
PROGRAMMING MANUAL

The ST7 family of HCMOS Microcontrollers has been designed and built around an industry standard 8-bit core and a library of peripheral blocks, which include ROM, EPROM, RAM, EEPROM, I/O, Serial Interfaces (SPI, SCI, I2C,...), 16-bit Timers, etc. These blocks may be assembled in various combinations in order to provide cost-effective solutions for application dedicated products.

The ST7 family forms part of the SGS-THOMSON Microelectronics 8-bit MCU product line, and finds place in a wide variety of applications such as automotive systems, remote controls, video monitors, car radio and numerous other consumer, industrial, telecom, multimedia and automotive products.

ST7 ARCHITECTURE

The 8-bit ST7 Core is designed for high code efficiency. It contains 6 internal registers, 17 main addressing modes and 63 instructions. The 6 internal registers include 2 Index registers, an Accumulator, a 16-bit Program Counter, a Stack Pointer and a Condition Code register. The two Index registers X and Y enable Indexed Addressing modes with or without offset, along with read-modify-write type data manipulations. These registers simplify branching routines and data modifications.

The 16-bit Program Counter is able to address up to 64K of ROM/EPROM memory. The 6-bit Stack Pointer provides access to a 64-level Stack and an upgrade to an 8-bit Stack Pointer is foreseen in order to be able to manage a 256-level Stack. The Core also includes a Condition Code Register providing 5 Condition Flags that indicate the result of the last instruction executed.

The 17 main Addressing modes, including Indirect Relative and Indexed addressing, allow sophisticated branching routines or CASE-type functions. The Indexed Indirect Addressing mode, for instance, permits look-up tables to be located anywhere in the address space, thus enabling very flexible programming and compact C-based code.

The 63-instruction Instruction Set is 8-bit oriented with a 2-byte average instruction size. This Instruction Set offers, in addition to standard data movement and logic/arithmetic functions, byte multiplication, bit manipulation, data transfer between Stack and Accumulator (Push/Pop) with direct stack access, as well as data transfer using the X and Y registers.

Depending of the target device, different methods of Interrupt priority management may be selected: the number of Interrupt vectors can vary from 6 to 16, and the priority level may be managed by software on some versions. Some peripherals include Direct Memory Access (DMA) between serial interfaces and memory.

Power-saving may be managed under program control by placing the device in WAIT or HALT mode.

A high test coverage is achieved for ST7 family devices thanks to the use of an autotest method based on "Cyclic Redundancy Checking" (CRC). This approach is based on the analysis of a data flow comprising not only input and output, but also internal data, which affords a detailed inside view of the behaviour of the core and of the peripherals.

ADDITIONAL BLOCKS

The additional blocks take the form of integrated hardware peripherals arranged around the central processor core. The following list details the features of some of the currently available blocks:

ROM	User ROM, in sizes up to 64K
EPROM	EPROM based devices, same sizes as ROM
RAM	Sizes up to several K byte
EEPROM	Sizes up to several K byte. Erase/programming operations do not require additional external power sources. Up to 32 bytes can be programmed or erased simultaneously.
TIMER	Different versions based on a 16-bit free running timer/counter are available. They can be coupled with either input captures, output compares or PWM facilities.
PWM	Software programmable duty cycle between 0% to 100% in up to 1024 steps. The outputs can be filtered to provide D/A conversion.
A/D CONVERTER	The Analog to Digital Converter uses a sample and hold technique. It has an 8-bit range.
I2C	Multi/master, single master, single slave modes, DMA or 1byte transfer, standard and fast I2C modes, 7 and 10-bit addressing.
SPI	The Serial peripheral Interface is a fully synchronous 4 wire interface ideal for Master and Slave applications such as driving devices with input shift register (LCD driver, external memory,...).
SCI	The Serial Communication Interface is a fast asynchronous interface which features both duplex transmission, NRZ format, programmable baud rates and standard error detection. The SCI can also emulate RS232 protocol.
WATCHDOG	It has the ability to induce a full reset of the MCU if its counter counts down to zero prior to being reset by the software. This feature is especially useful in noisy applications.
I/O PORTS	They are programmable from software to act in several input or output configurations on an individual line basis including high current and interrupt generation. The basic block has eight CMOS/TTL compatible lines.
LCD	Liquid Crystal Display drive with simple addressing in RAM and drive capability from 1 to 16 multiplexing rates.
Static DAC	True Digital to Analog Converter with up to 12-bit resolution.
DDC	Complete DDC interface for "plug and play" multimedia applications
SYNC PROC.	East/West deflection and synchronization processor for digital monitors.
RDS	Complete RDS decoder embedded in the device for radio applications.

New blocks are continuously being added to the peripheral block library to meet customers' specific needs with regard to the optimal integration level in high volume projects.

ST7 DEVELOPMENT SUPPORT

The ST7 family of MCUs is supported by a comprehensive range of development tools. This family presently comprises hardware tools (emulators, programmers), a software package (assembler-linker, debugger, archiver) and a C-compiler development tool.

The PC-compatible host system forms the platform for the assembler/linker and for the symbolic debugger; it also controls the emulator and enables object code to be downloaded through the RS232 serial link.

The real-time emulator is connected through the probe to the target application. It provides the proper electrical connections, thus allowing duplication of the MCU's functions in the target system. The user program can be executed in real time, in step-by-step mode, or by stepping over call modes.

Breakpoints can be included on instructions, on memory addresses, on address ranges, on the state of one of two output triggers, as well as in trap mode (automatic reset). A logical analyser mode can record four input signals as external events, using a 1K x 32-bit trace and six recording modes, with or without breakpoints. In addition, two output signals are available for synchronisation and for timing measurement.

Each member of the ST7 family has an exclusive probe, dedicated to the device and package. A remote programming tool is available to program EPROM and OTP devices independently (Epromer) or by batches of 10 parts (Gang programmer).

The ST7 assembler is used to translate the source code into relocatable machine code. It accepts a source file written in ST7 assembly language and transforms it into a linkable object file. The assembler recognizes the use of symbols, macros and conditional assembly directives. The ST7 linker/loader combines a number of object files into a single program, associating an absolute address to each section of code. It generates a binary file, containing the image of the ST7 EPROM or ROM memory content. The ST7 library archiver maintains libraries of software object files. Libraries may be used as entry for the linker/loader, together with object files. This allows the user to develop standard modules for repetitive use. The ST7 executable file formatter is responsible for generating an executable file. This file can be downloaded to the emulator or, via the debugger, to the Eprom or OTP device for evaluation and small volume production with the programmer or sent to SGS-THOMSON for production of ROM parts.

A C-compiler development environment is also available. It includes an editor, a compiler, a linker, a debugger and a simulator which are Windows™ compatible, and take full advantage of the ST7 architecture to generate excellent quality code.

1 GLOSSARY

mnem	mnemonic
src	source
dst	destination
cy	duration of the instruction in CPU clock cycles (internal clock)
lgth	length of the instruction in byte(s)
op-code	instruction byte(s) implementation (1..4 bytes)
mem	memory location
byte	a byte
short	represent a short 8-bit addressing mode
long	represent a long 16-bit addressing mode
EA	Effective Address: The final computed data byte address
Page Zero	all data located at [00..FF] addressing space (single byte address)
(XX)	content of a memory location XX
XX	a byte value
MS	Most Significant Byte of a 16-bit value (MSB)
LS	Least Significant Byte of a 16-bit value (LSB)
A	Accumulator Register
X	X Index Register
Y	Y Index Register
reg	A, X or Y register
ndx	index register, either X or Y
PC	16-bit Program Counter Register
SP	16-bit Stack Pointer
S	Stack Pointer LSB
CC	Condition Code Register:

1	1	1	H	I	N	Z	C
---	---	---	---	---	---	---	---

For each instruction, we show how it affects the CC flags:

Nothing	Flag not affected
Flag Name	Flag affected
0	Flag cleared
1	Flag set

Example:

H	I	N	Z	C
	0	N	Z	1

See the Core Description for further details on the CC Register content

2 ST7 CORE DESCRIPTION

2.1 INTRODUCTION

The CPU has a full 8-bit architecture. Six internal registers allow efficient 8-bit data manipulations. The CPU is able to execute 63 basic instructions. It features 17 main addressing modes and can address 6 internal registers.

2.2 CPU Registers

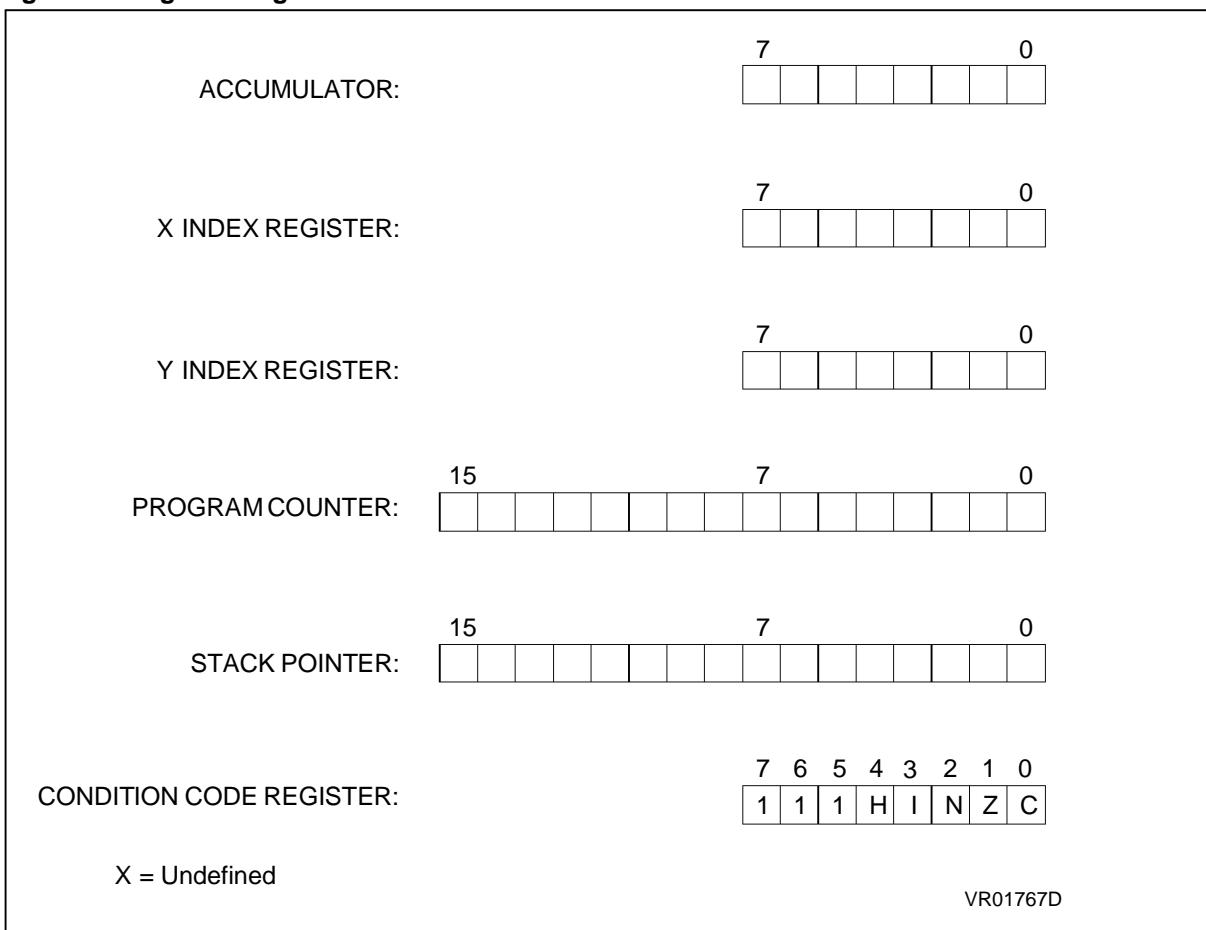

The 6 CPU registers are shown in the programming model in Figure 1. Following an interrupt, the registers are pushed onto the stack in the order shown in Figure 2. They are popped from stack in the reverse order. The Y register is not affected by these automatic procedures. The interrupt routine must therefore handle it, if needed, through the POP and PUSH instructions.

Accumulator (A). The accumulator is an 8-bit general purpose register used to hold operands and the results of the arithmetic and logic calculations as well as data manipulations.

Index Registers (X and Y). These 8-bit registers are used to create effective addresses or as temporary storage area for data manipulations. The cross assembler generates a PRECEDE instruction (PRE) to indicate that the following instruction refers to the Y register. The Y register is never automatically stacked. Interrupt routines must push or pop it by using the POP and PUSH instructions.

Program Counter (PC). The program counter is a 16-bit register used to store the address of the next instruction to be executed by the CPU. It is automatically refreshed after each processed instruction. As a result, the ST7 core can access up to 64 kb of memory.

Figure 1. Programming Mode

CORE DESCRIPTION (Cont'd)**Stack Pointer (SP):**

The stack pointer is a 16-bit register. The 6 least significant bits contain the address of the next free location of the stack. The 10 most significant bits are forced to a preset value. They are reserved for future extension of ST72 family.

The stack is used to save the CPU context on subroutines calls or interrupts. The user can also directly use it through the POP and PUSH instructions.

After an MCU reset, or after the Reset Stack Pointer instruction (RSP), the Stack Pointer is set to its upper value. It is then decremented after data has been pushed onto the stack and incremented after data is popped from the stack. When the lower limit is exceeded, the stack pointer wraps around to the stack upper limit. The previously stored information is then overwritten, and therefore lost.

