MHz POD for 80C550, 83C550, 87C550. PGA from POD. Use optional adapter for PLCC target.                              |
| POD-C575        | 12 MHz 87C575, 87C575 chip may have to be supplied by user.                                                             |
| POD-C592-PGA    | 12 MHz POD for 8XC592. 8XC592 chip may have to be supplied by user. PGA from POD. Use optional adapter for PLCC target. |
| POD-C592-PGA-16 | 16 MHz POD for 8XC592. 8XC592 chip may have to be supplied by user. PGA from POD. Use optional adapter for PLCC target. |
| POD-C752        | 12 MHz 83C752, 87C752 DIP POD. Includes EXT-DIP28.                                                                      |
| POD-C752-16     | 16 MHz 83C752, 87C752 DIP POD. Includes EXT-DIP28.                                                                      |
| POD-C054        | 12 MHz POD for 8XC053, 8XC054, 8XC055 (Micocontroller-for-Television-Video).                                            |
| POD-C575        | 16 MHz POD for 8XC575.                                                                                                  |

### POD BOARDS, 40 PIN EXTERNAL MODE

Port 2 is upper address bus only. Port 0 is address/data bus. P3.6 is WRITE, P3.7 is READ. On-board POD crystal is 12 MHz on all PODs of any frequency specification. Each step up in frequency rating covers all lower frequency steps.

| Order Number | Description         |
|--------------|---------------------|
| POD-31       | 12 MHz 8031 POD.    |
| POD-C31      | 12 MHz 80C31 POD.   |
| POD-32       | 12 MHz 8032 POD.    |
| POD-C32      | 12 MHz 80C32 POD.   |
| POD-C652     | 12 MHz 80C652 POD.  |
| POD-C31-1    | 16 MHz 80C31-1 POD. |
| POD-C32-16   | 16 MHz 80C32 POD.   |
| POD-C31-20   | 20 MHz 80C31 POD.   |
| POD-C31-24   | 24 MHz 80C31 POD.   |
| POD-C31-30   | 30 MHz 80C31 POD.   |
| POD-C31-33   | 33 MHz 80C31 POD.   |

-S version of the above boards allows P3.6, P3.7 to be used either as unidirectional I/O or write and read. (Example: POD-31-S; POD-C31-S-1; POD-C32-S-16.)

### EXTERNAL MODE PODS, 64-PIN, 68-PIN

Port 2 is upper address bus only. Port 0 is address/data bus. P3.6 is WRITE, P3.7 is READ. On-board POD crystal is 12 MHz on all PODs of any frequency specification. Each step up in frequency rating covers all lower frequency steps.

| Order Number    | Description                                                            |
|-----------------|------------------------------------------------------------------------|
| POD-C451-DIP    | 12 MHz 80C451 DIP POD.                                                 |
| POD-C451-DIP-16 | 16 MHz 80C451 DIP POD.                                                 |
| POD-C451-PGA    | 12 MHz 80C451 PLCC POD. PGA from POD.                                  |
| POD-C451-PGA-16 | 16 MHz 80C451 PLCC POD. PGA from POD.                                  |
| POD-C552-PGA    | 12 MHz 80C552 POD. PGA from POD. Use optional adapter for PLCC target. |
| POD-C552-PGA-16 | 16 MHz 80C552 POD. PGA from POD.                                       |
| POD-C562-PGA-16 | 16 MHz 80C562 POD. PGA from POD.                                       |

## BOX OPTIONS

Box units are AC line-powered. Emulator software runs under DOS on PC and uses a COM port at 110 baud to 115 kilobaud. Serial cable included.

| Order Number        | Description                                                               |
|---------------------|---------------------------------------------------------------------------|
| EMUL51-PC/BOX-S     | Serial Box. Select emulator separately; trace optional. POD not included. |
| EMUL51-PC/BOX-CS    | Serial Box with E128-16 Emulator and TR16-16 Trace. POD not included.     |
| EMUL51-PC/BOX-CS-20 | Serial Box with E128-20 Emulator and TR16-20 Trace. POD not included.     |
| EMUL51-PC/BOX-CS-24 | Serial Box with E128-24 Emulator and TR16-24 Trace. POD not included.     |
| EMUL51-PC/BOX-CS-30 | Serial Box with E128-30 Emulator and TR16-30 Trace. POD not included.     |

## MISCELLANEOUS OPTIONS

| Order Number                | Description                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMUL51-PC/PRG               | Universal Programmer (EPROM, 8751, 87C51, PAL).                                                                                                                              |
| EMUL51-PC/PRG751            | Programmer for 87C751, 87C752.                                                                                                                                               |
| EMUL51-PC/EXT-DIP24         | Additional extender cable for 24 pin DIP.                                                                                                                                    |
| EMUL51-PC/DIP24-ISO         | 24 pin DIP Isolator.                                                                                                                                                         |
| EMUL51-PC/DIP24-PLCC28      | 24 pin DIP to 28 pin PLCC.                                                                                                                                                   |
| EMUL51-PC/EXT-DIP24-PLCC28  | Extender cable, 24 pin DIP to 28 pin PLCC.                                                                                                                                   |
| EMUL51-PC/EXT-DIP28         | Extender cable, 28 pin DIP.                                                                                                                                                  |
| EMUL51-PC/DIP28-PLCC28      | 28 pin DIP to 28 pin PLCC.                                                                                                                                                   |
| EMUL51-PC/DIP28-ISO         | Additional 28 pin DIP Isolator.                                                                                                                                              |
| EMUL51-PC/DIP28-DIP24-ADAP  | 28-pin (0.600-In) to 24-pin (0.300-In) adapter to plug POD-C752 into 8XC751 target. The user is responsible for port and register compatibility.                             |
| EMUL51-PC/EXT-DIP40         | Extender cable for 40 pin DIP.                                                                                                                                               |
| EMUL51-PC/DIP40-ISO         | Additional 40 pin DIP Isolator.                                                                                                                                              |
| EMUL51-PC/DIP40-PLCC44      | 40 pin DIP to 44 pin PLCC.                                                                                                                                                   |
| EMUL51-PC/DIP40-ONCE-DIP40  | Clips over target microcontroller. Disables target micro to allow emulation without removing target chip. Works only on chips with on-chip emulation (ONCE) disable feature. |
| EMUL51-PC/DIP40-ONCE-PLCC44 | Clips over target microcontroller. Disables target micro to allow emulation without removing target chip. Works only on chips with on-chip emulation (ONCE) disable feature. |
| EMUL51-PC/PGA44-PLCC44      | PGA to PLCC adapter, 44 pin.                                                                                                                                                 |
| EMUL51-PC/PGA44-PLCC44-EL2  | PGA to PLCC "elevator" or "tower" rigid 2-inch extender-adapter.                                                                                                             |
| EMUL51-PC/EXT-DIP48         | Extender cable for 48 pin DIP.                                                                                                                                               |
| EMUL51-PC/DIP48-ISO         | 48 pin DIP Isolator.                                                                                                                                                         |
| EMUL51-PC/PGA68-PLCC68      | PGA to PLCC adapter unit, 68 pin.                                                                                                                                            |

**SOFTWARE PACKAGES**

**Order Number      Description**

**NOHAU Corporation**

SIMUL51-PC

Nohau 8031/8051 Simulator. Same interface as EMUL51-PC.

EMUL51-PC/SWSUB

EMUL51-PC emulator software update service, one year.

**Archimedes Software, Inc.**

ARCHM/C-8051PC

Archimedes C-8051PC V4 C-Compiler & Assembler.

ARCHM/SIM-8051PC

Archimedes 8051 Simulator/Debugger (SimCASE Sim-8051PC) for CC51, PL/M-51 & ASM.

Archimedes is a trademark of Archimedes Software, Inc.

**Avocet Systems, Inc.**

AVOCET/AVA51

Avocet Systems AvCase51 8051 Assembler

Avocet is a registered trademark of Avocet Systems, Inc.

**BSO/Tasking**

BSOTSK/C51PKG

BSO/Tasking 8051 Family C-Compiler and Assembler Package.

BSOTSK/PLM51PKG

BSO/Tasking 8051 Family PL/M Compiler and Assembler Package.

**Chip Tools, Inc.**

CV51-NOH

Chip Tools Chip View-51 High-Level/Low-Level Debugger Emulator interface for EMUL51-PC.

CV51-S

Chip Tools Chip View-51 High-Speed Simulator.

CV51-SNOH

Chip Tools Chip View-51 CV51-NOH + CV51-S Combo package.

Chip Tools and Chip View are trademarks of Chip Tools, Inc.

**Franklin Software, Inc.**

FRANKLIN/4010

Franklin 8051 Macro Assembler with Linker, Librarian, Object-to-Hex utility.

FRANKLIN/5020

Franklin V3 Very High Performance 8051 Compiler & Assembler.

FRANKLIN/7020

Franklin V5 Simulator/Debugger, Windowed Interface.

FRANKLIN/8220

Franklin Developers Kit with 5020 Compiler, 4010 Assembler and 7020 Simulator/Debugger.

Franklin is a trademark of Franklin Software, Inc.

**Intermetrics Microsystems Software, Inc./Whitesmiths, Ltd.**

INTERMET/C851HX

Intermetrics Whitesmiths C-Compiler and Assembler, Extended.

INTERMET/D851HXNOH

Intermetrics Whitesmiths C Source-Level Debugger/Emulator Version (Interface for EMUL51-PC).

INTERMET/D851HXSIM

Intermetrics Whitesmiths C Source-Level Debugger/Simulator Version.

Whitesmiths and CXDB are registered trademarks of Intermetrics, Inc.

The EMUL51-PC Emulator, Trace, POD, and Box hardware is sold with a one-year warranty. The EMUL51-PC Emulation software is sold with no warranty, but upgrades will be distributed to all customers up to one year from the date of purchase. Nohau Corporation makes no warranties, express or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. In no event will Nohau Corporation be liable for consequential damages. The SIMUL51-PC Simulator software includes updates for a period of one year. Third-party software and programmers sold by Nohau carry manufacturers' warranties.

## CHOOSING PODS for the EMUL51-PC

People sometimes ask: "How do I choose which POD to use for the 8051-family chip I want to emulate?"

Which POD you pick for your application depends on several things. What micro you are using, the frequency, the mode you are using it in, your target configuration, and price all play a part. The **EMUL51-PC ORDER INFORMATION** can help you choose among the POD types available from Nohau.

Nohau has several categories of PODs: (1) External-mode PODs; (2) Bondout PODs; and (3) "Hooks"-mode PODs.

### 1. External-Mode PODs

External or microprocessor-mode PODs have several clear advantages. They are the cheapest type of POD. They have easily-replaceable standard microcontrollers. Your program runs on the real production part, with most of the lines directly connected to your target. You can use them where your microcontroller has external program or external read-write memory. With this type of POD, Port 2 is used only for the upper address bus and not as port input-output (I/O). Port 0 is used as a multiplexed address and data bus. In most of these PODs, P3.6 can only be used as the write line and P3.7 as only the read line. The **POD-31** is a typical external POD.

Your target system shares Port 0 and Port 2 with the emulator. The emulator uses Port 0 to run its monitor code when it is not executing your code in real-time. When you are not running real-time emulation, the POD holds the Program Store ENable line (PSEN/) high so that your external read-only memory (ROM) is not enabled. It also holds the Read/ line and Write/ lines high so that none of your external read-write random access memory (RAM) or I/O is enabled.

But in the monitor (not emulating) mode, the address lines of both Port 2 and Port 0 are active and can output any address in the 64 kByte address range. It is up to your target system to prevent enabling any device unless the PSEN/ or the RD/ or the WR/ line goes low.

If you are emulating a ROM-less part, like the 8031, you can use the **POD-31** type of POD. You also might use this POD for some internal ROM applications. You could use it for designs that have all of Port 2 and Port 0 used as external buses. This is true even though the program can be executed from on-chip 8051 program memory in your final product. This is a case where your target schematic, rather than the device you are using lets you use this type of POD. So though the part may ultimately be an 8051 or 8751, you can use a **POD-31** because you are using the ports as buses.

If you are emulating the 80C31, 8032, 80C32 or 80C652, you can get external-mode PODs for these microcontrollers. With the **POD-31**, you can emulate all those parts in external mode at up to 12 MHz. You can get the POD with the correct micro installed, such as a **POD-32**. Or you can change among the types by changing the microcontroller component in the POD yourself.

16 MHz, 20 MHz, 24 MHz, 30 MHz and 33 MHz PODs are available for 40-pin parts. If you use a **POD-C31-1** with a 16 MHz rated emulator, you can support such parts as the 80C31-1, 80C32-1 and 80C652-1. Any higher-frequency POD and emulator set can support all the lower frequencies.

For emulating the 80C451, 80C552, or 80C562 other external mode PODs are available. PODs for dual inline package (DIP) parts have a DIP plug coming out of the bottom of the POD. PODs for plastic leaded chip carrier (PLCC) parts have a pin-grid array (PGA) plug coming out from the bottom of the POD. To plug a PGA POD into a PLCC socket, you can get an optional adapter. The PGA68-PLCC68 is a typical adapter. If your target board has feed-through holes and you solder a PGA socket into it, you don't need an adapter. If your target board already has a PGA socket, you don't need an adapter.

**POD-31-S:** All the above external PODs use P3.6 as WR/ and P3.7 as RD/. But there is a 40-pin external mode POD version that lets you use these two lines as I/O. The basic board is the **POD-31-S**. This special -S option lets you select whether the two lines are to be WR/ and RD/ or else I/O. They can be unidirectional port lines (input-input, input-output, output-input, or output-output). You also can get this POD in the variations of 16 MHz and 20 MHz and any of the 40-pin part variations listed above.

