HALL EFFECT DEVICES

TRANSISTOR ARRAYS

SPRAGUE ELECTRIC COMPANY

SEMICONDUCTOR DIVISION

INTERFACE AND LINEAR INTEGRATED CIRCUITS

115 Northeast Cutoff • Worcester, Mass. 01606 • 617/853-5000

DISCRETE SEMICONDUCTORS AND HALL EFFECT ICs

70 Pembroke Road • Concord, N.H. 03301 • 603/224-1961

Contents

SECTION 1 — GENERAL INFORMATION

Product Index	1-2
Part Numbering System	1-5
Cross-Reference (Competitive to Sprague)	1-7
How To Place An Order	1-15
Sprague Facilities	1-16
Engineering Bulletins	1-18
See Also:	
Sales Offices	Back Cover

SECTION 2 — HIGH-VOLTAGE INTERFACE DRIVERS

Selection Guide	2-2
UHP-480 through 482 Gas-Discharge Display Segment Drivers	2-3
UHD/UHP-490 and 491 Gas-Discharge Display Digit Drivers	2-5
UHP-495 Gas-Discharge Display Digit Driver	2-8
UDN-6116A through 6128A-2 Fluorescent Display Drivers	2-10
UDN-6116R through 6128R-2 Hermetic Fluorescent Display Drivers	2-10
UDN-6138A through 6148A-2 Fluorescent Display Drivers	2-10
UDN-6164A and 6184A Gas-Discharge Display Digit Drivers	2-14
UDN-7180A through 7186A Gas-Discharge Display Segment Drivers	2-16
Application Notes:	
A Monolithic IC Series for Gas-Discharge Displays	2-22
Trends in IC Interface for Electronic Displays	2-28

SECTION 3 — HIGH-CURRENT INTERFACE DRIVERS

Selection Guide	3-2
UHP-400 through 433-1 Quad Power and Relay Drivers	3-3
UHP-500 through 533 Quad Power and Relay Drivers	3-3
ULN-2001A through 2025A 7-Channel Darlington Drivers	3-14
ULN-2061M and 2062M Dual 1.5 A Darlington Switches	3-24
ULN-2064B through 2077B Quad 1.5 A Darlington Switches	3-24
UDN-2540B Quad NAND Power Driver	3-35
UDN-2580A through 2588A 8-Channel Source Drivers	3-37
UDN-2595A 8-Channel Sink Driver	3-44
ULN-2801A through 2825A 8-Channel Darlington Drivers	3-46
UDN-2841B through 2846B Quad 1.5 A Darlington Drivers	3-57
UTN-2886B SCR Array	3-63
UTN-2888A SCR Array	3-63
UDN-2949Z 2 A Half-Bridge Motor Driver	3-66
UDN-2952B and 2952W Full-Bridge Motor Drivers	3-70
UDN-2956A and 2957A Negative Supply, 5-Channel Source Drivers	3-72
UDN-2981A through 2984A 8-Channel Source Drivers	3-76
UDN-3611M through 3614M Dual Peripheral and Power Drivers	3-83
UDN-5703A through 5707A Quad Peripheral and Power Drivers	3-87
UDN-5711M through 5714M Dual Peripheral and Power Drivers	3-91
UDN-5733M Quad NOR Peripheral and Power Driver	3-90
Application Notes:	
Series ULN-2000A Darlington Arrays	3-95
Interface Integrated Circuits for Motor Drive Applications	3-102
Expanding The Frontiers Of Integrated Circuit Interface	3-109
Sprague High-Power Interface ICs	3-119

SECTION 4 — BiMOS AND COMPLEX ARRAY INTERFACE DRIVERS

UCN-4202A Stepper Motor Translator/Driver	4-2
UCN-4401A and 4801A BiMOS Latched/Drivers	4-9
UCN-4805A and 4806A BiMOS Latched Decoder/Drivers	4-12
UCN-4810A 10-Bit Serial-In, Latched Driver	4-16
UCN-4815A BiMOS Latch/Source Driver	4-19
UCN-4821A through 4823A 8-Bit Serial-In, Latched Drivers	4-22
Application Note:	
Sprague BiMOS — Muscle for the Microprocessor	4-26

SECTION 5 — INDUSTRIAL, MILITARY, AND AEROSPACE DEVICES

UHC/UHD-400 through 433-1 Quad Power and Relay Drivers	5-2
UHC/UHD-500 through 533 Quad Power and Relay Drivers	5-2
ULS-2001H through 2015H 7-Channel Darlington Drivers	5-7
ULQ-2001R through 2015R 7-Channel Darlington Drivers	5-7
ULS-2021H through 2025H 7-Channel Darlington Drivers	5-7
ULS-2064H through 2077H Quad 1.5 A Darlington Switches	5-17
ULS-2801H through 2815H 8-Channel Darlington Drivers	5-26
ULQ-2801R through 2815R 8-Channel Darlington Drivers	5-26
ULS-2821H through 2825H 8-Channel, 95 V Darlington Drivers	5-26
UDQ-2956R and 2957R Negative Supply, 5-Channel Source Drivers	5-36
UDS-2981H through 2984H 8-Channel Source Drivers	5-39
UDS-3611H through 3614H Dual Peripheral and Power Drivers	5-44
UCS-4401H and 4801H BiMOS Latched/Drivers	5-48
UDS-5703H through 5707H Quad Peripheral and Power Drivers	5-54
UDS-5711H through 5714H Dual Peripheral and Power Drivers	5-60
UDS-5733H Quad NOR Peripheral and Power Driver	5-59
UDS-5790H and 5791H Quad PIN Diode Drivers	5-66

See Also:

UHD-490 and 491 High-Voltage Display Drivers	2-5
ULS-2045H NPN Transistor Array	10-4
ULS-2083H Independent NPN Transistor Array	10-12
ULS-2140H Quad Current Switch	10-16
UGS-3019T/U Digital Hall Effect Switch	9-5
UGS-3020T/U Digital Hall Effect Switch	9-7
UGS-3030T/U Bipolar Hall Effect Switch	9-9
UGS-3075T/U Bipolar Hall Effect Switch	9-2
UGS-3076T/U Bipolar Hall Effect Switch	9-2
ULQ/ULS-8126R (SG2526/1526J) SMPS Controllers	10-37
ULS-8160R (SE5560F) Switched-Mode Power Supply Controller	10-42
Quality Assurance Flow Chart	5-70
Double-Deuce Program for High-Reliability Devices	5-72
High-Reliability Screening to MIL-STD-883	5-75

SECTION 6 — RADIO INTEGRATED CIRCUITS

Selection Guide	6-2
ULN-2111A F-M, I-F Amplifier/Limiter and Detector	6-3
ULN-2136A F-M, I-F Amplifier/Limiter and Detector	6-8
ULN-2204A A-M/F-M Radio System	6-14
ULN-2240A A-M/F-M Signal Processing System with Tuning Error and Level Muting	6-22
ULN-2241A A-M/F-M Signal Processing System	6-29
ULN-2242A (TDA1090) A-M/F-M Signal Processing System with Level Muting	6-36
ULN-2243A Mixer/I-F for F-M Radios	6-44
ULN-2245A Phase-Locked Loop Stereo Decoder	6-49
ULN-2249A A-M Radio System	6-52
ULX-3804A A-M/F-M Signal Processor	6-57
ULN-3809A Low-Voltage Phase-Locked Loop Stereo Decoder	6-63
ULN-3810A Phase-Locked Loop Stereo Decoder	6-66
ULX-3840A A-M/F-M Signal Processing System	6-69
ULN-3859A Low-Power, Narrow-Band, F-M I-F	6-76
ULN-3889A (TDA3189) I-F System for F-M Receivers	6-79
Application Notes:	
ULN-2204A Applications and Operation	6-86
A-M/F-M Radio Design Using the ULN-2240/41/42A	6-97
A Complete A-M/F-M Signal Processing System	6-108
The Development of High-Quality Receivers for A-M Stereo	6-116

SECTION 7 — TELEVISION INTEGRATED CIRCUITS

Selection Guide	7-2
ULN-2211B 2-Watt TV Sound Channel	7-3
ULN-2224A Chroma Demodulator	7-8
ULN-2260A AGC Control, Sync Separator, and Scan Processor	7-12
ULN-2261A Luminance Processor	7-15
ULN-2270B and 2270Q (TDA1170) Vertical Deflection System	7-19
ULN-2290B (TDA3190) and 2290Q (TDA1190Z) 4-Watt TV Sound Channel	7-25
ULN-3914A Chroma/Luma Processor	7-32
See Also:	
ULN-3702Z for use as Vertical Output Driver	8-22
Application Notes:	
ULN-2211B F-M Sound System	7-34
ULN-2260A Signal, Sync, and Scan Processor	7-50

SECTION 8 — AUDIO INTEGRATED CIRCUITS

Selection Guide	8-2
ULN-2231A Dual Audio Preamplifier	8-3
ULN-2280B 2.5-Watt Audio Power Amplifier	8-5
ULN-2283B Low-Power Audio Amplifier	8-11
ULN-3701Z (TDA2002) 5 to 10-Watt Audio Power Amplifier	8-19
ULN-3702Z (TDA2002A) 12-Watt Audio Power Amplifier	8-22
ULN-3703Z (TDA2003) 10-Watt Audio Power Amplifier	8-27
ULX-3777W Dual 10-Watt Audio Power Amplifier	8-29
ULX-3788W 20-Watt Audio Power Amplifier	8-31

SECTION 9 — HALL EFFECT DEVICES

Selection Guide	9-2
UGN-3013T/U Ultra Low-Cost Digital Switch	9-3
UGN/UGS-3019T/U Low-Cost Digital Switch	9-5
UGN/UGS-3020T/U Low-Cost Digital Switch	9-7
UGN/UGS-3030T/U Bipolar Digital Switch	9-9
UGN-3040T/U Ultra-Sensitive Digital Switch	9-11
UGN/UGS-3075T/U Bipolar Latch	9-2
UGN/UGS-3076T/U Bipolar Latch	9-2
UGN-3201M Dual Output Digital Switch	9-14
UGN-3203M Dual Output Digital Switch	9-14
UGN-3220S Dual Output Digital Switch	9-17
UGN-3501M Linear Output Hall Effect Sensor	9-19
UGN-3501T/U Linear Output Hall Effect Sensor	9-22
UGN-3604M Hall Effect Sensor Element	9-25
UGN-3605M Hall Effect Sensor Element	9-25
Application Note: Hall Effect Integrated Circuit Application Guide	9-27

Product Index in Numerical Order

TPQA-05 through 56	Quad Transistor Arrays	10-48
UHC/UHD-400 through 433-1	Hermetic Quad Power and Relay Drivers	5-2
UHP-400 through 433-1	Quad Power and Relay Drivers	3-3
UHP-480 through 482	High-Voltage Display Drivers	2-3
UHD/UHP-490 and 491	High-Voltage Display Drivers	2-5
UHP-495	High-Voltage Display Driver	2-8
UHC/UHD-500 through 533	Hermetic Quad Power and Relay Drivers	5-2
UHP-500 through 533	Quad Power and Relay Drivers	3-3
TPP-1000 and 2000	Medium-Power Darlington Arrays	10-47
ULN-2001A through 2015A	High-Current Darlington Drivers	3-14
ULS-2001H through 2015H	Hermetic High-Current Darlington Drivers	5-7
ULQ-2001R through 2015R	Hermetic High-Current Darlington Drivers	5-7
ULN-2021A through 2025A	High-Current, 95 V Darlington Drivers	3-14
ULS-2021H through 2025H	Hermetic High-Current Darlington Drivers	5-7
ULN-2031A through 2033A	Darlington Arrays	10-2
ULS-2045H	Hermetic NPN Transistor Array	10-4
ULN-2046A	NPN Transistor Array	10-4
ULN-2046A-1	NPN Transistor Array	10-6
ULN-2047A	Triple Differential Amplifier Array	10-7
ULN-2054A	Dual Differential Amplifier Array	10-8
ULN-2061M and 2062M	Dual 1.5 A Darlington Switches	3-24
ULN-2064B through 2077B	Quad 1.5 A Darlington Switches	3-24
ULS-2064H through 2077H	Hermetic Quad 1.5 A Darlington Switches	5-17
ULN-2081A	Common-Emitter NPN Transistor Array	10-11
ULN-2082A	Common-Collector NPN Transistor Array	10-11
ULN-2083A	Independent NPN Transistor Array	10-12
ULN-2083A-1	Independent NPN Transistor Array	10-14
ULS-2083H	Hermetic Independent NPN Transistor Array	10-12
ULN-2086A	NPN Transistor Array	10-15
ULN-2111A	F-M, I-F Amplifier/Limiter and Detector	6-3
ULN-2136A	F-M, I-F Amplifier/Limiter and Detector	6-8
ULN-2140A	Quad Current Switch	10-16
ULS-2140H	Hermetic Quad Current Switch	10-16
ULN-2204A	A-M/F-M Radio System	6-14
ULN-2211B	2-Watt TV Sound Channel	7-3
TPQ-2221 and 2222	Quad NPN Transistor Arrays	10-48
ULN-2224A	Chroma Demodulator	7-8
ULN-2231A	Dual Audio Preampfier	8-3
ULN-2240A	A-M/F-M Signal Processing System	6-22
ULN-2241A	A-M/F-M Signal Processing System	6-29
ULN-2242A	(TDA1090) A-M/F-M Signal Processing System	6-36
ULN-2243A	Mixer/I-F for F-M Radios	6-44
ULN-2245A	Phase-Locked Loop Stereo Decoder	6-49
ULN-2249A	A-M Radio System	6-52

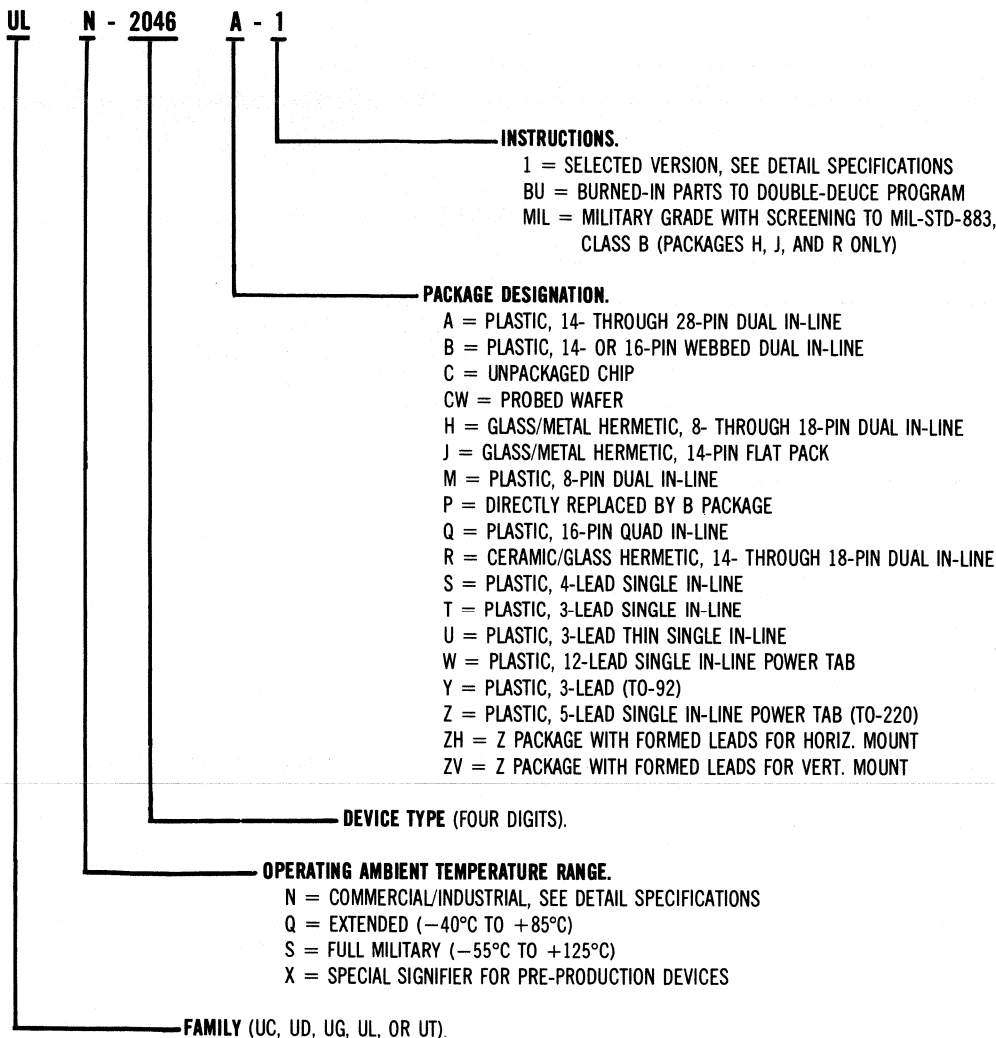

ULN-2260A	AGC, Sync, and Scan Processor	7-12
ULN-2261A	Luminance Processor	7-15
ULN-2270B and 2270Q	(TDA1170) Vertical Deflection System	7-19
ULN-2280B	Audio Power Amplifier	8-5
ULN-2283B and 2283B-1	Low-Power Audio Amplifier	8-11
ULN-2290B and 2290Q	(TDA3190 and TDA1190Z) 4-Watt TV Sound Channel	7-25
ULN-2350C and 2351C	Tuff Chip Semi-Custom Circuits	11-4
ULN-2401A	Lamp Monitor	10-18
ULN-2429A	Fluid Detector	10-20
ULN-2430M	Timer	10-23
TPQ-2483 and 2484	Quad NPN Transistor Arrays	10-48
UDN-2540B	Quad NAND Power Driver	3-35
UDN-2580A through 2588A	8-Channel High-Current Source Drivers	3-37
UDN-2595A	8-Channel Medium-Current Sink Driver	3-44
ULN-2801A through 2815A	High-Current Darlington Drivers	3-46
ULS-2801H through 2815H	Hermetic High-Current Darlington Drivers	5-26
ULQ-2801R through 2815R	Hermetic High-Current Darlington Drivers	5-26
ULN-2821A through 2825A	High-Current, 95 V Darlington Drivers	3-46
ULS-2821H through 2825H	Hermetic 95 V Darlington Drivers	5-26
UDN-2841B through 2846B	Quad 1.5 A Darlington Drivers	3-57
UTN-2886B and 2888A	SCR Arrays	3-63
TPQ-2906 and 2907	Quad PNP Transistor Arrays	10-48
UDN-2949Z	High-Current, Half-Bridge Motor Driver	3-66
UDN-2952B and 2952W	Full-Bridge Motor Drivers	3-70
UDN-2956A and 2957A	High-Current Source Drivers	3-72
UDQ-2956R and 2957R	Hermetic High-Current Source Drivers	5-36
UDN-2981A through 2984A	High-Current Source Drivers	3-76
UDS-2981H through 2984H	Hermetic High-Current Source Drivers	5-39
TPP-3000	Triple Medium-Power Darlington Switch	10-47
UGN-3013T/U	Ultra Low-Cost Hall Effect Switch	9-3
UGN/UGS-3019T/U	Low-Cost Digital Hall Effect Switch	9-5
UGN/UGS-3020T/U	Low-Cost Digital Hall Effect Switch	9-7
UGN/UGS-3030T/U	Bipolar Digital Hall Effect Switch	9-9
UGN-3040T/U	Ultra-Sensitive Digital Hall Effect Switch	9-11
UGN/UGS-3075T/U	Bipolar Latch	9-2
UGN/UGS-3076T/U	Bipolar Latch	9-2
UGN-3201M and 3203M	Dual Output Digital Hall Effect Switches	9-14
UGN-3220S	Dual Output Digital Hall Effect Switch	9-17
ULN-3304M	Schmitt Trigger	10-26
ULN-3305M	Dual Schmitt Trigger	10-29
ULN-3306M	Dual Schmitt Trigger	10-31
ULN-3330Y	Optoelectronic Switch	10-34
UGN-3501M	Linear Output Hall Effect Sensor	9-19
UGN-3501T/U	Linear Output Hall Effect Sensor	9-22
UGN-3604M and 3605M	Hall Effect Sensor Elements	9-25
UDN-3611M through 3614M	Dual Peripheral and Power Drivers	3-83
UDS-3611H through 3614H	Hermetic Peripheral and Power Drivers	5-44

GENERAL INFORMATION (Continued)

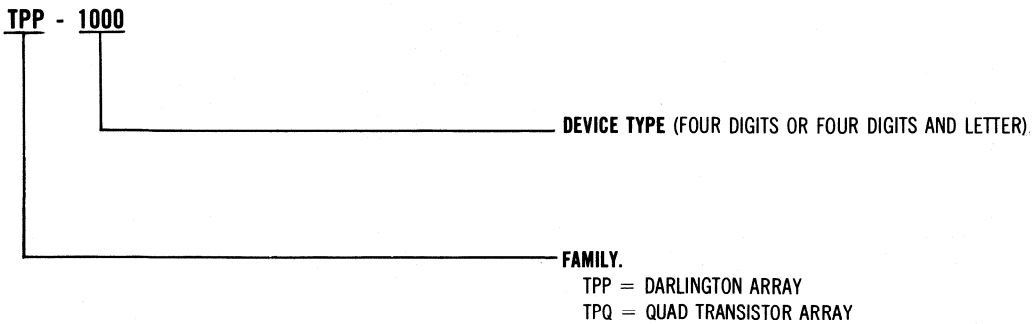

ULN-3701Z	(TDA2002) 5- to 10-Watt Audio Power Amplifier	8-19
ULN-3702Z	(TDA2002A) 12-Watt Audio Power Amplifier	8-22
ULN-3703Z	(TDA2003) 10-Watt Audio Power Amplifier	8-27
TPQ-3724 through 3725A	Quad NPN Transistor Arrays	10-48
ULX-3777W	Dual 10-Watt Audio Power Amplifier	8-29
ULX-3788W	20-Watt BTL Audio Power Amplifier	8-31
TPQ-3798 and 3799	Quad PNP Transistor Arrays	10-48
ULX-3804A	A-M/F-M Signal Processor	6-57
ULN-3809A	Phase-Locked Loop Stereo Decoder	6-63
ULN-3810A	Phase-Locked Loop Stereo Decoder	6-66
ULX-3840A	A-M/F-M Signal Processing System	6-69
ULN-3859A	Low-Power, Narrow-Band F-M I-F	6-76
ULN-3889A	(TDA3189) I-F System for F-M Receivers	6-79
TPQ-3904	Quad NPN Transistor Array	10-48
TPQ-3906	Quad PNP Transistor Array	10-48
ULN-3914A	Chroma/Luma Processor	7-32
TPP-4000	Medium-Power Quad Darlington Array	10-47
UCN-4202A	Stepper Motor Translator/Driver	4-2
TPQ-4258 and 4354	Quad PNP Transistor Arrays	10-48
UCN-4401A and 4801A	BiMOS Latch/Drivers	4-9
UCS-4401H and 4801H	Hermetic BiMOS Latched Drivers	5-48
UCN-4805A and 4806A	BiMOS Latched Decoder/Drivers	4-12
UCN-4810A	10-Bit Serial-In, Latched Driver	4-16
UCN-4815A	BiMOS Latch/Source Driver	4-19
UCN-4821A through 4823A	8-Bit Serial-In, Latched Drivers	4-22
TPQ-5400 through 5551	Quad Transistor Arrays	10-48
UDN-5703A through 5707A	Quad Peripheral and Power Drivers	3-87
UDS-5703H through 5707H	Hermetic Peripheral and Power Drivers	5-54
UDN-5711M through 5714M	Dual Peripheral and Power Drivers	3-91
UDS-5711H through 5714H	Hermetic Peripheral and Power Drivers	5-60
UDN-5733M	Quad NOR Peripheral and Power Driver	3-90
UDS-5733H	Hermetic Peripheral and Power Driver	5-59
UDS-5790H and 5791H	Hermetic Quad PIN Diode Drivers	5-66
TPQ-6001 through 6100A	Dual Complementary-Pair Transistor Arrays	10-48
UDN-6116A through 6128A-2	Fluorescent Display Drivers	2-10
UDN-6116R through 6128R-2	Hermetic Fluorescent Display Drivers	2-10
UDN-6138A through 6148A-2	Fluorescent Display Drivers	2-10
UDN-6164A and 6184A	Gas-Discharge Display Digit Drivers	2-14
TPQ-6501 through 6700	Dual Complementary-Pair Transistor Arrays	10-48
UDN-7180A through 7186A	Gas-Discharge Display Segment Drivers	2-16
ULN-8126A	Switched-Mode Power Supply Controller	10-37
ULN-8126R	(SG3526J) Hermetic SMPS Controller	10-37

Sprague Part Numbering Systems

CROSS-REFERENCE in Numerical Order

The suggested Sprague replacement devices are based on similarity as shown in currently published data. Exact replacement in all applications is not guaranteed and the user should compare the specifications of the competitive and recommended Sprague replacement.