A subroutine call occupies two locations and an interrupt five locations.

Condition Code Register (CC):

The Condition Code register is a 5-bit register which indicates the result of the instruction just executed as well as the state of the processor. These bits can be individually tested by a program and specified action taken as a result of their state. The following paragraphs describe each bit.

Half carry bit (H):

The H bit is set to 1 when a carry occurs between the bits 3 and 4 of the ALU during an ADD or ADC instruction. The H bit is useful in BCD arithmetic subroutines.

Interrupt mask (I):

When the I bit is set to 1, all interrupts are disabled. Clearing this bit enables them. Interrupts requested while I is set, are latched and can be processed when I is cleared (only one interrupt request per interrupt enable flag can be latched). This bit can be set/reset by software and is automatically set after reset or at the beginning of an interrupt routine.

Negative (N):

When set to 1, this bit indicates that the result of the last arithmetic, logical or data manipulation is negative (i.e. the most significant bit is a logic 1).

Zero (Z):

When set to 1, this bit indicates that the result of the last arithmetic, logical or data manipulation is zero.

Carry/Borrow (C):

When set, C indicates that a carry or borrow out of the ALU occurred during the last arithmetic operation on the MSB operation result bit. This bit is also affected during bit test, branch, shift, rotate and load instructions. See ADD, ADC, SUB, SBC instructions. In bit test operations, C is the copy of the tested bit. See BTJF, BTJT instructions. In shift and rotates operations, the carry is updated. See RRC, RLC, SRL, SLL, SRA instructions

This bit can be set/reset by S/W

Example: Addition: \$B5 + \$94 = "C" + \$49 = \$149

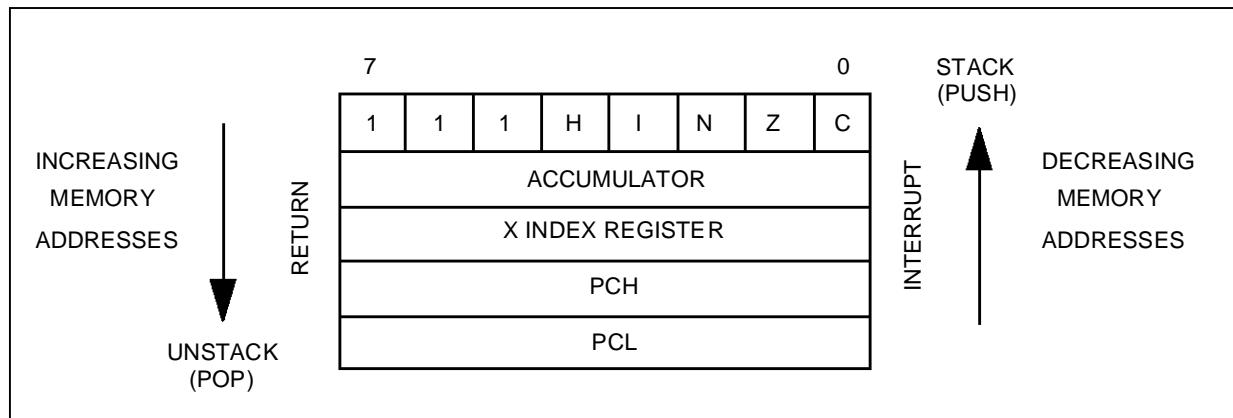

C	7	6	5	4	3	2	1	0
0	1	0	1	1	0	1	0	1

C	7	6	5	4	3	2	1	0
0	1	0	0	1	0	1	0	0

C	7	6	5	4	3	2	1	0
1	0	1	0	0	1	0	0	1

CORE DESCRIPTION (Cont'd)

Figure 2. Stacking Order

3 ST7 ADDRESSING MODES

The ST7 core features 17 different addressing modes which can be classified in 7 main groups:

Addressing Mode	Example
Inherent	nop
Immediate	ld A,#\$55
Direct	ld A,\$55
Indexed	ld A,(\$55,X)
Indirect	ld A,([\$55],X)
Relative	jrne loop
Bit operation	bset byte,#5

The ST7 Instruction set is designed to minimize the number of required bytes per instruction: To do so, most of the addressing modes can be split in two sub-modes called long and short:

- The long addressing mode is the most powerful because it can reach any byte in the 64kb addressing space, but the instruction is bigger and slower than the short addressing mode.
- The short addressing mode is less powerful because it can generally only access the page zero (00..FF range), but the instruction size is more compact, and faster. All memory to memory instructions are only working with short addressing modes (CLR, CPL, NEG, BSET, BRES, BTJT, BTJF, INC, DEC, RLC, RRC, SLL, SRL, SRA, SWAP)

Both modes have pros and cons, but the programmer doesn't need to choose which one is the best: the ST7 Assembler will always choose the best one.

ST7 Addressing Mode Overview:

Mode			Syntax	Destination	Ptr adr	Ptr size	Lgth
Inherent			nop				+ 0
Immediate			ld A,#\$55				+ 1
Short	Direct		ld A,\$10	00..FF			+ 1
Long	Direct		ld A,\$1000	0000..FFFF			+ 2
No Offset	Direct	Indexed	ld A,(X)	00..FF			+ 0
Short	Direct	Indexed	ld A,(\$10,X)	00..1FE			+ 1
Long	Direct	Indexed	ld A,(\$1000,X)	0000..FFFF			+ 2
Short	Indirect		ld A,[\\$10]	00..FF	00..FF	byte	+ 2
Long	Indirect		ld A,[\\$10.w]	0000..FFFF	00..FF	word	+ 2
Short	Indirect	Indexed	ld A,([\\$10],X)	00..1FE	00..FF	byte	+ 2
Long	Indirect	Indexed	ld A,([\\$10.w],X)	0000..FFFF	00..FF	word	+ 2
Relative	Direct		jrne loop	PC+/-127			+ 1
Relative	Indirect		jrne [\$10]	PC+/-127	00..FF	byte	+ 2
Bit	Direct		bset \$10,#7	00..FF			+ 1
Bit	Indirect		bset [\$10],#7	00..FF	00..FF	byte	+ 2
Bit	Direct	Relative	btjt \$10,#7,skip	00..FF			+ 2
Bit	Indirect	Relative	btjt [\$10],#7,skip	00..FF	00..FF	byte	+ 3

ADDRESSING MODES (Cont'd)

Inherent:

All related instructions are single byte ones. The op-code fully specify all required information for the CPU to process the operation. These instructions are single byte ones.

Example:

```
1000 98 rcf  
1001 9D nop
```

Action: Do the operation:

Inherent Instruction	Function
NOP	No operation
TRAP	S/W Interrupt
WFI	Wait For Interrupt (Low Power Mode)
HALT	Halt Oscillator (Lowest Power Mode)
RET	Sub-routine Return
IRET	Interrupt Sub-routine Return
SIM	Set Interrupt Mask
RIM	Reset Interrupt Mask
SCF	Set Carry Flag
RCF	Reset Carry Flag
RSP	Reset Stack Pointer
LD	Load
CLR	Clear
PUSH/POP	Push/Pop to/from the stack
INC/DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
MUL	Byte Multiplication
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles

ADDRESSING MODES (Cont'd)**Immediate:**

The required data byte to do the operation is following the op-code.

Immediate Instruction	Function
LD	Load
CP	Compare
BCP	Bit Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Operations

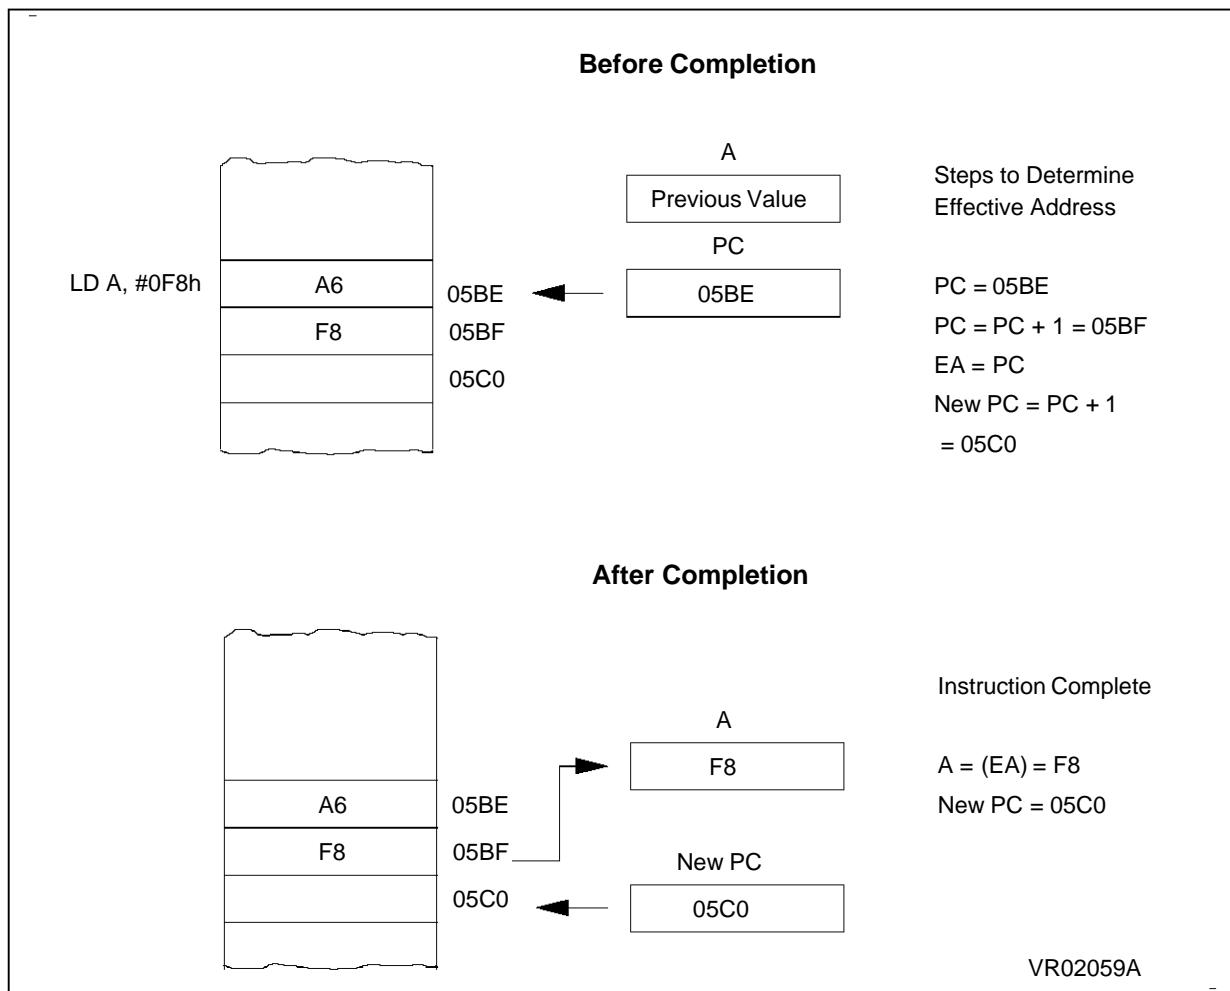

These are two byte instructions, one for the opcode and the other one for the immediate data byte.

Example:

1000	AEFF	ld	X,#\$FF
1002	A355	cp	X,#\$55
1004	A6F8	ld	A,#\$F8

Action: X = \$FF
 Compare (X, \$55)
 A = \$F8

Figure 3. Immediate Addressing Mode Example

ADDRESSING MODES (Cont'd)

Direct (short, long):

Addressing mode		Syntax	EA formula	Ptr Adr	Ptr Size	Dest adr
Short	Direct	(ptr)	(ptr)	op + 1	Byte	00..FF
Long	Direct	(ptr)	(ptr.w)	op + 1..2	Word	0000..FFFF

The required data byte to do the operation is found by its memory address, which follows the op-code.
The direct addressing mode is made of two sub-modes:

Available Long and Short Direct Instructions	Function
LD	Load
CP	Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Additions/Subtractions operations
BCP	Bit Compare

Short Direct Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Operations
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