## 2. Bondout PODs

Bondout PODs use special microcontrollers that the semiconductor manufacturers designed to perform all the functions of the part. They also have additional lines “bonded out” from the chip that allow control for emulation. PODs with these special chips cost more than PODs with widely available commercial chips, but give you a greater flexibility in how you use the ports. These PODs allow you to use any combination of internal or external mode of the chip, and respond to the state of the External Access (EA/) pin.

Nohau has bondout PODs for many different microcontrollers.

You can emulate the 80/80C51, 87/87C51, 80/80C31, 80C/83C/87C652, 83C/87C654, 80C/83C662 and 80C/83C851 with the **POD-C51B**. 16 MHz and 24 MHz versions are available.

To emulate the 83C451, 87C451 and 80C451 in the PLCC package, you can use the **POD-C451B-PGA**. See the previous discussion about PGAs.

For emulating the 80C/83C/87C552 and 80C/83C/87C562 you can use the **POD-C552B-PGA**. It also is available in a 16 MHz and 24MHz versions.

For emulating the 83C750, 87C750, 83C751 and 87C751, use the **POD-C751**. It has a 24 pin DIP plug on the bottom of the POD. You also can get an adapter to plug into 28 pin PLCC sockets. A 16 MHz version is available.

For emulating the 8XCL410, 8XCL31, and 8XCL51, use the **POD-CL410**.

For emulating the 83CL580, use the **POD-CL580** and a special adapter.

For emulating the 83CL781, 87CL781, 83CL782, 87CL782 and 80CL52, use the **POD-CL782**.

You should be aware of one small problem that most 8051 bondout parts have with serial communication. Specifically, if your program has written to SBUF, but the TI flag has not been set, and you then break emulation, the TI flag will never be set after you resume emulation.

Bondout PODs give you the best of both worlds. They let you mix how you use the ports. So you can emulate the single-chip mode using the ports as I/O. Or you can emulate external bus mode. Or you can emulate a mix of both modes.

## 3. “Hooks”-Mode PODs

The newest type of POD Nohau offers uses a different technique for emulating. Certain chips can be put into a proprietary “hooks” mode that multiplexes the port information in and out of the part. The chip can still put out address and data. Most have 16 MHz versions available. This group includes these PODs:

The **POD-C752** is for emulating the 83C752 and 87C752. It has a 28 pin DIP plug on the bottom of the POD. You also can get an adapter to plug into 28 pin PLCC sockets.

The **POD-C52** can emulate the 80/80C/87/87C51, 80/80C/87/87C52, 80/80C31 and 80/80C32. You can use this POD when you need to emulate the 8052-type parts in single-chip mode when you are using Timer 2.

The **POD-C528** can emulate the 80/80C/87/87C528 and 83/87C524.

The **POD-C592-PGA** can emulate the 8XC592. See the previous discussion about PGAs.

The **POD-C550-PGA** can emulate the 80/80C/87/87C550. It has a 44-pin PGA plug. You also can get an adapter to plug into 44-pin PLCC sockets.

The **POD-C558-16** can emulate the 83CE558 ad 89CE558.

The **POD-C575** can emulate the 8X575.

The **POD-C054** can emulate the 8XC053/054/055 “MTV” chip.

With the “Hooks”-Mode PODs, you use jumpers to select whether the code is to be fetched from the emulator RAM or from external ROM. You also select whether the read-write memory is in the emulator or on your target board. The ports on these PODs may have slightly different electrical characteristics than the

microcontroller. Specifically, some output signals can appear up to three clock cycles later than on the actual part. Also, some ports have greater current sink or sink and source capacity or slightly higher impedance than the actual part. For almost all applications, these differences will have no detrimental effects.

You can use any size **EMUL51-PC** emulator and optional trace board with any POD you choose in Nohau's **EMUL51-PC** family. Choose an emulator and trace board with frequencies as fast or faster than the frequency of your fastest POD. If you need more information about which POD would best fit your application, please contact Nohau.

# LCP

## 80C51 Family Programmers

The LCP family of 80C51 programmers supports the entire line of Philips 80C51 microcontroller derivatives. The LCP is a low cost approach to programming microcontrollers. It was designed to be used with a standard PC. The PC provides the "brains" or processing power and buffer memory. The LCP programmers are ideal for development purposes or short production runs. There are two models of the LCP programmer; one for the standard 40-pin DIP and 44-pin LCC devices, and the other for 24- and 28-pin DIP and 68-pin LCC devices.

- Low cost programmers for 80C51 family of microcontrollers
- Serially linked to IBM PC—program time is approximately 3 minutes for 32K bytes
- Programs and verifies code bytes and security bits
- Programs microcontroller from standard hexadecimal files from PC
- Provides one button function key routines for common operations
- Allows programming multiple devices with the same code using a single command to repeat the blank check/program/verify function

**P8051LCP40 SD Programs 40-Pin DIP and 44-Pin LCC Devices**

**P8051LCPX SD Programs 24- and 28-Pin DIP and 68-Pin LCC Devices**

# Microcontroller Programmers

## Description

- Serially linked to IBM compatible host by RS-232 serial link
- Programs and checks security bits
- Reads and verifies microcontroller code
- Can be used to program multiple devices with one keystroke per device
- Performs standard programming functions using PC function keys including:

- F1 Check Blank [Verifies all memory locations contain FF]
- F2 Program [Writes code from buffer into part]
- F3 Verify code [Ensures a match between the buffer code and the microcontroller code]

- F4 Verify Security bit [Checks status of security bit]
- F5 Auto Program (for multiple devices) [Allows sequential programming of several microcontrollers]
- F6 Read File (load buffer) [Reads a specified HEX file into the buffer from disk]
- F7 Read ROM (reads microcontroller ROM is not secured) [Loads code in microcontroller into PC buffer]
- F8 View buffer [Allows user to view code]
- F9 Setup [Calls the setup menu to select parameters]
- F10 Quit [Returns to programmer main menu or to DOS]

## Each Kit Includes:

(both kits contain the necessary hardware and software to program Philips microcontrollers using an IBM compatible PC/XT/AT)

- Programmer Board (165mm × 95mm) with Zero Insertion Force sockets, 9-pin D serial connector, and 9V power connector
- Software provided on 5.25" floppy (360K)
- User Manual with step-by-step instructions
- RS-232 Serial Cable with 9-pin D connector to attach to a computer serial port
- 9-pin D connector to 25-pin D connector adaptor
- 9V to 110V AC adaptor (North America only)
- AC adaptor for Europe and Asia

## Specifications:

- Circuit board—with Zero Insertion Force sockets (Board does not contain program buffer—buffer is kept in PC memory)  
RS-232 communication port for serial communications with a personal computer [Pin 2 RXD/TXD, Pin 3 TXD/RXD, and Pin 5 is Ground] (Jumper block on board)
- Serial Cable with D connectors (approximately 6 feet long)
- Programming software and manual (Software only runs on an IBM compatible PC/XT/AT under DOS 2.0 or higher)

## Development System for 80C51 and Derivatives

PDS51

### INTRODUCTION

The PDS51 is a board-level, full featured, In-Circuit Emulator for the Philips 80C51 family of Microcontrollers. It allows the user complete access to the internal registers and full execution control with no chip resources being consumed. As standard, the PDS51 is supplied with sufficient memory to enable emulation of the complete 64K of directly addressable code memory and a 28K line by 32 bit wide, real-time trace buffer.

The PDS51 system consists of two interconnected modules. One board (the motherboard), contains the systems that are common to any derivative emulation such as the control microcontroller, logic, communication interface and power supply. The second board (the daughterboard), contains the bondout microcontroller which determines the target devices able to be emulated. Most daughter boards are able to emulate more than one target, making the range of devices available for emulation broad with minimal expense.

External breakpoints, trace control, emulation running and fetch address controlled output trigger signals are provided for interfacing and synchronising to external equipment.

The PDS51 is controlled via an RS232 serial interface by a PC running terminal emulation or the PDS51-IDE debugger supplied. The Integrated Development Environment is a windowed command and display environment which runs on PC XT, AT, 386, 486 or compatibles.

*PDS51 pictured with PDB552*

### FEATURES

- Supports Philips 80C51 family
- Universal motherboard
- Bondout dependant Daughterboard
- In-Circuit emulation
- No stolen resources
- 64K emulation code space
- Hardware Breakpoints (to 64K) on:
  - Fetch address
  - Fetch address and external signal
- Real-time trace (28K steps by 32 bits)
- Traced information
  - Fetch address
  - Port pins
- External trace probes
  - Control info (inta, c1, movx)
- Conditional trace on:
  - Fetch address
  - External signal
- RS232 interface to PC
- Controlled via Terminal Emulation with SDS command set or Debugger
- Integrated Development Environment:
  - Window interface
  - Pull down menus
  - Symbolic or Source level debug
  - Borland style key strokes
  - File interface via Hex or OMF51
- Low cost

# Development System for 80C51 and Derivatives

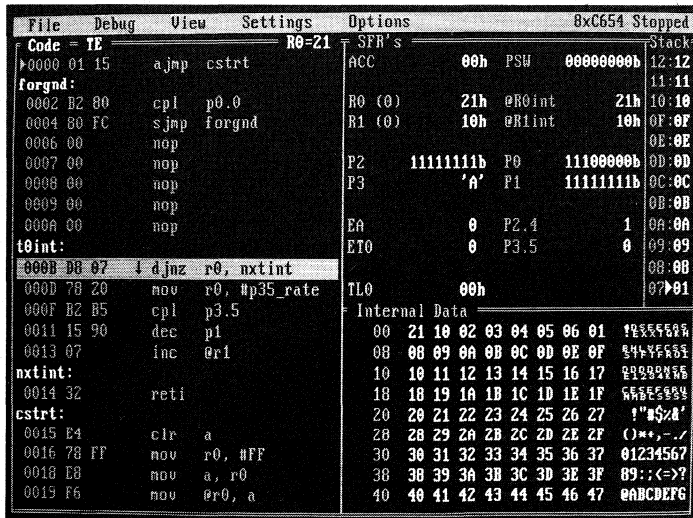

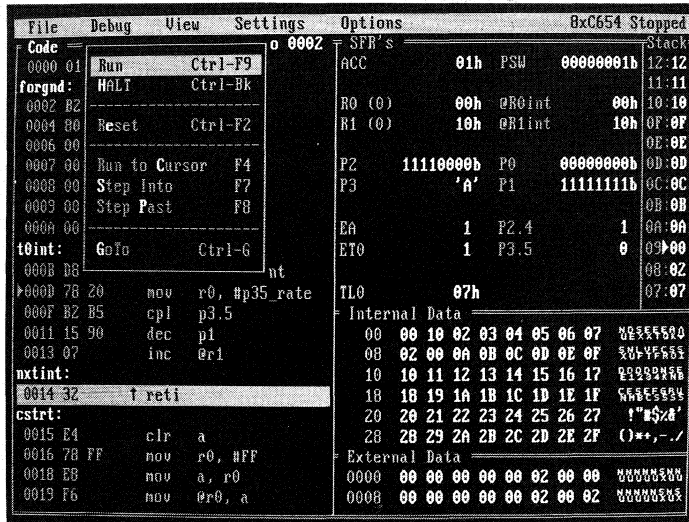

PDS51

## The PDS51-IDE INTEGRATED DEVELOPMENT ENVIRONMENT

The PDS51-IDE Integrated Development Environment provides an easy to use windowed environment that consists of five non-overlapping resizable panes that display Code, SFR's, internal data RAM, external data RAM (if enabled) and the stack area.

Borland compatible hot-keys provide fast and familiar access to frequently used functions, while pull down menus lead the new user to the desired operation.

File and DOS operations are integrated into the development environment with hot-key (or menu selected) entry to edit, assemble and load.

The code pane displays disassembled symbolic source or a full source listing and a cursor to direct operations. SFR and memory operands under the cursor are evaluated and displayed at the top of the pane.

Breakpoints, triggers, trace inhibits and external break points may be hot-key set and cleared at the cursor while remaining visible to the user as background shading of the source.

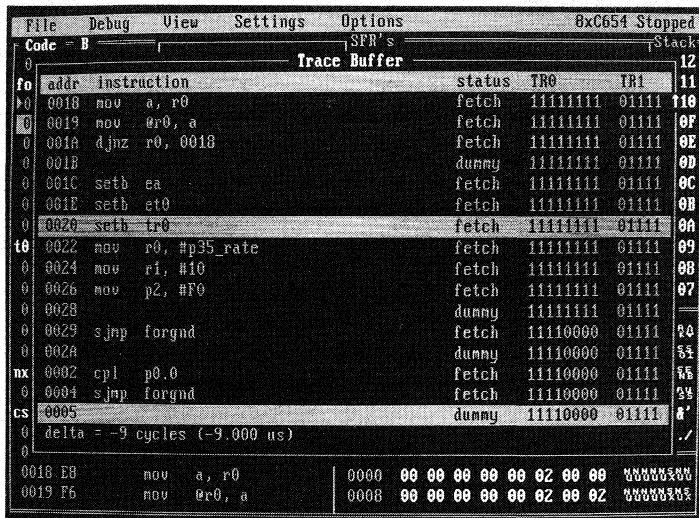

The SFR pane layout, content and display format are user defined and may be edited at any time. Valid display formats include hex, ascii, binary, signed and unsigned decimal.