Mfr. Abbreviations:		Competitive Part Number	Mfr.	Suggested Sprague Replacement
CS	Cherry Semiconductor	CA758E	RCA	ULX-3811A§
DI	Dionics, Inc.	CA1190E	RCA	ULN-2290B
EXR	Exar Integrated Systems	CA1190Q	RCA	ULN-2290Q

SG	Silicon General Inc.	CA3065	RCA	ULN-2165A*
SIG	Signetics Corp.	CA3066	RCA	ULN-2266A*
SGS	SGS/ATES	CA3067	RCA	ULN-2267A*
SPC	Sprague Products Co.*	CA3070	RCA	ULN-2124A*
SPR	Sprague Electric Co.	CA3071	RCA	ULN-2127A*
TI	Texas Instruments	CA3072	RCA	ULN-2228A*
TLF	AEG-Telefunken	CA3075	RCA	ULN-2129A*
TOKO	RCL Toko			
TOS	Toshiba Corp.			

‡European registration; manufactured by various companies including ITT, SGS/ATES, Siemens, Thomson-CSF, AEG-Telefunken, & Valvo.

¶Sprague device includes internal pull-down resistors.

*No longer manufactured — listed for reference only.

†Some differences in specified switching speed with the Sprague device being superior for use with inductive loads.

§Sprague engineering bulletin in preparation.

SPRAGUE FACILITIES

Sprague Electric Company manufactures active and passive components in 17 locations in the United States and in five countries in Europe and the Far East. Headquarters of the Semiconductor Division is located in Worcester, Mass. All semiconductor wafer fabrication is done in the Worcester plant, as

are all services integral to its support. Volume assembly operations are located both in Worcester and in Manila, Philippines. Marketing and sales offices and sales representatives are located throughout the United States and Canada, Latin America, Europe, Japan, Africa, and the Far East.

INTEGRATED CIRCUIT OPERATIONS, Worcester, Massachusetts

Semiconductor Operations

The integrated circuits operation of the Sprague Electric Semiconductor Division is located in a modern 115,000-square-foot plant in Worcester, Mass. Discrete components, such as transistors and diodes, and Hall effect integrated circuits are manufactured at the division's Concord, N.H., plant, which occupies some 30,000 square feet of floor space.

Sprague Electric is a leading manufacturer of volume integrated circuits serving the consumer, industrial controls, and peripherals markets. Production process technologies include complementary metal-gate MOS, high-voltage and high-current bipolar, and high-performance bipolar linear. This breadth of process technology makes it possible for Sprague Electric to manufacture optimal cost-performance integrated circuits.

TRANSISTOR OPERATIONS, Concord, New Hampshire

1

How Integrated Circuits are Shipped

Integrated circuits are shipped in one of these carriers:

A-Channel Anti-Static Plastic Tubing
TO-220 Plastic Magazine
Individual Plastic Box

Integrated circuit chips are shipped in either un-scribed wafer form or individually partitioned in a plastic box.

Quality Control and Reliability

All critical points in the manufacturing processes of Sprague Electric integrated circuits are carefully

monitored for compliance to engineering specifications. Electrical tests are made on 100% of the parts by automatic test systems. Lot sampling assures meeting customer A.Q.L. requirements. Calibration of test standards and equipment is performed at periodic intervals in order to maintain test accuracy.

Sprague Electric Company conducts a continuing reliability assurance program to detect deviations in device characteristics. Test samples are taken at random from each lot and are subjected to testing for performance evaluation and specification compliance. Routinely, finished samples are subjected to all electrical performance tests. A copy of the quality control inspection plan used for specific integrated circuits is available on request.

SERIES UHP-480 HIGH-VOLTAGE DISPLAY DRIVERS

Features:

- Reliable Monolithic Integrated Construction
- Low-Output Leakage Current
- High-Voltage Output Capability
- Small Size
- 130 Volt Breakdown

Description

SERIES UHP-480 display drivers are bipolar monolithic integrated circuits — high-voltage switches designed for interface applications between MOS or open-collector TTL logic and gas discharge displays. They are packaged in industry standard dual-in-line plastic packages and are available with 5 (UHP-480), 7 (UHP-481), or 8 (UHP-482) switches per package.

Applications

Sprague Series UHP-480 drivers may be used with gas discharge displays, such as Burroughs Panaplex[®], Cherry Plasma-Lux[®] and Beckman SP Series devices, intended for use in the cathode portion of the displays. Applications include calculators, DVM's, DMM's, DPM's, mini-computers, clocks, etc. These drivers replace the major portion of discrete components typically required to interface between a MOS calculator or counter/decoder circuit and a gas discharge display. Their high reliability and small size make them an excellent choice for applications where space is at a premium.

® Panaplex is a registered trademark of the Burroughs Corporation
 ® Plasma-Lux is a registered trademark of Cherry Electrical Products Corporation

TYPICAL CLOCK APPLICATION

DWG. NO. A-9413A

Type 206C and 216C are single in-line networks

Because of the high input impedance of these devices, they are susceptible to static discharge damage sometimes associated with handling and testing. Therefore, techniques similar to those used for handling MOS devices should be employed.

SERIES 490 and 491 HIGH-VOLTAGE DISPLAY DRIVERS

FEATURES

- Reliable Monolithic Integrated Construction
- Low Output Leakage Currents
- High Output Breakdown Voltages
- Small Size

Description

The Series 490 and 491 high-voltage display drivers are bipolar monolithic integrated circuits designed for interfacing MOS or other low-voltage circuitry with high-voltage gas discharge displays or loads. These drivers replace most of the discrete components normally required to drive multiplexed gas discharge displays from MOS calculator or clock circuits. The Series 490 and 491 high-voltage display drivers are intended for use in the anode portion of the display and are available with either 5 (Series 490) or 6 (Series 491) drivers per dual in-line package.

Applications

The Series 490 and 491 may be used in a variety of low-voltage to high-voltage interfacing applications such as are found in MOS calculators, digital clocks, etc. Their high reliability and small size make them an excellent choice for those applications where space is at a premium.

TYPICAL SMALL CALCULATOR APPLICATION

UHP-495 HIGH-VOLTAGE DISPLAY DRIVER

FEATURES

- Reliable Monolithic Integrated Construction
- Low Output-Leakage Currents
- High Output-Breakdown Voltages
- 14-Pin Dual In-Line Plastic Package

THIS MONOLITHIC integrated circuit is designed for use as an interface between MOS or other low-voltage circuitry and high-voltage gas-discharge displays or similar loads.

Type UHP-495 replaces most of the discrete components normally required to drive multiplexed gas-discharge displays with MOS calculator or clock circuits. The high-voltage bipolar interface is designed for use in the anode portion of a display. It has six drivers per package.

DWG. NO. A-9577A

SERIES UDN-6100A and UDN-6100R FLUORESCENT DISPLAY DRIVERS

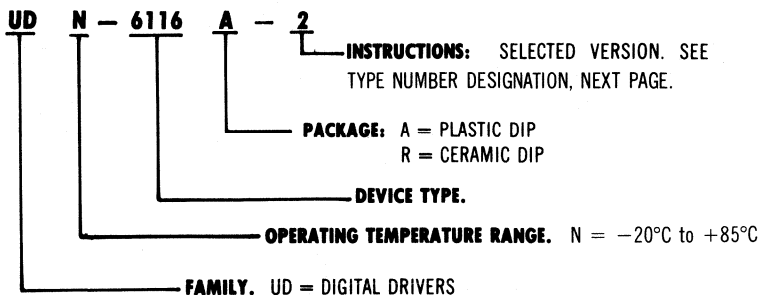

FEATURES

- Digit or Segment Drivers
- Low Input Current
- Integral Output Pull-Down Resistors
- High Output Breakdown Voltage
- Single or Split Supply Operation

CONSISTING of six or eight NPN Darlington output stages and the associated common-emitter input stages, these drivers are designed to interface between low-level digital logic and vacuum fluorescent displays. All devices are capable of driving the digits and/or segments of these displays and are designed to permit all outputs to be activated simultaneously. Pull-down resistors are incorporated into each output and no external components are required for most fluorescent display applications. The highest voltage parts (suffix A-1) are also used in gas-discharge display applications as anode (digit) drivers.

Twenty-four standard devices are listed, so that a circuit designer may select the optimum device for his application. Input characteristics, number of drivers, package style, and output voltage are tabulated for each device in the Device Type Number Designation chart. With any device, the output load is activated when the input is pulled towards the positive supply (active 'high'). All units operate over the temperature range of -20°C to $+85^{\circ}\text{C}$.

UDN-6164A AND UDN-6184A GAS-DISCHARGE DISPLAY DRIVERS

FEATURES

- TTL/MOS Compatible Inputs
- High Output Breakdown Voltage
- High Output Current Capability
- Low Power
- Reliable Monolithic Construction

THESE monolithic high-voltage bipolar integrated circuits dramatically reduce the number of discrete components required to link MOS, or other low-voltage circuitry, with the anodes of gas-discharge display panels.

Types UDN-6164A and UDN-6184A are used with multiplexed gas-discharge display panels, such as the Burroughs Panaplex[®], the Cherry Plasma-Lux[®], and the Beckman SP series, in calculator, clock, or instrumentation applications.

Each driver has appropriate level shifting, signal amplification, output off-state voltage bias, and 40 mA output current sourcing for sequential addressing of display panel anodes. The inputs include pull-down resistors for direct connection to open-drain PMOS logic.

Type UDN-6164A contains six drivers; Type UDN-6184A contains eight drivers. Applications with a greater number of digits may use any combination of units for minimum package count.

The devices can be used in a wide variety of low- to high-voltage applications. High reliability, small size, ease of installation, and low cost make them an ideal choice for many applications.

SERIES UDN-7180A

GAS DISCHARGE DISPLAY SEGMENT DRIVERS

FEATURES

- Reliable Monolithic Construction
- High Output Breakdown Voltage
- Low Power
- TTL/MOS Compatible Inputs

Dwg. No. A-9640A

Description

Series UDN-7180A segment drivers are monolithic high-voltage bipolar integrated circuits for interfacing between MOS or other low-voltage circuits and the cathode of gas-discharge display panels.

These drivers reduce substantially the number of discrete components required with panels (Beckman, Burroughs, Dale, Matsushita, NEC, Pantek, etc) in calculator, clock and instrumentation applications.

The UDN-7183A, UDN-7184A, and UDN-7186A drivers contain appropriate level shifting, signal amplification, current limiting, and output OFF-state voltage bias. The UDN-7180A driver requires external current limiting and is intended for higher-current applications or where individual outputs are operated at different current levels (i.e. with alpha-numeric displays). All inputs have pull-down resistors for direct connection to open-drain PMOS logic.

These devices provide output currents suitable for display segments in a wide variety of display sizes and number of display digits. Either a fixed split supply operation or a feedback-controlled scheme is allowed.

Applications

The Series UDN-7180A drivers can be used in a wide variety of low-level to high-voltage applications utilizing gas discharge displays such as those found in calculators, clocks, point-of-sale terminals, and instruments. Their high reliability combined with minimum size, ease of installation, and the cost advantages of a complete monolithic interface make them the ideal choice in many applications. A typical application showing the use of these devices, and their counterpart anode drivers, is shown.

A Monolithic IC Series for Gas-Discharge Display Interface

Introduction

The switching of the high voltages necessary for display panels such as the Burroughs Panaplex® has long presented difficulties to the semiconductor industry – particularly to IC manufacturers. It is difficult to fabricate devices capable of sustaining 200 volts or greater with standard IC processes of today. Solutions to the high voltage gas discharge display interface also must be inexpensive as well as functional; this cost/simplicity factor prohibits most unusual or exotic circuit designs and/or IC processes.

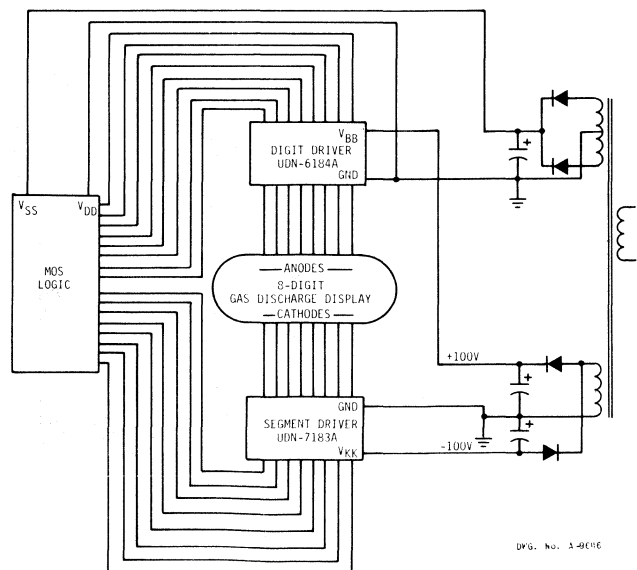

The earliest (and a great many recent) gas discharge interface schemes used discrete components, but that has been an increasingly cumbersome and expensive solution. Competition at the system level has largely come from LEDs, and a great many standard ICs are available for the smaller LEDs. In most instances, the small displays have gone to LEDs. However, the larger display applications are still an opportunity for gas discharge since character size and cost are not directly related. The cost impact upon the potential for gas discharge displays in many systems is a function of interface complexity and cost, and it was to this end that a joint Sprague/Burroughs effort was launched.

Early Sprague/Burroughs meetings were held to define the relevant factors involved in such a program and provide the necessary insight for both parties into

the capabilities of diode isolated ICs, the voltage and current requirements of the Panaplex displays, the need for minimization of power (battery systems), packaging of the circuits, component count and cost, etc. Add to this the potential for use with feedback controlled supplied, poorly regulated d-c supplies, the wide variety of numbers of display digits, the range of digit sizes (in use or contemplated), etc., and our task was not to be an easy one.

Our direction was determined by two factors: a history of fabricating 130-140 volt PN diode isolated display circuits, and a more recent effort to utilize compatible thin-film resistor technology. These factors, coupled with considerable expertise in designing and processing high voltage ICs, dictated an approach utilizing a split (± 100 V) supply. The split supply would provide the 200 volts needed to ionize the display and the resistor capability would greatly aid the incorporation of functions previously done by discrete components – including both input and output (segment) current limiting, pulldown (open drain PMOS), pullup and pulldown reference for IC outputs, and a high impedance voltage divider for the output OFF bias. All level shifting is accomplished via use of PNP or NPN transistors, and the capacitors previously required were negated.

Figure 1

DPG. NO. 3-4016

Basic Scheme

Replacing discrete components through incorporating their function into this IC series results in the block diagram of Figure 1 with its basic requirement for a single digit and single segment driver; a scheme capable of driving as many as eight digits and the eight segments. Additional digits or segments beyond the eight provided in an 18-lead DIP may be driven by combinations of packages beyond the minimum two necessary. Example: three ICs — two digit and one segment — will fulfill the needs of a 12 to 16 digit calculator.

Included in this series of high voltage interface are two digit driver packages: UDN-6164 (6-digit), and UDN-6184 (8-digit). Segment drivers include the UDN-7180, UDN-7183, UDN-7184, and UDN-7186, and the four offer current ranges compatible with display sizes from 0.250" to 1" panels, and others will be made available as needs are defined.

Digit Interface

The digit driver is the more complex of the two and its schematic is shown in Figure 2. Input address polarity is positive (active high in TTL parlance) and the circuit is designed to interface from TTL (4.5 volts from open collector — or using pull-up to V_{CC}), CMOS, PMOS, etc. Input current-limiting and one-half of the pull-down for open drain PMOS is the function of R_5 ; R_6 adds the second half of the pull-down to the ground bus. The protective value of R_4 and R_3 must be noted; a junction failure in Q_1 has the two resistors as a current limiter to the MOS (or TTL) output and will minimize the likelihood of destroying the low level logic outputs.

Input transistor Q_4 is a high voltage inverter and sinks the base current of PNP Q_3 . A positive input (4.5 to 20 V) will turn on Q_4 and this base current (65 μA typ.) for PNP Q_3 will turn on the output Darlington (Q_1 and Q_2) and source digit current.

2. All voltage measurements made with 10M Ω , DVM or VTVM.
3. Recommended V_{KK} operating range: -85 to -110 V.

PARTIAL SCHEMATIC

DWG. NO. A-11,364

Figure 2

Consistent ionization and extinguishing of the display panel is the result of the 60-75 volt swings available from both digit and segment ICs. The conditions that previously created problems for the direct MOS drive with minimal swings at the output have been very adequately handled with the increased output swings of the 6100/7100 series. Problems from leading zero blanking, low temperature, low ambient light, etc. which previously gave difficulty are well taken care of with this series of ICs.

Segment Interface

The segment driver circuit is shown in Figure 3 and the value of R_2 (segment limiting) is determined via masking for the appropriate display current. Its

counterpart pull-up resistor R_1 is also changed to some known ratio of R_2 . The ground terminal (#9) is referenced near, or connected directly to ground, and the V_{KK} line is typically a -90 to -100 volts.

The input PNP (Q_1) serves as a level translator and provides d-c level shifting to the output Darlington (Q_2 and Q_3). Emitter resistor (R_3) both limits the input current and furnished pull-down for open drain PMOS. An added intent is the measure of protection furnished the MOS by the very high impedance of R_3 .

The basic switching function is the combination of PNP Q_1 , Darlington Q_2 and Q_3 , and the associated resistors R_1 , R_2 , and R_3 . Address polarity is again active high. The input may be raised a maximum of 20 volts above ground and will function with input levels obtained from CMOS and open collector TTL (4.5 V).

TYPICAL APPLICATION

DWG. NO. A-9645A

Figure 4

available does not meet the requirements for an ideal display.

Gas discharge panels are a fine combination of aesthetics, reliability, low cost, large character size, multiplexing capability, etc., but have been impacted to some degree by the lack of an available and inexpensive, totally monolithic interface. The move toward IC interface for displays has stifled some potential — largely in favor of LEDs; although many applications requiring large characters and/or in high ambient light turn toward gas panels. The planar gas discharge display is a long way from obscurity, and the availability of this family of ICs should open up new areas as well as satisfying existing systems.

The intent from the inception of this program has been to produce and provide a standard, inexpensive and easy to use interface for gas discharge displays. A great many potential applications exist for these circuits in consumer and commercial products. From the calculator and digital clock areas this product also will find use in automotive dashboards, point-of-sale systems, electronic cash registers and scales, and instrumentation. The market for displays is still very elastic, and many applications for gas discharge panels are continuing to appear. The Sprague contribution to this market is this series of state-of-the-art interface ICs.