ADDRESSING MODES (Cont'd)**Short direct:**

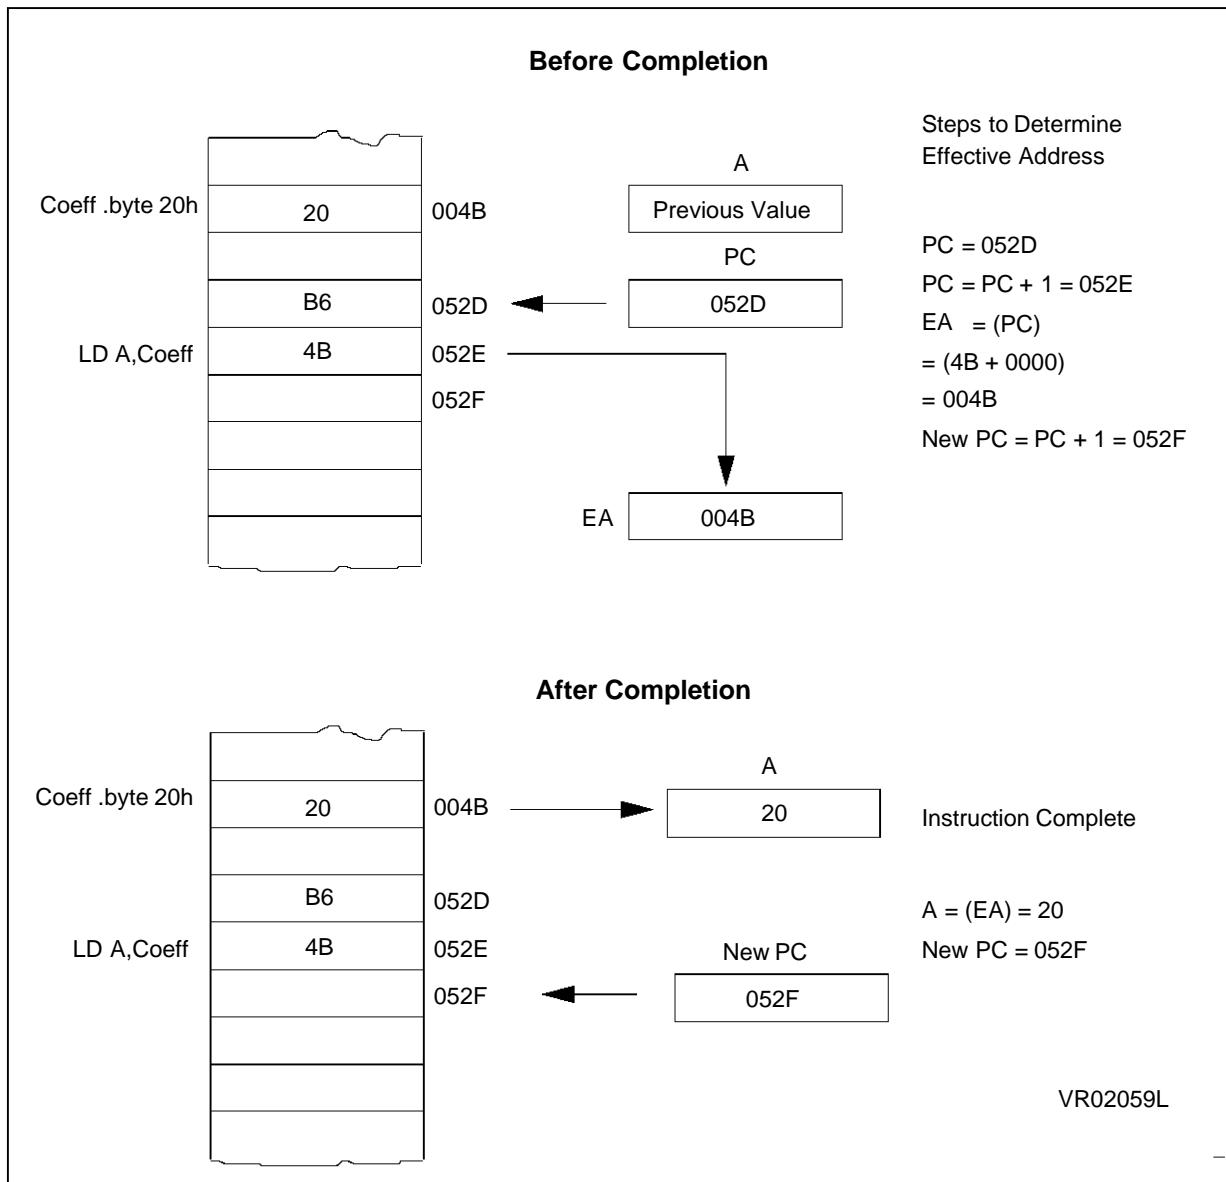

The address is a byte, thus require only one byte after the op-code, but only allow 00..FF addressing space.

Example:

```
004B 20      coeff   dc.b   $20
      052D B64B      Id      A,coeff
```

Action: $A = (\text{coeff}) = (\$4B) = \20

Figure 4. Short Direct Addressing Mode Example

ADDRESSING MODES (Cont'd)

Long direct:

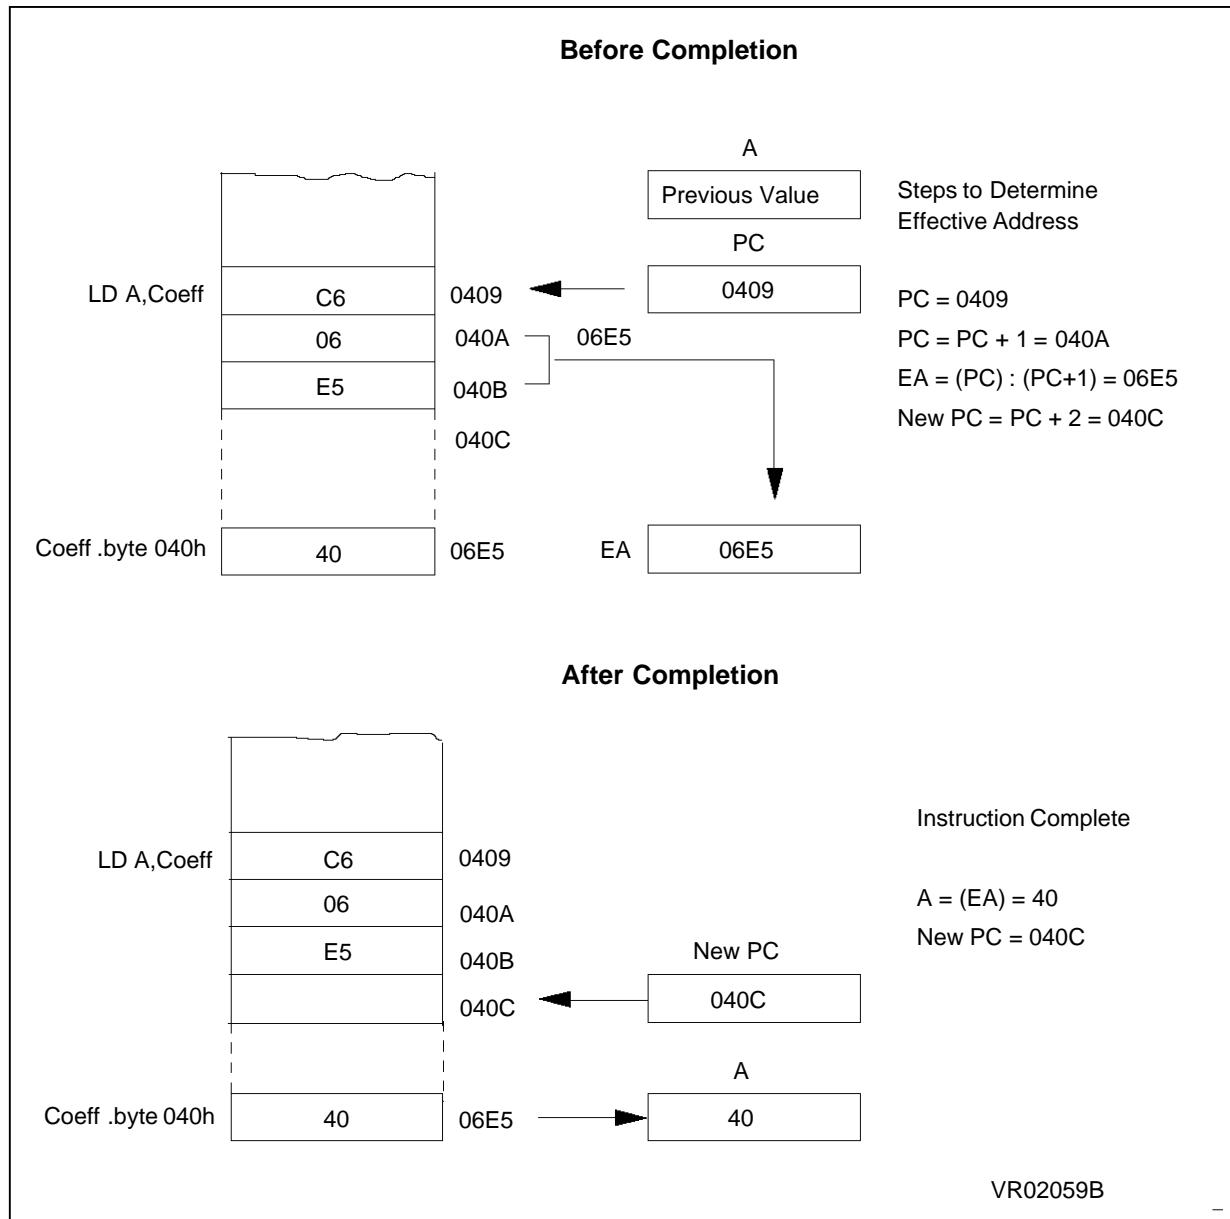

The address is a word, thus allowing 64 kb addressing space, but requires 2 bytes after the op-code.

Example:

0409	C606E5	Id	A,coeff
06E5	40	coeff	dc.b \$ 40

Action: $A = (\text{coeff}) = (\$06E5) = \40

Figure 5. Long Direct Addressing Mode Example

ADDRESSING MODES (Cont'd)**Indexed (no offset, short, long)**

Addressing mode			Syntax	EA formula	Ptr Adr	Ptr Size	Dest adr
No offset	Direct	Indexed	(ndx)	(ndx)	---	---	00..FF
Short	Direct	Indexed	(ptr,ndx)	(ptr + ndx)	op + 1	Byte	00..1FE
Long	Direct	Indexed	(ptr.w,ndx)	(ptr.w + ndx)	op + 1..2	Word	0000..FFFF

The required data byte to do the operation is found by its memory address, which is defined by the unsigned addition of an index register (X or Y) with an offset which follows the op-code.

The indexed addressing mode is made of three sub-modes:

No Offset, Long and Short Indexed Instructions	Function
LD	Load
CP	Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Additions/Subtractions operations
BCP	Bit Compare

No Offset and Short Indexed Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Operations
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

ADDRESSING MODES (Cont'd)

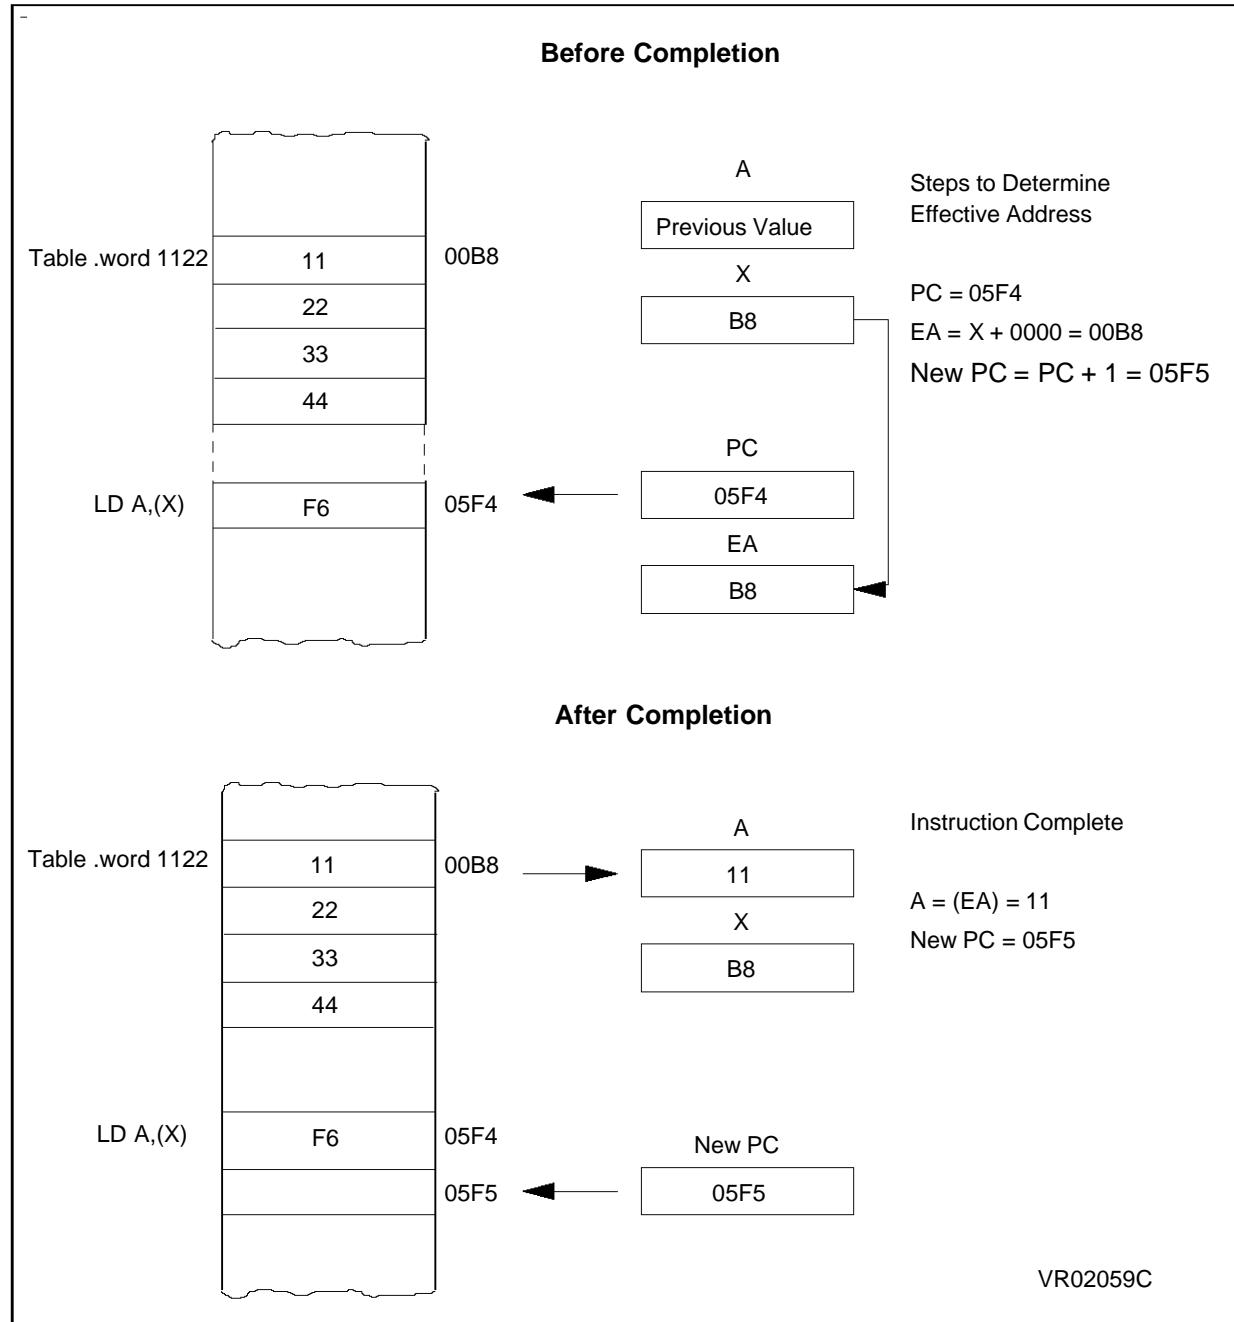

(no offset) Indexed:

There is no offset, (no extra byte after the op-code), but only allows 00..FF addressing space.