# Development System for 80C51 and Derivatives

PDS51

Data entry to SFR, internal and external memory may be made in hex, ascii, octal, decimal or binary at user discretion, reinforcing the fast and friendly interface concept.

The huge 28K x 32 bit trace buffer is loaded in real time to provide subsequent viewing of past events. Executed code is presented in symbolic format on a cycle by cycle basis along with 13 user selectable sampled inputs. Trace buffer viewing is aided by a cursor which is execution time referenced to the current program counter. Additional windows offer an execution profiler for identifying hot-spots for subsequent code optimization.

| TERMINAL EMULATION COMMAND SET            |                                                                                        |                               |                                                                                                                |

# Development System for 80C51 and Derivatives

PDS51

## SPECIFICATIONS

### Emulation:

- 64K bytes of code space
- in-circuit emulation via bondout
- no stolen resources

### Trace Memory:

- Real-time sampling
- 28K bytes deep 32 bits wide
- 16 bits address
- 13 bits of port lines or user signals via test clips (sampled S5P1)
- 3 bits of control (C1, inta, movx)
- input filtering on fetch address

### Break Points:

- Hardware based
- up to 64K on fetch address
- up to additional 64K on external signal and fetch address

### User Interfaces:

- (1) Dumb Terminal Emulation (not supplied)  
Command Line Instructions
- (2) Windowed full screen debug environment. Requires:  
PC XT/AT/386/486 or compatible  
MSDOS ver 3.10 or later  
512K bytes RAM or greater  
Monochrome/EGA/VGA Screen interface

### Interface Signals:

- (TTL, 47K pullup terminated)
- FT Force Trace I/P  
override trace input filter
- BP Breakpoint I/P  
external event breakpoint

- Fetch address sensitive  
(Sampled S2P1)
- EM Emulation O/P  
signals Emulation running
- ET External Trigger O/P  
Fetch address controlled  
trigger O/P  
64K resolution (updated S2P1)

### File Format:

Intel Hex, OMF51

### Serial Interface:

- RS232C
- Asynchronous, 8 data, no parity, 1 stop bit
- 9 Pin 'D' connector
- Rxd/Txd pin 2, 3 jumper swapable
- 9.6K/19.2K/38.4K/115.2K Baud jumper selectable
- Xon/Xoff handshaking

### Size:

Motherboard and daughterboard  
130mm x 110mm x 42mm (L.W.H.)

### Speed:

- 3.5 to 12 MHz
- no wait states
- no stolen cycles

### Power Supply:

- 9V nom (6.5 to 9.5V)
- 800mA max, 500mA typ (PDS51 + PDB654)
- 3.5mm Phono Plug centre positive connection

## ORDER CODES

- PDS51 Mother board complete with 64K of Emulation memory. Requires Daughter Board for operation
- PDB654 Daughter Board incorporating 654 bondout. With PDS51 emulates 87C654/652/51 Supplied with 40pin DIL footprint
- PDB52 Daughter Board incorporating 52 bondout. With PDS51 emulates 87C52/51 Supplied with 40pin DIL footprint
- PDB752 Daughter Board incorporating 752 bondout. With PDS51 emulates 87C752/751/750 Supplied with 28pin DIL and 24pin DIL footprints
- PDB528 Daughter Board incorporating 528 bondout. With PDS51 emulates 87C528/524 Supplied with 40pin DIL footprint
- PDB552 Daughter Board incorporating 552 bondout. With PDS51 emulates 87C552 / 562 / 654 / 652 / 51 Supplied with 68pin PLCC footprint and 40pin DIL footprint
- PDA44 Footprint adaptor DIL40 to PLCC44

## 80C51 - I<sup>2</sup>C Bus Evaluation Board

S87C00KSD

The S87C00KSD Evaluation Board is a low cost, stand-alone, board level product, designed for evaluation of the I<sup>2</sup>C Bus and Philips 80C51 derivative microcontrollers. Its modular board layout and modular software make it useful for fast prototyping and as an educational tool.

This attractive board is supplied with an 87C751 (OTP) microcontroller programmed with the demonstration software. Sockets for the 87C752, 87C654/528 and the 87C552 are included on the board. They are provided to facilitate customer development of software for these microcontrollers.

A comprehensive user manual is supplied which includes circuits, layouts, and demonstration source code listing. The user needs only to provide power from a 9V 200mA plug pack or similar DC power supply. A 3.5mm socket for this is provided on the board.

The S87C00KSD has 16 sections demonstrating and displaying 10 I<sup>2</sup>C-bus devices.

## Symbolic debugging package XRAY51 for the SDS 8051 emulator

OM4129

The XRAY<sup>TM</sup>51 package enables the software developer to monitor and control the execution of a target program using the same high-level or assembly-level terms, definitions and structures found in the original source program. It employs a window-oriented user interface which segregates the debugging information into meaningful areas. Two versions of XRAY51, each with identical user interface, are available:

- An emulator version\* using Philips' SDS 8051 emulation hardware as engine
- A simulator version\* using a software engine.

The emulator (debugger) facilitates debugging in real-time on a real target; the simulator supports debugging in an 8051 environment, simulated in software on the host system. Both versions control the execution of the program and allow the user to stop, start, and examine the target software by means of a powerful command language that employs C language expressions.

### XRAY51 HIGH-LEVEL DEBUGGER

The XRAY51 debugger helps to locate programming errors in the source code of C, PL/M or assembly language programs for the 8051 family of microcontrollers. The user can isolate these errors by controlling and monitoring program execution. For example, the user can single-step through the program at a specified number of microcontroller

instructions or high-level language lines. Variables can be accessed with respect to the source language in which they had been defined (i.e., PL/M or Assembly). Operating XRAY51 in Assembly mode, the user can manipulate the contents of all processor registers. Only those registers that are part of the selected 8051 derivative are allowed to be accessed.

Macros may be defined that can execute complex user command procedures and provide a variety of complex breakpoints.

When debugging with XRAY51, the user can examine the contents and modify the value of any variable, compute the value of C, PL/M source language expressions and assembly level address expressions, and define, remove, or display symbols.

Command files can be used to direct XRAY51 to read or write simulated microprocessor input/output from or to a file, allowing easy implementation of automated test sequences. Command files enable scripts of debugger commands to be processed automatically without the need of user interaction.

XRAY51 also allows a virtually unlimited number of user-defined windows.

### FEATURES

The XRAY51 debugger has been designed with the developer of embedded applications in mind. Its principal features are:

- Integrated PL/M-51 source-language and assembly-language debugging; toggle by function key at any time
- Window-oriented display which segregates debugging information into meaningful areas
- Symbolic debugging with C, PL/M-51 variables and C, PL/M-51 statements
- Simple and complex breakpoints
- Single-step execution
- User-definable screens and viewports—ability to write selected information
- Command macros
- Breakpoint macros (limited to the number of breakpoints of the SDS 8051)
- Command breakpoint macros may contain C statements, including: FOR, WHILE, DO, PRINTF, and FPRINTF
- On-line context-sensitive help
- Command files
- Output logging
- Fully supports SDS 8051 with the latest firmware version
- High-level trace
- Transparent ICE mode for direct control of SDS 8051
- Supports most 8051-derived microcontrollers, including the 80C51/31, 87C51, 8XC451/528/552/562/592/652/654/751/851, 8XCL410/710/51 and the 8051/31/52/32.

<sup>TM</sup> XRAY is a trademark of Microtec Research Inc., which holds all intellectual property rights for XRAY51.

\* The SDS 8051 emulator version of XRAY51 is available from Philips Semiconductors (type number OM4129) and is sourced from BSO/Tasking Software B.V., Amersfoort, The Netherlands. The simulator version is available from BSO/Tasking Software B.V.

## COMMANDS

Note, all commands can be issued in an abbreviated form.

### Session Control Commands

|      |                                             |
|------|---------------------------------------------|
| HOST | Enter the host operating system environment |
| LOAD | Load an object module for debugging         |
| QUIT | Terminate a debugging session               |

### Execution and Breakpoint Commands

|                  |                                                        |
|------------------|--------------------------------------------------------|
| BREAKINSTRUCTION | Set an instruction breakpoint                          |
| CLEAR GO         | Clear a breakpoint Start or continue program execution |
| GOSTEP           | Execute macro after each instruction step              |
| STEP             | Execute a specified number of instruction lines        |
| STEPOVER         | Step, but execute through procedures                   |

### Display Commands

|             |                                              |
|-------------|----------------------------------------------|
| DISASSEMBLE | Display disassembled memory (assembly mode)  |
| DUMP        | Display memory contents                      |
| EXPAND      | Display all local variables of a procedure   |
| FIND        | Search for a string                          |
| FOPEN       | Open a file or device for writing            |
| FPRINTF     | Print formatted output to a viewport or file |
| LIST        | Display source code                          |
| MONITOR     | Monitor variables                            |
| NEXT        | Find next occurrence of a string             |
| NOMONITOR   | Discontinue monitoring variables             |
| PRINTF      | Print formatted output to command viewport   |
| PRINTVALUE  | Print the value of a variable                |

### Memory Commands

|         |                                   |
|---------|-----------------------------------|
| COMPARE | Compare two blocks of memory      |
| COPY    | Copy a memory block               |
| FILL    | Fill a memory block with values   |
| SEARCH  | Search a memory block for a value |
| SETMEM  | Change the values of              |

|        |                                        |
|--------|----------------------------------------|
| SETREG | Change the contents of a register      |
| TEST   | Examine memory area for invalid values |

### Port I/O and Interrupt Commands

|             |                                                |
|-------------|------------------------------------------------|
| DIN         | Display input port buffer values               |
| DOUT        | Display output port buffer values              |
| INPORT      | Set or alter input port status                 |
| INTERRUPT   | Simulate an interrupt                          |
| NOINTERRUPT | Cancel pending interrupts                      |
| OUTPORT     | Set or alter output port status                |
| RIN         | Rewind input file associated with input port   |
| ROUT        | Rewind output file associated with output port |

### Symbol Commands

|              |                                            |
|--------------|--------------------------------------------|
| ADD          | Create a symbol                            |
| DELETE       | Delete a symbol from the symbol table      |
| PRINTSYMBOLS | Display symbol, type, and address          |
| SCOPE        | Specify current module and procedure scope |

### Utility Commands

|             |                                                         |
|-------------|---------------------------------------------------------|
| CEXPRESSION | Calculate the value of an expression                    |
| ERROR       | Set include-file error handling                         |
| HELP        | Display On-line help screen                             |
| INCLUDE     | Read in and process a command file                      |
| JOURNAL     | Record a debugger session in a file                     |
| LOG         | Record debugger commands and errors in a file           |
| MODE        | Select debugger mode (high or assembly)                 |
| OPTION      | Set debugger options for this session                   |
| PAUSE       | Pause simulation                                        |
| RESET       | Simulate microprocessor reset                           |
| RESTART     | Restart program counter to the program starting address |
| STARTUP     | Save the default start-up options                       |

### Macro Commands

|        |                          |
|--------|--------------------------|
| DEFINE | Create a macro           |
| SHOW   | Display the macro source |

### Viewport Commands

|         |                                             |
|---------|---------------------------------------------|
| VACTIVE | Activate a viewport                         |
| VCLEAR  | Clear data from a viewport                  |
| VCLOSE  | Remove a user-defined viewport or screen    |
| VMACRO  | Attach a macro to a viewport                |
| VOPEN   | Create a screen or viewport or change sizes |
| VSCREEN | Activate a screen                           |
| VSETC   | Set the cursor position for a viewport      |
| ZOOM    | Increase or decrease the size of a viewport |

### Function Key Commands

|           |                                                |
|-----------|------------------------------------------------|
| VACTIVE-1 | Activate the next viewport (counter clockwise) |
| VACTIVE+1 | Activate the next viewport (clockwise)         |
| MODE      | Change debugging mode (assembly/high)          |
| ZOOM      | Increase or decrease the size of a viewport    |
| HELP      | Access on-line help                            |
| VSCREEN   | Change the active screen                       |
| BACK UP   | Back up one command                            |
| STEP      | Execute one machine instruction or source line |
| STEP OVER | Step, but execute through procedures           |

### In-Circuit Emulator Commands

|       |                                            |
|-------|--------------------------------------------|
| ICE   | Communicate with in-circuit emulator (ICE) |
| NOICE | Return to debugger command mode            |

### RESTRICTIONS

- Up to 4 instruction breakpoints are allowed simultaneously.
- When an instruction has a breakpoint set, control is returned to XRAY *after* this instruction has been executed. However, the information about the break address returned is correct, so user actions (like macros) are executed as expected.
- In the current release, the TRACE capability of the SDS 8051 is supported by means of the ICE/NOICE command. The SDS 8051 TRACE information can be recorded in a journal file, by means of the JOURNAL command. The next release of XRAY51 will support emulator tracing within the debugger.

# Symbolic debugging package XRAY51 for the SDS 8051 emulator

OM4129

## HARDWARE/SOFTWARE REQUIREMENTS

XRAY51 software is supplied on 5 1/4" diskettes (3 1/2" diskettes are available on request) together with the documentation: the *XRAY51 User's Guide*, *XRAY51 Installation Guide* and the *XRAY51 Reference Manual*. XRAY51 will run on an MS-DOS computer equipped with a hard disk and at least 512kbyte RAM.

To work with XRAY51, you will also need:

- An ASM51 Intel-compatible relocatable cross-assembler and LINK51 Intel-compatible linking loader (version 1.0 or later).

If you want to use the high-level language capabilities of XRAY51, the following PL/M-51 compiler is required:

- PLMT151 (version 2.0 or later) with the ASM51 assembler

These products can be ordered from Philips Semiconductors. See Ordering Information.