TRENDS IN IC INTERFACE FOR ELECTRONIC DISPLAYS

Introduction

Display technology was truly set into high gear by the explosion of the electronic calculator business. Expansion at a phenomenal pace continues, encompassing a multitude of products, particularly high-volume consumer products (calculators, clocks, games, and watches). Recently, further stimulated by the "microprocessor revolution," with its far-reaching effects, and the resulting changeover to solid state design from electromechanical, mechanical, fluidic, or electrical systems, the vistas for displays have expanded well beyond the horizon. Products have been and are being developed, using microprocessors and displays, that never previously existed.

To augment this microprocessor revolution, semiconductor manufacturers are developing many new interface circuits useful with displays, although some of these will not be exclusively for display systems. To accomplish this, the present boundaries of device design, process, packaging, and electrical parameters will require continual extension and expansion.

Display Buffers

A continuing evolution of standard interface ICs is needed to buffer low-level logic from high-voltage and/or high-current loads. Some of this buffer development will serve display systems. Since there already is a broad assortment of buffers (particularly for low- to medium-current LED applications), the ongoing development in simple or low-order interface will mainly concentrate upon further reduction in discrete component count, package improvement (particularly for high-current/high-power devices), improvements in device current, voltage, switching speed, and greater reliability.

Figures 1, 2, and 3 show some Sprague interface ICs that represent buffer circuits; other vendors supply similar, or identical, high-current or high-voltage buffers to allow operation of displays from low-level logic. Two basic changes have occurred relatively recently:

1. Greater use of 18-pin DIPs for eight driver channels (Source Driver, Figure 2).
2. Creation of sourcing functions (Figures 2 and 3; useful for LED, gas-discharge, vacuum fluorescent, incandescent, and electromagnetic displays, depending upon device ratings). While further buffer designs are needed (particularly in high-current (> 2 A) and high-voltage (> 100 V) circuits), the main emphasis will be toward the incorporation of logic and control circuitry with output buffers.

Complex Interface

Paralleling (though lagging) the microprocessor LSI revolution is the area of greatest future for IC display circuits: The need for complex, smart or high-order interface. This will be MSI to LSI logic (with perhaps some linear functions) combined with suitable output buffers.

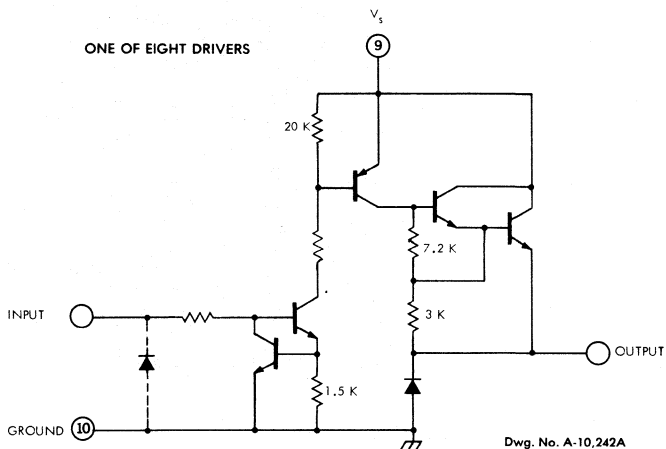

Figure 2B

SERIES UDN-2980 SOURCE DRIVER

Display interface ICs (similar to the MOS I/O control chips), both custom and standard product, are becoming available in this category. High-volume applications may justify custom ICs, but the more general trend will be toward standard, off-the-shelf designs — chiefly due to the high costs of developing custom ICs.

The higher voltage displays (gas-discharge, vacuum fluorescent, a-c plasma, and d-c electroluminescent) may share some circuits (if appropriately planned and designed), particularly in the area of matrix displays. It is difficult to imagine, however, much commonality between high-current LEDs, high-voltage gas-discharge or a-c plasma, and low-power LCDs,

Figure 3
8-DIGIT/8-SEGMENT HIGH-CURRENT LED INTERFACE

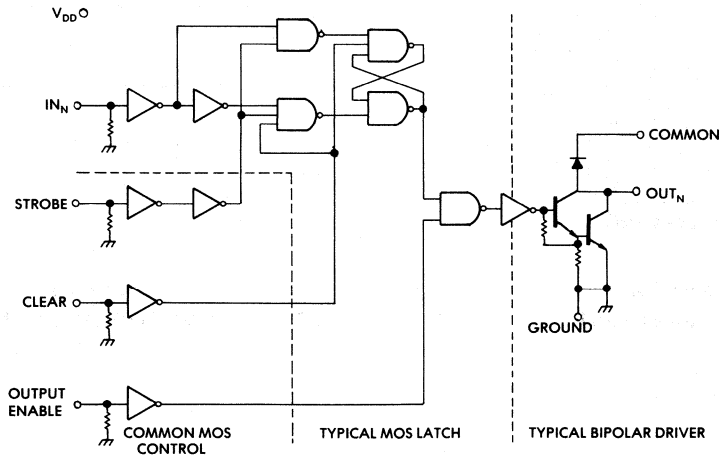

although they should share considerably the development of cellular CAD circuit designs. Basic shift registers, latches and decoders do have considerable commonality.

In Figure 4 is a pinout and logic diagram of the first BiMOS Sprague IC combining logic and output drive. Although not expressly intended for display applications, this BiMOS (CMOS logic and bipolar outputs) IC has a great deal of utility to engineers working with lower voltages and high currents (LEDs, incandescent and electromagnetic displays). Type UCN-4801A is a parallel-in/parallel-out unit composed of eight 'D' latches and eight 350 mA/50 V bipolar Darlington outputs.

DWG. NO. A-10,495A

Figure 4B
UCN-4801A BIMOS LATCH/DRIVER

More recently, Sprague has designed a serial-in/parallel-out BiMOS interface IC expressly for use with vacuum fluorescent displays. Figure 5 shows the UCN-4810A 10-bit serial-in/parallel-out interface for use with VF displays; the use of serial data allows 10 output lines, data in and data out in a standard 18-lead DIP. It makes possible both fewer IC packages and simpler PC board wiring, although it is slower than a parallel data approach. It uses only a single pin of the I/O ports.

Figure 5A
UCN-4810A PINOUT

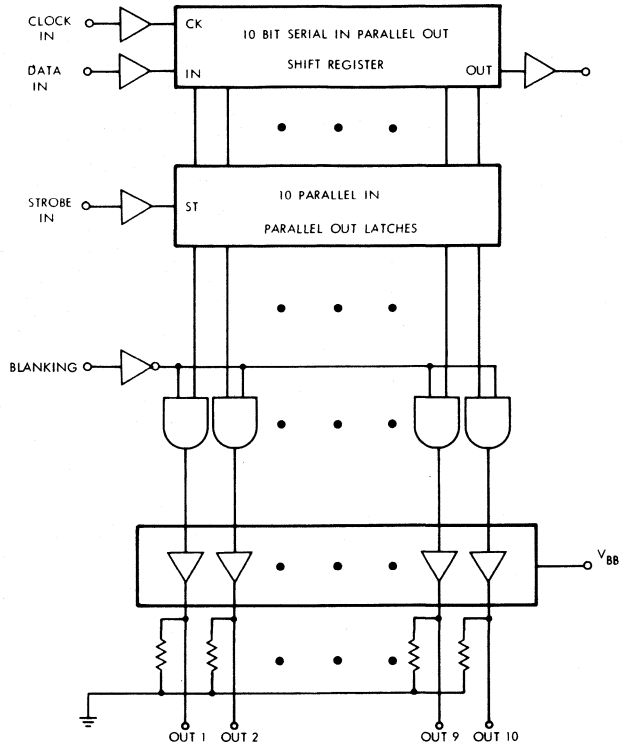

Figure 5B
UCN-4810A VF DRIVER BLOCK DIAGRAM

A slightly more recent design for vacuum fluorescent displays is the Sprague UCN-4815A. This is a 22-lead, 8-bit parallel-in/parallel-out BiMOS unit. The unit may have data inputs and a strobe bus (see Figure 6). The chip enable/blanking pin provides control of VF buffers. A power-on-clear is internally incorporated.

UCN-4815A PARALLEL 8-BIT VF INTERFACE

Device Technologies

With the exception of LCD displays (which at least until recently have been largely, if not entirely, driven by MOS) the display and interface technologies in high-volume use are mainly associated with bipolar semiconductors. Early display interface ICs (particularly devices such as the 7447 and 7448) were aimed at LED technology and represent MSI with modest output capability. The increasing use of higher voltage displays, multiplexed high-current applications, and the need for greater circuit complexity and low pin count will dictate other technologies, such as I²L, BiMOS, CMOS/DMOS, and possibly DMOS.

Standard Bipolar

Standard bipolar technology, long associated with TTL or linears (early op amps), appears very limited in scope for the future. Circuit density and supply power requirements will dictate other processes for functions beyond the simple MSI level. The advantages of standard bipolar ICs appear to be in the areas of simple high-current, high-power or high-voltage interface. In particular, applications requiring the combination of high voltages (≈ 100 V) or multiple high-current outputs (≈ 2 A) will restrict the logic/control circuitry to a low level. Cost, chip size and package power dissipation will restrict this circuitry largely to versatile, simple buffers.

I²L

Anticipated to increase significantly is the use of I²L for systems of low to modest voltages (LEDs through VF). The present limits of I²L appear to be limited to applications below the 50- to 60-volt level. I²L, with its combination of circuit density, low power and reasonable switching speeds should make a fine match for LEDs or other low-voltage display applications. For higher voltages (> 25 or 30 V), prospects the penalty of reduced circuit density may diminish its cost effectiveness. Some increase in standoff voltage may be afforded by the uses of cascaded output transistors or process improvements, thus reducing the need to sacrifice logic density. Without a standard I²L logic family, the main market penetration would appear to be custom designs although there is a definite opportunity for standard interface for lower voltage applications, particularly LEDs and vacuum fluorescent.

BiMOS

BiMOS, a combination of CMOS and bipolar for interface ICs, seems to fit a technology niche of higher breakdown voltages than I^2L , especially where logic power and supply voltage range (5 to 15 V) is important. BiMOS or BiFET ICs, which are presently on the market, are largely related to operational amplifiers, although other uses, such as the Sprague application of BiMOS to interface, are emerging.

Currently, it is feasible to design and manufacture BiMOS interface with breakdown voltages in the 80 to 100 V range. With additional time and greater concentration on increasing BV, it appears that higher voltages (≥ 150 V) for output buffers could be obtained. By obtaining breakdowns in the 120 V to 160 V range, BiMOS then becomes a viable IC technology for interface for the higher voltage displays: d-c gas-discharge with ± 100 to ± 130 V; a-c plasma with 160 to 170 V, and glow transfer or d-c electroluminescent (DCEL) opportunities with a range of 120-150 volts.

Switching speeds and output configurations (active pull-down or resistive) are critical to matrix displays (particularly a-c plasma) with large numbers of drive lines. Adding active pull-down or pull-up will tend to increase chip size (and cost), thus adding to the potential overall difficulty of BiMOS with its greater process complexity and slightly longer manufacturing cycle. This does appear to be a very key technology for the near future. Its product niche will include for applications requiring 60 to 100 V (or more) breakdowns, low-power logic, wide supply range, modest speeds, and MSI to small LSI.

CMOS/DMOS

Chiefly being carried on by Texas Instruments, CMOS /DMOS display interface appears to be intended for much of the same display market as BiMOS. Product information now available indicates 60 to 100 V breakdown (DMOS outputs), CMOS logic, low to modest output currents (≈ 25 mA), and logic speeds to 4 MHz. Designs now being promoted are targeted toward a-c plasma and vacuum fluorescent panels.

Two apparent disadvantages now appear to exist:

1. Logic operates from 12 V $\pm 10\%$ (may be done to provide maximum speed).
2. Output drive current is insufficient for high-current displays (without 100 mA, or more, the larger matrix panels will use discretes or another technology).

These shortcomings may be modified with time, although it is doubtful if 500 mA to 1 A DMOS outputs are practical.

Summary

A bright future exists for IC interface in display systems; the combination of logic (from MSI to small LSI) with suitable output buffers will further assist display designs. The following IC Technology-Display Interface matrix lists the key characteristics and primary display applications of various semiconductor technologies. Since many of these characteristics are changing, the table lists the device characteristics either now available or for the near future.

The most dynamic technologies for the immediate future appear to be BiMOS, I²L, CMOS/DMOS, and, perhaps soon, DMOS. Sprague, Dionics, RCA, Texas Instruments, National Semiconductor, and others are using these device technologies to carve market niches where suitable. The dynamics of the IC market make for an uncertain future for any supplier of display circuitry unable or unwilling to continue the technological advancement necessary to meet the changing demands of the display market.

IC TECHNOLOGY — DISPLAY INTERFACE

<u>Technology</u>	<u>Breakdown V</u>	<u>Output I</u>	<u>Speed</u>	<u>LOGIC</u>		<u>Supply Power</u>	<u>Primary Display Suitability</u>
				<u>Complexity (max)</u>	<u>Range</u>		
Linear Process Bipolar	10 to ≈170 V	<10 mA to 2 A	<1 MHz	MSI	5 V	High	LEDs, GD, VF, ACP, DCEL, EM

SERIES UHP-400, UHP-400-1 and UHP-500 POWER and RELAY DRIVERS

FEATURES

- Inputs Compatible with DTL/TTL
- 500mA Output Sink Current Capability
- Pinning Compatible with 54/74 Logic Series
- Transient Protected Outputs on Relay Drivers
- High Voltage Output - 100V Series UHP-500, 70V Series UHP-400-1, 40V Series UHP-400

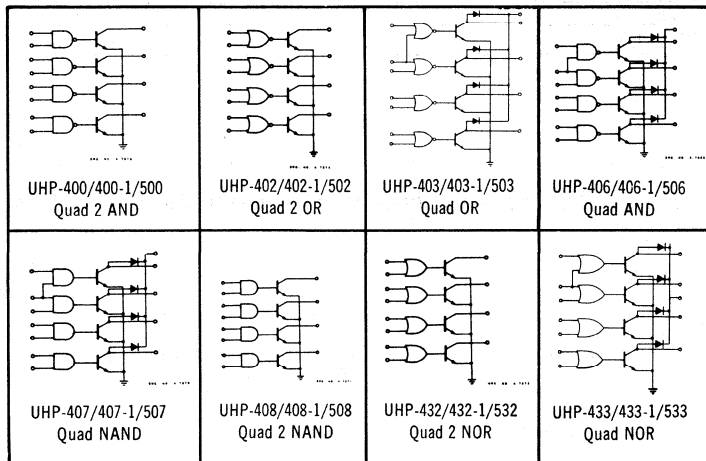

3

Description

These power and relay drivers are bi-polar monolithic circuits and incorporate logic gates and high-current switching transistors on the same chip. Each output transistor is capable of sinking 500mA in the ON state. In the OFF state, Series UHP-400 devices will sustain 40V, Series UHP-400-1 devices will sustain 70V, and Series UHP-500 devices will sustain 100V.

Applications

The UHP-400, UHP-400-1, and UHP-500 Series Power Drivers are ideally suited for driving incandescent lamps, relays, solenoids, and other interface devices with up to 1A output current per package.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}	7V
Input Voltage, V_{in}	5.5V
Output Off-state Voltage, V_{off}	
Series UHP-400	40V
Series UHP-400-1	70V
Series UHP-500	100V
Output On-State Sink Current, I_{on}	500mA
Suppression Diode Off-State Voltage, V_{off}	
Series UHP-400	40V
Series UHP-400-1	70V
Series UHP-500	100V
Suppression Diode On-State Current, I_{on}	500mA
Operating Free-Air Temperature Range, T_A	-20°C to +85°C
Storage Temperature Range, T_S	-65°C to +150°C

RECOMMENDED OPERATING CONDITIONS

	Min.	Nom.	Max.	Units
Supply Voltage (V_{CC})	4.75	5.0	5.25	V
Operating Temperature Range	0	+25	+85°	°C
Current into any output (ON state)			250	mA

Series UHP-14-pin plastic dual in-line; copper lead frame and epoxy encapsulation standard for high power handling capability.*

Thermal Resistance:

Junction to case, ϕ_{jc}	40°C/W
Junction to still air, ϕ_{ja}	60°C/W

* ϕ_{ja} of 60°C/W permits operation of four outputs continuously and simultaneously at 250mA with a junction temperature which will not exceed +150°C (ϕ_{jc}) at a +85°C ambient.

SERIES ULN-2000A HIGH-VOLTAGE, HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

THESE high-voltage, high-current Darlington arrays are comprised of seven silicon NPN Darlington pairs on a common monolithic substrate. All units feature open collector outputs and integral diodes for inductive load transient suppression. Peak inrush currents to 600 mA (Series ULN-2000A and ULN-2020A) or 750 mA (Series ULN-2010A) are permissible, making them ideal for driving tungsten filament lamp loads.

The Series ULN-2001A devices are general purpose arrays which may be used with standard bipolar digital logic using external current limiting, or with most PMOS or CMOS directly. All are pinned with outputs opposite inputs to facilitate ease of circuit board layout and are priced to compete directly with discrete transistor alternatives.

The Series ULN-2002A was specifically designed for use with 14 to 25 V PMOS devices. Each input has a Zener diode and resistor in series to limit the input current to a safe value in that application. The Zener diode also means excellent noise immunity for these devices.

The Series ULN-2003A has a 2.7 k Ω series base resistor to each Darlington pair, and thus allows operation directly with TTL or CMOS operating at a supply voltage of 5 V. These devices will handle numerous interface needs – particularly those beyond the capabilities of standard logic buffers.

The Series ULN-2004A features a 10.5 k Ω series input resistor to permit their operation directly from CMOS or PMOS outputs utilizing supply voltages of 6 to 15 V. The required input current is below that of the Series ULN-2003A while the required input voltage is less than that required by the Series ULN-2002A.

The Series ULN-2005A is especially designed for use with standard and Schottky TTL where higher output currents are required and loading of the logic output is not a concern. These devices will sink a minimum of 350 mA when driven from a “totem

pole” logic output. Typical voltage and current levels for both the Series ULN-2003A and ULN-2005A are shown in the graphs.

The Series ULN-2000A is the original high-voltage, high-current Darlington array. The output transistors are capable of sinking 500 mA and will sustain at least 50 V in the OFF state. Outputs may be paralleled for higher load current capability. The Series ULN-2010A devices are similar except that they will sink 600 mA. The Series ULN-2020A will sustain 95 V in the OFF state.

All Series ULN-2000A Darlington arrays are furnished in a 16-pin dual in-line plastic package.

Device Type Number Designation

$V_{CE(MAX)}$ = $I_{C(MAX)}$ =	50 V 500 mA	50 V 600 mA	95 V 500 mA
	Type Number		
General Purpose PMOS, CMOS	ULN-2001A	ULN-2011A	ULN-2021A
14 - 25 V PMOS	ULN-2002A	ULN-2012A	ULN-2022A
5 V TTL, CMOS	ULN-2003A	ULN-2013A	ULN-2023A
6 - 15 V CMOS, PMOS	ULN-2004A	ULN-2014A	ULN-2024A
High Output TTL	ULN-2005A	ULN-2015A	ULN-2025A

**ABSOLUTE MAXIMUM RATINGS at 25°C Free-Air Temperature
for any one Darlington pair (unless otherwise noted)**

Output Voltage, V_{CE} (Series ULN-2000, 2010A)	50 V
(Series ULN-2020A)	95 V
Input Voltage, V_{IN} (Series ULN-2002, 2003, 2004A)	30 V
(Series ULN-2005A)	15 V
Continuous Collector Current, I_C (Series ULN-2000, 2020A)	500 mA
(Series ULN-2010A)	600 mA
Continuous Input Current, I_{IN}	25 mA
Power Dissipation, P_D (one Darlington pair)	1.0 W
(total package)	2.0 W*
Operating Ambient Temperature Range, T_A	-20°C to +85°C
Storage Temperature Range, T_S	-55°C to +150°C

*Derate at the rate of 16.67 mW/°C above 25°C.

Under normal operating conditions, these devices will sustain 350 mA per output with $V_{CE(SAT)} = 1.6$ V at 70°C with a pulse width of 20 ms and a duty cycle of 34%.

3

ULN-2061M through ULN-2077B 1.5 A DARLINGTON SWITCHES

FEATURES

- TTL, DTL, PMOS, CMOS Compatible Inputs
- Transient Protected Outputs
- Handle Loads to 480 Watts
- Plastic Dual In-Line Packages
 With Heat Sink Contact Tabs (Quad Arrays)

HIGH-VOLTAGE, HIGH-CURRENT Darlington Arrays ULN-2061M through ULN-2077B are designed to interface low-level logic to a variety of peripheral loads such as relays, solenoids, d-c and stepper motors, multiplexed LED and incandescent displays, heaters, and similar loads to 480 watts (1.5 A per output, 80 V, 26% duty cycle).

The devices are specified with a minimum output breakdown of 50 volts and $V_{CE(SUS)}$ minimum of 35 volts measured at 100 mA, or, a minimum output breakdown of 80 volts, $V_{CE(SUS)}$ minimum of 50 volts; and an output current specification of 1.5 A (saturated).

Dual driver Type ULN-2061M and ULN-2062M arrays are used for common-emitter (externally connected), or emitter-follower applications. Both devices are supplied in miniature 8-pin dual in-line plastic packages.

Quad driver Types ULN-2064B, ULN-2065B, ULN-2068B and ULN-2069B are intended for use with TTL, low-speed TTL, and 5V MOS logic. The ULN-2065B and ULN-2069B are selected for the 80 V minimum output breakdown specification. The ULN-2068B and ULN-2069B incorporate predriver stages and are most suitable for applications requiring high gain (low input current loading).

Types ULN-2066B, ULN-2067B, ULN-2070B and ULN-2071B are similar to the preceding quad drivers except that they are designed for use with PMOS and 12 V CMOS logic. The ULN-2070B and ULN-2071B both use a predriver stage and are best suited for use where current is restricted by MOS output ratings.

