# RC4191/RC4192/RC4193 <br> Micropower Switching Regulator 

## Features

- High efficiency - 85\% typical
- Low quiescent current - $215 \mu \mathrm{~A}$
- Adjustable output -1.3 V to 30 V
- High switch current - 200 mA
- Bandgap reference -1.31 V
- Accurate oscillator frequency $- \pm 10 \%$
- Remote shutdown capability
- Low battery detection circuitry
- Low component count
- 8-lead packages

## Description

The RC4191/4192/4193 series of monolithic ICs are low power switch mode regulators intended for miniature power supply applications. These DC-to-DC converter ICs provide all of the active components needed to create supplies for micropower circuits. Contained internally are an oscillator, switch, reference, comparator, and logic, plus a discharged battery detection circuit.

These regulators can achieve up to $85 \%$ efficiency in most applications while operating over a wide supply voltage range, 2.2 V to 30 V , at a very low quiescent current drain of $215 \mu \mathrm{~A}$.

## Block Diagram

The standard application circuit requires just seven external components for step-up operation: an inductor, a steering diode, three resistors, a low value timing capacitor, and an electrolytic filter capacitor. The combination of simple application circuit, low supply current, and small package make the RC4193 adaptable to a wide range of miniature power supply applications.

The RC4193 is most suited for single ended step-up (VOUT > VIN) circuits because the NPN internal switch transistor is referenced to ground. It is complemented by Raytheon's micropower switching regulator, the RC4391, which is dedicated to step-down (VOUT < $\mathrm{V}_{\mathrm{IN}}$ ) and inverting VOUT $\left.=-V_{\text {IN }}\right)$ applications. Between the two devices the ability to create all three basic switching regulator configurations is assured. Refer to the RC4391 data sheet for stepdown and inverting applications.

The RC4191/92/93 series of micropower switching regulators consists of three devices, each with slightly different specifications. The RM4191 has a $1.5 \%$ maximum output voltage tolerance, $0.2 \%$ maximum line regulation, and operation to 30 V . The RC4192 has a $3.0 \%$ maximum output voltage tolerance, $0.5 \%$ maximum line regulation, and operation to 30 V . The RC4193 has a $5.0 \%$ maximum output voltage tolerance, $0.5 \%$ maximum line regulation, and operation to 24 V . Other specifications are identical for the RC4191, RC4192 and RC4193. Each type is available in commercial, industrial, and military temperature ranges, and in plastic and ceramic DIPs and S0-8 packages.

## Applications Discussion

## Simple Step-Up Converter

The most common application, the step-up regulator, is derived from a simple step-up (VOUT > VBAT)
DC-to-EC Converter (Figure 6).

Figure 6. Simple Set-Up Converter
When switch S is closed, the battery voltage is applied across the inductor L. Charging current flows through the inductor, building up a magnetic field, increasing as the switch is held closed. While the switch is closed, the diode D is reverse biased (open circuit) and current is supplied to the load by the capacitor C. Until the switch is opened, the inductor current will increase linearly to a maximum value determined by the battery voltage, inductor value, and the amount of time the switch is held closed
$(\operatorname{IMAX}=\mathrm{VBAT} / \mathrm{L} x$ TON). When the switch is opened, the magnetic field collapses, and the energy stored in the magnetic field is converted into a discharge current which flows through the inductor in the same direction as the charging current. Because there is no path for current to flow through the switch, the current must flow through the switch, the current must flow through the diode to supply the load and charge the output capacitor.

If the switch is opened and closed repeatedly, at a rate much greater than the time constant of the output RC, then a constant DC voltage will be produced at the output.

An output voltage higher than the input voltage is possible because of the high voltage produced by a rapid change of current in the inductor. When the switch is opened, the inductor voltage will instantly rise high enough to forward bias the diode, to VOUT + VD.

In the complete RC4193 regulator, a feedback control system adjusts the on time of the switch, controlling the level of inductor current, so that the average inductor discharge current equals the load current, thus regulating the output voltage.

## Complete Step-Up Regulator

A complete schematic of the minimum step-up application is shown in Figure 7. The ideal switch in the DC-to-DC Converter diagram is replaced by an open collector NPN transistor Q1. CF functions as the output filter capacitor, and D1 and LX replace D and L.

When power is first applied, the current in R1 supplies bias current to pin 6 (IC). This current is stabilized by a unity gain current source amplifier and then used as bias current for the 1.31 V bandgap reference. A very stable bias current generated by the bandgap is mirrored and used to bias the remainder of the chip. At the same time the RC4193 is starting up, current will flow through the inductor and the diode to charge the output capacitor to VBAT - VD.

At this point, the feedback (pin 7) senses that the output voltage is too low, by comparing a division of the output voltage (set by the ratio of R 2 to R 3 ) to the +1.31 V reference. If the output voltage is too low then the comparator output changes to a logical zero. The NOR gate then effectively ANDs the oscillator square wave with the comparator signal; if the comparator output is zero AND the oscillator output is low, then the NOR gate output is high and the switch transistor will be forced on. When the oscillator goes high again, the NOR gate output goes low and the switch transistor will turn off. This turning on and off of the switch transistor performs the same function that opening and closing the switch in the simple DC-to-DC Converter does; i.e., it stores energy in the inductor during the on time and releases it into the capacitor during the off time.

The comparator will continue to allow the oscillator to turn the switch on and off until enough charge has been delivered to the capacitor to raise the feedback voltage above 1.31 V .

Thereafter, this feedback system will vary the duration of the on time in response to changes in load current or battery voltage (see Figure 8). If the load current increases (waveform $C$ ), then the transistor will remain on (waveform $D$ ) for a longer portion of the oscillator cycle (waveform B), thus allowing the inductor current (waveform E ) to build up to a higher peak value. The duty cycle of the switch transistor varies in response to changes in load and time.

## Notes:

1. Index area: a notch or a pin one identification mark shall be located adjacent to pin one. The manufacturer's identification shall not be used as pin one identification mark.
2. The minimum limit for dimension "b2" may be $.023(.58 \mathrm{~mm})$ for leads number $1,4,5$ and 8 only.
3. Dimension "Q" shall be measured from the seating plane to the base plane.
4. This dimension allows for off-center lid, meniscus and glass overrun.
5. The basic pin spacing is $.100(2.54 \mathrm{~mm})$ between centerlines. Each pin centerline shall be located within $\pm .010(.25 \mathrm{~mm})$ of its exact longitudinal position relative to pins 1 and 8.
6. Applies to all four corners (leads number $1,4,5$, and 8 ).
7. "eA" shall be measured at the center of the lead bends or at the centerline of the leads when " $\alpha$ " is $90^{\circ}$.
8. All leads - Increase maximum limit by $.003(.08 \mathrm{~mm})$ measured at the center of the flat, when lead finish applied.
9. Six spaces.