Contact your local Philips representative for specific enquiries. Ask for the following leaflets:

*Stand-alone debug station for 80C51/8051-based systems*, ordering code 9398 366 00011;

*PL/M-51 compiler package for 80C51/8051-based systems*, ordering code 9398 366 20011;

*Cross-assembler package for 80C51/8051-based systems*, ordering code 9393 366 30011.

## SOFTWARE MAINTENANCE AND SUPPORT

After a 90-day warranty period, in which all support will be given free of charge, a software update and support agreement can be taken out with Philips for a modest annual fee. Philips realizes your need for fast and comprehensive support, and with a support license, you get direct access to a development team that can solve your problems.

## ORDERING INFORMATION

| TYPE NUMBER             | DESCRIPTION                                                                   |
|-------------------------|-------------------------------------------------------------------------------|
| OM4129                  | XRAY51 high-level language debugger for the SDS 8051; MS-DOS                  |
| <b>Related Products</b> |                                                                               |
| OM4142                  | Cross-assembler package comprising the ASM51 assembler, and the LINK51 linker |
| OM4144                  | Compiler package comprising the PLMT11                                        |

Orders can be placed via your local Philips Semiconductors sales representative. May be purchased from BSO Tasking, Tel. (800)458-8276 or (617)320-9400.

## 8051 C cross-compiler

OM4136

## INTRODUCTION

The BSO/Tasking C-51 cross-compiler (OM4136) offers a new approach to high-level language programming for the 8051 family. It is a very powerful combination of our extensive 8051 knowledge and our ANSI compliant C compilers. The result of this combination is a compiler that is fast, efficient and supports all the members of the 8051 family.

## FEATURES

- Supports:
  - Full ANSI Standard
  - All members of the 8051 family
  - Reentrant programming
  - Extremely efficient and powerful pointer arithmetic
  - Inline assembly programming
  - Inline expansion of predefined functions (`_rol`, `_ror`, etc.)
  - Full Intel OMF51 and IEEE695 version 4.0 object formats
  - Data overlay mechanism
  - Full calling interface (with parameter passing) to BSO/Tasking PL/M-51 (OM4144)
  - Fast 8-bit *char* arithmetics
  - C-level access to chips' SFRs
  - C-level bit-type and interrupt
- Generates Intel-compatible assembly source
- Outputs symbolic information for source level debugging using XRAY51
- Produces very efficient, fast executing and reliable code
- Code is ROMable
- Supports 4 memory models to best meet application requirements
- Separate compilation of program modules
- Embodies integral standard preprocessor
- Is one-pass, fast and compact (no intermediate code or files)
- 3-layer design simplifies maintenance
- Complete set of UNIX-like compiler options
- Comes with C library and run-time support, including I/O calls (+ *printf*), memory management, floating point, math and arithmetic functions
- C libraries in source code included for learning and tuning purposes
- The OM4136 product is for IBM PC DOS as host. From BSO/Tasking, the

C-compiler is also available on the hosts: (micro)VAX (VMS or Ultrix), IBM PC (Xenix), IBM PS/2 (OS/2, AIX), IBM RISC System/6000, SUN-3/-4 (SUN-OS), HP9000/300 (HP-UX) and Apollo (UNIX)

- Generates reentrant and relocatable code and relocatable data
- Same calling sequence on all hosts
- Same source and generated assembly code can be used on all hosts
- Automatic installation and self test
- Benchmarks and application notes are available on request

## C LANGUAGE

Although intended as a general purpose high-level programming language, C is perhaps most powerful in the area of real-time system programming for embedded microcontrollers.

ANSI C features economy of expression, is well defined, has an improved type checking, supports structured and modular programming and has a rich set of data- and operator-types that map to virtually every single address space microcontroller/processor. Since the operators and type definitions generally match well with the instruction sets and word lengths of most microcontrollers, C is very efficient in terms of code size and execution speed.

## COMPILER TECHNOLOGY

The 8051 C compiler was built using the latest compiler technology, including optimization and multi-layering. It is essentially a one pass compiler, translating on a function-by-function basis, achieving very fast compilation and a large span for the optimization process. A significant effort was made to obtain a well-defined, layered product.

The top layer basically consists of a lexical and grammar analyzer with co-routine structures to serve both the pre-processing and compilation needs. The grammar analyzer is produced by an LALR(1) parser generator, eliminating a potential source of error.

A second layer separates the actual code generation layer from the top layer and is merely intended to simplify re-targeting of the compiler to other target processors. It was designed to represent the translated program independent from the language and the target. This is where most of the optimizations are done.

The code-generation layer is driven both by the second layer and by a set of tables and rules reflecting the target assembly language and the behavior of individual instructions.

## IMPLEMENTATION DEPENDENT DATA

This section outlines features of the C-51 compiler which, for the most part, are specific to the 8051 family of microcontrollers.

## Compiler Options

The following options are supported:

- a specify function parameter size
- b specify default register bank number
- C specify 8051 derivative type
- D define named identifier to the preprocessor
- E only run the preprocessor
- f read command line options from file
- g generate high-level debugging information for XRAY51 hll-debugger
- I force preprocessor to look for include files in the specified directory
- m specify memory sizes for static allocation checking
- M select memory model
- n write output to screen instead of output file
- o write output to named output file
- O controlled optimization
- r specify ROM size for optimal jump-type generation
- R control segment assignment
- s merge C source with generated assembly code
- S put strings in ROM only
- t do not produce module summary information
- U remove any initial definition of named identifier
- v do not generate code for interrupt vectors
- w suppress warning messages

## Data Sizes

| Type                        | Size (in bytes)           |
|-----------------------------|---------------------------|
| <i>bit</i>                  | 1 bit                     |
| <i>char</i>                 | 1                         |
| <i>short int</i>            | 2                         |
| <i>int</i>                  | 2                         |
| <i>long int</i>             | 4                         |
| <i>float, (long) double</i> | 4 (IEEE single precision) |
| pointer type                | 1 or 2*                   |

\*NOTE: Pointers to *data*, *idata* and *pdata* have a size of 1, whereas pointers to *rom*, *xdata* and functions have a size of 2.

## 8051 C cross-compiler

OM4136

**Code Optimization**

The compiler intermediate layer performs general code-optimization and the code-generator does some final optimizations that are specific to the 8051.

**General Optimizations:**

- Register allocation
- Branch optimization
- Dead code elimination
- Constant folding
- Arithmetic simplification

**Code Generator Optimizations:**

- Store-copy optimization
- Peephole optimization

**Adaptation to Target Environment**

Cross-compilers are used to develop embedded microcontroller applications, where the hardware environment in which they will run is not fixed in advance. The 8051 compiler allows flexible adaptation to different target environments:

- The compiler supports 4 different memory models. This allows the compiler to generate the best possible code for a particular hardware implementation.
- Interrupt service routines can be written in C or assembly (through special controls)

- Generated code is ROMable
- 8051 derivative is switch selectable
- User-controlled mapping of code and data

**Pragmas**

The *#pragma* directive is intended to supply target dependent data to the compiler, without violating the C language. In C-51, pragmas are used to merge C lines with generated assembly, to control code generation for interrupt service routines and to support inline assembly programming.

**LIMITATIONS**

The use of several C constructs is restricted to a maximum number, as proposed by ANSI. Both the preprocessor and compiler meet these 'environmental requirements of a conforming implementation'. As an additional constraint however, the number of statements in a function body is restricted to approximately 1800.

**DOCUMENTATION**

The compiler is shipped with the 8051 C Compiler User Manual.

Additional information about the C language can be found in "The C Programming Language" (second edition), by B. Kerighan and D Ritchie (1988, Prentice Hall).

**RELATED PRODUCTS**

The C51 compiler (OM4136) is part of a complete programming and development package for the 8051 family of microcontrollers. This incorporates a HLL debugger, XRAY-51 (OM4129) in combination with Philips' SDS-8051 emulator, PL/M-51 compiler (OM4144), cross-assembler and (optimizing) linker (OM4142), all available from Philips Semiconductors.

**SOFTWARE MAINTENANCE AND SUPPORT**

After a 90 days warranty period, in which all support will be given free of charge, a software support contract is available from BSO/Tasking at a modest annual fee. BSO/Tasking realizes the need for fast and thorough support in this complex area where a lot of time may be wasted before a (afterwards simple) problem is isolated and/or tackled. With a support license, you can use BSO/Tasking resources to solve your problem. You will get a direct access to experienced engineers. Furthermore, you receive (free of charge) the periodical *BSO/Tasking Newsletter*, regarding revisions, hints and documentation corrections.

**Memory Models**

| MODEL            | DATA ALLOCATION                                           | APPLICATION                                       |
|------------------|-----------------------------------------------------------|---------------------------------------------------|
| <i>small</i>     | static, in on-chip direct addressable RAM ( <i>data</i> ) | fast programs in small environments               |
| <i>auxpage</i>   | static, in first page of external RAM ( <i>pda</i> )      | derivatives with 256 bytes on-chip "external" RAM |
| <i>large</i>     | static, in external RAM ( <i>xda</i> )                    | fast, non reentrant with large external RAM       |
| <i>reentrant</i> | dynamic + static, in external RAM ( <i>xda</i> )          | large, reentrant programs in large environments   |

**ORDERING INFORMATION**

| TYPE NUMBER             | DESCRIPTION                                          |

## Cross-assembler package for 80C51/8051-based systems

OM4142 (ASM51)

This package comprises the cross-assembler for translating 8051 assembly language programs into relocatable object code:

- The ASM51\* macroassembler which accepts Intel-compatible assembler source programs and produces relocatable '...OBJ' object files. An absolute or executable 'A.OUT' load-image is obtained using the LINK51 linker.

The absolute object file can be modified to IEEE format to serve as input to the XRAY51 debugger.

### FEATURES

- Produces relocatable object code, listing files and diagnostic messages
- Accepts Intel-compatible source programs (ASM51)
- Supports most 8051-derived microcontrollers including the 80C51/31, 87C51, 8XC451/528/552/562/592/652/654/751/851, 8XCL410/710 and the 8051/31/52/32.
- Compatible with PL/M-51 compilers
- Conversion to IEEE object code format
- Compatible with XRAY51 High-Level/Assembly-Level Debugger
- Includes many utilities such as, Librarian, Cross-reference generator, object code-convertors
- Supports segment overlay at the Assembly level
- C and MPL (Macro Programming Language) compatible macro preprocessors included
- Separate linking phase.

### OPERATION

The input to both assemblers usually comes from a preprocessor which interprets preprocessor directives in the source program to deal with file inclusion, macro definition and replacement, conditional text inclusion, etc. Two preprocessors are available as separate programs, allowing the programmer to use either the C preprocessor directives or Intel's Macro Programming Language, or even a mixture of both.

The output may then be assembled using the ASM51. Depending on the selected member of the 8051 family, the ASM51 assembler enables or disables the names of special function registers that are applicable. For the ASM51, this is easily solved by target-dependent inclusion of a specific equate list in the source file.

The assembler translates a source program into relocatable object code using three different passes. The program syntax, assembler directives and user-defined symbols are checked and processed during the first pass. In the second pass, all generic forward jumps and calls are optimized. In the third pass, relocatable code is generated.

To obtain a single executable load image, all necessary relocatable objects, including library modules, are linked together using the proper linker (i.e., LINK51). This executable load image may then be converted to an ASCII file that may be downloaded into an EPROM programmer or an emulator.

The assembler is capable of generating symbolic debug information to accommodate information for the XRAY debugger.

### ASSEMBLER LIMITATIONS

The number of user-defined symbols and macro parameters is limited only by the available heap space. Save/restore nesting is restricted to 16 levels.

### DIFFERENCES BETWEEN PHILIPS' ASM51\* AND INTEL'S ASM51

Unlike Intel's ASM51, which restricts the use of register equates to the A and R0-R7 registers, Philips' ASM51 puts no constraints on register name assignment. And it can optimize generic JMP and CALL instructions, even when they contain a forward reference. In such cases, Intel's ASM51 will always produce code for a LJMP and LCALL, which takes 50% more code.

Philips' ASM51 supports four new directives that are not available in the Intel ASM51:

- \$listall generate a listfile in every pass (not only in the final one). This improves diagnostics.
- \$(no)-optimize enable (default) or disable generic JMP/CALL optimization.
- \$debuginfo control symbolic debug information generation.

Since the \$gen, \$genonly, \$nogen, \$include and \$macro directives are already dealt with during the preprocessing stage, these can be ignored by Philips' ASM51.

Similarly, \$(no)-xref and \$(no)-symbols directives are ignored—report utilities are

available to accomplish the same task. And the \$workfiles is no longer useful and is ignored too.

Philips' ASM51 recognizes ?SYMB, ?LINE and ?FILE symbols that are used to pass debug information towards the object module. Philips' ASM51 recognizes the C-like #line directive to adjust the line number and file name. This directive is generated by both preprocessors to synchronize the output line with the original input. This improves the error diagnostics of Philips' ASM51 compared with those of its competitors, since error messages now refer to the proper (include) file and line number.

A powerful addition is the overlay() which gives the programmer full control of the section overlay strategy.

### UTILITY PACKAGE

Several utility programs are included for your convenience. Amongst these are a C preprocessor (cpp) and an Intel MPL-compatible preprocessor (mpl) to deal with the various preprocessor directives and macros.