Example:

00B8	11223344	table	dc.w	\$1122, \$3344
05F2	AEB8		ld	X,#table
05F4	F6		ld	A,(X)
Action:	X = table			
	A = (X) = (table) = (\$B8) = \$11			

Figure 6. No offset Indexed Addressing Mode Example

ADDRESSING MODES (Cont'd)**Short Indexed:**

The offset is a byte, thus require only one byte after the op-code, but only allow 00..1FE addressing space.

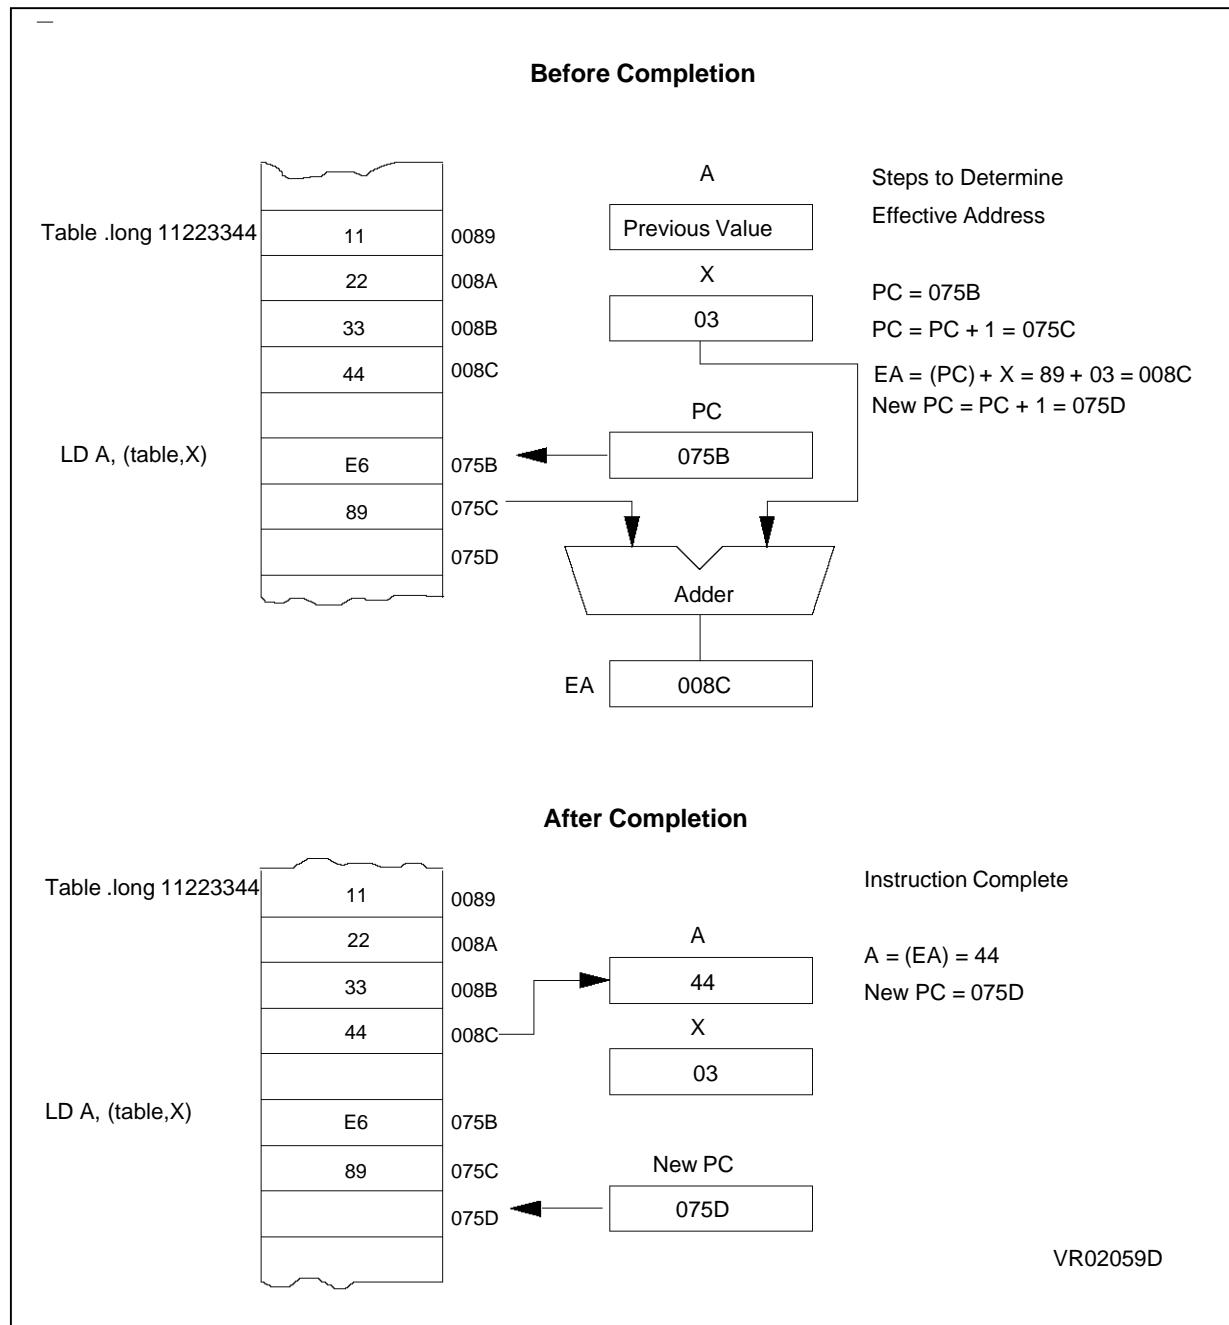

Example:

0089	11223344	table	dc.l	\$11223344
0759	AE03		ld	X,#3
075B	E689		ld	A,(table,X)

Action: X = 3

$$A = (\text{table}, X) = (\$89, X) = (\$89, 3) = (\$8C) = \$44$$

Figure 7. Short Indexed - 8-bit offset - Addressing Mode Example

ADDRESSING MODES (Cont'd)

Long Indexed:

The offset is a word, thus allowing 64 kb addressing space, but requires 2 bytes after the op-code.

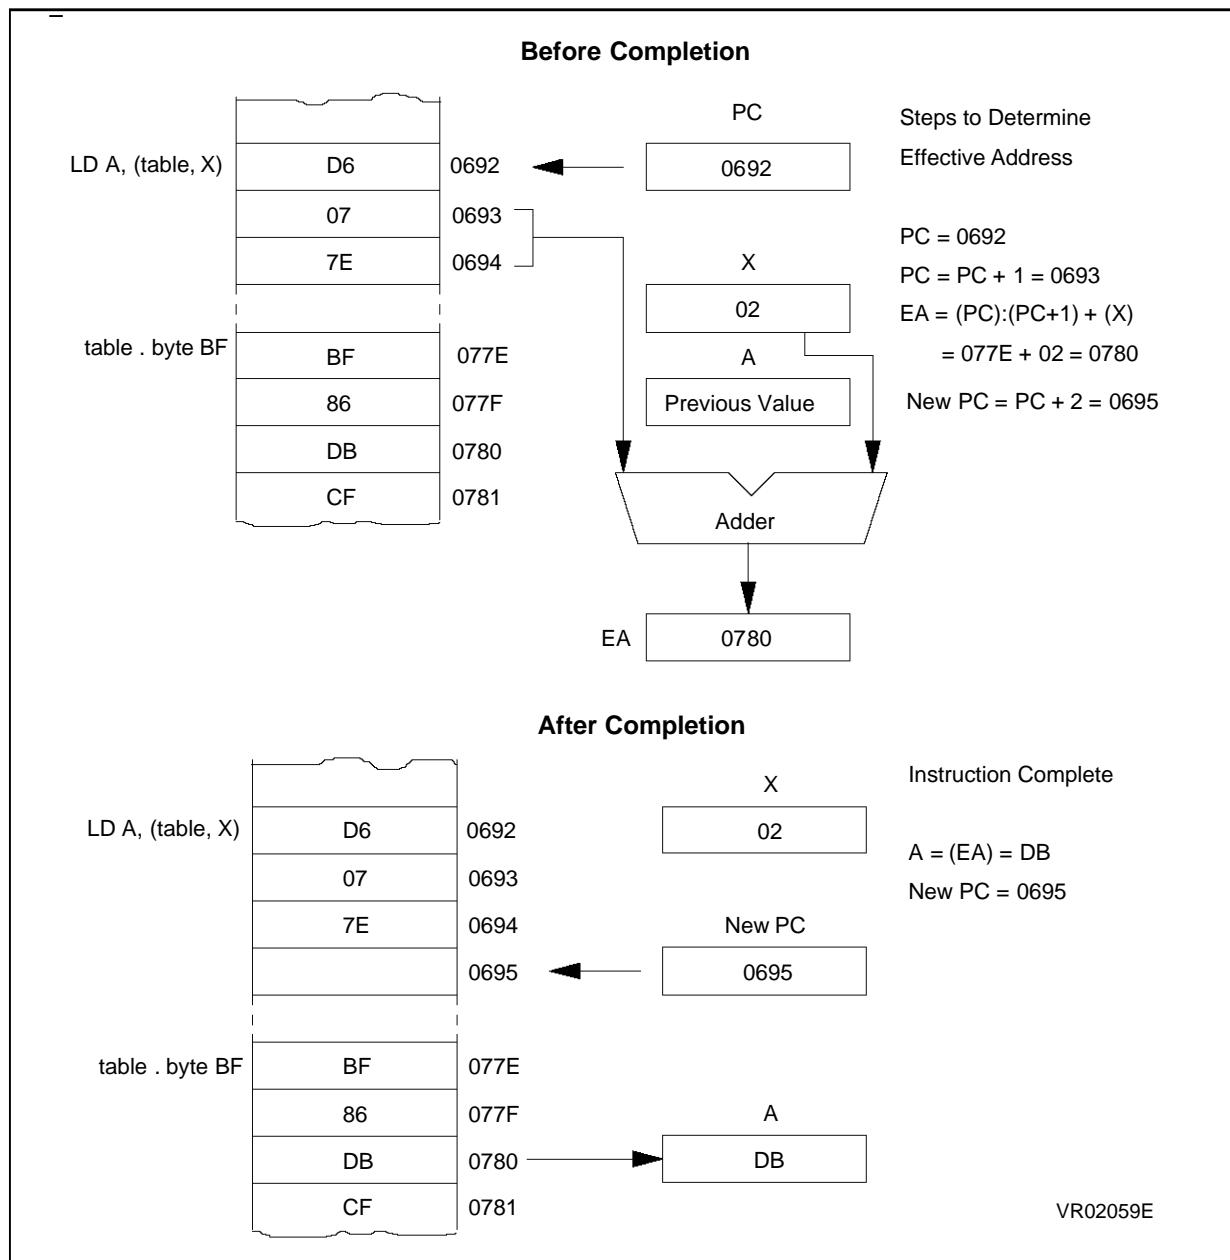

Example:

0690	AE02	Id	X,#2
0692	D6077E	Id	A,(table,X)
077E	BF	table	dc.b \$BF
	86		dc.b \$86
	DBCF		dc.w \$DBCF

Action: X = 2

$$A = (\text{table}, X) = (077E, X) = (077E, 2) = (0780) = \$DB$$

Figure 8. Long Indexed - 16-bit offset - Addressing Mode Example

ADDRESSING MODES (Cont'd)

Indirect (short, long):

Addressing mode		Syntax	EA formula	Ptr Adr	Ptr Size	Dest adr
Short	Indirect	((ptr))	((ptr))	00..FF	Byte	00..FF
Long	Indirect	((ptr.w))	((ptr.w))	00..FF	Word	0000..FFFF

The required data byte to do the operation is found by its memory address, located in memory (pointer).

