

RC6303

Triple Video Amplifier with Separate Enable Inputs

Features

- Triple video amplifier
- Independently enabled amplifiers
- 90 MHz -3 dB Bandwidth ($A_V = 2$)
- 20 MHz ± 0.1 dB gain flatness
- Stable at $A_V \geq 2$
- 0.06% differential gain ($A_V = 2$, $R_L = 150\Omega$)
- 0.06° differential phase ($A_V = 2$, $R_L = 150\Omega$)
- High CMRR (100dB), High PSRR (80 dB)
- Dual $\pm 5V$ power supply
- Low offset 1.0 mV
- 16-pin narrow SO package
- 300 V/ μs slew rate
- Fast settling time: 0.1% in 35 ns
- TTL or CMOS compatible enable inputs

Applications

- RGB amplifier
- 3:1 crosspoint switch
- RGB switch
- Video instrumentation amplifier
- Selectable gain amplifier
- Active filter

Description

The RC6303 consists of three low power, wide band voltage feedback operational amplifiers. Each channel is capable of delivering a load current of at least 35mA. Each amplifier can be independently enabled or disabled with a TTL or CMOS signal. When disabled, the amplifier is in a high impedance output state, presenting a very high input to output isolation.

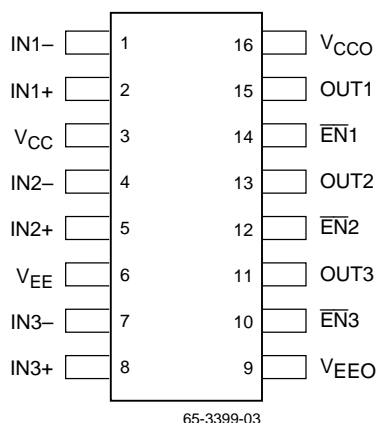

The amplifiers are optimized for video applications with gain ≥ 2 where low differential gain and low phase distortion are significant requirements.

The layout is optimized for minimal crosstalk between amplifiers.

Applications Discussion

Each of the three sections of the RC6303 is provided with an Enable input, thus the part is useful for selecting and multiplexing. A three-channel video multiplexer can be built with just one RC6303 and a decoder, as shown in Figure 1.

Note that RC6303 enable time is shorter than its disable time, hence a make-before-break action is provided, minimizing switching transients on the signal output.

An RGB switch is shown in Figure 2.

Capacitive Load

The RC6303 can drive a capacitive load from 10 to over 100 pF. In back terminated video applications, bandwidth will only be limited by the RC time constants of the external output components. A minimum 10 pF capacitive load is required. When driving a 75Ω cable, place the 75Ω source termination resistor as close to the amplifier output as possible.

Enable/Disable

The enable pins (10, 12, 14), when pulled to a TTL or CMOS logic low or when tied to ground, activate each amplifier individually. When pulled to a TTL or CMOS logic high, the amplifier is tri-stated and presents a high impedance at its output. When disabled the amplifier's power consumption drops, and the non-inverting input signal is isolated from its respective output.

DC Accuracy

Since the RC6303 is a voltage-feedback amplifier, the inverting and non-inverting inputs have similar impedances and bias currents. To minimize offset voltage, match the source resistances seen by inverting and non-inverting inputs.

Feedback Components

Because the RC6303 is a voltage-feedback amplifier, it facilitates using reactive (capacitive and inductive) feedback components for implementing filters, integrators, sample/hold circuits, etc. The feedback network and the parasitic capacitance at the inverting (summing junction) input create a pole and affect the transfer function of the circuit. For stable operation, minimize the parasitic capacitance and equivalent resistance of the components used in the feedback circuit.

Circuit Board

High-frequency applications require good grounding, power supply decoupling, low parasitic capacitance and inductance, and good isolation between the inputs to minimize their crosstalk. Avoid coupling from output to input to prevent positive feedback.