In many cases, the format of the object code produced is not suitable for EPROM-programmers, emulators or debuggers. Therefore, several utilities are included to convert the code to Intel HEX (oct\_ihex), Motorola SO-S9 (oct\_srec) or IEEE-695 (oct\_ieee) or vice-versa (ocf\_ihex, ocf\_srec).

An optional utility package is available separately from Tasking Software B.V. It contains UNIX-like utilities to obtain a (cross-reference) list of all user-defined symbols in a program ('axref' and 'anm'), and the 'asize' utility to get information about the section sizes.

### HARDWARE/SOFTWARE REQUIREMENTS AND INSTALLATION

OM4142 software comes to you on 5<sup>1/4</sup>" diskettes (3<sup>1/2</sup>" diskettes are available on request) together with extensive documentation, including two Assembler Reference Guides, Preprocessor Manuals, Utility and Installation Guide. The software requires an MS-DOS computer with a hard disk and at least 512k byte RAM installed. Software installation is simple, well-documented and can be verified afterwards using an automatic verification program.

\* Sourced from BSO/Tasking Software B.V., Amersfoort, The Netherlands, which holds all intellectual property rights for this software.

## Cross-assembler package for 80C51/8051-based systems

OM4142 (ASM51)

### RELATED PRODUCTS

The OM4142 assembler is part of a complete programming and development package for the 8051 family of microcontrollers. For both assemblers, there is an excellent PL/M-51 compiler available from Philips offering the convenience and benefits of high-level language programming, resulting in a dramatic increase of programmer productivity. Testing and debugging can be accelerated using the High-Level/Assembly-Level XRAY51 debugger. Contact your local Philips Semiconductors software sales office for more information. Ask for the following leaflets:

*Symbolic debugging package XRAY51 for the SDS 8051 emulator*, ordering code 9398 366 10011;

*PL/M-51 compiler package for 80C51/8051-based systems*, ordering code 9398 366 20011;

*Stand-alone debug station for 80C51/8051-based systems*, ordering code 9398 366 00011.

### SOFTWARE MAINTENANCE AND SUPPORT

After a 90-day warranty period, in which all support will be given free of charge, a software update and support agreement can

be taken out with Philips for a modest annual fee. Philips realizes your need for fast and comprehensive support, and with a support license, you get direct access to a development team that can solve your problems.

## PL/M-51 compiler package for 80C51/8051-based systems

OM4144 (PLMTI51)

This package comprises the cross-compiler (PLMTI51\*) which efficiently translates programs written in the PL/M-51 language into 8051 Assembly. The PLMTI51 generates Intel-compatible source, which can be assembled and linked using Philips' ASM51 and LINK51 programs.

This compiler embodies the latest techniques. It is built upon a YACC-based parser. Intermediate code is built using tree structures that are optimized into new trees by the compiler before code-generation starts. An internal peephole optimizer further improves the density of the generated code.

It can be ordered under the Philips' type number OM4144.

### FEATURES

- State-of-the-art compiler: fast, single-pass, memory-based
- Fully compatible with the Intel PL/M-51 language definition
- Fully compatible with Philips' ASM51/LINK51 cross-assembler and linker
- Produces highly optimized code
- Supports most 8051-derived microcontrollers, including the 80C51/31, 87C51, 8XC451/528/552/562/592/652/654/751/851, 8XCL410/710/51 and the 8051/31/52/32
- Both compilers support the XRAY51 high-level language debugger, available from Philips
- Supports in-line assembly code
- Optional IEEE single-precision floating point package
- Includes several utility programs: pr, grep, aar, cpp, scf\_i51, ocf\_o51, ocf\_ihex, ocf\_ieee, ocf\_srec, ocf\_ihex, ocf\_srec, makelib and pack
- Utility library included in source code
- Combiner performs optimization at load-file level (Philips' ASM51 only)
- Easy tailoring to application and target hardware
- Produces relocatable code and data
- Available for many hosts besides the IBM PC (MS-DOS), for example: (micro-)VAX, (VMS, Ultrix), HP9000/300 (HP-UX), SUN-3 (Sun-OS); available from BSO/Tasking Software B.V.
- Supports optimize(4): intermodule overlay optimization
- Supports 15 interrupts

- Automatic installation with self-test
- Benchmarks available on request

### PL/M-51

PL/M-51 is a structured, high-level programming language derived from the Intel PL/M-80 language and adapted to the specific capabilities of the 8051 family of single-chip microcontrollers. It supports Boolean processing and allows efficient access to all microcontroller hardware functions.

Software development in PL/M-51 combines the ease of programming in a high-level language with access to all of the 8051 I/O and memory—features that are normally only available to assembly language programmers.

The Philips' implementation of PL/M-51 is an extremely fast single-pass optimizing compiler that is fully compatible with the Intel PL/M-51 language definition.

### IMPLEMENTATION-DEPENDENT DATA

#### Data Types

- Data types BIT, BYTE and WORD are allowed for variables, arrays, structures or combinations thereof.
- Memory types MAIN, IDATA, REGISTER, AUXILIARY and CONSTANT are supported.
- Data can be stored at fixed locations using AT, or stored dynamically using BASED pointer variables.

#### Procedures

- BIT, BYTE or WORD typed procedures, returning a value upon completion
- Untyped procedures, invoked with a CALL statement
- Optional procedure attributes:
  - USING(n), specifies the register bank (n) to be used by the procedure.
  - INTERRUPT(n), defines an interrupt procedure for interrupt (n).

#### Statements

- Control statements: do while ... end, do ... to ... by ... end
- Conditional statements: if ... then ... else ...
- Miscellaneous statements: do ... end, do case ... end, call, goto, enable/disable

### Library Routines

#### Internal (Built-in) Procedures:

|        |           |
|--------|-----------|
| LENGTH | PROPAGATE |
| WORD   | ROL       |
| EXPAND | SCR       |
| SHR    | SIZE      |
| SCL    | BOOLEAN   |
| TIME   | SHL       |
| LAST   | ROR       |
| DOUBLE | TESTCLEAR |

#### PLM51.LIB:

Library routines used by the compiler.

#### UTIL51.LIB or util51.oa, util51:

Assembler utility libraries for both compiler versions, consisting of procedures for string manipulation. It contains the routines MOV, RMV, CMP, FNDB, FNDW, SKPB, SKPW, SETB and SETW for each memory type and for each register bank.

### Re-entrancy

The generated code is not re-entrant, because PL/M-51 is not defined as a language with re-entrant procedures. Because of the limited size of internal RAM, the local and formal parameters of procedures are not put on the stack, but on static areas, which can be overlaid by the compiler using \$OPTIMIZE(3).

### Compiler Controls

ROM(s), REGISTERBANK(n), OPTIMIZE(n), (NO)INTVECTOR, (END)ASM, INCLUDE, SAVE/RESTORE, (NO)LIST, (NO)SOURCE, (NO)CODE, (NO)DEBUG, (NO)OBJECT, SET/RESET, EJECT and IF/ELSF/ELSE/ENDIF

### Differences Between Philips' and Intel's PL/M-51

- Philips' PL/M-51 allows bit-structures to be ATed at byte-variables in bit-addressable memory
- Philips' PL/M-51 supports floating point
- Invocation and compiler controls are mostly different
- Object modules are not generated
- Error messages are mostly different
- Different assembly language interfacing (only for Philips' plm51)
- Compiler limits always the same or better than Intel's

\* Sourced from BSO/Tasking Software B.V., Amersfoort, The Netherlands, which holds all intellectual property rights for this software.

## PL/M-51 compiler package for 80C51/8051-based systems

OM4144 (PLMTI51)

### Code Optimization

Five levels of optimization are supported:

- Level 0: performs folding of constant expressions and of address calculations, in case a constant offset exists.
- Level 1: performs all of level 0 plus elimination of unreachable code, strength reduction of expressions and partial condition evaluation at runtime.
- Level 2: performs all of levels 0 and 1 plus machine code (peephole) optimizations and register history.
- Level 3: performs all of levels 0, 1, and 2 plus automatic overlaying of on-chip RAM variables.
- Level 4: performs all of the other levels plus support of intermodule overlay of on-chip data.

### General Optimizations

- Store-copy optimization
- Local constant propagation
- Register allocation
- Peephole optimization
- Dead code elimination
- Constant folding
- Index simplification

### Object-code Optimizations

- Branch optimization (sjmp, ajmp, ljmp, acall, lcall)
- Effective address optimization

### 8051-Specific Optimizations

- Optimal use of the range of address modes of the 8051 family
- Overlay of local data and formal parameters done by \$OPTIMIZE(3)/(4)

### Easy Adaptation to Target Environment

Cross-compilers are used to develop embedded microprocessor applications, where the hardware environment in which they will run is not fixed beforehand. Adaptation to the target hardware environment takes place via the files headx. These files are used to define all system-dependent set-ups such as the

power-on-restart vector, the initial stackpointer value, the definitions of segments needed by the PL/M-51 code and the mapping of those segments to the physical addresses. The files can be modified by the user to match his specific needs.

The PL/M-51 cross-compiler can accommodate different target environments, because:

- The location of the stack is held in a special target set-up file (head\_xx file) which can be changed to match your requirements
- This target set-up file also allows general housekeeping tasks to be executed before program start-up
- Simple interfacing to target operating systems and low-level I/O and system routines
- Code and data segments can be placed anywhere in the 64kbyte data and address space of the 8051 processor
- Efficient calls to library routines can be in PL/M or assembler (in-line)
- A user-written interrupt handler can be made by specifying \$NOINTVECTOR
- The generated code is ROMable.

### Restrictions

The PL/M-51 compiler has a few restrictions listed here for completeness:

- Nesting of all LITERALLY invocations: 8
- Nesting of INCLUDE controls: 8
- Nesting of blocks: 32
- Number of elements in a factored list: no limit
- Number of characters in an input line: 160
- Number of switch names (conditional compilation): 20
- Length of a string constant: 254
- Number of cases in a DO CASE block: 84
- Number of EXTERNAL items: no limit
- Number of non-EXTERNAL procedures in module: no limit
- Number of names in a module: memory dependent

### UTILITY PACKAGE

Several utility programs are included for your convenience. Amongst these are a C preprocessor (cpp), an Intel MPL compatible preprocessor (mpl)—both part of the 8051 Cross-Assembler—to deal with the various preprocessor directives and macros. Pagination and pattern search commands 'pr' and 'grep' come with the PL/M-51 compiler package.

In many cases, the format of the produced object code is not suitable for EPROM-programmers, emulators or debuggers. Therefore, several utilities are included (in the 8051 cross-assembler) to convert the code to Intel HEX (oct\_ihex), Motorola S0-S9 (oct\_srec) or IEEE-695 (oct\_ieee) or vice-versa (oct\_ihex, ocf\_srec) or to archive object modules (aar).

### OPTIONAL SOFTWARE

An optional utility package is available separately from BSO/Tasking Software B.V. It contains UNIX-like utilities to obtain a (cross-reference) list of all user-defined symbols in a program ('axref' and 'anm'). Part of this package is the 'asize' utility to get information about the section sizes, 'asort' to sort or merge files, 'astrip' to remove symbols and relocation information, 'adump' to display the contents of an object file.

Also available is an IEEE floating-point library for the 8051 family.

### HARDWARE/SOFTWARE REQUIREMENTS AND INSTALLATION

OM4144 software comes to you on 5<sup>1/4</sup>" diskettes (3<sup>1/2</sup>" diskettes are available on request) together with the extensive *PL/M-51 Application Manual*.

The software requires an MS-DOS (Rel. 3.0 or higher) computer with a hard disk and at least 512kbyte RAM installed. Software installation is simple, well-documented and can be verified afterwards using an automatic verification program.

## PL/M-51 compiler package for 80C51/8051-based systems

OM4144 (PLMTI51)

### RELATED PRODUCTS

The OM4144 compilers are part of a complete programming and development package for the 8051 family of microcontrollers, a package which includes a cross-assembler and (optimizing) linker. Testing and debugging can be accelerated using the high-level/assembly-level XRAY-51 debugger in combination with Philips' SDS 8051 emulator, or the 8051 Simulator (available from Tasking software B.V.). Contact your local Philips Semiconductors sales office for more information.

Ask for the following leaflets:

*Symbolic debugging package XRAY51 for the SDS 8051 emulator*, ordering code 9398 366 10011;

*Cross-assembler package for 80C51/8051-based systems*, ordering code 9398 366 30011;

*Stand-alone debug station for 80C51/8051-based systems*, ordering code 9398 366 00011.

More information about the PL/M-51 Language can be found in the *PL/M-51 User's Guide*, available from Intel (ordering code: 121966-003).

### SOFTWARE MAINTENANCE AND SUPPORT

After a 90-day warranty period, in which all support will be given free of charge, a

software update and support agreement can be taken out with Philips for a modest annual fee. Philips realizes your need for fast and comprehensive support, and with a support license, you get direct access to a development team that can solve your problems.

## Stand-alone debug station for 80C51/8051-based systems

## SDS 8051

### THREE CONFIGURATIONS TO SUIT YOUR 8051 PROJECTS

For efficient, accurate software and hardware development and integration, there is no substitute for fully transparent, real-time emulation. But development must be cost-effective, and the key to that is to have *one* emulation unit which can fit exactly into *all* your development projects irrespective of their scope and stage of development.

If you are developing with the 8051 family, such a unit is the SDS 8051.\* Three configurations suit all your projects without requiring modifications or extras:

#### Stand-Alone Operation

A VDU Terminal is all that is needed to integrate and debug with the SDS 8051. And because you can do basic emulation without putting demands on computer resources, the smallest user as well as the big development team can take advantage of the SDS 8051.