Isolated Darlington arrays Types ULN-2074B through ULN-2077B are identical to Types ULN-2064B through ULN-2067B except for the isolated Darlington pin-out and the deletion of suppression diodes. These switches are for emitter-follower or similar isolated Darlington applications.

All of the quad Darlington arrays (suffix "B" devices) are supplied in a 16-pin plastic dual in-line package with heat-sink contact tabs. A copper-alloy lead frame provides maximum power dissipation using standard cooling methods. This lead configuration facilitates easy attachment of external heat sinks for increased power dissipation with standard IC sockets and printed wiring boards.

NOTES:

1. Input voltage is with reference to the substrate (no connection to any other pins) for the ULN-2061/62M and ULN-2074/75/76/77B; reference is ground for all other types.
2. Input current may be limited by maximum allowable input voltage.

COMMON-ANODE LED DRIVERS

(The Series UDN-2980A devices can also be used in similar applications for currents to 500 mA)

COMMON-CATHODE LED DRIVERS (Types ULN-2068/70B are also applicable)

UDN-2540B QUAD NAND POWER DRIVER

DESIGNED for use in extremely harsh electrical environments, Type UDN-2540B quad NAND driver links low-level signal processing circuits and medium-power inductive loads.

The inputs are compatible with most TTL, DTL, LS TTL, 5 V to 15 V CMOS, and PMOS logic. The outputs include transient suppression diodes for inductive loads such as relays, solenoids, d-c and stepping motors. This device can also be used to drive incandescent or heater loads.

SERIES UDN-2580A 8-CHANNEL SOURCE DRIVERS

FEATURES

- TTL, CMOS, PMOS, NMOS Compatible
- High Output Current Ratings
- Internal Transient Suppression
- Efficient Input/Output Pin Structure

THIS versatile family of integrated circuits, originally designed to link NMOS logic with high-current inductive loads, will work with many combinations of logic- and load-voltage levels, meeting interface requirements beyond the capabilities of standard logic buffers.

Series UDN-2580A source drivers can drive incandescent, LED, or vacuum fluorescent displays. Internal transient-suppression diodes permit the drivers to be used with inductive loads.

Type UDN-2580A is a high-current source driver used to switch the ground ends of loads that are directly connected to a negative supply. Typical loads are telephone relays, PIN diodes, and LEDs.

Type UDN-2585A is a driver designed for applications requiring low output saturation voltages. Typical loads are low-voltage LEDs and incandescent displays. The eight non-Darlington outputs will simultaneously sustain continuous load currents of -120 mA at ambient temperatures to $+70^{\circ}\text{C}$.

Type UDN-2588A, a high-current source driver similar to Type UDN-2580A, has separate logic and driver supply lines. Its eight drivers can serve as an interface between positive logic (TTL, CMOS, PMOS) or negative logic (NMOS) and either negative or split-load supplies.

Types UDN-2580A and UDN-2588A are rated for operation with output voltages of up to 50 V. Selected devices, carrying the suffix “-1” on the Sprague part number, have maximum ratings of 80 V.

Types UDN-2580A and UDN-2585A are furnished in 18-pin dual in-line plastic packages; Type UDN-2588A is supplied in a 20-pin dual in-line plastic package. All input connections are on one side of the packages, output pins on the other, to simplify printed wiring board layout.

For simplification, these devices are characterized on the following pages with specific voltages for inputs, logic supply (V_S), load supply (V_{EE}), and collector supply (V_{CC}). Typical use of the UDN-2580A and UDN-2580A-1 is with negative referenced logic. The more common application of the UDN-2585A, UDN-2588A, and UDN-2588A-1 is with positive referenced logic supplies. In application, the devices are capable of operation over a wide range of logic and supply voltage levels:

TYPICAL OPERATING VOLTAGES

V_S	$V_{IN(ON)}$	$V_{IN(OFF)}$	V_{CC}	$V_{EE(MAX)}$	Device Type
0 V	-15 V to -3.6 V	-0.5 V to 0 V	NA	-25 V	UDN-2585A
				-50 V	UDN-2580A
				-80 V	UDN-2580A-1
+5 V	0 V to +1.4 V	+4.5 V to +5 V	NA	-20 V	UDN-2585A
				-45 V	UDN-2580A
				-75 V	UDN-2580A-1
			≤5 V	-45 V	UDN-2588A
			-75 V	UDN-2588A-1	
+12 V	0 V to +8.4 V	+11.5 V to +12 V	NA	-13 V	UDN-2585A
				-38 V	UDN-2580A
				-68 V	UDN-2580A-1
			≤12 V	-38 V	UDN-2588A
			-68 V	UDN-2588A-1	
+15 V	0 V to +11.4 V	+14.5 V to +15 V	NA	-10 V	UDN-2585A

UDN-2595A 8-CHANNEL CURRENT-SINK DRIVER

FEATURES

- 200 mA Current Rating
- Low Saturation Voltage
- TTL, CMOS, NMOS Compatible
- Efficient Input/Output Pin Format
- 18-Pin Dual In-Line Plastic Package

DEVELOPED for use with low-voltage LED and incandescent displays requiring low output saturation voltage, Type UDN-2595A meets many other interface needs, including those exceeding the capabilities of standard logic buffers.

The eight non-Darlington outputs of this driver can simultaneously sink load currents of 200 mA at ambient temperatures of up to +85°C.

The eight-channel driver's active low inputs can be linked directly to TTL, Schottky TTL, DTL, 5 to 16 V CMOS, and NMOS logic. All input connections are on one side of the package, output connections on the other, for simplified layout of printed wiring boards.

Type UDN-2595A is supplied in an 18-pin dual-in-line plastic package with a copper lead frame that maximizes the driver's power-handling capabilities. A hermetically sealed version of Type UDN-2595A, with reduced package power dissipation ratings, is available on special order.

This device complements Sprague Type UDN-2585A, an eight-channel source driver.

	$V_{\text{IN(OFF)}}$	$I_{\text{OUT}} = 100\text{ }\mu\text{A}$, $T_A = 70^\circ\text{C}$	4.6	—	V
Input Capacitance	C_{IN}		—	25	pF
Supply Current	I_{SS}	$V_{\text{IN}} = 0.4\text{ V}$, $I_{\text{OUT}} = 100\text{ mA}$	—	6.0	mA
		$V_{\text{IN}} = 0.4\text{ V}$, $I_{\text{OUT}} = 100\text{ mA}$, $V_S = 15\text{ V}$	—	20	mA

NOTES:

1. Negative current is defined as coming out of the specified device pin.
2. The $V_{\text{IN(ON)}}$ voltage limit guarantees a minimum output sink current per the specified conditions.
3. I_{SS} is measured with any one of eight drivers turned ON.

SERIES ULN-2800A HIGH-VOLTAGE, HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

IDEALLY SUITED for interfacing between low-level digital logic circuitry and high-power peripheral loads, the Series ULN-2800A high-voltage, high-current Darlington transistor arrays feature peak load current ratings of 600 mA (Series ULN-2800A and ULN-2820A) or 750 mA (Series ULN-2810A) for each of the eight drivers in each device. Under the proper conditions, high-power loads of up to 4 A at 50V (200 W at 23% duty cycle) or 3.2 A at 95 V (304 W at 33% duty cycle) can be controlled. Typical loads include relays, solenoids, stepping motors, multiplexed LED and incandescent displays, and heaters. All devices feature open collector outputs and integral diodes for inductive load transient suppression.

The Series ULN-2801A devices are general purpose arrays which may be used with standard bipolar digital logic using external current limiting, or with most PMOS or CMOS directly. All are pinned with outputs opposite inputs to facilitate ease of circuit board layout and are priced to compete directly with discrete transistor alternatives.

The Series ULN-2802A was specifically designed for use with 14 to 25 V PMOS devices. Each input has a Zener diode and resistor in series to limit the input current to a safe value in that application. The Zener diode also means excellent noise immunity for these devices.

The Series ULN-2803A has a 2.7 k Ω series base resistor to each Darlington pair, and thus allows operation directly with TTL or CMOS operating at a supply voltage of 5 V. These devices will handle numerous interface needs – particularly those beyond the capabilities of standard logic buffers.

The Series ULN-2804A features a 10.5 k Ω series input resistor to permit their operation directly from CMOS or PMOS outputs utilizing supply voltages of 6 to 15 V. The required input current is below that of the Series ULN-2803A while the required input voltage is less than that required by the Series ULN-2802A.

The Series ULN-2805A is especially designed for use with standard and Schottky TTL where higher output currents are required and loading of the logic

D-G. NO. A-10.322

output is not a concern. These devices will sink a minimum of 350 mA when driven from a “totem pole” logic output.

The Series ULN-2800A is the standard high-voltage, high-current Darlington array. The output transistors are capable of sinking 500mA and will withstand at least 50 V in the OFF state. Outputs may be paralleled for higher load current capability. The Series ULN-2810A devices are similar except that they will sink 600mA. The Series ULN-2820A will withstand 95 V in the OFF state.

All Series ULN-2800A Darlington arrays are furnished in an 18-pin dual in-line plastic package.

TYPE UDN-2841B through UDN-2846B QUAD 1.5 AMPERE DRIVERS

FEATURES

- Inputs Compatible with DTL/TTL/LS TTL/CMOS/PMOS
- High Voltage Output: -50 V
- High Current Gain
- Sink from Negative Supply: UDN-2841B and UDN-2842B
- Source to Negative Supply: UDN-2843B and UDN-2844B
- Sink & Source Combination: UDN-2845B and UDN-2846B

THIS SERIES of quad Darlington switches is especially designed for high-current, high-voltage peripheral driver applications. It is intended to provide solutions to interface problems involving electronic discharge printers, d-c motor drive (bipolar or unipolar), telephone relays, PIN diodes, LEDs, and other high-current loads operating from negative supplies.

Types UDN-2841B and UDN-2842B are intended for sinking applications in which the load is connected to ground and the IC output switches the negative supply. The input PNP transistor in each driver serves as a level translator and the first NPN stage provides sufficient current gain to drive the output Darlington.

Type UDN-2843B and UDN-2844B quad drivers are primarily intended for switching the ground end of loads which utilize negative supply voltages. The NPN Darlington outputs are operated as emitter followers in this application.

Type UDN-2845B and UDN-2846B devices are sink-and-source combinations in a single dual in-line package. Either device can be used for bipolar switching applications in which both ends of the load are floating.

The UDN-2841B, UDN-2843B, and UDN-2845B I.C.s are intended for use with 5 V TTL, Schottky TTL, DTL, and CMOS logic. The UDN-2842B,

UDN2844B, and UDN-2846B feature a higher input impedance and are intended for use with 8 V to 15 V PMOS and CMOS logic.

All types reduce component count, lower system cost, reduce circuit and board complexity, and provide solutions for many interface requirements.

TYPICAL BIPOLAR MOTOR DRIVE APPLICATION

TYPICAL ELECTROSENSITIVE PRINTER APPLICATION

UTN-2886B and UTN-2888A MONOLITHIC SCR ARRAYS

FEATURES

- Low Input Current
- TTL, LSTTL and CMOS Compatible
- Momentary Inrush Current Capability to 2 A
- Minimum Forward Blocking Voltage 35 V
- Use with Full-Wave or Half-Wave Sources

INTENDED FOR USE with microprocessors that are strobing power loads, these monolithic SCR arrays will interface to high-current loads including lamps, relays, and solenoids. The use of multiple SCRs in a single package reduces component count, insertion costs, assembly time, and circuit space, while improving overall circuit reliability.

Each array contains multiple SCRs with integral current limiting and gate-to-cathode resistors. In all cases, the maximum allowable SCR current rating at +25°C is 800 mA continuous or 2 amperes non-recurring peak. Outputs may be paralleled for higher load current capability within the limits of the allowable package power dissipation rating.

The UTN-2886B array contains four individual SCRs and two pairs of paralleled SCRs (pins 8-9 and 1-16). Each SCR is capable of continuous and simultaneous operation at 250 mA (500 mA at pins 9 and 16) at an ambient temperature of +50°C. The 16-lead package with heat-sink contact tabs allows maximum power dissipation with standard cooling methods. Further increases in power dissipation can be obtained by attaching an external heat sink to the webbed leads.

The UTN-2888A SCR array contains eight isolated devices, each capable of continuous and simultaneous operation at 200 mA at an ambient temperature of +50°C.

These SCR arrays operate from an unfiltered half-wave (50 or 60 Hz) or full-wave (100 or 120 Hz) rectified source. They are not intended for use with a-c sources, and will not sustain commercial a-c line voltages (115 VAC).

TYPICAL LAMP APPLICATION

TYPICAL WAVEFORMS

3

APPLICATION NOTES

1. These devices normally operate from an unfiltered half-wave or full-wave rectified source. They *cannot* be operated with a bidirectional (unrectified) a-c source.

2. During operation, the SCR is turned ON by application of a positive voltage to the input. The SCR will remain ON, even though the input voltage is removed or made slightly negative, until the anode-to-cathode voltage is reduced to below the anode OFF voltage.

3. When using multiple SCRs and a common supply, gate-to-anode leakage currents can hold the

supply voltage above the anode OFF voltage and prevent proper turn-OFF. To insure proper operation, resistor R should be used as shown in the typical application. The maximum resistor value is determined from:

$$R = \frac{V_{AK(OFF)}}{(n-1) I_{GA}} = \frac{400 \text{ mV}}{(n-1) 250 \mu A}$$

where n is the number of SCRs being used in the system. Note that n = 2 for pin 8-9 and pin 1-16 of the UTN-2886B.

4. Various combinations of number of outputs conducting, duty cycle, and ambient temperature must be held within the allowable package power dissipation limits shown.

UDN-2949Z HIGH-CURRENT BIPOLAR HALF-BRIDGE MOTOR DRIVER

FEATURES

- 3.5 A Peak Output
- 32 V Output Breakdown
- Output Transient Suppression
- TTL, CMOS, PMOS, NMOS Compatible Inputs
- High-Speed Chopper (to 100 kHz)
- Low Standby Current (10 mA)
- TO-220 Style Package

THE UDN-2949Z is a monolithic half-bridge motor driver supplied in a power-tab TO-220 style package. The circuit combines sink and source drivers with diode protection, gain and level shifting systems, and a voltage regulator for single-supply operation. The unit is specifically designed for servomotor drive applications using pulse-width modulation (chopping).

The chopper drive mode is characterized by a minimum power dissipation requirement, low saturation voltages, and low chopper storage times for the NPN sink driver. Predriver stages reduce input drive requirements while allowing the output to switch currents of 2 amperes. Output d-c current accuracies of better than 10% at 100 kHz can be obtained.

The PNP sourcing driver is turned ON by an active high input while the NPN sinking driver is activated with a low input. These inputs are completely compatible with TTL, low-voltage CMOS, PMOS, and NMOS.

The UDN-2949Z may be used in pairs (full-bridge) for d-c stepper motor or brushless a-c motor drive applications. Such applications may require an external ground clamp diode (1N4000) connected at the output of each device in order to minimize package power dissipation.

DWG. NO. A-11,177

Single-chip construction and the power-tab TO-220 style package provide improved cost-effectiveness and reliability over discrete component motor drive systems with excellent power dissipation capability, minimum size, ease of installation, and heat sinking.

The package heat tab is at ground potential. Multiple devices may share a common heat sink without insulating hardware.

The UDN-2949Z power driver may be used in stepper-motor bipolar bridge-driver circuits, for example, with the Sprague UCN-4202A Stepper Motor Translator/Driver.

TEST FIGURE 1

TEST FIGURE 2

APPLICATION NOTES

1. The source and sink outputs should not be ON simultaneously (V_2 High, V_5 Low). High "crossover" currents could degrade or destroy the device.

2. Do not assume from the Logic Truth Table that both inputs can be connected (V_4 High or Low only). The sink driver is considerably faster than the source driver. An input shift from high-to-low levels could produce a condition where both drivers are ON, and that condition could occur for as long as $5 \mu\text{s}$.

3. It is recommended that the inputs be driven separately, and that the sink driver input

not be pulled low (turned ON) for at least $5 \mu\text{s}$ (max. source t_{PD}) after the source driver input is pulled low (turned OFF). The sink driver should be allowed to go high (turned OFF) at least 750 ns (max. sink t_{PD}) before the source driver goes high (turned ON).

UDN-2952B AND UDN-2952W FULL-BRIDGE MOTOR DRIVERS

FEATURES

- High Output Current
- Adjustable Short-Circuit Protection
- Thermal Shutdown
- Internal Clamp Diodes
- TTL, DTL, PMOS, CMOS Compatible
- DIP or SIP Packaging

FULL-BRIDGE motor driver IC Types UDN-2952B and UDN-2952W have both the logic circuitry and Darlington-pair power drivers for bidirectional control of d-c motors operating at currents of up to 2 A.

The integrated circuits carry extensive circuit protection. Output current-limiting is determined by the user's selection of sensing resistors. Both drivers have thermal shutdown networks that disable motor drive if the circuits' power dissipation ratings are exceeded. Internal transient suppression is built into both.

Type UDN-2952B is in a 16-pin dual in-line package with heat-sink contact tabs. The lead configuration enables easy attachment of a heat sink while fitting a standard integrated circuit socket or printed wiring board layout. Type UDN-2952W, for higher power requirements, is in a 12-pin single in-line power tab package.

Both drivers have tab temperature ratings of +70°C and require external heat sinks.

FUNCTIONAL BLOCK DIAGRAM

Dwg. No. A-11,367A

UDN-2956A and UDN-2957A

HIGH-VOLTAGE, HIGH-CURRENT SOURCE DRIVERS

COMPRISED of five common collector NPN Darlington output stages, the associated common base PNP input stages, and a common “enable” stage, the UDN-2956A and UDN-2957A high-voltage, high-current source drivers are used to switch the ground end of loads which are directly connected to a negative supply. Typical loads include telephone relays, PIN diodes, and LEDs. Both devices will sustain output OFF voltages of -80 V and will source currents to -500 mA per driver. Under normal operating conditions, these units will sustain load currents of -200 mA on each of the five drivers simultaneously at ambient temperatures up to $+70^\circ\text{C}$.

The UDN-2956A driver is intended for use with MOS (PMOS or CMOS) logic input levels operating with supply voltages from 6 V to 16 V . The UDN-2957A driver has appropriate input current limiting resistors for operation from TTL, Schottky TTL, DTL, and 5 V CMOS . With either device, the input and enable levels must both be biased towards the positive supply to activate the output load.

Integral transient suppression diodes allow these devices to be used with inductive loads without the need for discrete diodes. In order to maintain isolation between drivers, the substrate should be connected to the most negative supply applied.

Input connections are on one side of the dual in-line package, output connections on the other side to simplify printed wiring board layout.

The UDN-2956A and UDN-2957A high-voltage, high-current drivers are supplied in 14-lead dual in-line packages conforming to JEDEC outline

TO-116 (MO-001AA). Hermetically-sealed versions of these devices (with reduced package power dissipation capability) are available.

SERIES UDN-2980A HIGH-VOLTAGE, HIGH-CURRENT SOURCE DRIVERS

FEATURES

- TTL, DTL, PMOS, or CMOS Compatible Inputs
- 500 mA Output Source Current Capability
- Transient-Protected Outputs
- Output Breakdown Voltage to 80 V

RECOMMENDED for applications requiring separate logic and load grounds, load supply voltage to +80 V, and load currents to 500 mA, Series UDN-2980A source drivers are used as interfaces between standard low-power digital logic and relays, solenoids, stepping motors, and LEDs.

Under normal operating conditions, these devices will sustain 120 mA continuously for each of the eight outputs at an ambient temperature of +50°C and a supply of +15 V. All devices in this series incorporate input current limiting resistors and output transient suppression diodes.

Type UDN-2981A and UDN-2983A drivers are for use with +5 V logic systems — TTL, Schottky TTL, DTL, and 5 V CMOS. Type UDN-2982A and UDN-2984A drivers are intended for MOS interface (PMOS and CMOS) operating from supply voltages

of 6 to 16 V. Types UDN-2981A and UDN-2982A will sustain a maximum output OFF voltage of +50 V, while Types UDN-2983A and UDN-2984A will sustain an output voltage of +80 V. In all cases, the output is switched ON by an active high input level.

Series UDN-2980A high-voltage, high-current source drivers are supplied in 18-lead dual in-line packages. On special order, hermetically-sealed versions of these devices (with reduced package power dissipation capability) can also be furnished.

FEATURES

- Four Logic Types
- DTL/TTL/PMOS/CMOS Compatible Inputs
- Low Input Current
- 300 mA Continuous Output Current
- Sustaining Voltage of 80 V
- Pin-for-Pin Replacement for Series LM3600N
- Pin-for-Pin Replacement for SN75451BP thru SN75454BP and 75461 thru 75464

3

Description

These "mini-DIP" dual 2-input peripheral and power drivers are bi-polar monolithic integrated circuits incorporating AND, NAND, OR, or NOR logic gates, and high-current switching transistors on the same chip. The two output transistors are capable of simultaneously sinking 300 mA continuously at ambient temperatures of up to +70°C. In the OFF state, these drivers will sustain at least 80 V.

Applications

The Series UDN-3600M dual drivers are ideally suited for interface between low-level or high-level logic and high-current/high-voltage loads. Typical applications include driving peripheral loads such as incandescent lamps, light-emitting diodes, memories, heaters, and other non-inductive loads of up to 600 mA (both drivers in parallel).

With appropriate external diode transient suppression, the Series UDN-3600M drivers can also be used with inductive loads such as relays, solenoids, and stepping motors.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}	7.0 V

SERIES UDN-5700A QUAD 2-INPUT PERIPHERAL and POWER DRIVERS

— TRANSIENT PROTECTED OUTPUTS

FEATURES:

- Four Logic Types
- DTL/TTL/PMOS/CMOS Compatible Inputs
- Low Input Current
- 300 mA Continuous Output Current
- Sustaining Voltage of 80 V

Description

These 16-lead quad 2-input peripheral and power drivers are bi-polar monolithic integrated circuits incorporating AND, NAND, OR, and NOR logic gates, high-current switching transistors, and transient suppression diodes on the same chip. The four output transistors are capable of simultaneously sinking 300 mA continuously at ambient temperatures of up to +70°C. In the OFF state, these drivers will sustain at least 80 V.

