NOTES:

- 1. The viewing angle range is defined as shown in Figure 3.
- 2. Contrast ratio is defined as follows:

When input signal is applied to the unit to select (turn on) the LCD dots (pixels) to be measured in the optical characteristics test method as defined in Figure 4.

Contrast ratio =
Photodetector output voltage with non-select waveform being applied
Photodetectoroutput voltage with select waveform being applied

Measurement wave length: $\lambda = 580 \text{ nm}$

3. When input signal for selecting or non-selecting the dots to be measured are applied using the optical characteristics test method shown in Figure 4. The response characteristics of the photodetector output are measured as shown in Figure 5.

PIN DESCRIPTION

V_{DD} and V_{SS} Pins

 V_{DD} and V_{SS} pins are for the power supply. V_{SS} pin is grounded, and V_{DD} pin is supplied with +5 V. Each voltage necessary to drive LCD is generated in the unit.

RS Pin

The controller LSI contains two 8-bit registers: instructions register (IR) and data register (DR). RS pin selects these registers.

IR serves to store instruction codes for display clear, shift, etc. and address information for display data RAM (DD RAM), character generator RAM (CG RAM); DR serves to temporarily store data to be written into DD RAM and CG RAM.

'0': Instruction register (Write)Busy flag register; address counter (Read)

'1': Data register (Read/Write)

R/W Pin

Read or write selection signal pin.

'0': Write

'1': Read

E Pin

Data read or write operation enable signal pin.

DB₀ to DB₇ Pins

Tri-state bidirectional data bus pins. The bus allows data to be transmitted to or received from the external circuit. DB_7 serves also as busy flag output. When the unit is interfaced to a microcomputer with 4-bit parallel outputs, DB_0 to DB_3 pins are not used.

V₀ Pin

Viewing angle is varied and contrast is adjusted by changing input voltage between +5 V to 0 V by applying bias voltage to the LCD driver.