#### Connection to a Host Computer

Most development tasks will, however, need the power of a host computer or Microcomputer Development System, and Philips' SDS (Stand-alone Debugging Station) can work with both. The process of writing the software and designing the hardware can be done on the computer, with an SDS used to debug and integrate the software with the hardware. SDS 8051 supports a wide range of hosts. It has its own in-line assembler in firmware, but you may also use the separate MS-DOS cross-assembler.

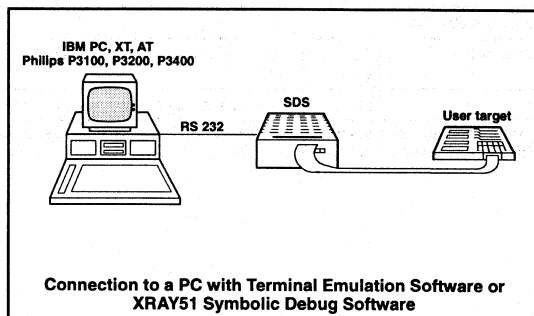

#### Connection to a PC

The SDS 8051 operates with an IBM PC or XT, or compatible, e.g., Philips P3100 series, so you can use it in your usual work environment. The SDS can be operated from a PC using readily available terminal emulation software, or the XRAY™51 symbolic debugging package, the latter allowing you to use your own source labels on screen in SDS displays and commands, and having a DOS toggle switch.

If you work in a development team, shared access to files and programs is of course essential to maximize productivity. Programs can be downloaded from any host computer to the SDS memory, using a PC or terminal as a workstation to operate the SDS.

#### FEATURES

- Real-time, fully transparent emulation
- Works stand-alone from a VDU terminal, PC or other computer
- Full hardware emulation using a dedicated probe—operates according to the exact specifications of the target microcontroller, including maximum speed
- Interfacing signals to external equipment
- Full assembly-level debugging and HLL debugging
- Single-step and breakpoint facilities
- Large trace memory with hardware qualifiers

\*SDS 8051: Generic name for Philips Stand-alone Debugging Station for the 8051 family of microcontrollers; for type numbers, see Ordering Information. The 8051 family includes the 80C51/31, 87C51, 80CL51, 8XC053/054/451/528/550/552/562/592/652/654/751/752/851, the 8XCL410/710 and the 8051/31/52/32. Debugging stations are also available for Philips 8400 microcontroller family and the 5010/5011 digital signal processors.

## Stand-alone debug station for 80C51/8051-based systems

SDS 8051

### UNEQUALLED EMULATION

SDS 8051 provides complete, high-quality emulation for development with the 8051 family of microcontrollers. Standard features include:

### Fully Transparent Real-Time Emulation

You can develop on the SDS 8051 with the chip running in real time—no stretched clock cycles or wait states to disrupt system timing in the prototype. And emulation is fully transparent—since no resources from the 8051 memory, I/O or interrupt space are used for monitoring emulation, all are available to the target and user program.

### In-Circuit Emulation or Simulation

The SDS 8051 is versatile—you can tailor operation to suit the state of the prototype. If no prototype hardware is available, the SDS may be used for simulation, so the software can still be tested. The emulation mode runs the program in the prototype so far as it has been developed, with resources transferred in stages to the prototype. Hardware, software and their integration are fully tested.

### Full Real-Time Hardware Emulation and Breakpoint Setting

The SDS 8051 has an 80C51 (or derivative) bond-out chip in the emulation probe. This, and only this, can ensure that hardware emulation is truly real-time, and it also allows you to set hardware breakpoints. These can be set on any combination of addresses, register values or branch instructions,

allowing you to investigate program flow in detail and to debug very quickly. When a breakpoint condition is met, the entire CPU is frozen and, besides the full interrupt status, the status of all timers (frozen by a special bond-out chip feature) is displayed.

### Alterable Memory and Processor Registers

For really quick fault-finding, the SDS allows you to alter, and to display, memory and CPU register values as required, allowing parts of the program to be repeatedly tested using convenient values.

In addition, the SDS has an emulator-resident in-line assembler which is particularly useful when changing your program—there being no need for repeated up-loading and down-loading.

### Disassembly

Of course, there is no need to remember binary code references when developing software with the SDS 8051—instructions are entered in assembly language. In addition, on-board memory can be disassembled into the originally programmed instruction mnemonics.

### Trace Memory

SDS 8051 has a 2048-line trace memory for quick checking of the program flow. The display shows the address, opcode/operand, disassembly, instruction status (such as RD OPC, WR) and the contents of microcontroller ports and/or eight user test clips.

### Hardware Qualifier Bits

The trace memory has qualifier bits for selecting the information to be captured in the trace memory. These bits enable cycles to be selected, for example, capture only on fetches from emulation memory, or on interrupt acknowledge cycles. Selecting the information before capture overcomes the drawback of software qualifiers which select the information afterwards, relying on luck for it to be in the trace memory!

### Debugger Commands

The microprocessor development command language employed by the SDS 8051 has been designed for ease of use. Commands form a subset of, and are similar to, the widely used ICE™ language.

When the XRAY51 symbolic debugging package is used, the commands are the XRAY commands. These and the SDS commands are listed below (at the end of this description).

### Software Packages

The XRAY51 high-level debugger, and cross-assemblers and cross-compilers for the SDS 8051 are described on the next page. Each package supports most 8051-derived microcontrollers including the 80C51, 83C053, 83C054, 80C451, 80C528, 80C550, 80C552, 80C562, 80C592, 80C652, 80C654, 83C751, 83C752, 80C851, 80C852, and 8XCL410/710.

### TYPICAL EMULATION PROBE

## Stand-alone debug station for 80C51/8051-based systems

SDS 8051

### SYMBOLIC DEBUGGING PACKAGE (XRAY51)

The XRAY51 debugger helps to locate programming errors in the source code of C, PL/M or assembly language programs for the 8051 family. With XRAY51, the user can isolate these errors by controlling and monitoring program execution using the same high-level or assembly level terms, definitions and structures found in the original source program. For example, the user can single-step through the program a specified number of microcontroller instructions or high-level language lines. Variables can be accessed with respect to the source language in which they had been defined. Operating XRAY51 in Assembly mode, the user can manipulate the contents of all processor registers. Only those registers that are part of the selected 8051 derivative are allowed to be accessed.

Macros may be defined that can execute complex user command procedures and provide a variety of complex breakpoints.

When debugging with XRAY51, the user can examine the contents and modify the value of

any variable, compute the value of C, PL/M source language expressions and assembly level address expressions, and define, remove, or display symbols.

Command files can be used to direct XRAY51 to read or write simulated microprocessor input/output from or to a file, allowing easy implementation of automated test sequences. Command files enable scripts of debugger commands to be processed automatically without the need of user interaction.

XRAY51 also allows a virtually unlimited number of user-defined windows.

A simulator version of XRAY51 having the same features as the emulator is available.

#### Features

- Integrated C, PL/M-51 source-language and assembly-language debugging; toggle by function key at any time
- Window-oriented display with well-organized segregation of debugging information
- Symbolic debugging with C, PL/M-51 variables and C, PL/M-51 statements
- Simple and complex breakpoints
- Single-step execution
- User-definable screens and viewports—ability to write selected information
- Command macros
- Breakpoint macros (limited to the number of breakpoints of the SDS 8051)
- Command and breakpoint macros may contain C statements, including: FOR, WHILE DO, PRINTF, and FPRINTF
- On-line context-sensitive help
- Command files
- Output logging
- Fully supports SDS 8051 with the latest firmware version
- High-level trace
- Transparent ICE mode for direct control of SDS 8051

### HIGH-LEVEL XRAY51 SCREEN

## Stand-alone debug station for 80C51/8051-based systems

SDS 8051

### CROSS-ASSEMBLER

The ASM51 cross-assembler\* is available for translating 8051 assembly language programs into relocatable object code:

It accepts Intel-compatible assembler source programs and produces relocatable '-.OBJ' object files. An absolute or executable 'A.OUT' load-image is obtained using the LINK51 linker.

The assembler is a powerful development tool with many directives, so a source file is easily composed, and translation to code is fast.

The assembler directives support features such as the inclusion of ASCII strings, checking module length, forcing a start address, allocating bytes to labels used in current or other modules and module definition.

A very powerful feature is the macroprocessor which includes tools such as macro-substitution, file inclusion and conditional assembly.

### ASM51 Features

- Produce relocatable object code, listing files and diagnostic messages
- Accept Intel-compatible source programs
- Compatible with Tasking's PL/M-51 compilers
- Conversion to IEEE object code format
- Compatible with XRAY51 High-Level/Assembly-Level Debugger
- Include many utilities such as, Librarian, Cross-reference generator, object code-convertors
- Support segment overlay at the Assembly level
- C and MPL (Macro Programming Language) compatible macro preprocessors included
- Separate linking phase

### CROSS-COMPILERS

Two cross-compilers\* are available for efficiently translating programs written in the PL/M-51 language into 8051 Assembly:

- **PLM51:** generates Intel-compatible source, which can be assembled and linked using the ASM51 and LINK51 programs.
- **C-51:** generates Intel-compatible assembly source, which can be assembled and linked using ASM51 and LINK51.

Both compilers are always supplied together, allowing you to choose the one that suits your requirements best.

### PLM51 Features

- Fast, single-pass, memory-based compilers that are fully compatible with the Intel PL/M-51 language definition
- Fully compatible with ASM51/LINK51
- Produce highly optimized code
- Support the XRAY51 high-level debugger
- Support in-line assembly code
- Optional IEEE single-precision floating point package
- Include several utility programs: pr, grep, aar, cpp, scf\_i51, ocf\_o51, ocf\_ihex, ocf\_ieee, ocf\_srec, ocf\_ihex, ocf\_srec, makelib and pack
- Utility library included in source code
- Combiner performs optimization at load-file level
- Easy tailoring to application and target hardware
- Produce relocatable code and data
- Support optimize(4): intermodule overlay optimization
- Support 15 interrupts
- Automatic installation with self-test
- Available for many hosts besides the IBM PC (MS-DOS), for example: (micro-)VAX, (VMS, Ultrix), HP9000/300 (HP-UX), SUN-3 (Sun-OS); available from BSO/Tasking Software B.V.

### C-51 Features

- Supports ANSI C with powerful 8051 extensions:
  - *bit*-type to use the on-chip bit addressable area
  - *interrupt <number>* and *using <registerbank>* for interrupt servicing at C-level
- Generates Intel-compatible Assembly source

- Supports HLL-debugger XRAY51 (in combination with ASM51)
- Supports all members of the 8051 family
- Produces very efficient and reliable code
- Code is ROMable
- Easy migration from BSO/Tasking PL/M-51 to BSO/Tasking C-51 through mixed language programming
- Supports 4 memory models to best meet application requirements
- Separate compilation of program modules
- Embodies integral standard preprocessor
- Is one-pass, fast and compact (no intermediate code or files)
- 3-layer design simplifies maintenance
- Complete set of UNIX-like compiler options
- Comes with C library and run-time support, including I/O calls (+ *printf*), memory management, floating point math, and arithmetic functions
- Available on many hosts: (micro)VAX (VMS or Ultrix), IBM PC (DOS, Xenix), IBM 6150, SUN-3/-4/-386i (SUN-OS), HP9000-300 (HP-UX), Apollo (UNIX)
- Generates re-entrant + relocatable code and relocatable data
- Same calling sequence on all hosts
- Same source and generated assembly code can be used on all hosts
- Automatic installation and self test
- Benchmarks and application notes are available on request.

# Stand-alone debug station for 80C51/8051-based systems

SDS 8051

## XRAY51 AND SDS COMMANDS

### XRAY51 Commands

XRAY51 uses a powerful command language that employs C language expressions. Note, all commands can be issued in an abbreviated form.