Applications

The Series UDN-5700A quad drivers are ideally suited for interface between low-level or high-level logic and high-current/high-voltage loads. Typical applications include driving peripheral loads such as incandescent lamps, light-emitting diodes, memories, and heaters.

The integral transient suppression diodes allow their use with inductive loads such as relays, solenoids, or stepping motors without the need for discrete diodes. For non-inductive loads, the diode common bus can be used as a convenient lamp test.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}	7.0 V
Input Voltage, V_{IN}	30 V
Output Off-State Voltage, V_{OFF}	80 V
Output On-State Sink Current, I_{ON}	600 mA
Suppression Diode Off-State Voltage, V_{OFF}	80 V
Suppression Diode On-State Current, I_{ON}	600 mA
Power Dissipation, P_D	2.0 W
Each Driver	0.8 W
Derating Factor Above 25°C	16.7 mW/°C or 60°C/W
Operating Free-Air Temperature Range, T_A	-20°C to +85°C
Storage Temperature Range, T_S	-55°C to +150°C

RECOMMENDED OPERATING CONDITIONS

	Min.	Nom.	Max.	Units

SERIES UDN-5700M DUAL PERIPHERAL and POWER DRIVERS

— TRANSIENT PROTECTED OUTPUTS

FEATURES

- Four Logic Types
- DTL/TTL/PMOS/CMOS Compatible Inputs
- Low Input Current
- 300 mA Continuous Output Current
- Sustaining Voltage of 80 V

Description

These “mini-DIP” dual peripheral and power drivers are bi-polar monolithic integrated circuits incorporating AND, NAND, OR, or NOR logic gates, high-current switching transistors, and transient suppression diodes on the same chip. The two output transistors are capable of simultaneously sinking 300 mA continuously at ambient temperatures of up to +70°C. In the OFF state, these drivers will sustain at least 80 V.

Applications

The Series UDN-5700M dual drivers are ideally suited for interface between low-level or high-level logic and high-current/high-voltage loads. Typical applications include driving peripheral loads such as incandescent lamps, light-emitting diodes, memories, and heaters with a load current of up to 600 mA.

The integral transient suppression diodes allow the use of these drivers with inductive loads such as relays, solenoids, or stepping motors without the need for discrete diodes. When not required for transient suppression, the diode common bus can be used to perform the “lamp test” function.

Series ULN-2000A Darlington Transistor Arrays*

— Description and Application

Introduction

The increased use of electronic circuits in systems formerly built with mechanical, electro-mechanical, or hydraulic components has resulted in systems becoming more precise, more reliable, generally less expensive, smaller, more efficient, and faster. Although the drive capabilities of monolithic integrated logic circuits are adequate for most information processing applications, there now exists a large and rapidly growing number of system applications where the current-carrying and/or voltage-sustaining capability of the integrated circuit logic is inadequate. Typically, these deficiencies arise when the logic must control such peripheral components as relays, solenoids, punches, stepping motors, and a variety of indicators (incandescent, LED, or gas discharge lamps and displays).

A very common solution to this output interface inadequacy has been the addition of discrete power transistors (or SCRs) and associated passive components to the logic output in order to obtain the necessary current and/or voltage capability. Although this provides a very satisfactory electrical solution, the large number of discrete components often required, high assembly labor costs, and space (packaging) limitations often mean additional problems and cost. A simple, and less expensive solution is the use of monolithic integrated circuits.

The Series ULN-2000A is comprised of four different high-voltage/high-current interface circuits. They are capable of controlling resistive, inductive, or tungsten filament loads of up to 125 watts and are compatible with all standard digital logic families (DTL, TTL, PMOS, and CMOS) without the need for additional discrete components.

High-Voltage and High-Current Capability

A large number of interface problems have been simplified by the Series ULN-2000A high-voltage, high-current Darlington transistor arrays. These devices are suitable for voltage, current, and gain levels beyond the limits of other monolithic buffers and arrays.

The four devices in the ULN-2000A series are all comprised of seven silicon NPN Darlington pairs on a common monolithic substrate. All units feature open collector outputs and integral suppression diodes for use with inductive loads.

All devices have an output sink current capability of 500 mA although peak inrush currents to 600 mA are permissible, making them ideal for use with tungsten filament lamps. All of the outputs will sustain "OFF" voltages of at least 50 volts. Each individual Darlington circuit may therefore switch up to 25 watts (50 V at 500 mA).

A definite asset of monolithic device technology is the very fine match between adjacent outputs when used in parallel. Applications requiring a sink current beyond the capability of a single output can be accommodated by parallel outputs. Continuous operation of all outputs at the maximum rated current is not allowed because of power dissipation limitations imposed by the package. However, as illustrated in Figure 1, under certain conditions, the Series ULN-2000A Darlington arrays are capable of switching loads totaling more than 125 watts at an ambient temperature of +70°C.

3

*Examples and data in this application note applies equally to Series ULN-2800A Darlington arrays.

Figure 1
COLLECTOR CURRENT AS A FUNCTION OF DUTY CYCLE AND NUMBER OF OUTPUTS

High-Power Capability

A primary limitation of many interface circuits is the power dissipation of the device package. Until recently, very little concern was expressed for monolithic integrated circuit power dissipation. Improvements in silicon device technology have brought about a growing number of monolithic circuits capable of power considerably in excess of present package technology.

The Series ULN-2000A is supplied in a 16-pin dual in-line plastic package with a copper lead frame. Shown in Figure 2 is a comparison of the allowable package power dissipation for the industry standard iron-nickel alloy (Kovar) lead frame and the Sprague copper lead frame used on these devices. As shown, at an ambient temperature of +70°C, the Kovar lead frame allows only 0.64 watts while the copper lead frame allows 1.33 watts. At +25°C the copper lead frame permits a package power dissipation of 2.0 watts!

Actual power dissipation in any application for the Series ULN-2000A devices is the sum of the individual driver power dissipations. In turn, the individual driver dissipation is the product of the collector-emitter saturation voltage, the collector current, and the duty cycle. The collector-emitter saturation voltage is dependent on the collector current and, to a lesser extent, operating temperature.

Figure 2
ALLOWABLE AVERAGE PACKAGE POWER DISSIPATION AS A FUNCTION OF AMBIENT TEMPERATURE

The Basic Darlington Array

The first, and basic array, in this series, is the Type ULN-2001A. This is a general-purpose version with input current limiting normally accomplished via the use of an appropriate discrete resistor connected in series with each input. It is also possible to utilize the intrinsic current limiting of many MOS outputs as shown in Figure 4; a typical P-channel characteristic.

The use of TTL in such a manner is not recommended due to the higher currents and resultant high level of package power dissipation. Outputs of most PMOS and CMOS circuits will not normally source currents of any significance due to their high source impedance.

DWG. NO. A-9595

(each driver)

Figure 3

TYPE ULN-2001A SCHEMATIC

14 to 25 Volts PMOS Applications

The Type ULN-2002A Darlington array was specifically designed for use with 14 to 25 volt PMOS devices. Each input has a 7 V Zener diode and a 10,500 ohm resistor (nominal values) to limit the input current to within the capability of most PMOS of the type specified. The basic circuit diagram is shown in Figure 5 with a typical application. Note that there are *no* pull-down resistors or other external discrete components necessary. The incorporation of the Zener diode also results in excellent noise immunity for this array.

TTL and CMOS INTERFACE

The ULN-2001A and ULN-2002A allow only a limited number of input options. Shown in Figure 6 is the basic circuit diagram of the Type ULN-2003A. This device has a series base input resistor to each Darlington pair, and thus allows operation directly with TTL or CMOS logic operating at a supply voltage of 5 V (or 12 V CMOS using FET characteristics).

A guarantee of 200 mA output sink current capability (saturated) is provided with the worse case TTL logic *I* level of 2.4 volts. Low-power Schottky-clamped TTL logic is generally specified to have a minimum V_{out} of 2.7 volts. The ULN-2003A is guaranteed to sink 250 mA under this input condition. With the more typical input of 3 volts, the ULN-2003A Darlington pair will sink at least 300 mA in the "ON" state.

DWG. NO. A-10,174

Figure 4
TYPICAL P-CHANNEL
DRAIN CHARACTERISTIC

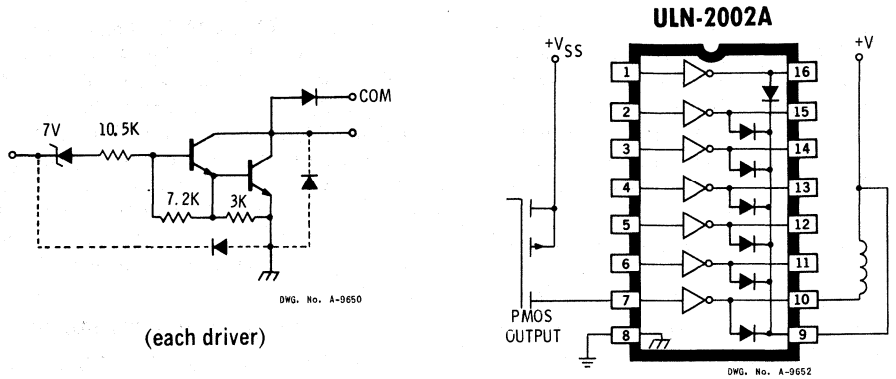

Figure 5
TYPE ULN-202A SCHEMATIC AND APPLICATION

TTL totem pole outputs are not specified between the 400 μ A logic *I* fanout condition and the maximum output short-circuit current (20 to 55 mA for the 7400 series). Between these rather wide limits lies the required ULN-2003A input current. The maximum Type ULN-2003A input current level is specified at 1.35 mA at the extrapolated TTL maximum logic *I* level of 3.85 V.

The ULN-2003A Darlington array will handle a great many interface needs – particularly those beyond the capabilities of TTL buffers. Also shown in Figure 6, is a typical application of the ULN-2003A Darlington array. Of particular interest in this application is an unusual use of the transient-suppression diodes for a non-inductive load. The lamp test feature can of course be used with any of the devices in this series.

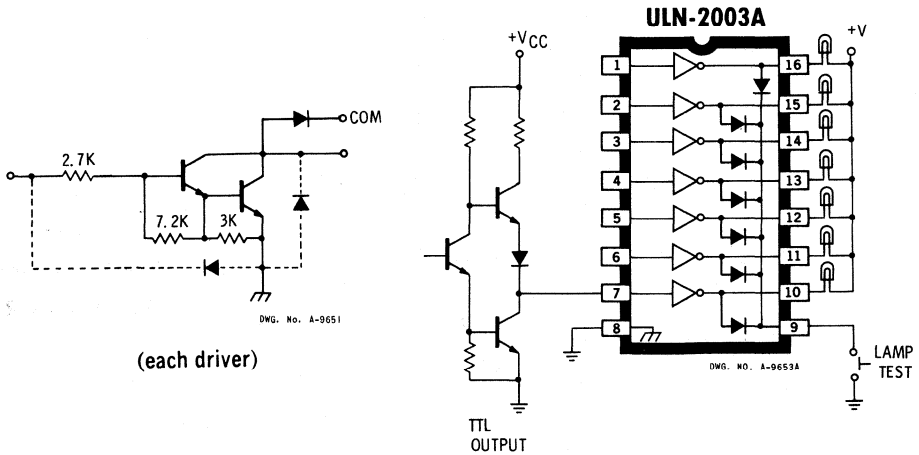

Figure 6
TYPE ULN-2003A SCHEMATIC AND APPLICATION

The diodes are designed to handle the same current and voltage as the output transistors. Switching can be accomplished through an ordinary switch or an appropriate power transistor. With the standard +70°C ambient and the most widely used lamps (2 No. 327 or 2 No. 387 lamps per output) there is no problem with continuous operation.

6 to 15 Volt CMOS or PMOS Applications

The Type ULN-2004A Darlington array has an appropriate series input resistor (nominally 10.5 kΩ) to allow its operation directly from CMOS or PMOS logic outputs utilizing supply voltages of between 6 and 15 V.

Shown in Figure 7 is a typical application of this array. Although the discrete output buffer could be used to increase the output capability of any of the devices in this series, this is most often done by paralleling outputs as was described earlier.

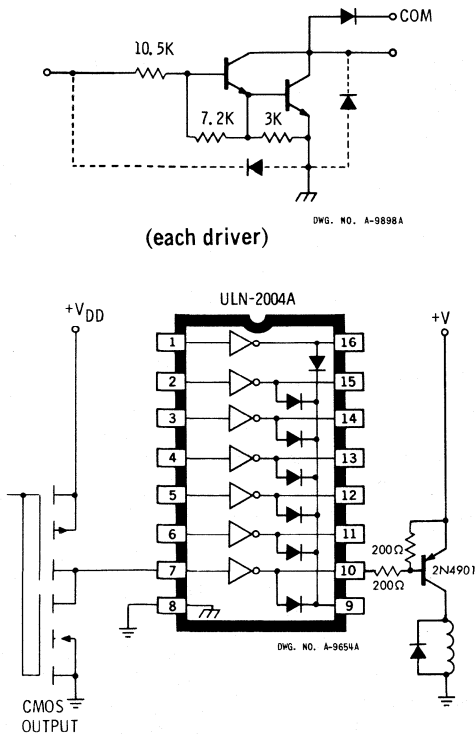

Figure 7

Type ULN-2004A SCHEMATIC AND APPLICATION

Input Current

The Darlington collector current (output in saturation) at an ambient temperature of +25°C, for any input current is the same for all four devices in this series and is shown in the graph of Figure 8. More accurately, the maximum input current for any collector current is described by the equation:

$$I_{IN(\mu A)} = I_{C(mA)} + 140 \mu A$$

where I_m is the input current in microamperes, I_C is the collector current in milliamperes, and the figure 140 represents the maximum shunt current through the emitter-base resistors. The typical input current can be described as:

$$I_{IN(\mu A)} = 0.58 I_{C(mA)} + 110 \mu A$$

where the figure 0.58 is an adjustment for the typical Darlington current gain and the figure 110 represents the typical shunt current.

Figure 8

COLLECTOR CURRENT AS A FUNCTION OF INPUT CURRENT

3

HIGH-CURRENT INTERFACE DRIVERS (Continued)

The input current as a function of input voltage is shown in Figure 9 for the ULN-2002A, ULN-2003A, and the ULN-2004A. The Type ULN-2001A Darlington array is not shown since input current is more a function of the external circuitry. Systems utilizing either CMOS or PMOS logic should be evaluated for intrinsic current limiting as was shown in Figure 4.

Figure 9

INPUT CURRENT AS A FUNCTION OF INPUT VOLTAGE

Low Available Drive Current Operation

Occasionally, applications featuring minimum available input drive current and a high output load current have shown the Type ULN-2003A and ULN-2004A Darlington arrays to be inadequate for the particular requirement under worst case conditions. This usually results from the restricted drive current available from a TTL or CMOS gate operating from a nominal supply of 5 volts.

Under worst case conditions with a low logic 1 voltage (2.4 V), and a high input resistor value (3.51 k Ω), the available load current is reduced to only 145 mA. Compounding this problem would be the effect that a high drive current requirement would have on the logic output voltage since that is normally specified at only 400 μ A. If the gate output is connected to additional logic elements, a minimum logic 1 voltage of 2.0 V must be maintained and at that level the worst case Darlington load current would be reduced to only 31 mA!

A simple solution to this problem is through the use of inexpensive pull-up resistors as shown in Figure 10. The minimum resistor value is determined by the maximum allowable sink current (16 mA for TTL, 360 μ A for CMOS), the minimum logic 0 output voltage, and the maximum supply voltage as per the following equation:

$$R_p \geq \frac{V_s - V_{OUT(0)}}{I_{OUT}}$$

For standard TTL, the minimum value for R_p is about 316 Ω with values between 3000 Ω and 5000 Ω being used customarily. Multiple pull-up resistors in a single in-line package are shown in Sprague Engineering Bulletin No. 7041; resistors in a dual in-line package are shown in Bulletin No. 7042.

Conclusion

Since the Series ULN-2000A high-voltage, high-current Darlington transistor arrays are quite conservatively designed, the basic product is fully capable of being ordered to higher voltages and/or higher currents than the standard specifications. Presently, parts are available to withstand up to 95 volts on the output. Parts with this higher voltage rating would create a potential for switching loads far in excess of 125 watts! Aside from the higher power handling capability, the higher voltage rating is required for driving plasma or gas-discharge displays.

Although not intended for high power applications, there is also available a Series ULS-2000H with hermetic sealing and an operating temperature range to +125°C. These parts are recommended for military and aerospace applications as well as commercial and industrial control applications where severe environments may be encountered.

Cer-DIP, industrial-grade hermetic devices, Series ULQ-2000R, are rated for use over the temperature range of -40°C to +85°C, permitting their use in commercial and industrial applications requiring a moderate package power dissipation (1 W at $T_A = +85^\circ\text{C}$).

All of these Darlington transistor arrays offer a common solution to a great many interface needs. The minimal component count and straightforward printed wiring board layout offer benefits in cost reduction, simplicity of board layout, and savings in space. Other benefits are a reduction in insertion costs, and lower handling and inventory costs than other alternatives. Cost benefits from some of these factors are not very tangible. However, fewer components, less complex boards, etc. usually result in lower system manufacturing costs.

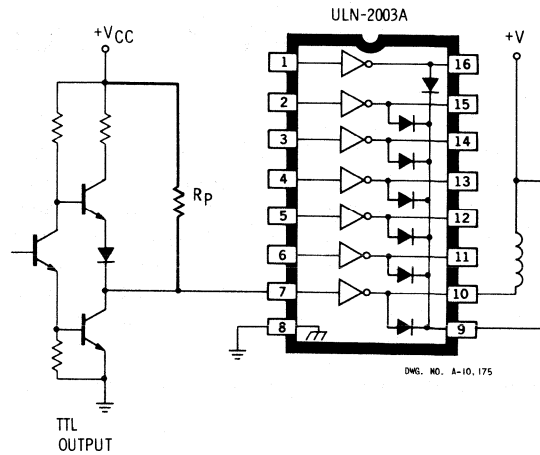

Figure 10
USE OF PULL-UP RESISTORS
TO INCREASE DRIVE CURRENT

INTERFACE IC MOTOR DRIVE APPLICATIONS

THE INCORPORATION OF LOGIC systems and power drivers into a monolithic integrated circuit requires special skill and experience. Sprague Electric Company has developed such skill, and has long been a leader in solid-state interface technology and devices.

Improved systems reliability and performance, lower component counts, space savings

and cost economy are some of the benefits to be derived from the use of Sprague Interface ICs. An increasing number of these Sprague devices are especially designed for or are easily adapted to motor drive applications. The availability of these devices is especially significant in view of the increasing use of microprocessor-based controls for servo and stepper motors.

UCN-4202A STEPPER MOTOR TRANSLATOR/DRIVER

THE UCN-4202A will drive permanent magnet (PM) stepper motors rated to 500 mA and 15 V with a minimum of external components required, or, the device may be used as a logic translator to drive discrete high-power transistors or the Sprague UDN-2949Z Half-Bridge Motor Driver.

With the MONOSTABLE RC timing pin (Pin 11) tied to V_{CC} (Pin 16) the circuit performs a full-step function. States B and D are stationary states and a separate input pulse is required to move through each of four output states.

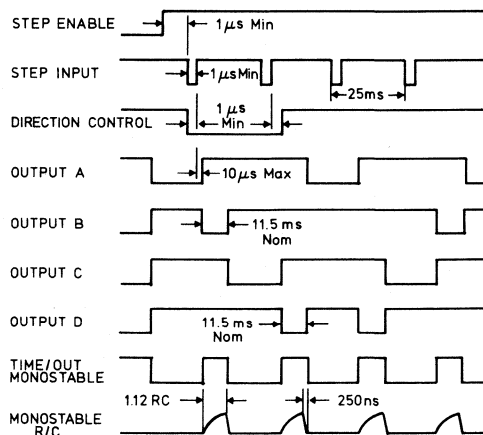

The UCN-4202A internal step logic activates one of four output sink drivers to step the load from one position to the next. The logic is activated when the STEP INPUT (Pin 10) is pulled low for at least $1 \mu s$ and then allowed to return high. The sequence of states is determined by the DIRECTION CONTROL (Pin 12), either A-B-C-D, or A-D-C-B.

In the double-step mode states B and D are transition states with durations determined by the MONOSTABLE RC timing (Pin 11). Improved motor torque is obtained at double the nominal motor step angle, and motor stability is improved for high step rates.

RECOMMENDED MAX. OPERATING CONDITIONS

Output Voltage, V_{CE}	13.5 V
Output Current, I_{OUT}	500 mA
Supply Voltage, V_{CC}	5.5 V
Supply Voltage, V_K	13.5 V
Input Voltage, V_{IN}	5.5 V

Timing Conditions - Double-Step Mode

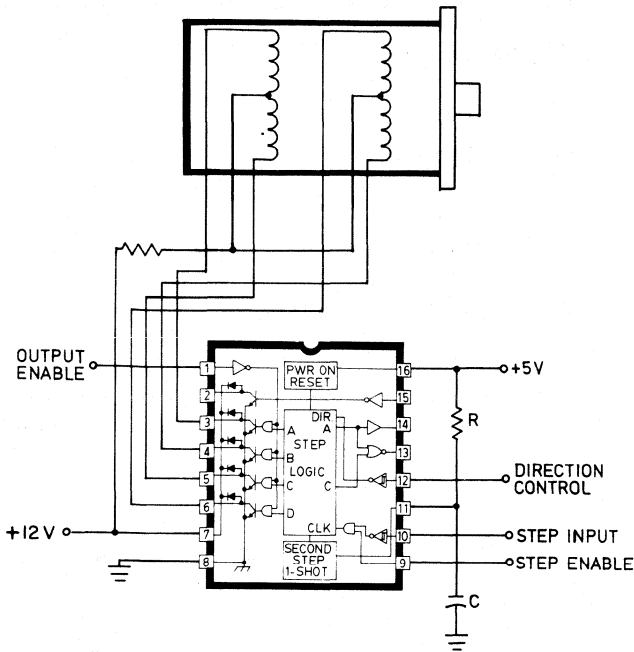

DWG. NO. A-11,186

NOTE: State B and State D Output pulse duration is typically 11.5 ms, with $R = 510 k\Omega$, and $C = 0.02 \mu F$.