The pointer address follows the op-code. The indirect addressing mode is made of two sub-modes:

Available Long and Short Indirect Instructions	Function
LD	Load
CP	Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Additions/Subtractions operations
BCP	Bit Compare

Short Indirect Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Operations
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

ADDRESSING MODES (Cont'd)

Short Indirect:

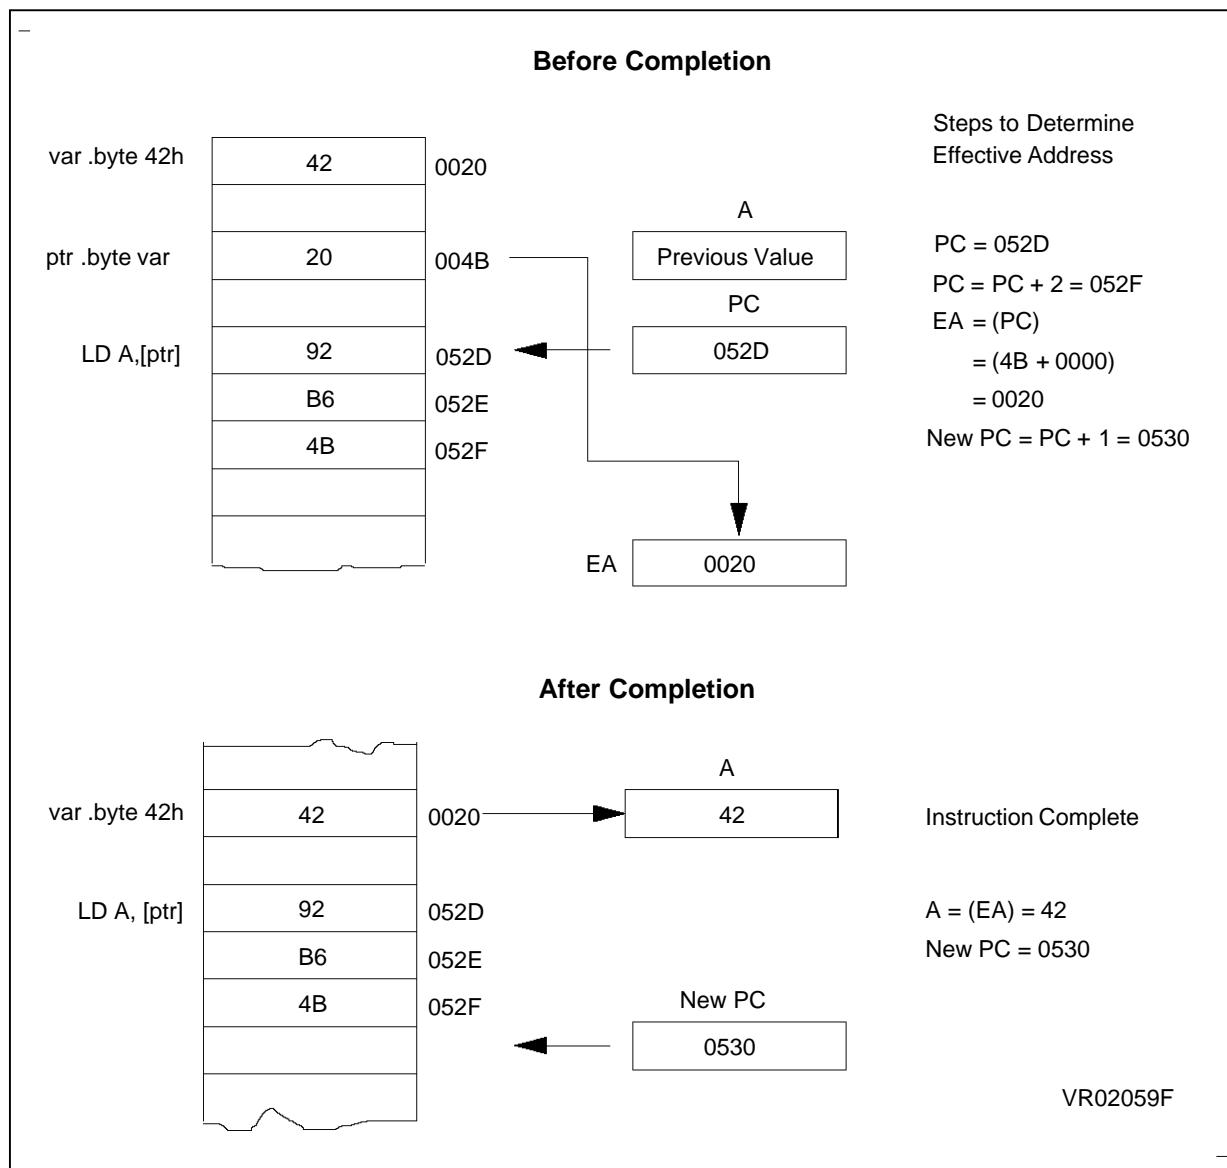

The pointer address is a byte, the pointer size is a byte, thus allowing 00..FF addressing space, and requires 1 byte after the op-code.

Example:

0020	42	var	dc.b	\$42
004B	20	ptr	dc.b	var
052D	92B64B		ld	A,[ptr]

Action: $A = [ptr] = ((ptr)) = ((\$4B)) = (\$20) = \42

Figure 9. Short Indirect Addressing Mode Example

ADDRESSING MODES (Cont'd)**Long Indirect:**

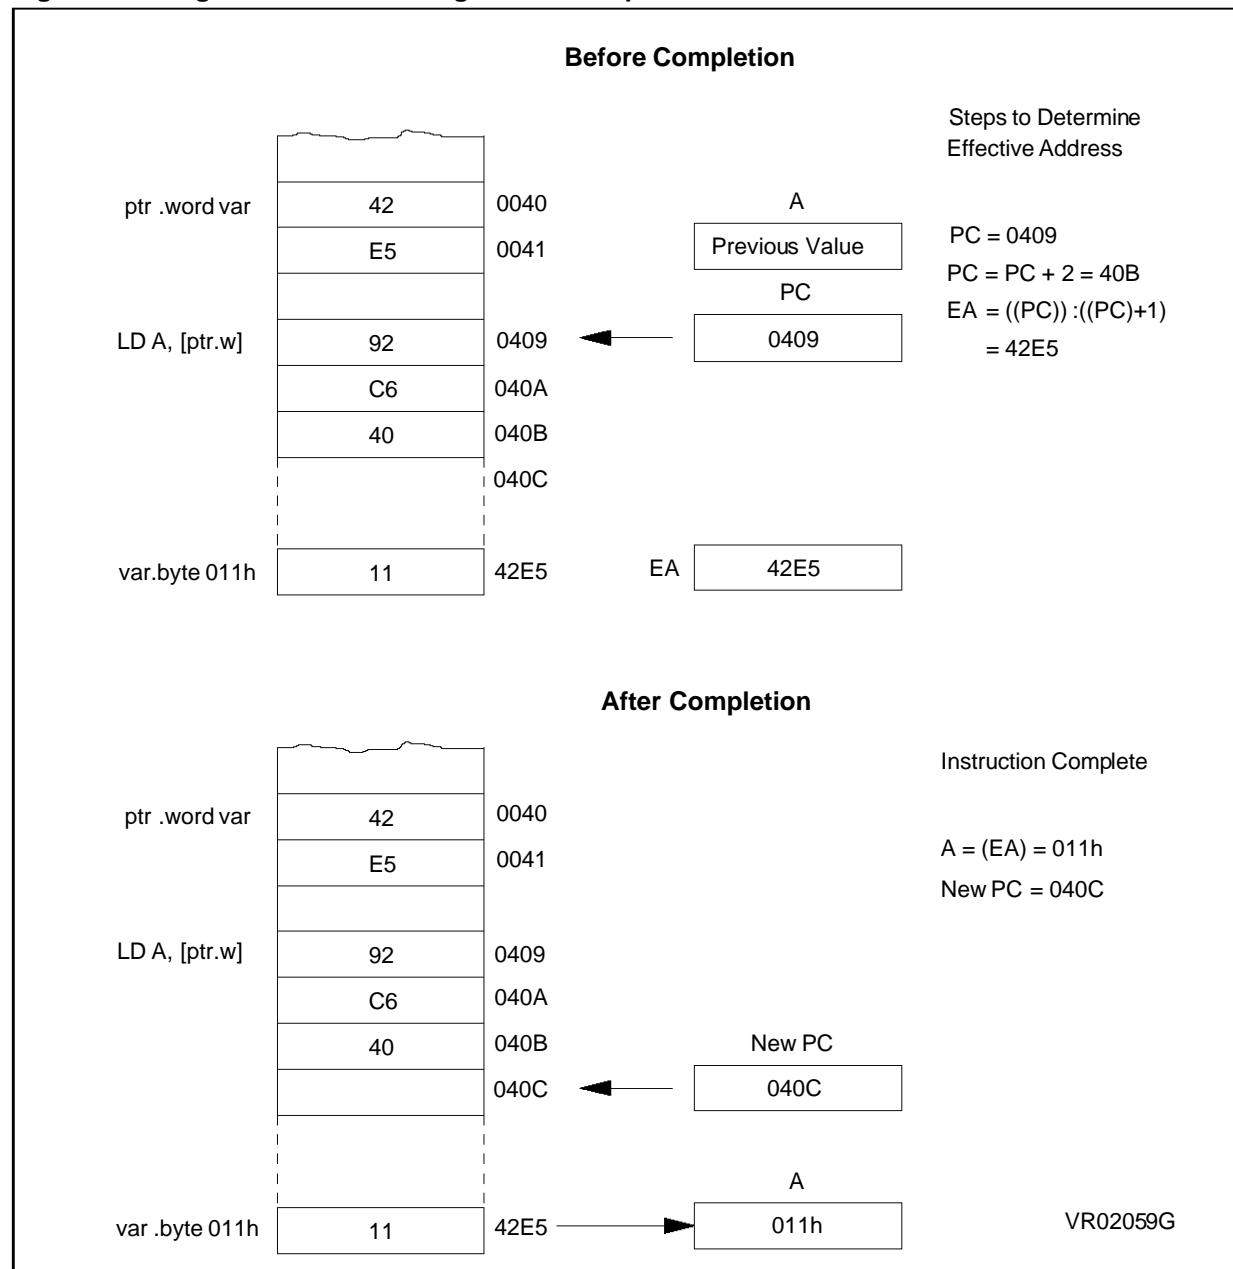

The pointer address is a byte, the pointer size is a word, thus allowing 64 kb addressing space, and requires 1 byte after the op-code.

Example:

0040	42E5	ptr	dc.w	var
0409	92C640		ld	A,[ptr.w]
42E5	11	var	dc.b	\$11

Action: A = [ptr.w] = ((ptr.w)) = ((\$40.w)) = (\$42E5) = \$11

Figure 10. Long Indirect Addressing Mode Example

ADDRESSING MODES (Cont'd)

Indirect indexed (short, long):

Addressing mode			Syntax	EA formula	Ptr Adr	Ptr Size	Dest adr
Short	Indirect	Indexed	([ptr],ndx)	((ptr) + ndx)	00..FF	Byte	00..1FE
Long	Indirect	Indexed	([ptr.w],ndx)	((ptr.w) + ndx)	00..FF	Word	0000..FFFF

This is a combination of indirect and short indexed addressing mode. The required data byte to do the operation is found by its memory address, which is defined by the unsigned addition of an index register value (X or Y) with a pointer value located in memory. The pointer address follows the op-code.

The indirect indexed addressing mode is made of two sub-modes:

Long and Short Indirect Indexed Instructions	Function
LD	Load
CP	Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Additions/Subtractions operations
BCP	Bit Compare

Short Indirect Indexed Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Operations
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

ADDRESSING MODES (Cont'd)**Short indirect indexed:**

The pointer address is a byte, the pointer size is a byte, thus allowing 00..1FE addressing space, and requires 1 byte after the op-code.