### Session Control Commands

**HOST** Enter the host operating system environment  
**LOAD** Load an object module for debugging  
**QUIT** Terminate a debugging session

### Execution and Breakpoint Commands

**BREAK**  
**INSTRUCTION** Set an instruction breakpoint  
**CLEAR** Clear a breakpoint  
**GO** Start or continue program execution  
**GOSTEP** Execute macro after each instruction step  
**STEP** Execute a specified number of instruction lines  
**STEPOVER** Step, but execute through procedures

### Display Commands

**DISASSEMBLE** Display disassembled memory (assembly mode)  
**DUMP** Display memory contents  
**EXPAND** Display all local variables of a procedure  
**FIND** Search for a string  
**FOPEN** Open a file or device for writing  
**FPRINTF** Print formatted output to a viewport or file  
**LIST** Display source code  
**MONITOR** Monitor variables  
**NEXT** Find next occurrence of a string  
**NOMONITOR** Discontinue monitoring variables  
**PRINTF** Print formatted output to a command viewport  
**PRINTVALUE** Print the value of a variable

### Memory Commands

**COMPARE** Compare two blocks of memory  
**COPY** Copy a memory block  
**FILL** Fill a memory block with values  
**SEARCH** Search a memory block for a value  
**SETMEM** Change the values of memory locations  
**SETREG** Change the contents of a register  
**TEST** Examine memory area for invalid values

### Port I/O and Interrupt Commands

**DIN** Display input port buffer values  
**DOUT** Display output port buffer values

**INPORT** Set or alter input port status  
**INTERRUPT** Simulate an interrupt  
**NOINTERRUPT** Cancel pending interrupts  
**OUTPUT** Set or alter output port status  
**RIN** Rewind input file associated with input port  
**ROUT** Rewind output file associated with output port

### Symbol Commands

**ADD** Create a symbol  
**DELETE** Delete a symbol from the symbol table  
**PRINTSYMBOLS** Display symbol, type, and address  
**SCOPE** Specify current module and procedure scope

### Utility Commands

**CEXPRESSION** Calculate the value of an expression  
**ERROR** Set include-file error handling  
**HELP** Display on-line help screen  
**INCLUDE** Read in and process a command file  
**JOURNAL** Record a debugger session in a file  
**LOG** Record debugger commands and errors in a file  
**MODE** Select debugger mode (high or assembly)  
**OPTION** Set debugger options for this session  
**PAUSE** Pause simulation  
**RESET** Simulate microprocessor reset  
**RESTART** Restart program counter to the program starting address  
**STARTUP** Save the default startup options

### Macro Commands

**DEFINE** Create a macro  
**SHOW** Display the macro source

### Viewport Commands

**VACTIVE** Activate a viewport  
**VCLEAR** Clear data from a viewport  
**VCLOSE** Remove a user-defined viewport or screen  
**VMACRO** Attach a macro to a viewport  
**VOPEN** Create a screen or viewport or change sizes  
**VSCREEN** Activate a screen  
**VSETC** Set the cursor position for a viewport  
**ZOOM** Increase or decrease the size of a viewport

### Function Key Commands

**VACTIVE-1** Activate the next viewport (counter clockwise)  
**VACTIVE+1** Activate the next viewport (clockwise)  
**MODE** Change debugging mode (assembly/high)

**ZOOM** Increase or decrease the size of a viewport  
**HELP** Access on-line help  
**VSCREEN** Change the active screen  
**BACK UP** Back up one command  
**STEP** Execute one machine instruction or source line  
**STEP OVER** Step, but execute through procedures

### In-Circuit Emulator Commands

**ICE** Communicate with in-circuit emulator (ICE)  
**NOICE** Return to debugger command mode

## SDS Commands

### Power-Up Commands

**RESET** Back to initialization

### Program Execution Commands

**BRn** Break at given address (n = 0, 1, 2, 3)  
**BRR** Break within given address range  
**BRB** Break at branch instruction  
**BV** Break on internal RAM value  
**GO** Initiates program execution (specified addresses)  
**(FROM, TILL)** Executes single instruction or instructions (from a specified address)  
**STEP (FROM)** User-defined memory address on display  
**UD** Display executed instruction flow (real time)  
**TRACE** Display interrupt enable, priority and status of all interrupt sources  
**INT**

### Memory Access Commands

**DBYTE** Displays specified byte from internal data memory  
**XBYTE** Displays specified byte from external data memory  
**CBYTE** Displays specified byte from code memory  
**RBYTE** Displays specified byte from on-chip register memory  
**RBIT** Displays specified bit from on-chip bit-addressable memory  
**ASM** Assemble single instruction mnemonic into program memory  
**DASM** Disassemble memory values into mnemonics

### Memory Set Commands

All registers can be set and displayed by commands equal to their names (PSW, SCON, P3, TH1, TL1, TL0, etc.)

### Serial I/O Interface Commands

**SAVE** Copies data from SDS 8051 program memory to host disk file  
**LOAD** Transfers file from host to SDS 8051

# Stand-alone debug station for 80C51/8051-based systems

SDS 8051

**SDS 8051 SPECIFICATION**

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Power supply                  | <ul style="list-style-type: none"> <li>- 110/220V AC, 50/60 Hz</li> </ul>                                                                                                                                                                                                                                                                                                                                                   |
| Cables                        | <ul style="list-style-type: none"> <li>- Mains cable;</li> <li>- RS232/V24 cable for connection to an IBM PC/XT</li> </ul>                                                                                                                                                                                                                                                                                                  |

**ORDERING INFORMATION<sup>1</sup>**

All of the 8051 development tools listed below are available from your local Philips Semiconductors sales office. The symbolic debugging package, cross-assembler and compiler are sourced from Tasking Software B.V., Amersfoort, The Netherlands, which holds all intellectual property rights for these products.

**Stand-alone debug station** OM4120S  
(excluding probe) for the 8051 family

**Symbolic debugging package XRAY51** OM4129  
**SDS-Window debugger** OM1089

**Cross-assembler for MS-DOS** OM4142  
(Tasking)

**Cross-assembler for MS-DOS** OM1024  
(2500)

**PL/M-51 compiler for MS-DOS** OM4144

**C-51 compiler** OM4136

**Emulation probes<sup>4</sup>:**  
for 8032/8052/80C32/80C52<sup>3</sup>: OM4111+  
(DIL/PLCC interface) OM4110

for 80C51/80C31/8051/8031: OM1092+  
(DIL/PLCC interface) OM1097

for 80CL51: OM1079  
(DIL interface)

for 8XC053/054: OM5054  
(SDIP interface)

for 8XCL410/411: OM1079  
(DIL interface)

for 8XCL781/782/52: OM5012+  
(DIL interface) OM1079

for 8XCL580: OM5004+  
OM1079

for 83CL168/167/268/267: OM4840+  
(SDK 64 interface) OM1079

for 8XC451: OM4123  
(PLCC interface)

for 8XC528/524: OM4111+  
(DIL/PLCC interface) OM4110

for 8XC550: OM5055+  
(DIL/PLCC interface) OM4110

for 8XC552/562: OM1092+  
(PLCC interface) OM1095

for 8XCE558 OM4271+  
(No QFP-80 adapter) OM4110

for 8XC592: OM4112+  
(PLCC interface) OM4110

for 8XCE598 OM4114+  
(No QFP-80 adapter) OM4110

for 8XC652/654: OM1092+  
(DIL/PLCC interface) OM1096

for 8XC751: OM1094  
(DIL/PLCC interface)

for 8XC752: OM5072  
(DIL interface)

for 8XC851: OM1092  
(DIL/PLCC interface)

for 83C852: OM4119

**Adapters:<sup>2</sup>**  
for 8XC451: 68-pin PLCC probe to  
64-pin DIL socket OM4124

for 80C51: 40-pin DIL probe to  
44-pin PLCC socket OM4125

for 80C51 DIL 40 types:  
DIL-40 socket to QFP-44 footprint: OM4117

for 8XC552/562 PLCC-64 socket to  
QFP-80 footprint: OM4116

for 8XCE598/558 QFP-80 footprint: OM4115

for 83C852: contactless card reader  
adapter OM4118/1

ISO contact card reader  
adapter OM4118/2

AFNOR contact and reader  
adapter OM4118/3

**Conversion kits:**  
for converting the OM1092 to an:  
8XC552/562 probe OM1095  
8XC652/654 probe OM1096  
80C31/80C51 probe OM1097

**NOTES:**

1. A minimum SDS configuration must include an OM4120S and an emulation probe. A minimum PC configuration must include 256 kbytes system memory running MS-DOS 3.0 (or later releases), one floppy disk drive and a monochrome monitor. However, we recommend using an IBM PC/XT (or compatible) with 640 kbytes RAM, hard disk drive, floppy disk drive and a color monitor. The SDS software can be supplied on 3 1/2" or 5 1/4" diskettes. Conversion kits require the OM1092.
2. Support for QFPs will be available in the near future.
3. Minor restrictions.
4. All probes 16MHz, except OM4123 (12MHz) and OM4119 (6MHz)

## Package outlines

### SOT101/0410D 24-PIN (300 mils wide) PLASTIC DUAL IN-LINE (N) PACKAGE

**NOTES:**

1. Controlling dimension: inches. Metric are shown in parentheses.
2. Package dimensions conform to JEDEC Specification MS-001-AF for standard Dual In-Line (DIP) package 0.300 inch row spacing (plastic) 24 leads (Issue B, 7/85).
3. Dimension and tolerancing per ANSI Y14, 5M - 1982.
4. "T", "D", and "E" are reference datums on the molded body and do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.010 inch (0.25mm) on any side.
5. These dimensions measured with the leads constrained to be perpendicular to plane T.
6. Pin numbers start with Pin #1 and continue counterclockwise to Pin #24 when viewed from the top.

## SOT261/0401F 28-PIN (300 mils wide) PLASTIC LEADED CHIP CARRIER (A) PACKAGE

- NOTES**
- Package dimensions conform to JEDEC Specification MO-047-AB for Plastic Leaded Chip Carrier 28 leads, 0.050 inch (1.27mm) lead spacing, square. (Issue A, 10/31/84).
  - Controlling dimensions: inches. Metric dimensions in mm are shown in parentheses.
  - Dimensioning and tolerancing per ANSI Y14.5M-1982.
  - Datum plane "H" located at the top of mold parting line and coincident with top of lead, where lead exits plastic body.
  - Location to datum "A," "B," and "C," to be determined at plane "H." These datums do not include mold flash. Mold flash protrusion shall not exceed 0.010" (0.25mm) on any side.
  - Datum "D," "E" and "F-G" are determined where these center leads exit from the body at plane "H."
  - Pin numbers continue counterclockwise to Pin 28 (top view).
  - Signetics order code for product packaged in a PLCC is the suffix "A" after the product number.
  - Applicable to packages with pedestal only.
  - Location of Pin #1 mark is optional. Mark on chamfered side is preferred.

### NOTES

1. Package dimensions conform to JEDEC Specification MO-047-AC for Plastic Leaded Chip Carrier 44 leads, 0.050 inch (1.27mm) lead spacing, square. (Issue A, 10/31/84).
2. Controlling dimensions: inches. Metric dimensions in mm are shown in parentheses.
3. Dimensioning and tolerancing per ANSI Y14.5M-1982.
4. Datum plane "H" located at the top of mold parting line and coincident with top of lead, where lead exits plastic body.
5. Location to datum "A," and "B," to be determined at plane "H." These datums do not include mold flash. Mold flash protrusion shall not exceed 0.010" (0.25mm) on any side.
6. Datum "D-E" and "F-G" are determined where these center leads exit from the body at plane "H."
7. Pin numbers continue counterclockwise to Pin 44 (top view).
8. Signetics order code for product packaged in a PLCC is the suffix "A" after the product number.

Applicable to packages with pedestal only.

## 0413B 28-PIN (600 mils wide) PLASTIC DUAL IN-LINE (N) PACKAGE

**NOTES:**

1. Controlling dimension: Inches. Metric are shown in parentheses.
2. Package dimensions conform to JEDEC Specification MS-011-AB for standard Dual In-Line (DIP) package 0.600 inch row spacing (plastic) 28 leads (Issue B, 7/84).
3. Dimension and tolerancing per ANSI Y14, 5M - 1982.
4. "T", "D", and "E" are reference datums on the molded body and do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.010 inch (0.25mm) on any side.
5. These dimensions measured with the leads constrained to be perpendicular to plane T.
6. Pin numbers start with Pin # 1 and continue counterclockwise to Pin #28 when viewed from the top.

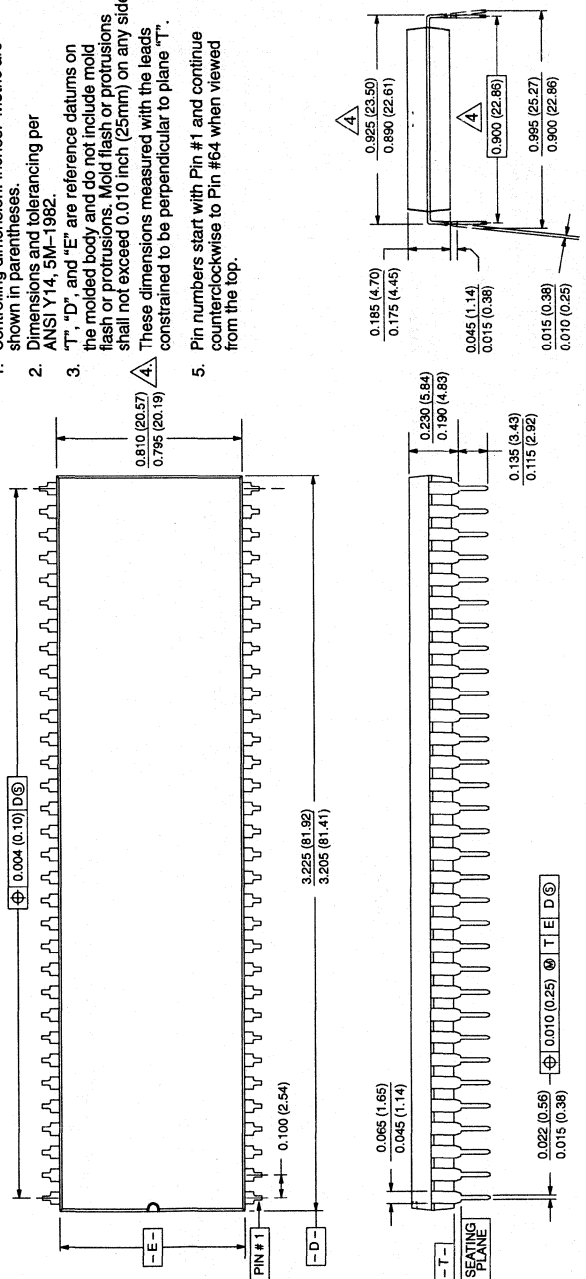

# Package outlines

## 0414B 64-PIN (900 mils wide) PLASTIC DUAL IN-LINE (N) PACKAGE

**NOTES:**

1. Controlling dimension: Inches. Metric are shown in parentheses.
2. Dimensions and tolerancing per ANSI Y14, 5M-1982.
3. "T", "D", and "E" are reference datums on the molded body and do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.010 inch (25mm) on any side. These dimensions measured with the leads constrained to be perpendicular to plane "T".
5. Pin numbers start with Pin #1 and continue counterclockwise to Pin #64 when viewed from the top.

