ADVANCE DATA

- 50/ 60 Hz AC SUPPLY
- INPUT FOR PYROELECTRICAL SENSOR
- INPUT FOR PHOTORESISTIVE SENSOR
- SENSOR FILTER AMPLIFIER
- PROGRAMMABLE ON-TIMER
- TRIAC OUTPUT AND RELAY OUTPUT
- SHORT CIRCUIT PROTECTION
- LOW QUIESCENT CURRENT
- TWO-WIRE TECHNIQUE

### DESCRIPTION

The UAA4713 is a monolithic integrated circuit intended to control triac or relay switch for AC-mains timer applications. The device can be used in a wide range of industrial and consumer applications as light control, automatic door opening detector, fire alarm, fluid level control .

The circuit processes the output signal of an infra-red pyroelectric detector which senses temperature changes caused by heat radiation of the human body.

If the sensor detects a temperature change, a programmable timer will start and switch a lamp or other loads to the mains.

A further input for a photo-resistive sensor allows to program circuit operation depending on the day-light intensity.

Internal circuits avoid false triggering of the external actuators. (see functional diagram).

## UAA4713

### SYSTEM DESCRIPTION (see Functional Diagram)

If a heat source moves in front of the IR-detector, the sensor delivers a quasi sinusoidal AC-signal in the  $\mu\text{V}$  to  $\text{mV}$  range. The operational amplifier amplifies the sensor signal by 72dB.

To reject an unwanted signal, a band pass filter is needed. If the AC-level at pin 14 exceeds the window comparator thresholds, the programmable timer will start. To suppress short sensor signals, a 50ms time filter is implemented between the window comparator output and the programmable timer. This function improves the noise immunity.

After the reset of the timer a second timer will provide a 600ms dead time to prevent retriggering of the timer. This function avoids restarting of the timer, when the turned off lamp temperature decreases

The lamp switched by the triac can be located close to the sensor.

To avoid circuit operation during day-time, a photo resistor (LDR) senses the light intensity and switches off the circuit. The capacitor at pin 2 prevents circuit start-up during short shadow phases, when a person passes by the sensor.

From the analog input pin 1 via the AD-converter the on-time duration can be programmed in 7

steps (see  $t_{\text{TIM}}$  table in the electrical characteristics). The timer is clocked by the mains frequency.

Two outputs for various applications are available.

Pin 5 is the trigger output for triac gate.

Pin 4 output can be used to switch a relay or other loads.

The zero crossing detector provides the firing pulse for the triac at the right time, shortly after the zero crossing of the AC-signal.

The RC-network at pin 7 supplies current to the circuit via a double wave rectification which is provided by a split power supply. Due to the capacitive energy transfer into pin 7, the circuit will also be supplied with current if the triac is fired. A short wire for circuit supply is not needed.

The circuit works similar to a simple two-terminal switch and can be installed in parallel with ordinary mechanical pulse switches (fig. 4).

After a short supply connection via an external pulse switch, the circuit timer will also start without a sensor signal.

Therefore the circuit can also be used as an ordinary light timer without the IR-moving sensor feature.

**APPLICATION INFORMATION**

**1. HOW TO CHOOSE THE TRIAC ASSOCIATED TO THE MOTION DETECTOR UAA4713**

**Analysis of the Triac Associated to the Motion Detector UAA4713**

Associated with the UAA4713, the Triac is defined by the driver output stage (Triac output pin 5) and the characteristics of the load.

The Triac is consequently defined by:

- 1) The gate sensitivity
- 2) The surge current capability
- 3) The RMS Triac current
- 4) The blocking voltage capability

**1) The gate sensitivity**

The "Triggering gate current" is the parameter to be taken into consideration. The  $I_{GT}$  is given at 25°C. as a maximum value required to trigger the Triac.

ex. BTA06-600CW =  $I_{GT \max}$  (mA) = 35mA

The UAA4713 Triac output provides a current of 65mA typical.

$$I_{Tout} = 65mA(Typ) = I_G$$

In order to control the Triac properly  $I_G$  should be greater than  $1.5 \times I_{GT}$  or

$$I_{Tout} > 1.5 I_{GT}$$

For this reason it is suggested to use a snubberless Triac of the CW series ( $I_{GT} < 35mA$ ).

**2) The surge current capability**

In the Triac databook the surge current capability of the Triac is given by the non repetitive surge peak current:

$I_{TSM}$

ex. BTA06-600CW

$I_{TSM}$  at  $T_J \text{ initial} = 25^\circ C$

t = 8.3mA: 63A

t = 10ms: 60A

The choice of the Triac is defined by the following application parameters:

- a) The starting performance, and the ratio of the nominal resistance to the cold resistance, KR

$$I_{max} > KR \times I_{nominal} \times \sqrt{2}$$

- b) The thermal fast fuse behaviour during short-circuit condition.

$$(I^2t) \text{ (Triac)} > (I^2t) \text{ (fuse)}$$

To select the  $I_{Tsm}$  (given as a minimum value) the following table is suggested.

Mains: $V_{AC}$ (V)	240V	110V
Power (W)	$I_{Tsm}(\text{min})$	$I_{Tsm}(\text{min})$
600	50	80
1000	80	120
>1000	>100	>150

**3) RMS Triac Current**

The RMS Triac current  $I_{TRMS}$  is defined by the light power P:

$$I_{TRMS} > 1.25 \times P \times V_{AC}$$

It depends also on the heat sink which has to limit the junction temperature in the worse case conditions ( $T_{amb \max}$  and  $I_{TRMS}$ ).

With the snubberless triac  $I_{TRMS}$  ranges from 6A to 25A.

**4) Blocking Voltage Capability**

The maximum blocking voltage  $V_{DRM}$  is defined by the mains:

Country	Mains Voltage (V) $V_{AC}$	$V_{DRM}$ (V)
EUROPE	240	600
USA	110	400

**5) Conclusion:**

Selector guide with the above parameters the optimal device selection for a given power to be controlled is given in the following table:

LIGHT POWER (W)	MAINS VOLTAGE $V_{AC}$ (V)	
	240	110
600	BTA 06 600 CW	BTA 08 400 CW
1,000	BTA 08 600 CW	BTA 12 400 CW
> 1,000	BTA X 600 CW X = 10 X = 12 X = 16	BTA X 400 CW X = 12 X = 16 (A)