Example:

0040 00 table dc.b 0,1,2,3

0041 01

0042 02

0043 03

0089 40 ptr dc.b table

0759 AE03 ld X,#3

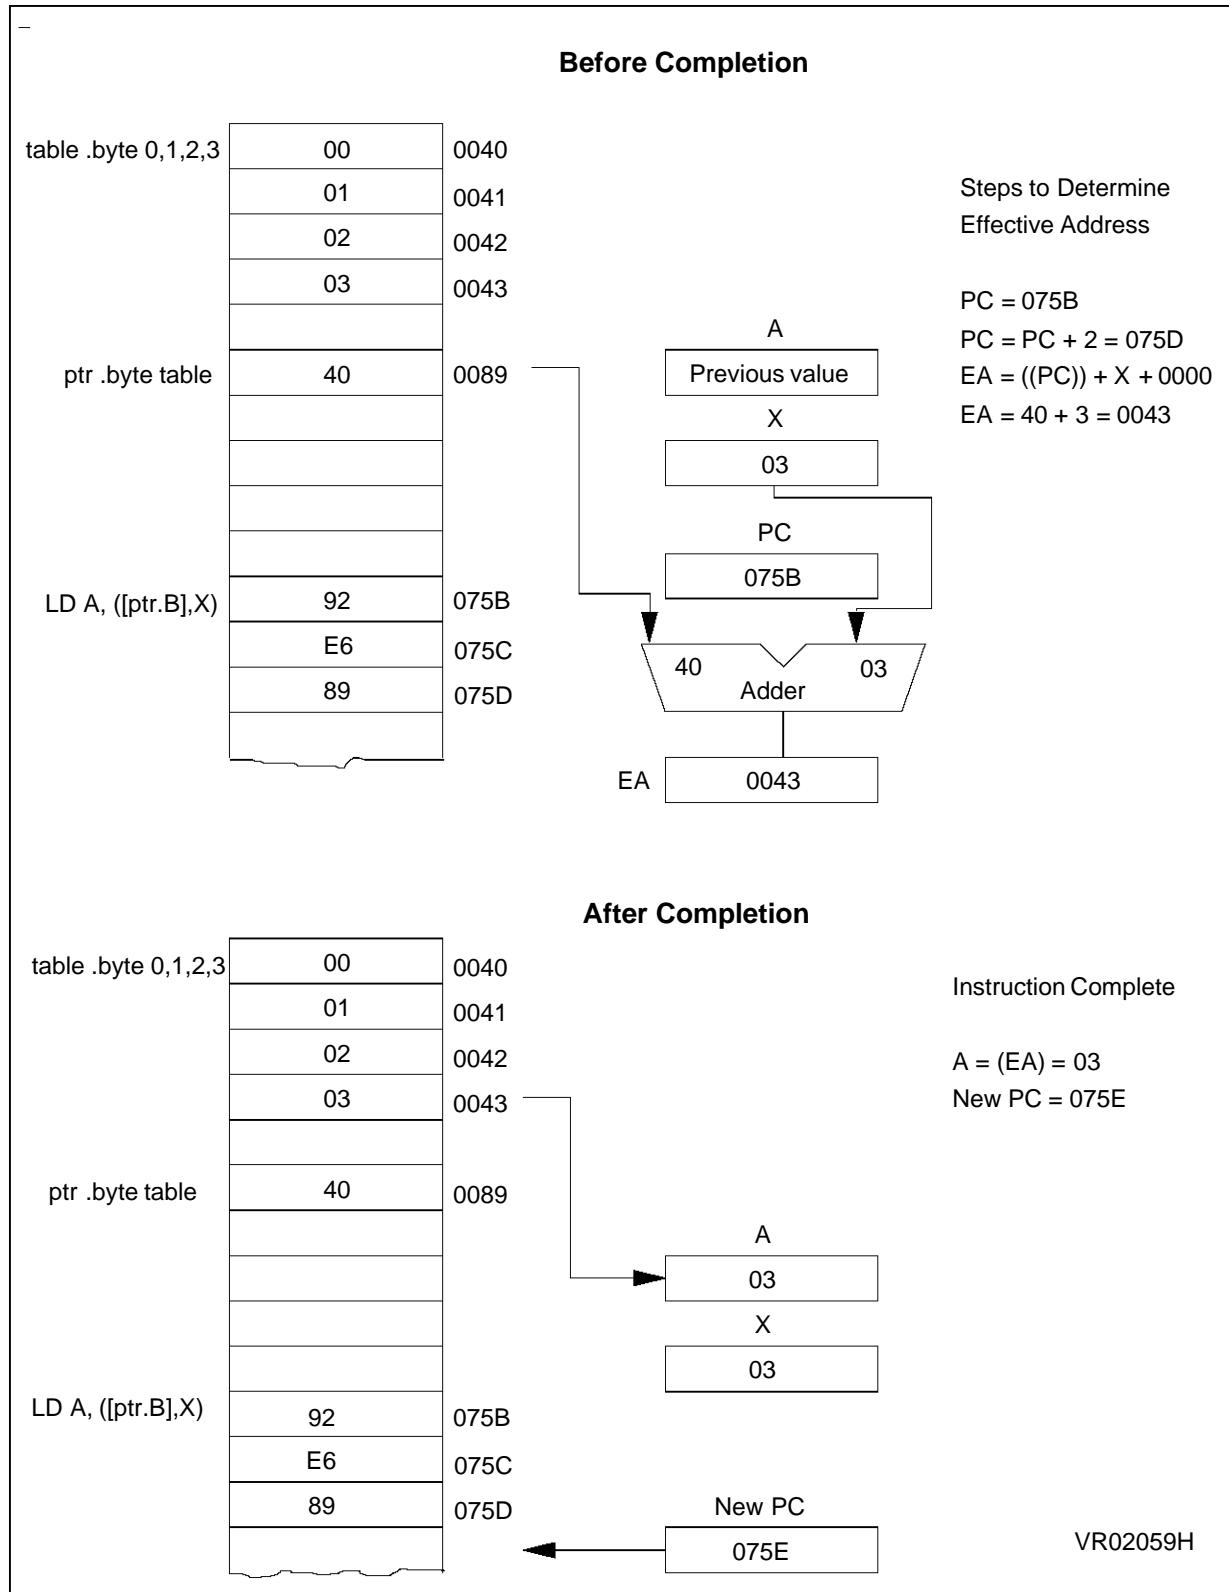

075B 92E689 ld A,([ptr],X)

Action:

X = 3

A = ([ptr],X) = ((ptr), X) = ((\\$89), 3) = (\$40, 3) = (\$43) = 3

Figure 11. Short Indirect Indexed Addressing Mode Example

ADDRESSING MODES (Cont'd)**Long indirect indexed:**

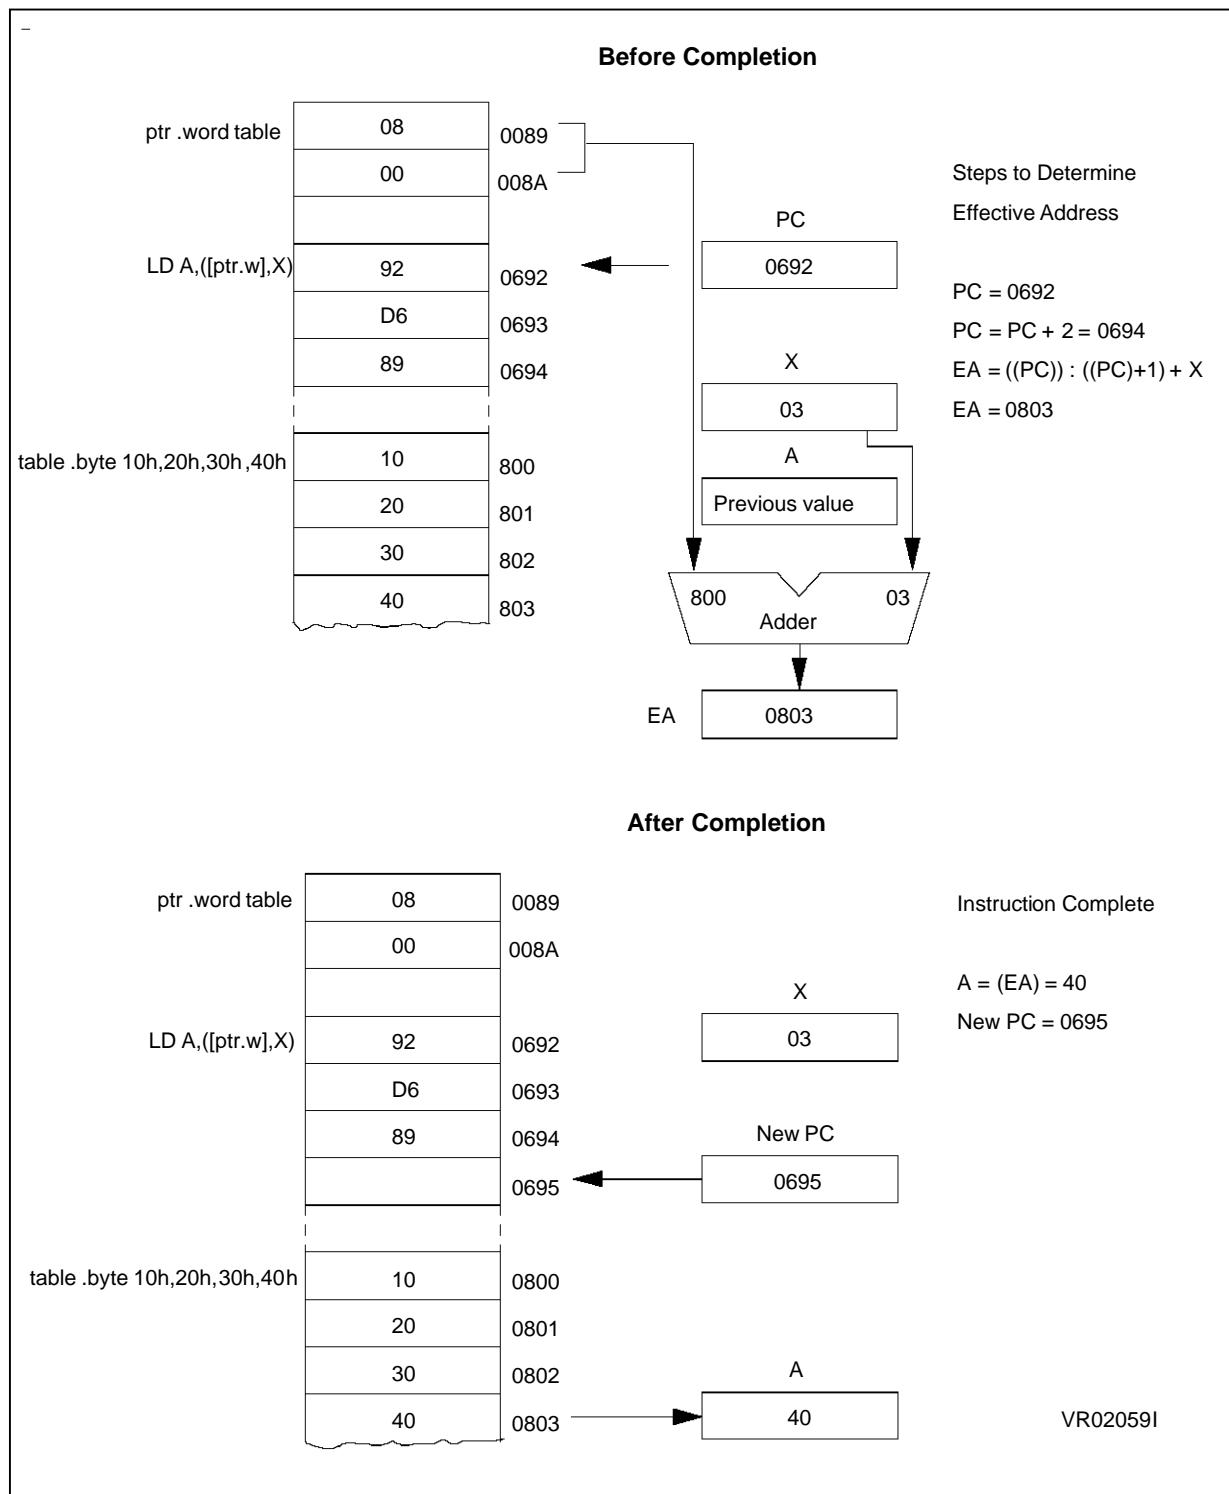

The pointer address is a byte, the pointer size is a word, thus allowing 64 kb addressing space, and requires 1 byte after the op-code.

Example:

0089	0800	ptr	dc.w	table
0800	10203040	table	dc.b	\$10,\$20,\$30,\$40
0690	AE03		Id	X,#3
0692	92D689		Id	A,([ptr.w],X)
				X = 3
				A = ([ptr.w],X) = ((ptr.w), X) = ((\\$89.w), 3)
				= (\$0800,3) = (\$0803) = \$40

ADDRESSING MODES (Cont'd)

Figure 12. Long Indirect Indexed Addressing Mode Example

ADDRESSING MODES (Cont'd)**Relative mode (direct, indirect):**

Addressing mode		Syntax	EA formula	Ptr Adr	Ptr Size	Dest adr
Direct	Relative	oft	PC = PC + oft	op + 1	---	PC +/- 127
Indirect	Relative	[oft]	PC = PC + (oft)	00..FF	Byte	PC +/- 127

This addressing mode is used to modify the PC register value, by adding an 8-bit signed offset to it.

The relative addressing mode is made of two sub-modes:

Available Relative Direct/Indirect Instructions	Function
JRxx	Conditional Jump
CALLR	Call Relative

ADDRESSING MODES (Cont'd)

Relative (Direct):

The offset is following the op-code.