SERIES ULN-2800A DARLINGTON ARRAYS and SERIES UDN-2980A HIGH-CURRENT SOURCE DRIVERS

THE COMBINATION of separate 8-channel source and sink driver ICs provides a single or twin motor drive interface solution for "crossover" currents which may occur during switching transitions. No timing provisions are necessary provided the external resistance limits "crossover" currents to the maximum specified for the ICs (± 500 mA).

Flyback voltage should not exceed the recommended V_S level (+35 V or +50 V). With a UDN-2982A/ULN-2803A combination and a +24 V supply the flyback voltage should not exceed +35 V [$V_S(\text{max}) + V_{\text{Zener}}(\text{max}) + V_{\text{clamp}}(\text{max}) \leq 35$ V].

Single motor drives may be accommodated by paralleling both inputs and outputs of each IC

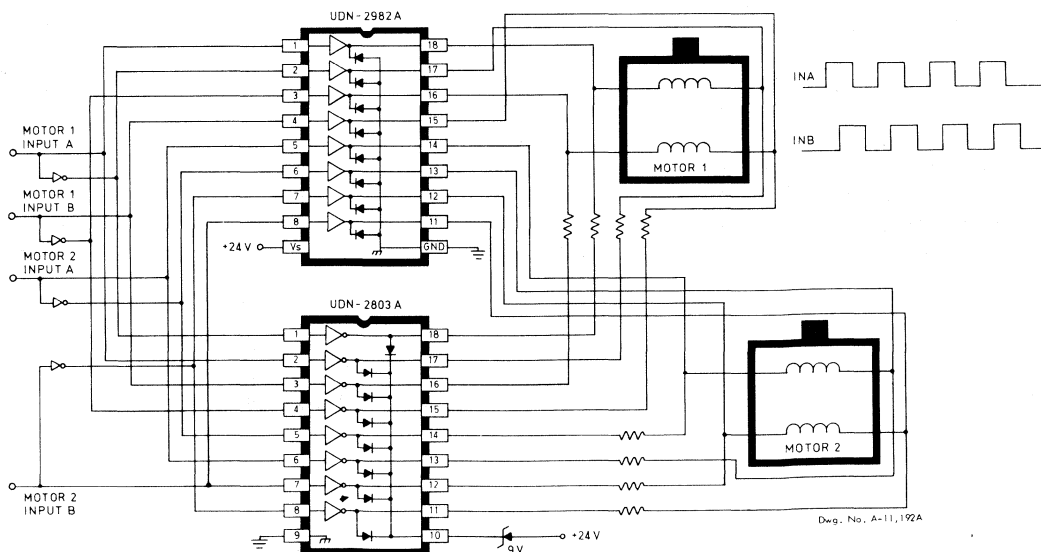

(max $I_{\text{OUT}} = \pm 1.0$ A; DIP rating allows ≈ 350 mA max).

Stepper motor bridge driver circuits using techniques such as that illustrated below should achieve greater reliability and space economy, cost reduction and improved performance.

RECOMMENDED MAX. OPERATING CONDITIONS

Supply Voltage, V_S	
UDN-2982A and ULN-2803A	35 V
UDN-2982A and ULN-2823A	50 V
Peak Output (100 ms), I_{OP}	± 350 mA
Continuous Output Current, I_{OUT}	
Single Motor	± 300 mA
Independent Operation Twin Motors	± 300 mA
Simultaneous Operation Twin Motors	± 150 mA

UDN-2982A and ULN-2803A Twin Motor Combination

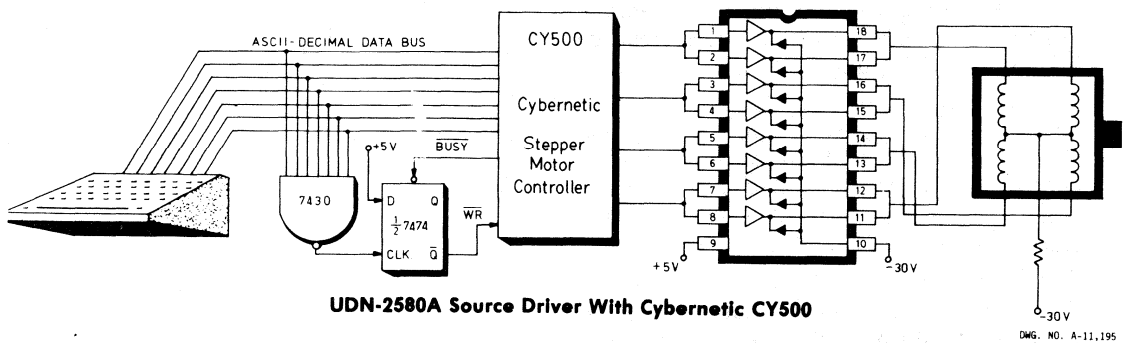

UDN-2580A SOURCE DRIVER

THE UDN-2580A SOURCE DRIVER serves as a direct interface from the Cybernetic Micro Systems CY500 Motor Controller, utilizing paralleled inputs and outputs. This IC is most useful with supplies of up to -35 V. A selected version (UDN-2580A-1) is available for operation to -50 V.

RECOMMENDED MAX. OPERATING CONDITIONS

Output Voltage, V_{CE}	35 V*
Output Current, I_{OUT}	-350 mA

*Referenced to $-V$ ($+5$ V and -30 V shown)

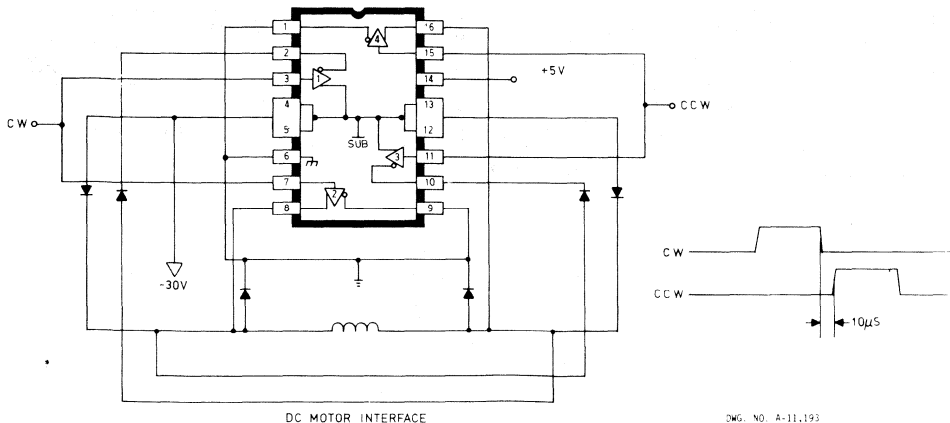

3

UDN-2845B and UDN-2846B QUAD DRIVERS

THESE QUAD DRIVERS are designed to handle high current loads operating from negative supplies. The d-c motor interface shown uses external diodes for clamping and commutation. A $10 \mu s$ interval between input transitions is recommended to prevent "cross-over" current damage to the IC.

RECOMMENDED MAX. OPERATING CONDITIONS

Output Voltage, V_{CE}	-35 V
Output Current, I_{OUT}	-1.5 A
Supply Voltage, V_S	5.0 V
Input Voltage, V_{IN}	
UDN-2845B	5.0 V
UDN-2846B	12 V

UCN-4401A and UCN-4801A BIMOS LATCH/DRIVERS

THESE HIGH-VOLTAGE, high-current latch/drivers are comprised of four or eight CMOS data latches, a Darlington transistor driver for each latch, and CMOS control circuitry for the common CLEAR, STROBE, and DUTY CYCLE CONTROL functions. Data bits can be sent to the latch/drivers at rates from 500 kHz ($V_{DD} = 5\text{ V}$) to 1 MHz ($V_{DD} = 12\text{ V}$).

Microprocessor power can be utilized more effectively in motor drive systems incorporating UCN-4401A or UCN-4801A latch/drivers. The appropriate motor windings can be activated (usually at millisecond rates) while the microprocessor spends nearly 100% of its time performing other functions.

A full-step drive scheme implemented with the 4-latch UCN-4401A provides 350 mA for each output. The 8-latch UCN-4801A may be used for systems operating more than one motor, with 300 mA available for each output.

RECOMMENDED MAX. OPERATING CONDITIONS

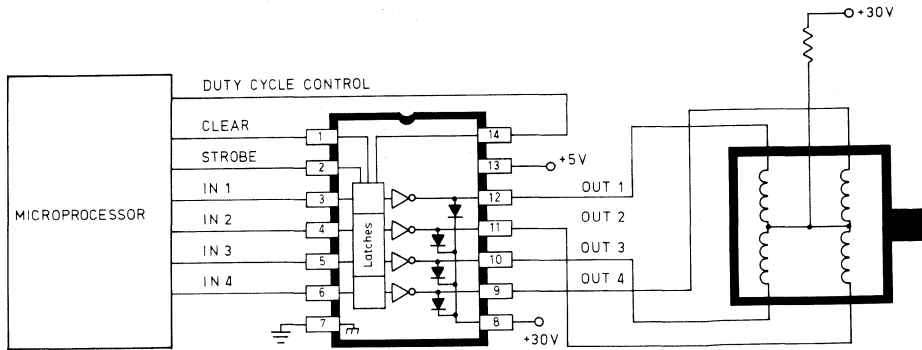

Output Voltage, V_{CE}	35 V
Output Current, I_{OUT}	350 mA
Supply Voltage, V_{DD}	15 V
Input Voltage, V_{IN}	V_{DD}

- A. Minimum strobe pulse width.....300 ns
- B. Minimum data pulse width.....300 ns
- C. Minimum data set-up time.....100 ns
- D. Minimum data hold time.....100 ns
- E. Minimum duty cycle control pulse width.....300 ns

EXPANDING THE FRONTIERS OF IC INTERFACE FOR ELECTRONIC DISPLAYS

INTRODUCTION

The original monolithic high-voltage/high-current power drivers from Sprague were capable of sustaining 100 V and sinking load currents of 250 mA on each of four outputs. That 1970 peripheral driver capability has since been expanded and improved on to solve many of the most difficult display interfaces. Our newest devices are rated for operation to 130 V, sourcing or sinking to 1.5 A, and as many as eight drivers per package (not all together) with inputs for TTL, Schottky TTL, DTL, CMOS, and PMOS.

LAMP (INCANDESCENT) INTERFACE

Utilizing marketing inputs that related to existing hybrid interface circuits, a group at Sprague designed and manufactured monolithic ICs which initially were largely used for aircraft indicator lamp interface. Although not widely known, these quad driver units were developed quite independently (and simultaneously) to the ubiquitous TI 75451 series of high-speed, low-voltage peripheral drivers. A concentration upon circuit design factors, improvements in DIP packaging (copper alloy lead frames), and tighter, tougher control of diffusion-related

parameters has allowed the manufacture of quad power drivers rather than the dual mini-DIPs offered by TI.

An increased awareness for improvements in reliability and space and power reductions provided a rather successful military market for Sprague lamp and relay interface; early success was evident in military aircraft indicator lamp interface, a tough application for TTL type ICs due to severe inrush currents resulting in secondary breakdown during "turn on". The increased current sinking capability of the Sprague ICs offers a solution to lamp interface that usually obviates the need for "warming" resistors (across the output) which slightly warm the lamp filament and thus minimize problems associated with cold lamp filaments.

The relay driver types of Sprague IC drivers (and other similar transient-protected ICs) are somewhat more useful than the so-called general purpose types, since the diode common terminal may be switched for a system lamp test. As shown in Figure 1, only a single connection to each DIP is required.

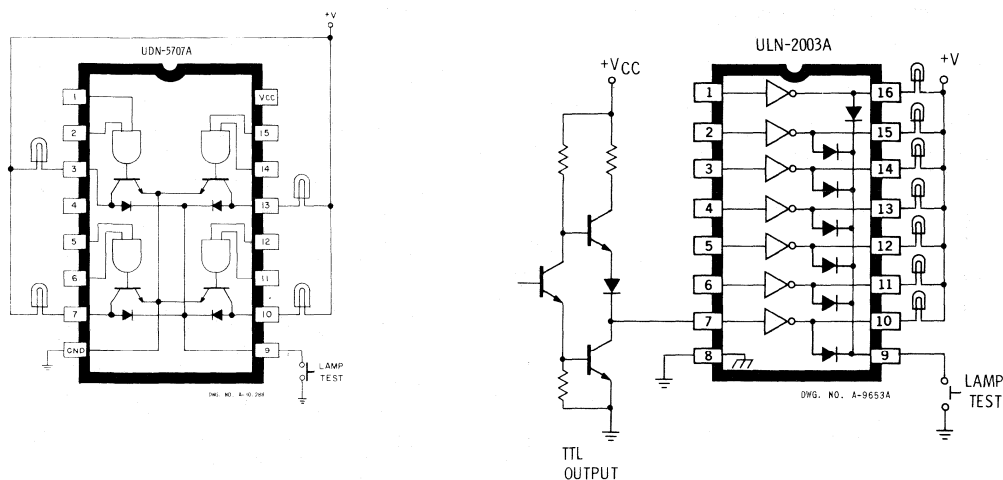

Figure 1

HIGH-CURRENT INTERFACE DRIVERS (Continued)

The high current-sinking capability of the Sprague ICs allows such loads as the #327 or #387 lamps (usually two in parallel - 28 V at 40 mA each) to be driven without difficulty of secondary breakdown. The device beta will usually not allow sinking of the 10 to 13 times (nominal value) inrush current of cold lamps; but the lamp rapidly reaches a current level within the device output limitations (Figure 2 shows current as a function of time for a single #327 lamp). Sustaining this instantaneous inrush current and its peak power has been a key element in the success of many lamp interface circuits.

GAS DISCHARGE DISPLAY ICs

Early in 1972, Sprague successfully produced its first high-voltage IC designed for gas discharge displays - a five channel, 130 V unit for cathode (segment) interface. Subsequently, other circuits, both cathode and anode drivers, were produced; most of which were used in calculator applications with the Burroughs Panaplex® II. In Figure 3 is shown a display interface system utilizing the UHP-481 and UHP-491 display drivers, associated thick-film networks, and discretes. This was a step forward, but still required external discrete components.

Through a collaborative effort begun late in 1973 between Sprague Electric and Burroughs Corp. a newer, more efficient interface scheme evolved. Featured in "Electronic Displays '75", this series of monolithic IC interface devices for the high-voltage gas discharge panels has been one of the trailblazers in the world of display interface ICs. Intended for use in multiplexed display systems, these ICs present one of the easiest and least expensive solutions to a

difficult interface problem. A combination of high-voltage bipolar techniques with thin-film resistor technology (circuit resistors sputtered over the IC dielectric) has provided both digit (anode) and segment (cathode) interface.

To facilitate a minimum component interface, a split supply (± 100 V) is employed to allow d-c level-shifting (rather than capacitors or >200 V transistors) and both digit and segment drivers incorporate all pull-up, pull-down, current limiting, off-bias reference, etc. which were formerly required in discrete and/or hybrid systems. With the combination of the digit and segment drivers (each capable of withstanding 120 V), the split power supply approach affords PN diode IC technology suitable for driving a display usually requiring a 180 V minimum ionization voltage (equivalent to ± 90 V in the split system).

The use of the Series UDN-6100/7100A gas discharge display drivers shows the need for only two monolithic ICs for displays of up to eight digits and eight segments as shown in Figure 4. Systems requiring digit or segment counts greater than eight employ additional driver ICs, and with the exception of the Type UDN-7180A segment driver, the segment ICs all have outputs with internal current-limiting resistors for the display segments. The UDN-7180A device, for reasons of package power dissipation and/or dissimilar segment currents (certain 14 or 16 segment alphanumeric panels) can also be used, but must have external, discrete current-limiting resistors.

Figure 2

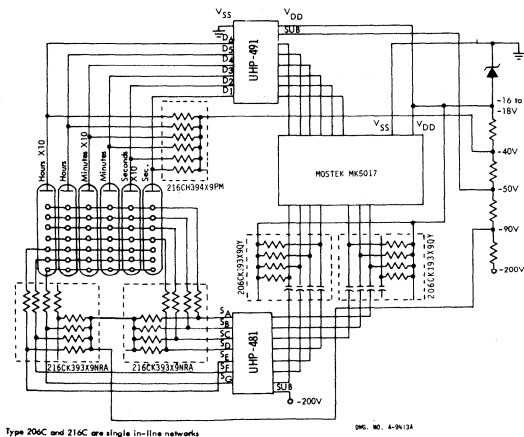

Figure 3

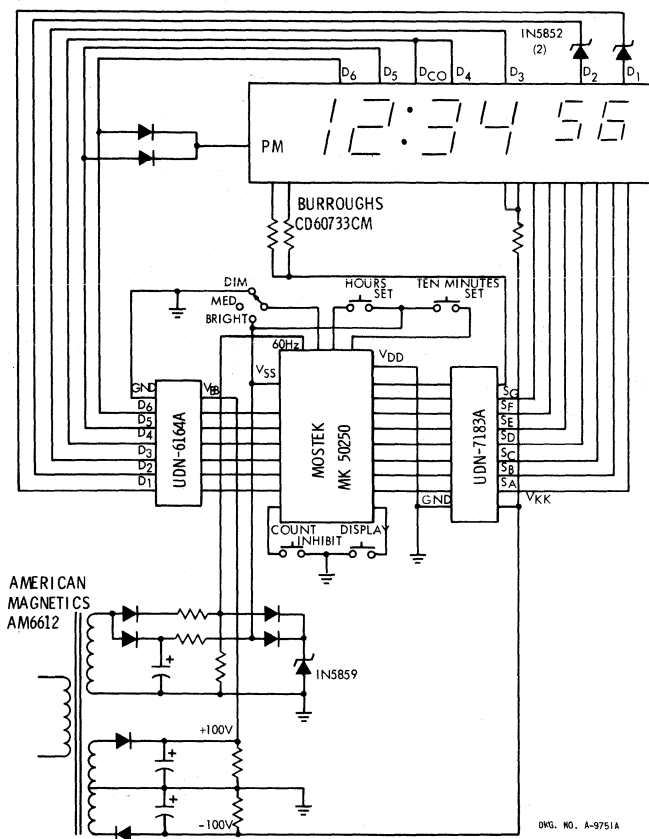

Figure 4

Higher current applications are difficult for both programmable current and switching type display drivers. Segment currents beyond 2.5 or 3 mA present package power dissipation limitations to most dual in-line packages. By using external resistors, the Type UDN-7180A driver allows segment currents of up to 14 mA.

The transistor switch with current-limiting resistor scheme used in Sprague gas discharge display drivers

also minimizes problems associated with gas panel arcing which can destroy programmable current circuits. Some of the gas display manufacturers recommend the use of series resistors in each segment line to prevent destruction to the semiconductor interface circuit should such a panel arc occur. Without these series resistors (internal thin-film resistors in Sprague devices) the IC can be destroyed by the high voltage and resulting high current should the panel voltage drop to a very-low level during an arc.

LED INTERFACE

With the obvious abundance and variety of LED interface integrated circuits it would seem unlikely that there are still systems in search of an IC hardware solution to further minimize cost, component count, space, etc.; but this is definitely the case. The deficiencies are chiefly related to the limited number of current-sourcing circuits and/or high-current drivers.

The efficiency of LED displays has improved, but with the larger digits (up to 1" presently) most of the IC drivers are unable to switch the higher currents required in multiplexed systems. The rule-of-thumb generally applied uses the suggested d-c current - multiplied by the number of digits in the display. For example, a multiplexed display of 160 mA peak current will give approximately the same light intensity output as a steady 20 mA in each of eight digits. Of particular difficulty is the switching of currents associated with the lower efficiency yellow and green LEDs. Sprague has provided monolithic integrated circuit solutions to applications requiring segment currents of 350 mA and digit currents of up to 1.5 amperes!

Many of the Sprague ICs used in high-current LED applications were originally designed for use with electro-mechanical loads (relays, solenoids, motors, etc.) although the high-voltage ratings of the drivers are obviously not a concern. A combination of high-current, high-voltage Darlington drivers is shown in Figure 5.

The ULN-2074B source driver is utilized as a modified emitter-follower. Through the use of discrete diodes in the common collector line, allowing the base to be switched to a potential higher than the collector, it is then possible to obtain a saturated output. This prevents the usual emitter-follower problems associated with gain, the MOS output impedance, and power. It is also possible to now better define the voltage at the emitter output and to then provide suitable segment current-limiting resistors for the LEDs.

The ULN-2002A sink driver is a high-current Darlington array with the capability of switching multiplexed LEDs with an available limit of 155 mA for each of the seven drivers when used at a 100% duty cycle. Even the more inefficient yellow or green LEDs can be driven with higher output currents at lower duty cycles (400 mA at a 28% duty cycle).