853-0414B 05360

# Package outlines

## 0415C 40-PIN (600 mils wide) PLASTIC DUAL IN-LINE (N) PACKAGE

**NOTES:**

1. Controlling dimension: inches. Metric are shown in parentheses.
2. Package dimensions conform to JEDEC Specification MS-011-AC for standard Dual In-Line package 0.600 inch row spacing (plastic) 40 leads (Issue B, 7/85).
3. Dimension and tolerancing per ANSI Y14, 5M - 1982.
4. "T", "D", and "E" are reference datums on the molded body and do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.010 inch (0.25mm) on any side. These dimensions measured with the leads constrained to be perpendicular to plane T.
5. Pin numbers start with Pin #1 and continue counterclockwise to Pin #40 when viewed from the top.

# Package outlines

## 0586B 24-PIN (300 mils wide) CERAMIC DUAL IN-LINE (F) PACKAGE (WITH WINDOW (FA) PACKAGE)

**NOTES:**

1. Controlling dimension: Inches. Millimeters are shown in parentheses.
2. Dimension and tolerancing per ANSI Y14.5M-1982.
3. "T", "D", and "E" are reference datums on the body and include allowance for glass overrun and meniscus on the seal line, and lid to base mismatch.
4. These dimensions measured with the leads constrained to be perpendicular to plane T.
5. Pin numbers start with Pin #1 and continue counterclockwise to Pin #24 when viewed from the top.
6.  $\text{\textcircled{6}}$  Denotes window location for EPROM products.

853-0586B 06688

# Package outlines

## 0589B 28-PIN (600 mils wide) CERAMIC DUAL IN-LINE (F) PACKAGE (WITH WINDOW (FA) PACKAGE)

- NOTES:**
1. Controlling dimension: Inches. Millimeters are shown in parentheses.
  2. Dimension and tolerancing per ANSI Y14. 5M-1982.
  3. "T", "D", and "E" are reference datums on the body and include allowance for glass overrun and meniscus on the seal line, and lid to base mismatch.
  4. These dimensions measured with the leads constrained to be perpendicular to plane T.
  5. Pin numbers start with Pin #1 and continue counterclockwise to Pin #28 when viewed from the top.
  6. Denotes window location for EPROM products.

853-0589B 06688

# Package outlines

## 0590B 40-PIN (600 mils wide) CERAMIC DUAL IN-LINE (F) PACKAGE (WITH WINDOW (FA) PACKAGE)

**NOTES:**

1. Controlling dimension: inches. Millimeters are shown in parentheses.
2. Dimension and tolerancing per ANSI Y14.5M-1982.
3. "T", "D", and "E" are reference datums on the body and include allowance for glass overrun and meniscus on the seal line, and lid to base mismatch.
4. These dimensions measured with the leads constrained to be perpendicular to plane T.
5. Pin numbers start with Pin #1 and continue counterclockwise to Pin #40 when viewed from the top.
6. Denotes window location for EPROM products.

853-0590B 06688

# Package outlines

## 1118D 44-PIN PLASTIC QUAD FLAT PACK (B) (MEC) PACKAGE

- NOTES:**
1. Package dimensions conform to MEC specification.
  2. Controlling dimensions are in mm. Dimensions in parentheses are in inches.
  3. Pin numbers start with Pin #1 and continue counterclockwise to Pin #44 when viewed from top.
- ⚠ Molded identification may be replaced by other unique feature within this zone to indicate Pin #1 location.

853-1118D 06184

# Package outlines

## 1240C 68-PIN CHIP CARRIER, J-BEND (L) PACKAGE

**NOTES:**

1. Controlling Dimensions: Inches  
Millimeters are shown in parenthesis.
  2. Dimension and tolerancing per ANSI Y14.5M-1982
- ⚠ When a window lid is used, the overall package thickness must increase by a minimum of .010 inch (0.25mm) and a maximum of .040 inch (1.020mm).

853-1240C 07434

# Package outlines

## 1472A 44-PIN CERQUAD J-BEND (K) PACKAGE

**NOTES:**

1. All dimensions and tolerances to conform to ANSI Y14.5-1982.
2. UV window is optional.
3. Dimensions do not include glass protrusion. Glass protrusion to be 0.003 inches maximum on each side.
4. Controlling dimension millimeters.
5. All dimensions and tolerances include lead trim offset and lead plating finish.
6. Backside solder relief is optional and dimensions are for reference only.

853-1472A 05854

# Package outlines

## 1473A 68-PIN CERQUAD J-BEND (K) PACKAGE

**NOTES:**

1. All dimensions and tolerances to conform to ANSI Y14.5-1982.
2. UV window is optional.
3. Dimensions do not include glass protrusion. Glass protrusion to be 0.005 inches maximum on each side.
4. Controlling dimension millimeters.
5. All dimensions and tolerances include lead trim offset and lead plating finish.
6. Backside solder relief is optional and dimensions are for reference only.

## 1680 42-PIN PLASTIC SSOP (SHRINK SMALL OUTLINE PACKAGE) DUAL IN-LINE (D/K) PACKAGE

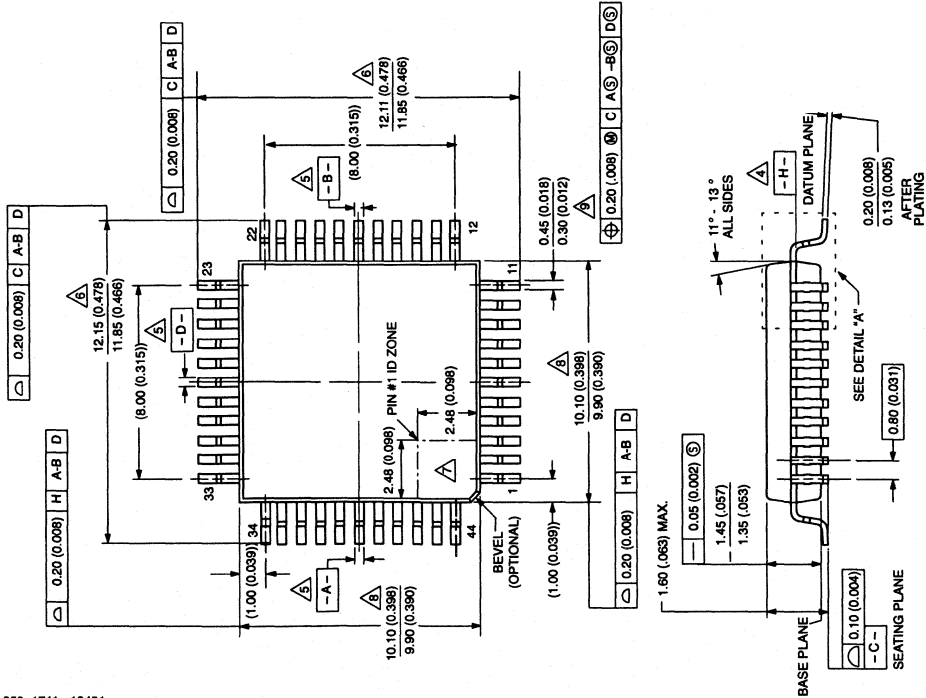

## Package outlines

### 1711 – 44-PIN PLASTIC THIN QUAD FLAT PACKAGE

**NOTES:**

1. Package dimensions conform to JEDEC registration MO-136-1992.
  2. Controlling dimensions: millimeters. Dimensions in inches are shown in parentheses.
  3. Dimension and tolerancing per ANSI Y14.5M-1982.
- △ Datum plane "H" is located at the mold parting line and is coincident with the lead where the lead exits the plastic body at the bottom of the parting line.
- △ Datums "A-B" and "D" to be determined at datum plane "H".
- △ To be determined at seating plane "C".
- △ Details of Pin 1 Identifier are optional but must be located within the zone indicated.
- △ Package body dimensions do not include mold protrusion. Allowable protrusion is 0.25mm per side, but it includes mold mismatch.
- △ Lead width does not include dambar protrusion. Allowable dambar protrusion shall be 0.08 mm / 0.003" total in excess of this dimension at maximum material condition. Dambar cannot be located on the lower radius or the foot.

**DATA HANDBOOK SYSTEM**

Philips Semiconductors data handbooks contain all pertinent data available at the time of publication and each is revised and reissued regularly.

Loose data sheets are sent to subscribers to keep them up-to-date on additions or alterations made during the lifetime of a data handbook.

Catalogs are available for selected product ranges (some catalogs are also on floppy discs).

Our data handbook titles are listed here.

**Integrated Circuits**

| <i>Book</i> | <i>Title</i>                                                                         |
|-------------|--------------------------------------------------------------------------------------|
| IC01        | Semiconductors for Radio and Audio Systems                                           |
| IC02        | Semiconductors for Television and Video Systems                                      |
| IC03        | Semiconductors for Telecom Systems                                                   |
| IC04        | CMOS HE4000B Logic Family                                                            |
| IC05        | Advanced Low-power Schottky (ALS) Logic Series                                       |
| IC06        | High-speed CMOS Logic Family                                                         |
| IC08        | 100K ECL Logic Families                                                              |
| IC10        | Memories                                                                             |
| IC11        | General-purpose/Linear ICs                                                           |
| IC12        | Display Drivers and Microcontroller Peripherals (planned)                            |
| IC13        | Programmable Logic Devices (PLD)                                                     |
| IC14        | 8048-based 8-bit Microcontrollers                                                    |
| IC15        | FAST TTL Logic Series                                                                |
| IC16        | ICs for Clocks and Watches                                                           |
| IC18        | Semiconductors for In-car Electronics and General Industrial Applications (planned)  |
| IC17        | RF/Wireless Communications                                                           |
| IC19        | Semiconductors for Datacom: LANs, UARTs, Multi-protocol Controllers and Fibre Optics |
| IC20        | 80C51-based 8-bit Microcontrollers                                                   |
| IC21        | 68000-based 16-bit Microcontrollers (planned)                                        |
| IC22        | ICs for Multi-media Systems (planned)                                                |
| IC23        | QUBIC Advanced BiCMOS Bus Interface Logic ABT, MULTIBYTE™                            |
| IC24        | Low Voltage CMOS & BiCMOS Logic                                                      |

**Discrete Semiconductors**

| <i>Book</i> | <i>Title</i>                                                |
|-------------|-------------------------------------------------------------|
| SC01        | Diodes                                                      |
| SC02        | Power Diodes                                                |
| SC03        | Thyristors and Triacs                                       |

| SC05        | Low-frequency Power Transistors and Hybrid IC Power Modules |
| SC06        | High-voltage and Switching NPN Power Transistors            |
| SC07        | Small-signal Field-effect Transistors                       |
| SC08a       | RF Power Bipolar Transistors                                |
| SC08b       | RF Power MOS Transistors                                    |
| SC09        | RF Power Modules                                            |
| SC10        | Surface Mounted Semiconductors                              |
| SC13        | Power MOS Transistors including TOPFETs and IGBTs           |
| SC14        | RF Wideband Transistors, Video Transistors and Modules      |
| SC15        | Microwave Transistors                                       |
| SC16        | Wideband Hybrid IC Modules                                  |
| SC17        | Semiconductor Sensors                                       |

**Professional Components**

|      |                                      |
|------|--------------------------------------|
| PC01 | High-power Klystrons and Accessories |
| PC06 | Circulators and Isolators            |

**MORE INFORMATION FROM PHILIPS SEMICONDUCTORS?**

For more information about Philips Semiconductors data handbooks, catalogs and subscriptions contact your nearest Philips Semiconductors national organization, select from the **address list on the back cover of this handbook**. Product specialists are at your service and inquiries are answered promptly.

## OVERVIEW OF PHILIPS COMPONENTS DATA HANDBOOKS

Our sister product division, Philips Components, also has a comprehensive data handbook system to support their products. Their data handbook titles are listed here.

### Display Components

| Book | Title                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------|
| DC01 | Colour Display Components<br>Colour TV Picture Tubes and Assemblies<br>Colour Monitor Tube Assemblies |
| DC02 | Monochrome Monitor Tubes and Deflection Units                                                         |
| DC03 | Television Tuners, Coaxial Aerial Input Assemblies                                                    |
| DC05 | Flyback Transformers, Mains Transformers and General-purpose FXC Assemblies                           |

### Magnetic Products

|      |                                              |
|------|----------------------------------------------|
| MA01 | Soft Ferrites                                |
| MA03 | Piezoelectric Ceramics<br>Specialty Ferrites |
| MA04 | Dry-reed Switches                            |

### Passive Components

|      |                                                          |
|------|----------------------------------------------------------|
| PA01 | Electrolytic Capacitors                                  |
| PA02 | Varistors, Thermistors and Sensors                       |
| PA03 | Potentiometers and Switches                              |
| PA04 | Variable Capacitors                                      |
| PA05 | Film Capacitors                                          |
| PA06 | Ceramic Capacitors                                       |
| PA07 | Quartz Crystals for Special and Industrial Applications  |
| PA08 | Fixed Resistors                                          |
| PA10 | Quartz Crystals for Automotive and Standard Applications |
| PA11 | Quartz Oscillators                                       |

### Professional Components

|      |                                                        |
|------|--------------------------------------------------------|
| PC04 | Photo Multipliers                                      |
| PC05 | Plumbicon Camera Tubes and Accessories                 |
| PC07 | Vidicon and Newvicon Camera Tubes and Deflection Units |
| PC08 | Image Intensifiers                                     |
| PC12 | Electron Multipliers                                   |