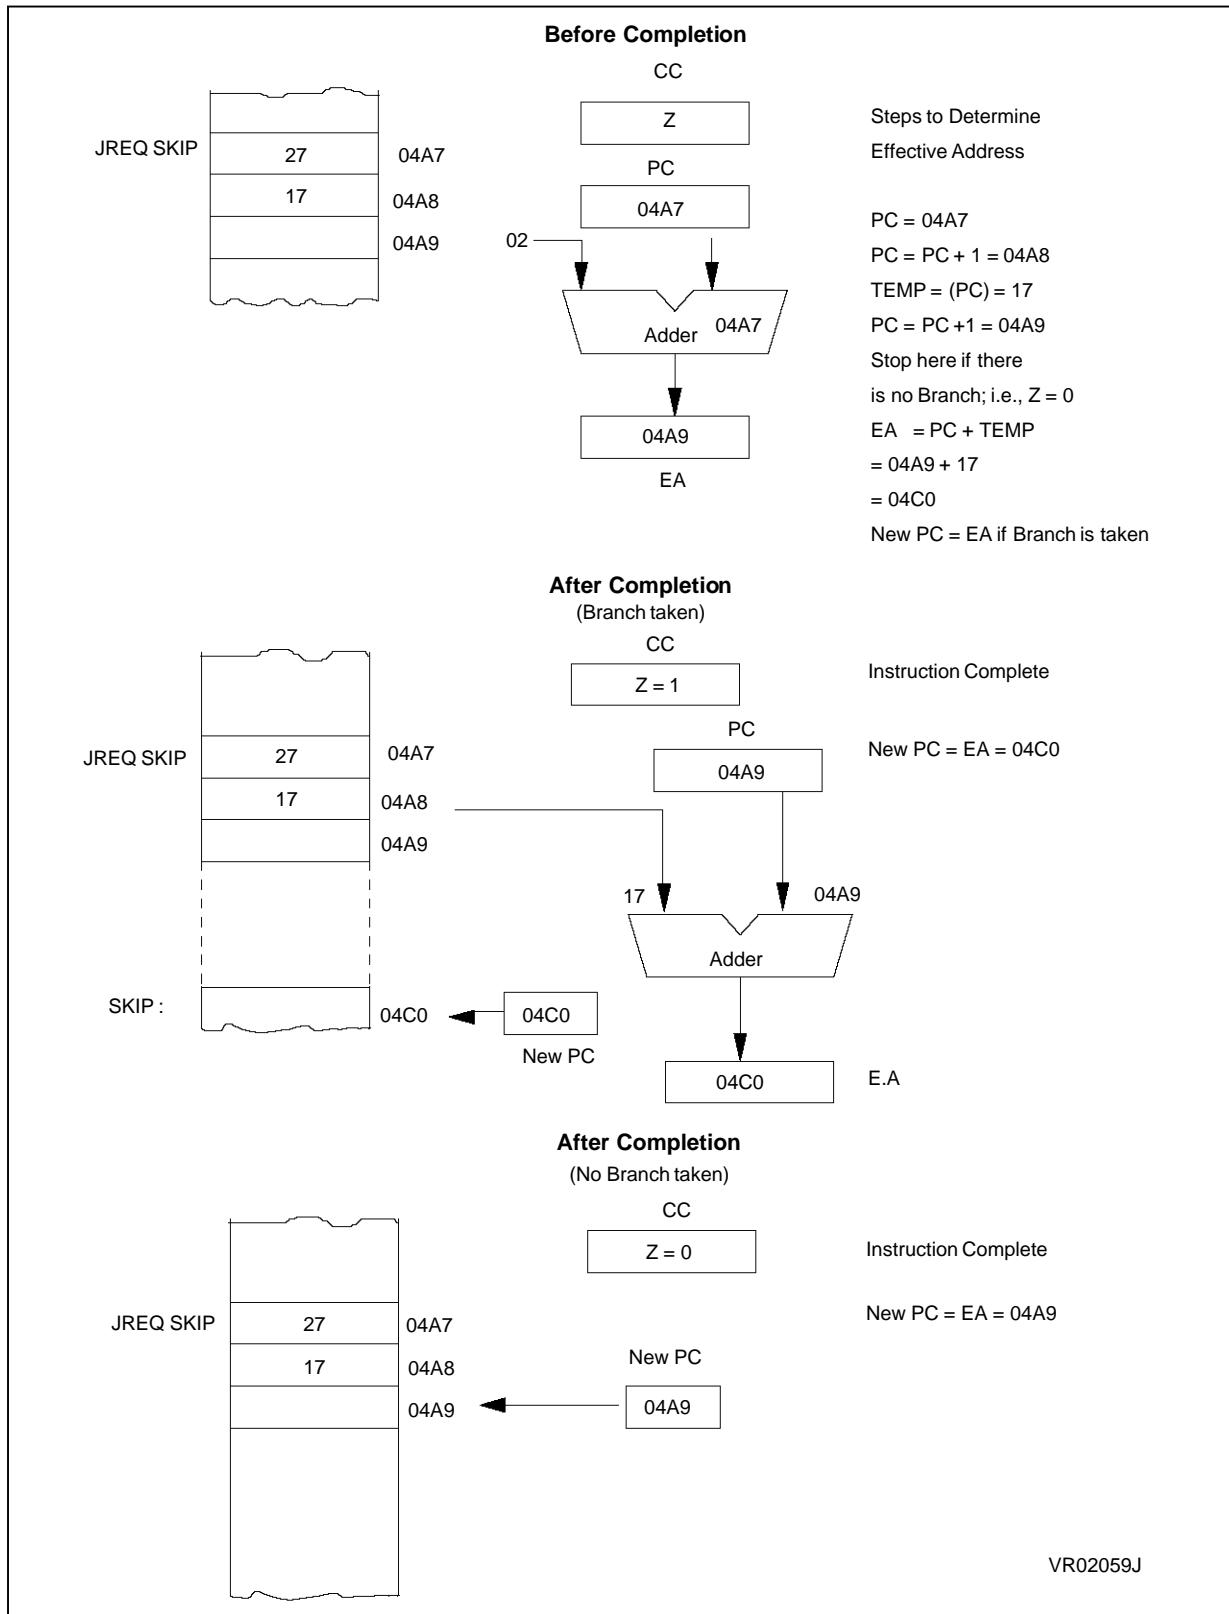

Example:

04A7	2717	jreq	skip
04A9	9D	nop	
04AA	9D	nop	
04C0	20FE	skip	jra * ; Infinite loop

Action: if ($Z == 1$) then $PC = PC + \$17 = \$04A9 + \$17 = \$04C0$
else $PC = PC = \$04A9$

ADDRESSING MODES (Cont'd)

Figure 13. Relative Direct Indexed Addressing Mode Example

ADDRESSING MODES (Cont'd)

Relative Indirect:

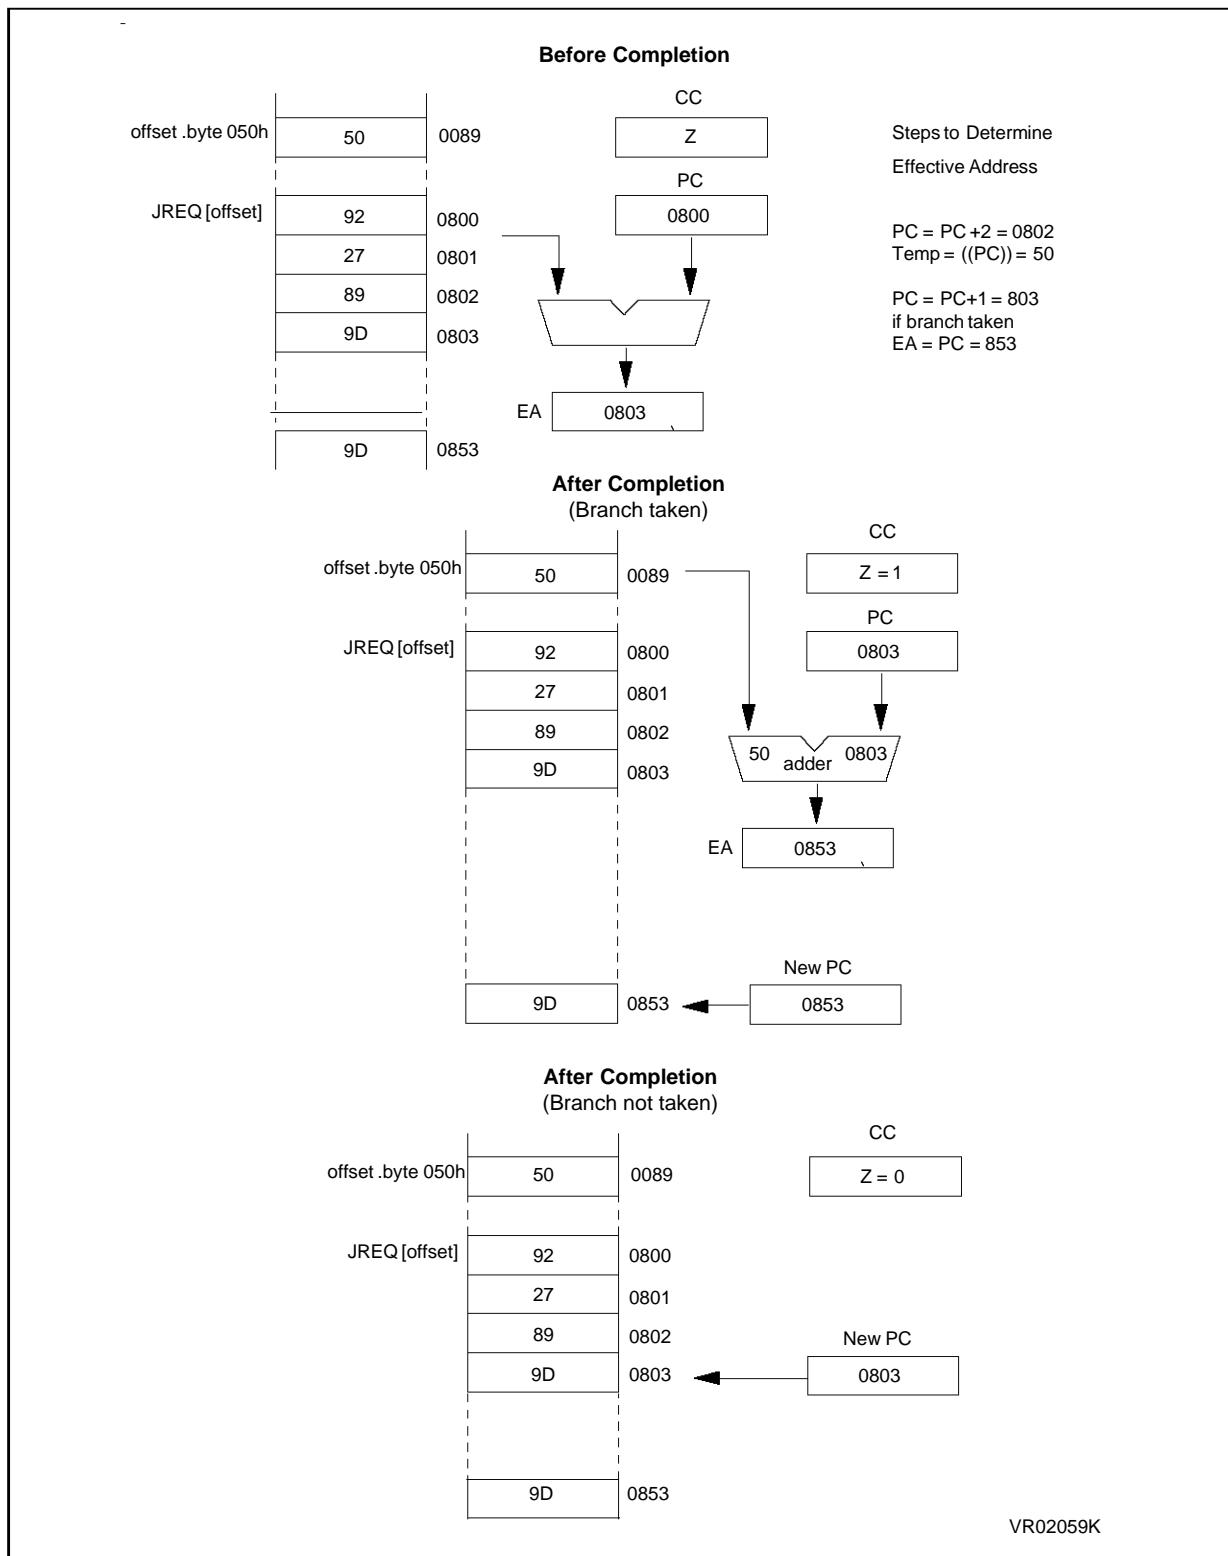

The offset is defined in memory, which address follows the op-code.

Example:

0089	50	offset	dc.b	\$50
0800	922789		jreg	[offset]
0803	9D		nop	
0853	9D		nop	

ADDRESSING MODES (Cont'd)

Figure 14. Relative Indirect Indexed Addressing Mode Example

4 ST7 INSTRUCTION SET

4.1 INTRODUCTION

This chapter describes all the ST7 instructions. They are 63 and are described in alphabetical order. However, they can be classified in 13 main groups as follows:

Load and Transfer	LD	CLR						
Stack operation	PUSH	POP	RSP					
Increment/Decrement	INC	DEC						
Compare and Tests	CP	TNZ	BCP					
Logical operations	AND	OR	XOR	CPL	NEG			
Bit Operation	BSET	BRES						
Conditional Bit Test and Branch	BTJT	BTJF						
Arithmetic operations	ADC	ADD	SUB	SBC	MUL			
Shift and Rotates	SLL	SRL	SRA	RLC	RRC	SWAP	SLA	
Unconditional Jump or Call	JRA	JRT	JRF	JP	CALL	CALLR	NOP	RET
Conditional Branch	JRxX							
Interruption management	TRAP	WFI	HALT	IRET				
Code Condition Flag modification	SIM	RIM	SCF	RCF				

Using a pre-byte

The instructions are described with one to four opcodes.

In order to extend the number of available opcodes for an 8-bit CPU (256 op-codes), three different prebytes are defined. These prebytes modify the meaning of the instruction they precede.