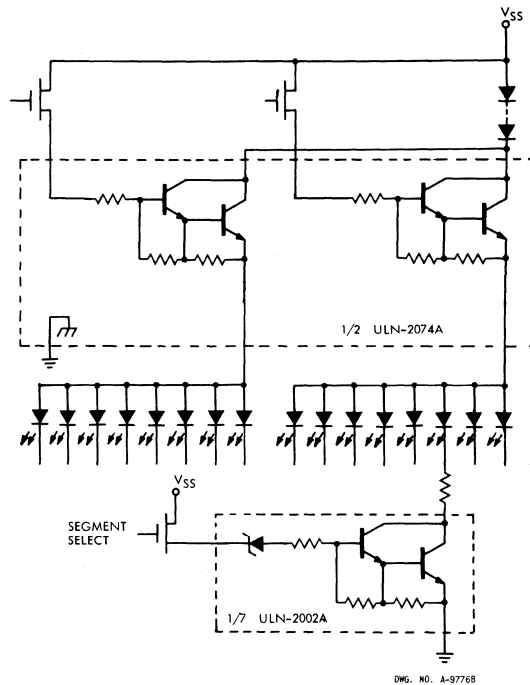

Figure 5

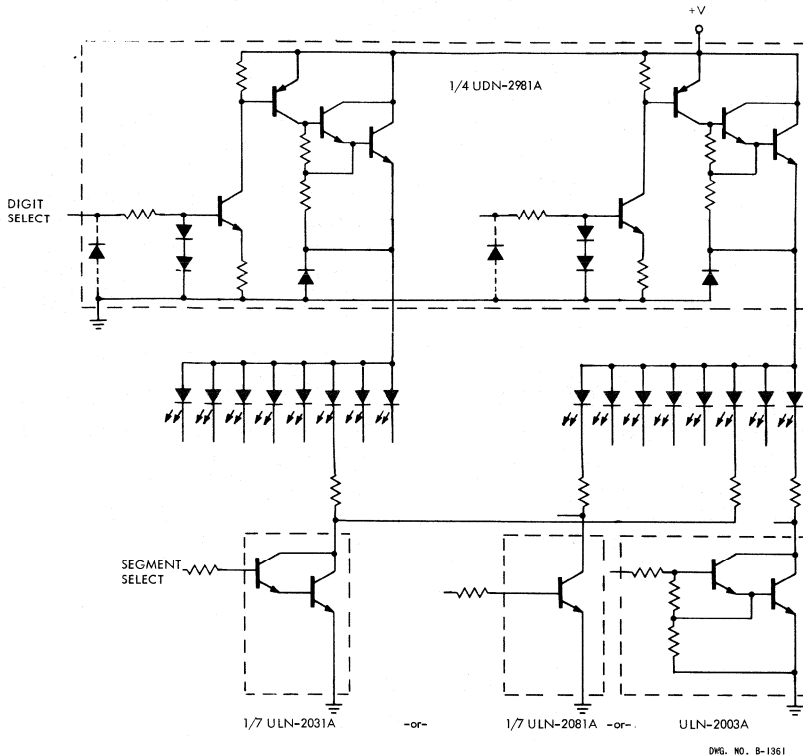

Figure 6

A new eight-channel source driver is shown as a digit switch for common anode LEDs in Figure 6. The Series UDN-2980A drivers will handle output currents to a maximum of 500 mA. Two basic versions of the driver will allow interface from TTL, Schottky TTL, DTL, PMOS, and CMOS levels. Other versions of the ULN-2003A driver are also available for use with the various logic levels.

Of the three sink drivers shown, the ULN-2003A is probably the better choice from a standpoint of both input and component count. It also has straightforward in-out pinning. The ULN-2031A and ULN-2081A devices offer lower cost. They are also interchangeable from a pinning aspect although the output ON voltage will be dissimilar.

A common-cathode LED configuration is shown in Figure 7 for currents of up to 1.5 A per digit! In the series UDN-2980A source driver is used to switch the segment side, the ULN-2064B or ULN-2074B to switch the digit side. As has been shown with Figure 6, the IC package power dissipation must be considered with high-current applications.

The three examples that have been shown for LED interface represent only a very-small portion of the total applications area. The high-current capabilities and high gain of the Sprague drivers represent potential solutions to many difficult LED display systems - alphanumeric, seven-segment, or matrix; common-cathode or common-anode; continuous or multiplexed.

A-C PLASMA DISPLAY INTERFACE

Plasma displays, such as those manufactured by National Electronics/NCR (USA) and NEC or Fujitsu (Japan), all have one common element with their gas discharge cousin - both types use a neon gas mixture. The plasma panels emit an orange glow when switched at rather high frequencies, and light output intensity is a function of frequency. The a-c term for the plasma display is something of a misnomer since these panels actually operate from a toggled d-c supply (usually in the area of 20 kHz).

The panel is basically a neon-filled capacitor, and has plates (electrodes) which are covered with the dielectric - between which is the neon mixture. Switching this capacitive load presents a problem

HIGH-CURRENT INTERFACE DRIVERS (Continued)

with high peak currents in addition to the older problem of the high voltages which are associated with gas displays. Drive circuits use supply voltages of 150 to 260 V (depending on unipolar or bipolar drive), and the semiconductors used must switch instantaneous currents in the order of several hundred milliamperes for the larger displays.

Several high-voltage, high-current arrays made at Sprague Electric can provide an answer to one side of the a-c plasma display interface. The Series ULN-2020A Darlington drivers are rated at 95 V while the Series UHP-500 power drivers are rated at 100 V. They are both able to handle the application shown in Figure 8 (a basic d-c, non-multiplexed clock interface rather than a more complex multiplexed system). The ULN-2022A is specifically designed for 14 to 25 V PMOS logic levels while the UHP-506 is intended for

use with TTL.

The high-current diodes that are internal to the Sprague arrays are utilized in the unipolar drive scheme connected to a suitable OFF reference. In one POS application, a set of 14 ULN-2023A Darlington drivers replaced more than 400 discrete components. The cost and space savings in such a machine are considerable, and a very complex printed wiring board was greatly simplified.

Further improvements in interface and plasma displays will no doubt evolve, and thus benefit all concerned - display and interface vendor along with the end user. Plasma displays are well-suited to custom panels (particularly those with various size of characters) and with improvements in IC breakdown voltages some further simplification of interface should evolve.

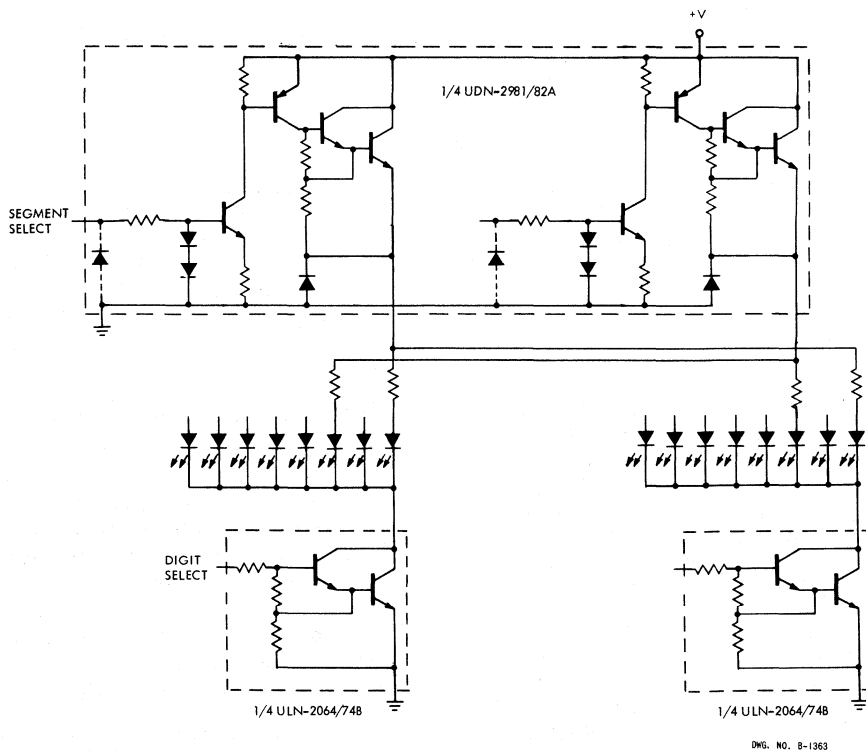

Figure 7

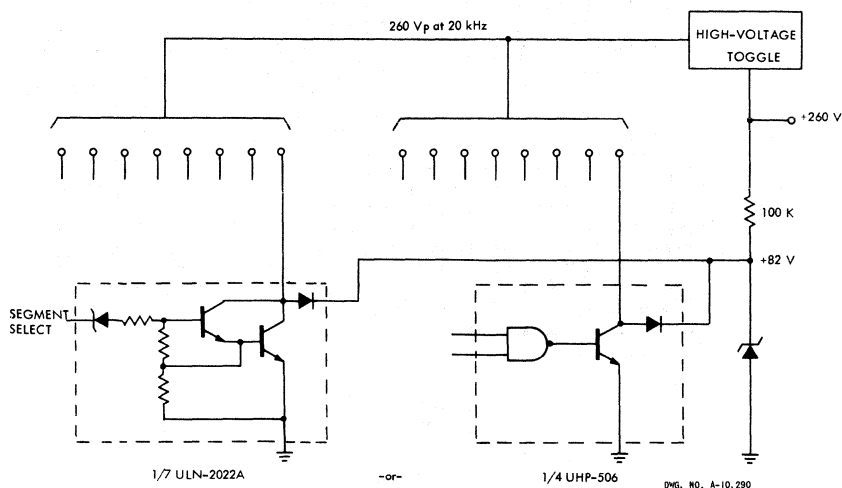

Figure 8

FLUORESCENT DISPLAY INTERFACE

Although the vast majority of fluorescent displays are directly driven from MOS logic (handheld and low-cost desk calculators), there is an emerging need for interface integrated circuits for use with the larger characters (higher currents) and the higher voltages coming into use. These blue-green display panels originated in Japan, and the manufacturers are quite aggressively pursuing markets such as POS systems, locks, cash registers, appliances, automotive displays, etc. Larger and/or more complex styles are being made, including displays with alphanumeric capability (a starburst 14 or 16-segment pattern).

Modest voltage capability (60 or 70 volts) is all that is required of a semiconductor device to drive these panels, and the currents are in the 20 to 30 mA region. These electrical requirements are well within the capability of many gas discharge digit drivers. In Figure 9, the UHP-491 is shown used with pull-down resistors connected to each output. When both the segment (equivalent to a vacuum tube anode) and the digit (controlled by the grid) are switched sufficiently positive with respect to the cathode filament), the appropriate display digit/segment are energized.

Another multiplexed configuration is shown in Figure 10; the difference being that a push-pull type of MOS output is in use, and the pull-down rail does not allow the UHP-491 substrate, V_{DD} , and output potentials to be the same. The substrate and output are tied to the most-negative rail, while the V_{DD} terminal connects to the -12 V line for the MOS.

Since these solutions using the older gas discharge digit driver circuits require the use of appropriate pull-down resistors, either in discrete or thick-film network form, a more suitable solution employs the circuit shown in Figure 11. The UDN-6118/28A devices are designed specifically for use with fluorescent displays and include internal pull-down resistors so that up to eight segments and eight digits will require only two packages and a greatly simplified power supply. The Type UDN-6118A driver is compatible with TTL, Schottky TTL, DTL, and 5 volt CMOS. The Type UDN-6128A driver is for use with 6 to 15 volt PMOS or CMOS logic.

The future of fluorescent displays looks rather strong, particularly if competition further reduces prices. For the moment at least, these displays will not seriously tax the capability of IC interface except, perhaps, from a price/cost standpoint.

Figure 13

GLOW TRANSFER - BAR GRAPH & MATRIX PANELS

Neon-based display technology has shifted into many new market areas. The Burroughs Self-Scan® is a solution to many alphanumeric applications; the newer bar graph is a solid state replacement for analog instrumentation. Both use the glow transfer principle of the dot matrix Self-Scan display.

The nominal voltage for this type of panel is 250 V. High-voltage gas discharge drivers (Series UHP-480) or Darlington arrays (Series ULN-2020A) afford a cathode interface to the glow transfer panel. With a typical display current of 3 to 5 mA, the gas discharge drivers are perfectly adequate. For higher current applications, the Darlington arrays are a solution.

As illustrated in Figure 13, the bar graph cathode easily driven with a Series UHP-480 driver. Sign level shifting is inexpensively accomplished with capacitors; the OFF reference, pull-up, and pull down is done with a few discretes. The anodes driven with two discrete transistors ($BV_{CES} \geq 120 V$). By utilizing a negative supply, the level shifting easily done in the cathode side. If a positive supply were used, relatively complex d-c level shifting would be required in the anode side. The few discretes necessary in the circuit shown are generally a viable solution when faced with cost and space parameters for the system.

SUMMARY

The phenomenal growth in display technology has largely come as a result of the electronic calculator, and electronic displays will pervade all our lives in an ever-increasing number of products. The use of digital displays in appliances, gasoline pumps, electronic games (even pinball machines), etc., etc., etc., will also require that a continuing evolution of interface integrated circuits meet the challenges of higher brightness, increased currents, improved reliability, and lower system costs.

Both the display and semiconductor industries have demonstrated that they will meet the challenges of today, and these challenges then become routine with tomorrow.

SPRAGUE HIGH-POWER INTERFACE ICs

Introduction

Spurred on by the tremendous impact of the microprocessor, solid state electronics is well into its '3rd' revolution. Increasingly the hardware solutions of past circuit designs have become 'software' (μP) resolutions; and with increasing necessity for newer, superior, lower cost components to complete the system. To be effective, the μP and other custom LSI counterparts must rely on interface from their low level logic to high-voltage/high-power loads.

To further augment this '3rd' revolution, Sprague continues to introduce new, high performance interface ICs which are designed to overcome the large numbers of discretes very often required in such systems. New functions are becoming available along with increased power handling capability, high voltages, etc. The units covered in this paper are:

- Series UDN-2840B Quad 1.5 A Switches**
- UDS-5790H/5791H Quad PIN Diode Interface**
- UDN-2580A NMOS Compatible 8-Channel Source Driver**

Series UDN-2840B QUAD 1.5 A SWITCHES

This series originated from a requirement to provide a monolithic interface for electronic discharge printers; subsequently other functions have been provided from the basic chip design. Three basic products make up the series, but by providing both 5 V logic compatibility and 12-15 V MOS compatibility, the series contains a total of six types (see Table 1).

Types UDN-2841B and UDN-2842B are intended for sinking current to a negative supply rail; an example of this is the electronic discharge or electrosensitive printer. Both devices are capable of sinking 1.5 A in each output and standing off -50 volts. A typical electrosensitive printer from Japan

Figure 1

will require -35 to -40 volts and peak currents of approximately 1 A (usually at a very low duty cycle).

Type UDN-2843B and UDN-2844B are sourcing circuits capable of switching the ground side of a load which may be connected to a negative supply of up to -50 volts. These types are for general purpose applications such as motors, solenoids, relays, filaments, etc. to the maximum output current of 1.5 A each.

Types UDN-2845B and UDN-2846B are combination sourcing/sinking devices. The four outputs are broken into source (2) and sink (2) for possible uses as a bidirectional or bridge type driver. Primary applications are d-c and stepping motor drive. The UDN-2845B has two sink outputs from the UDN-2841B and two source outputs from the UDN-2843B, and the UDN-2846B combines the UDN-2842B and UDN-2844B types for MOS compatibility.

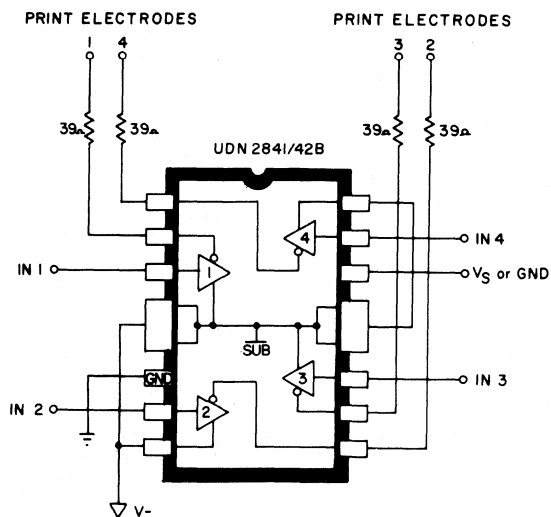

All devices (basic schematic Figure 1) are specified to have a minimum collector-emitter sustaining voltage of 35 volts; this is specified at 100 MA and until recently has not been a specification for monolithic circuits. Sprague Electric ICs are increasingly being characterized in a manner to provide the maximum useful information for the designer, but without getting bogged down in superfluous device specifications.

Table 1
SERIES UDN-2840B 1.5 A QUAD

Type	I _{OUT}	V _{OUT} (OFF)	Outputs		Compatibility	
			Sink	Source	TTL, DTL 5 V MOS	10-15 V MOS
UDN-2841B	1.5 A	-50 V	4		X	
UDN-2842B	1.5 A	-50 V	4			X
UDN-2843B	1.5 A	-50 V		4	X	
UDN-2844B	1.5 A	-50 V		4		X
UDN-2845B	1.5 A	-50 V	2	2	X	
UDN-2846B	1.5 A	-50 V	2	2		X

APPLICATIONS

- UDN-2841** Electrosensitive Printers, Motor Drives, General Purpose High-Current
- UDN-2842** Electrosensitive Printers, Motor Drives, General Purpose High-Current
- UDN-2843** Motor Drive, Solenoids, other General Purpose High-Current Loads
- UDN-2844** Motor Drive, Solenoids, other General Purpose High-Current Loads
- UDN-2845** Bidirectional D-C and Stepping Motors, Other High-Current Loads
- UDN-2846** Bidirectional D-C and Stepping Motors, Other High-Current Loads

When switching inductive loads, the output transistor should be protected by a suitable clamping technique. The simplest approach is to use diode clamps to the supply; in Figure 2A the UDN-2841/42B uses a discrete diode on each output. Also in Figure 3A and Figure 4, a straight diode clamp is shown for the UDN-2843/44B (Figure 3A) and for the UDN-2845/46B (Figure 4).

For improved turn-off, it may be possible to use a combination diode/Zener diode scheme; in Figures 2B and 3B the Zener diode will allow the flyback voltage to rise above the supply voltage, thus speeding up the turn-off of the load. An appropriate

resistor value might be also substituted; a 1 A load operating with a 15Ω resistor will produce similar results to a 15 V Zener diode. In Figure 5, the combination Zener/clamp diode is shown for a 'bridge' configuration such as Figure 4.

The allowable output current and duty cycle as a function of the number of drivers activated is shown in Figure 6A. This graph is for a +70°C ambient and will insure that the device junction temperature will not exceed a +150°C level. Figure 6A is for the 'B' package without any heat sinking; package rating is 45°C/W or a derating of 22.2 mW/°C for this copper alloy plastic DIP.

Figure 2A

Figure 2B

Figure 3A

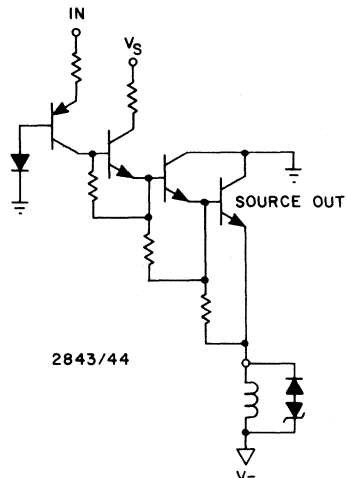

Figure 3B

3

Figure 4

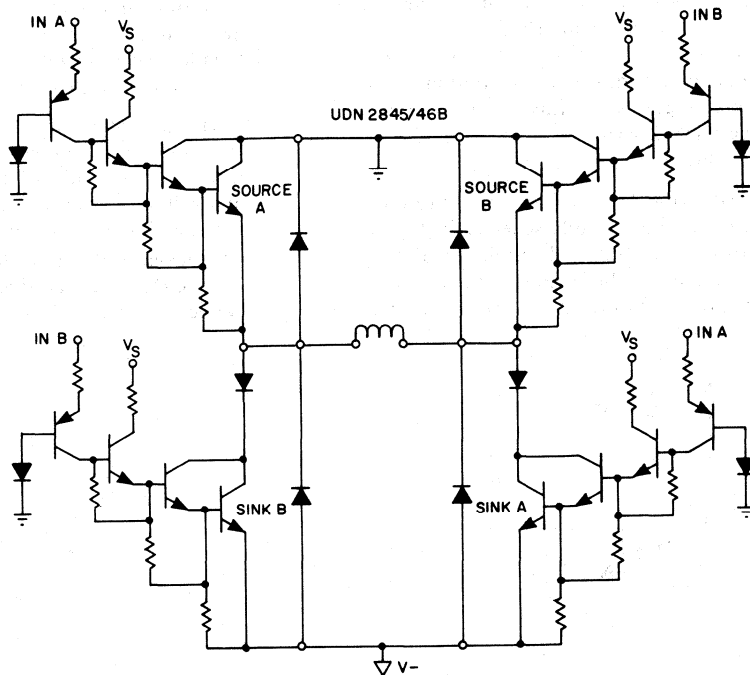

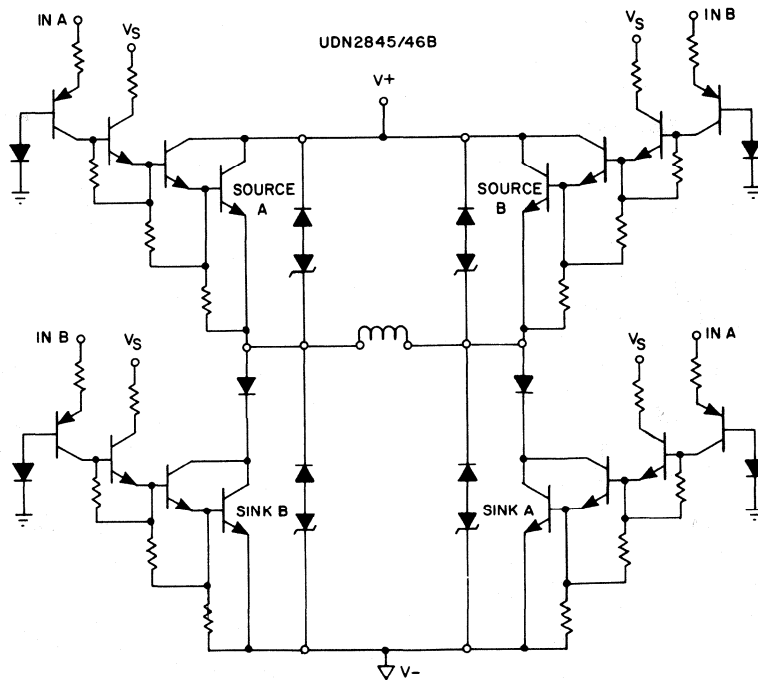

Figure 5

UDN 2841-2846B

Figure 6A

UDN 2841-46B

Figure 6B

HIGH-CURRENT INTERFACE DRIVERS (Continued)

Through the use of a Staver V-7 heat sink, the package rating may be improved nearly twice that of Figure 6A; the rating of this package with the V-7 heat sink drops to a maximum of 27.5°C/W or a derating of 36.4 mW/°C. In figure 6B the allowable output current and duty cycle at +70°C with the addition of the Staver V-7 heat sink is shown. Both Figures 6A and 6B assume worst case limits of V_{ON} , I_S , DIP rating, etc.