The whole instruction becomes:

- PC-2 End of previous instruction
- PC-1 Prebyte
- PC Op-code
- PC+1 Additional word (0 to 2) according to the number of bytes required to compute the effective address

These prebytes enable instruction in Y as well as indirect addressing modes to be implemented. They precede the opcode of the instruction in X or the instruction using direct addressing mode. The prebytes are:

- PDY 90 Replace an X based instruction using immediate, direct, indexed or inherent addressing mode by a Y one.
- PIX 92 Replace an instruction using direct, direct bit, or direct relative addressing mode to an instruction using the corresponding indirect addressing mode.
It also changes an instruction using X indexed addressing mode to an instruction using indirect X indexed addressing mode.
- PIY 91 Replace an instruction using indirect X indexed addressing mode by a Y one.

4.2 INSTRUCTION SET SUMMARY

Mnemo	Description	Function/Example	Dst	Src
ADC	Add with Carry	A = A + Mem + C	A	Mem
ADD	Addition	A = A + Mem	A	Mem
AND	Logical And	A = A . Mem	A	Mem
BCP	Bit compare A, Memory	tst (A . Mem)	A	Mem
BRES	Bit Reset	bres Byte, #3	Mem	
BSET	Bit Set	bset Byte, #3	Mem	
BTJF	Jump if bit is false (0)	btjf Byte, #3, Jmp1	Mem	
BTJT	Jump if bit is true (1)	btjt Byte, #3, Jmp1	Mem	
CALL	Call subroutine			
CALLR	Call subroutine relative			
CLR	Clear		reg, Mem	
CP	Arithmetic Compare	tst(Reg - Mem)	reg	Mem
CPL	One Complement	A = FFH-A	reg, Mem	
DEC	Decrement	dec Y	reg, Mem	
HALT	Halt			
IRET	Interrupt routine return	Pop CC, A, X, PC		
INC	Increment	inc X	reg, Mem	
JP	Absolute Jump	jp [TBL.w]		
JRA	Jump relative always			
JRT	Jump relative			
JRF	Never jump	jrf *		
JRIH	Jump if Port INT pin = 1	(no Port Interrupts)		
JRIL	Jum if Port INT pin = 0	(Port interrupt)		
JRH	Jump if H = 1	H = 1 ?		
JRNH	Jump if H = 0	H = 0 ?		
JRM	Jump if I = 1	I = 1 ?		
JRNM	Jump if I = 0	I = 0 ?		
JRMI	Jump if N = 1 (minus)	N = 1 ?		
JRPL	Jump if N = 0 (plus)	N = 0 ?		
JREQ	Jump if Z = 1 (equal)	Z = 1 ?		
JRNE	Jump if Z = 0 (not equal)	Z = 0 ?		
JRC	Jump if C = 1	C = 1 ?		
JRNC	Jump if C = 0	C = 0 ?		
JRULT	Jump if C = 1	Unsigned <		

ST7 Programming Manual

INSTRUCTION SET SUMMARY (Cont'd)

Mnemo	Description	Function/Example	Dst	Src	H	I	N	Z	C
JRUGE	Jump if C = 0	Jmp if unsigned >=							
JRUGT	Jump if (C + Z = 0)	Unsigned >

LD	Load	dst <= src	reg, Mem	Mem, reg			N	Z	
MUL	Multiply	X,A = X * A	A, X, Y	X, Y, A	0				0
NEG	Negate (2's compl)	neg \$10	reg, Mem				N	Z	C
NOP	No Operation								
OR	OR operation	A = A + Mem	A	Mem			N	Z	
POP	Pop from the Stack	pop reg pop CC	reg CC	Mem Mem	H	I	N	Z	C
PUSH	Push onto the Stack	push Y	Mem	reg, CC					
RCF	Reset carry flag	C = 0							0
RET	Subroutine Return								
RIM	Enable Interrupts	I = 0			0				
RLC	Rotate left true C	C <= A <= C	reg, Mem				N	Z	C
RRC	Rotate right true C	C => A => C	reg, Mem				N	Z	C
RSP	Reset Stack Pointer	S = Max allowed							
SBC	Subtract with Carry	A = A - Mem - C	A	Mem			N	Z	C
SCF	Set carry flag	C = 1							1
SIM	Disable Interrupts	I = 1			1				
SLA	Shift left Arithmetic	C <= A <= 0	reg, Mem				N	Z	C
SLL	Shift left Logic	C <= A <= 0	reg, Mem				N	Z	C
SRL	Shift right Logic	0 => A => C	reg, Mem				0	Z	C
SRA	Shift right Arithmetic	A7 => A => C	reg, Mem				N	Z	C
SUB	Substraction	A = A - Mem	A	Mem			N	Z	C
SWAP	SWAP nibbles	A7-A4 <=> A3-A0	reg, Mem				N	Z	
TNZ	Test for Neg & Zero	tnz lbl1					N	Z	
TRAP	S/W trap	S/W interrupt					1		
WFI	Wait for Interrupt						0		
XOR	Exclusive OR	A = A XOR Mem	A	M			N	Z	

ADC**Addition with Carry****ADC****Syntax**

adc dst,src e.g.: adc A,#\$15

Operation

dst <= dst + src + C

Description

The source byte, along with the carry flag, is added to the destination byte and the result is stored in the destination byte. The source is a memory byte, and the destination is the A register.

Instruction Overview:

mnem	dst	src
ADC	A	Mem

Condition Flags

H	I	N	Z	C
H		N	Z	C

Detailed Description:

ADD

Addition

ADD

Syntax

add dst,src e.g.: add A,#%11001010

Operation

dst <= dst + src

Description

The source byte is added to the destination byte and the result is stored in the destination byte. The source is a memory byte, and the destination is the A register.

Instruction Overview

mnem	dst	src
ADD	A	Mem

Condition Flags

AND**Logical****AND****Syntax**

and dst,src e.g.: and A,#%00110101

Operation

dst <= dst AND src

Description

The source byte, is ANDed with the destination byte and the result is stored in the destination byte. The source is a memory byte, and the destination is the A register.

Truth Table:

AND	0	1
0	0	0
1	0	1

Instruction Overview

mnem	dst	src
AND	A	Mem

Condition Flags

BCP**Logical Bit Compare****BCP****Syntax**

bcp src,dst e.g.: bcp A,#%10100101

Operation

{N, Z} <= src AND dst

Description

The source byte, is ANDed to the destination byte. The result is lost but condition flags N and Z are updated accordingly. The source is a memory byte, and the destination is A register. This instruction can be used to perform bit tests on A.

Instruction Overview

mnem	dst	src
BCP	A	Mem

BRES**Bit Reset****BRES****Syntax**

bres dst,#pos pos = [0..7] e.g.: bres PADR,#6

Operation

dst <= dst AND (2**pos)

Description

Read the destination byte, reset the corresponding bit (bit position), and write the result in destination byte. The destination is a memory byte. The bit position is a constant. This instruction is fast, compact, and does not affect any register. Very useful for boolean variable manipulation.

Instruction Overview

mnem	dst	bit position
BRES	Mem	#pos

Condition Flags

H	I	N	Z	C

BTJF**Bit Test and Jump if False****BTJF****Syntax**

btjf dst,#pos,rel pos = [0..7], rel is relative jump label
 e.g.: btjf PADR,#3,skip

Operation

PC = PC + 3
 PC = PC + rel IF (dst AND (2**pos)) = 0

Description

Read the destination byte, test the corresponding bit (bit position), and jump to 'rel' label if the bit is false (0), else continue the program to the next instruction. The tested bit is saved in the C flag. The destination is a memory byte. The bit position is a constant. The jump label points to an memory location around the instruction (relative jump). This instruction is used for boolean variable manipulation, H/W register flag tests, or I/O polling method. This instruction is fast, compact, and does not affect any register. Very useful for boolean variable manipulation.

BTJT

BTJT

Bit Test and Jump if True

BTJT

Syntax

btjt dst,#pos,rel pos = [0..7], rel is relative jump label
 e.g.: btjt PADR,#7,skip

Operation

PC = PC + 3
 PC = PC + rel IF (dst AND (2**pos)) <> 0

Description

Read the destination byte, test the corresponding bit (bit position), and jump to 'rel' label if the bit is true (1), else continue the program to the next instruction. The tested bit is saved in the C flag. The destination is a memory byte. The bit position is a constant. The jump label points to an memory location around the instruction (relative jump). This instruction is used for boolean variable manipulation, H/W register flag tests, or I/O polling method.

CALL**CALL Subroutine (Absolute)****CALL****Syntax**

CALL dst e.g.: call divide32_16

Operation

PC = PC+lgth
 (SP--) = LSB (PC)
 (SP--) = MSB (PC)
 PC = dst

Description

The current PC register value is pushed onto the stack, then PC is loaded with the destination address. This instruction should be used versus CALLR when developing a program.

Instruction Overview

LD

CP

Compare

CP

Syntax

cp dst,src e.g.: cp A,(tbl,X)

Operation

{N, Z, C} = Test(dst - src)

Description

The source byte is subtracted from the destination byte and the result is lost. However, N, Z, C are updated according to the result. The destination is a register, and the source is a memory byte. This instruction generally is placed just before a conditional jump instruction.

HALT

HALT Oscillator (CPU + Peripherals)

HALT

Syntax

HALT

Operation

I = 0, The Oscillator is stopped till an interrupt occur.

Description

The interrupt mask is reset, allowing interrupts to be fetched. Then the Oscillator is stopped thus stopping the CPU and all internal peripherals, reducing the microcontroller to its lowest possible power consumption. The micro will continue the program upon an external interrupt, by restarting the oscillator (with 4096 clock cycles delay), and then, fetching the corresponding external interrupt, which is generally either an I/O interrupt or an external Reset.

NEG

Negate (Logical 2-Complement)

NEG

Syntax

neg dst e.g.: neg (X)

Operation

dst <= (dst XOR FF) + 1, or 00 - dst

Description

The destination byte is read, then each bit is toggled (inverted), and the result is incremented before it is written at the destination byte. The destination is either a memory byte or a register. The Carry is cleared if the result is zero. This instruction is used to negate signed values. This instruction is compact, and does not affect any register when used with RAM variables.

IRET

WFI

Wait for Interrupt (CPU Stopped, Low Power Mode)

WFI

Syntax

WFI

Operation

I = 0, The CPU Clock is stopped till an interrupt occur. Internal Peripheral are still running.

Description

The interrupt flag is cleared, allowing interrupts to be fetched. Then the CPU clock is stopped, reducing the microcontroller to a lower power consumption. The micro will continue the program upon an internal or external interrupt.

Instruction Overview

5 SOFTWARE Library

In order to simplify and hasten the development of any ST7 application, many useful standard routines are shown in this chapter. They are general purpose ones, since they do not interact with any H/W cell. These routines are split in 8 main groups:

Table of Contents:

5.1 Tips:

- How to increment up to XX?
- How to decrement down to XX?
- How to convert Hex to Decimal?
- How to convert Hex to Percentage?
- How to compute a parity bit?

5.2 Emulate Standard Sub-Routine Call Implementation SWI XX

5.3 Dynamic Bit Set/Reset

5.4 Implementation of jump call vector tables

5.5 Check that a 16 bit value is inside a range by medium and delta

5.6 Check that a 16 bit value is in between min and max

5.7 Word unsigned multiply

5.8 Long by Word unsigned division

SOFTWARE LIBRARY (Cont'd)**5.1 TIPS GENERAL TRICKS****Trick 1:How to increment A up to XX?**

```
cp      A,#XX
adc    A,#0
```

Trick 2:How to decrement A down to XX?

```
cp      A,#XX
adc    A,#$FF
```

Trick 3:How to convert A, hexa value in \$00..\$99 Decimal?

```
add   A,#$66
jrh   skip1
sub   A,#$06

skip1 jrc   skip2
       sub   A,#$60

skip2 nop
```

; Each nibbles represent 2 decimal digits 0..9,0..9

Trick 4:How to convert a \$00..\$FF (A) value into 00..100 percentage range?

```
push  X
ld    X,#101
mul   A,X
ld    A,X
pop   X
```

Trick 5:How to deduce a parity bit of X content value ? (Returned in C)

```
ld    Y,#8
clr  A

loop srl  X
      adc  A,#0
      dec  Y
      jrne loop

      srl  A
```

SOFTWARE LIBRARY (Cont'd)

5.2 SWI Immediate, Standard Sub-Routine call implementation

Action: Call standard and translatable general H/W purpose routine

Usage: XX = 00..7F

MACRO: SWI XX
TRAP
JRF XX

MEND

Advantage: Build standard library
Register Context automatically saved
Can be modified to simulate extra registers (XX = Data address)

Variable definition:

BYTES

segment 'ram'

ptr ds.w 1
SH equ \$01 ; Stack MSB Fixed Value

WORDS

segment 'rom'

jump     ld     A,{ptr+1},X
          push  A
          ld     A,ptr,X
          push  A
          ret
```

SOFTWARE LIBRARY (Cont'd)

5.5 CHKRNG, Check range

Inputs: WORD delta The delta tolerance, unsigned
WORD valmed The range middle, unsigned
WORD X:A The value to test, unsigned

Action: Test if valmed - delta =< X:A =< valmed + delta

Output: C = 1 if the test failed

Sub-routine: chkminmax Described in this chapter

Variable definition:

BYTES

segment 'ram'

delta ds.w 1

WORDS

segment 'ram2'

valtyp ds.w 1
valmed ds.w 1

Program Listing:

```
chkrng    ld      valtyp,X
          ld      {valtyp+1},A; Save typical value

          ld      A,{valmed+1};
          add   A,{delta+1};
          ld      {valmax+1},A;
          ld      A, valmed
          adc   A,delta
          ld      valmax,A; max = med + delta

          jrnc   no_ovfmax
          ld      A,#$FF