No doubt other applications will arise in the future, but these figures are representative of power interface applications which may be simplified through the use of these Sprague power integrated circuits to replace discrete components. Additionally, cost and space reductions should be achieved with the Series UDN-2840B quad 1.5 A switches.

UDS-5790H and UDS-5791H Quad Peripheral Drivers for PIN Diodes

These monolithic, high-voltage ICs are a natural evolution from the several years of Sprague expertise with high-voltage and high-current power and display ICs. Designed for driving PIN diode phase shifters for radar antenna systems, this quad 300 mA

offers a new high in breakdown voltage (120 V) for monolithic power/peripheral drivers.

Supplied in a fully hermetic 16-lead, side-brazed ceramic DIP, the PIN diode drivers are subjected to the screening procedures specified in MIL-STD-883 method 5004, class B, paragraphs 3.1.1 through 3.1.6. Also made available is a 168 hour burn-in per method 1015, condition A if so required and specified.

In Table 2, the Absolute Maximum Ratings and the Recommended Operating Conditions are specified. The 5.0 V (nom) supply allows the use of the UDS-5790/91H with TTL, LS TTL, DTL, and 5 V CMOS. The UDS-5790H is a non-inverting type while the UDS-5791H is an inverting type which more frequently corresponds to the discrete or hybrid circuits in use.

Figures 7A and 7B indicate the device pinouts; the in/out configuration tends to simplify PCB layout and the outputs are separated (isolated) from the inputs. All pins labelled R_X require a discrete resistor to determine base current for the output NPN suitable external resistors should be based upon the minimum output transistor gain of 30 (across the full operating temperature range).

Table 2

ABSOLUTE MAXIMUM RATINGS over free-air operating temperature range

Supply Voltage, V_{CC}	+6.0 V
Supply Voltage, V_{EE}	-6.0 V
Input Voltage, V_{IN}	V_{CC}

Storage Temperature Range, T_S	-65°C to +150°C

RECOMMENDED OPERATING CONDITIONS

	Min.	Nom.	Max.	Units
Supply Voltage, V_{CC}	4.0	5.0	5.5	V
Supply Voltage, V_{EE}	-1.5	-3.0	-5.5	V
Output ON-State Current, I_{ON}			300	mA
Operating Ambient Temperature Range, T_A	-55	+85	+125	°C

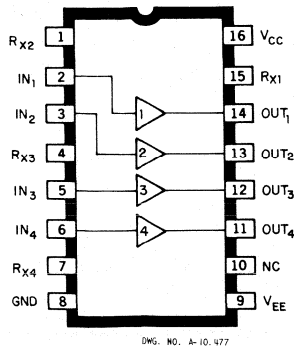

Figure 7A

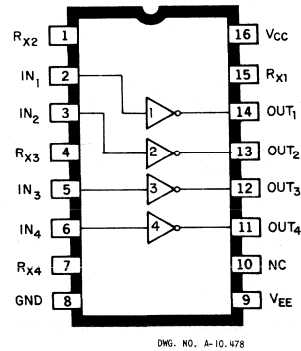

Figure 7B

3

Use of the external resistors minimizes system and package dissipation and junction temperature, while allowing greater output current and/or duty cycles under any ambient temperature. Control of the base drive is enhanced; and the device V_{ON} specifications are guaranteed over the entire -55°C to $+125^{\circ}\text{C}$ temperature range — with only an overdrive of 25%. A PIN diode current of 300 mA requires a resistor value calculated to provide an output NPN base current of 12.5 mA to adequately insure saturation, ven at -55°C .

In Figure 8 the circuit diagram for the UDS-5790H non-inverting type is shown; use of a grounded-base input stage is employed. For the UDS-5791H (inverting) type in Figure 9, a common emitter input is utilized. Both types specify the maximum pre-driver collector voltage so that an appropriate resistor (R_X) may be chosen for the combination of required output load current and supply voltages in use.

Figure 8

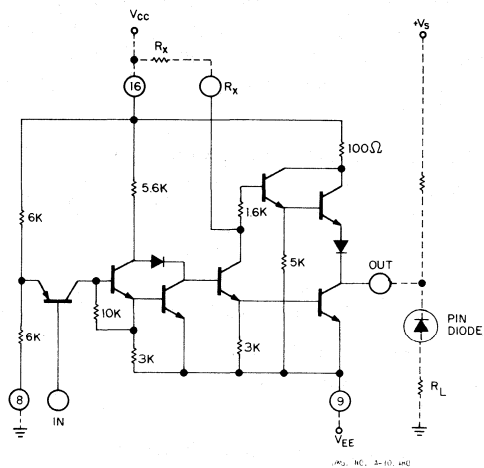

Figure 9

HIGH-CURRENT INTERFACE DRIVERS (Continued)

For a calculation of the necessary maximum resistor value, it is necessary to use the following information:

1. Output load current, I_{OUT}
2. Minimum positive supply voltage, V_{CC}
3. Minimum negative supply voltage, V_{EE}
4. Minimum output NPN gain, h_{FE}
5. Maximum predriver collector voltage, V_X

To make an actual calculation, the nominal supply voltages will be used; but the output current, gain, and predriver voltage will be in accordance with the specifications.

$$R_X = \frac{(V_{CC} - V_{EE}) - V_X}{\frac{I_{OUT}}{h_{FE}} \times 1.25}$$

$$R_X = \frac{(5.0 \text{ V} + 3.0 \text{ V}) - 1.5 \text{ V}}{300 \text{ mA} \div 30 \times 1.25} \leq 510 \text{ (Std value)}$$

For an output current of 150 mA, the solution is:

$$R_X = \frac{(5.0 \text{ V} + 3.0 \text{ V}) - 1.5 \text{ V}}{(150 \text{ mA} \div 30) \times 1.25} \leq 1000 \text{ (Std value)}$$

The hermetic dual in-line package is rated at $90^\circ\text{C}/\text{W}$ or a derating factor ($G\theta_{ja}$) of $11.1 \text{ mW}/^\circ\text{C}$; the allowable power dissipation for this device is shown in Figure 10. The maximum junction temperature should not exceed $+150^\circ\text{C}$ (the zero power level of Figure 10).

The maximum power dissipation is a combination of $V_{CE} - I_{OUT}$, $I_{CC} \times (V_{CC} - V_{EE})$, and $V_X \times I_X$. For a 300 mA load at $+85^\circ\text{C}$, the power is:

- (1) $0.7 \text{ V} \times 300 \text{ mA} \leq 210 \text{ mW}$
- (2) $4.1 \text{ mA} \times 11.0 \text{ V} \leq 45.1 \text{ mW}$
- (3) $1.5 \text{ V} \times 12.5 \text{ mA} \leq 18.75 \text{ mW}$ or $\leq 273.9 \text{ mW}$

For an OFF output, the power is:

- (4) $115 \text{ V} \times 100 \mu\text{A} \leq 11.5 \text{ mW}$
- (5) $3.4 \text{ mA} \times 11.0 \text{ V} \leq 37.4 \text{ mW}$

Partitioning the PIN phase shifter loads is an effective technique of minimizing the power in any single device. The quad might be used in the manner shown in Figure 11. The appropriate choice will allow all four outputs to be ON continuously without

Figure 10

exceeding the package power dissipation rating. The conditions of Figure 11 (75 mA, 150 mA, 225 mA and 300 mA) will allow operation at an ambient temperature of $+85^\circ\text{C}$ and the chip junction temperature will be below the $+150^\circ\text{C}$ upper limit.

Figure 11

The Sprague PIN diode interface drivers are designed to provide a cost saving monolithic solution to phased array radar. Although primarily intended for MIL-STD-883 high reliability military and aerospace programs, the units are also available in a commercial package and temperature range (plastic DIP and 0°C to +85°C) if required.

JDN-2580A 8-Channel High-Voltage, High-Current Source Driver.

This 8-Channel IC design originates from a need to provide an interface from NMOS to high current inductive loads. The device functions like a PNP; but an NPN Darlington has been added to provide suitable current gain. By switching the input low the output is turned ON and the load current is sourced from the compound PNP/NPN/NPN output. Maximum ratings are shown in Table 3.

In Figure 12, the basic circuit diagram is shown; a typical NMOS interface might involve -5 V, GND, and solenoid loads of -20 to -30 V. The UDN-580A affords an interface to these higher voltages and offers high current outputs of -500 mA (max).

As is usually done with devices of this type, the input is the in-opposite-out version shown in Figure 3. The unit is packaged in an 18-lead plastic DIP utilizing Sprague copper alloy lead frame technology

Figure 12

for improved thermal capacity and device electrical performance.

With NMOS logic operating from negative supplies, the interface to high current inductive loads (solenoids, relays, etc.) is depicted in Figure 14. Most NMOS includes depletion load and is capable of pulling the input of the UDN-2580A sufficiently high to turn off the device. For those few instances where either open drain NMOS is to be used, or the depletion load is excessively high, external pull-up resistors may be employed.

Figure 13

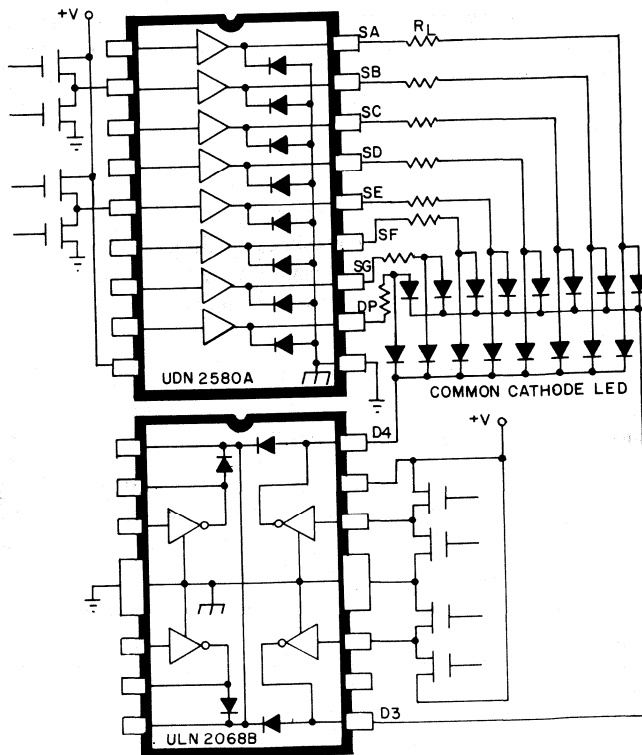

Figure 14

Although the UDN-2580A is chiefly intended for high voltage inductive loads, it will help solve high-current, low-voltage designs as well. In Figure 15, the UDN-2580A is used as a source driver for

multiplexed common-cathode LEDs; the UDN 2580A is a high current segment driver, while the ULN-2068B quad is the high current (1.5 A max) digit driver.

Figure 15

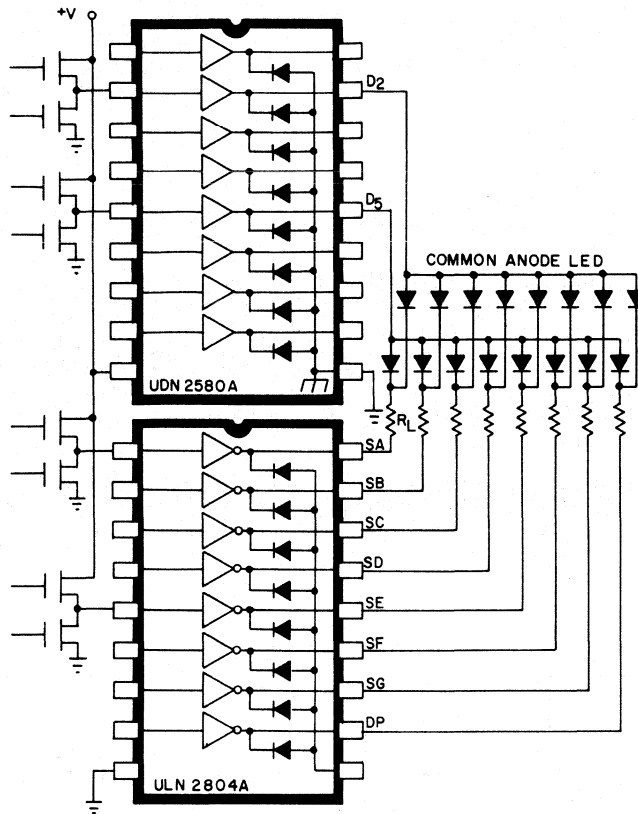

Figure 16

Alternatively, the UDN-2580A may be employed as a digit driver for common-anode LEDs; shown in Figure 16 is the UDN-2580A sourcing current for an eight digit application. Combined with this is the ULN-2804 Darlington array for a segment switch. This pair of units affords an eight digit/eight segment solution to high-current MUXed LED or incandescent displays. For most of the LED ap-

plications, it would be necessary to use a supply of 7 to 8 volts to effectively switch the LEDs; thus it makes the UDN-2580A and other high current interface attractive for CMOS applications. The combination of $V_f(\text{LED})$ and source and sink driver V_{ON} preclude the use of such ICs much below the 7 volt level, since some portion of the supply must be across the segment limiting resistor (R_L).

It is also possible to employ the UDN-2580A as a predriver for power semiconductors for very high-current loads, thus considerably reducing the need for discretes in many MOS-based systems. Shown in Figure 17A is the UDN-2580A source driver providing base current for a power NPN; with its ~ 350 mA output capability (NPN base drive) a load current of 3 to 5 amps is quite readily available. For higher currents, the use of a power Darlington may be the solution.

For a-c loads, it is possible to use the UDN-2580A source driver for providing gate current for power thyristors. Shown in Figure 17B is an interface to a high current Triac; this is a scheme using a pulse transformer for isolation and some current limiting should be provided.

For allowable duty cycle, output currents, and number of outputs activated, the $+70^\circ\text{C}$ limits are shown in Figure 18. This graph assumes worst case

output voltage, package rating, and $+70^\circ\text{C}$ ambient; **under these conditions the chip junction temperature will be less than $+150^\circ\text{C}$.**

Conclusion

Three new, high performance Sprague interface integrated circuits have recently been developed. They tend to simplify certain system designs while offering size and cost reductions. The UDN-2841B and UDN-2842B will greatly simplify an emerging printer technology; the UDS-5790/91H will replace hybrids and discretes for PIN phase shifter arrays; and the UDN-2580A will further augment the use of NMOS LSI in a variety of systems. All of this is the result of customer and sales inquiries along with an understanding of the industry needs for improved power interface ICs. Custom interface designs are also becoming a greater factor, and Sprague Electric will also help to lead the way in solving these problems.

UCN-4202A STEPPER MOTOR TRANSLATOR/DRIVER

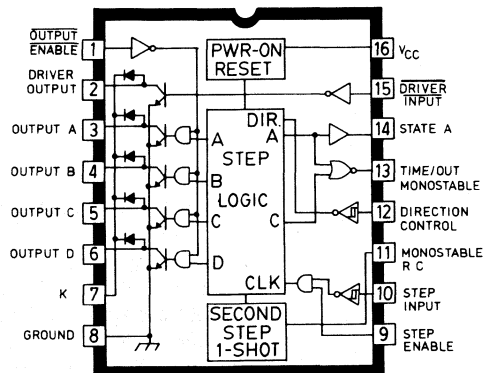

FEATURES

- 600 mA Power Drivers
- 15 V Sustaining Voltage
- 20 V Output Breakdown
- Full-Step or Double-Step Operation
- Single-Input Direction Control
- Power-On Reset
- Transient Suppression Diodes
- Schmitt Trigger Inputs

THE UCN-4202A Translator/Driver is specifically designed for driving small-to-medium permanent magnet (PM) stepper motors rated to 500 mA and 15 V. This monolithic integrated circuit employs a full-step, double pulse drive scheme that produces up to 90% utilization of the available PM stepper motor torque.

The UCN-4202A is a unique bipolar I²L design containing approximately 100 logic gates, suitable input/output circuitry for TTL compatibility, and 600 mA outputs with internal inductive load suppression. The circuit operates with a minimum of external components, and provides an additional uncommitted driver.

The PM stepper motor is controlled by the integral step logic. To step the load from one position to the next, the STEP INPUT is pulled down to a logic low for at least 1 μ s, then allowed to return to a logic high. The step logic is activated on the positive-going edge, which in turn activates one of four output sink drivers. The DIRECTION CONTROL determines the sequence of states (A-B-C-D, or A-D-C-B).

DWG. NO. A-11,184

In the full-step mode the MONOSTABLE RC timing pin is tied to V_{CC} , making states B and D stationary states. A separate input pulse is required to move through each of the four output states.

The UCN-4202A will also perform a double-step function. In the double-step mode, states B and D are transition states with duration determined by the MONOSTABLE RC timing. Improved motor torque is obtained at double the nominal motor step angle, and motor stability is improved for high step rates.

Higher current ratings, or bipolar operation can be obtained by using the UCN-4202A as a logic translator to drive discrete high-power transistors or the Sprague UDN-2949Z Half-Bridge Motor Driver.

MAXIMUM COLLECTOR CURRENT AS A FUNCTION OF MOTOR TIME CONSTANT AND STEP RATE

- Notes:
1. Values shown take into account static d-c losses ($V_{SAT}I_{OUT}$ and $V_{CC}I_{CC}$) as well as switching losses induced by inductive flyback through the clamp diodes with $V_K = 12$ volts. Maximum package power dissipation is assumed to be 1.33 watts at +70°C. Higher package power dissipation may be obtained at lower operating temperatures.
 2. Use of external discrete flyback diodes will eliminate power dissipation resulting from switching losses and will allow the full 500 mA output capability (Output A, B, C, or D and the Driver Output) under all conditions.

FUNCTIONAL DESCRIPTION

Power-On Reset

An internal RS flip-flop sets the Output A "ON" with the initial application of power. This state occurs approximately 30 μs after the logic supply voltage reaches 4 volts with supply rise times of up to 10 ms/V. Once reset, the circuit functions according to the logic input conditions.

Step Enable

Pin 9 (Step Enable) must be held high to enable the step pulses for advancing the motor to reach the translator logic clock circuits. Pulling this pin low inhibits the translator logic.

Step Input

Pin 10 (Step Input) is normally high. The logic will advance one position on the positive transition after the input has been pulled low for at least 1 μs . The Step Input current specification is compatible with NMOS and CMOS.

Direction Control

The direction of output rotation is determined by the logic level at pin 12. If the input is held high the rotation is A-D-C-B; if pulled low the rotation is A-B-C-D. This input is also NMOS and CMOS compatible.

Output Enable

Outputs A through D are inhibited (all outputs "OFF") when pin 1 (Output Enable) is at high level. This condition creates a potential for wire-ORing of device outputs, or other potential control functions such as chopping or bi-level drive.

Transient Suppression

All five power outputs are diode protected against inductive transients. However, Zener diode or resistor "flyback" voltage techniques are not allowed.

Full-Step/Double-Step

Full-Step operation is the most commonly used drive technique. The UCN-4202A is capable of unipolar drive without external active devices, either in a full-step mode (pin 11 Monostable RC tied high), or in a double-step mode (pin 11 connected to RC timing). The double-step mode provides improved torque characteristics, while the specified angular increment is doubled.

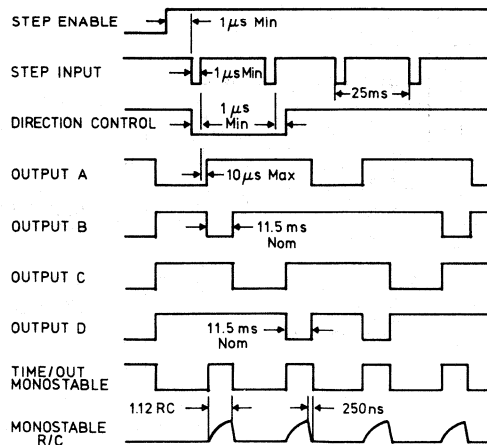

FIG. NO. A-11,186

TIMING CONDITIONS (Double-Step Mode)

Note: State B and State D output pulse duration is typically 11.5 ms when $R = 510 \text{ k}\Omega$ and $C = 0.02 \mu\text{F}$.

UCN-4401A and UCN-4801A BiMOS LATCH/DRIVERS

FEATURES

- High-Voltage, High-Current Outputs
- Output Transient Protection
- CMOS, PMOS, NMOS, TTL Compatible Inputs
- Internal Pull-Down Resistors
- Low-Power CMOS Latches

THESE high-voltage, high-current latch/drivers are comprised of four or eight CMOS data latches, a bipolar Darlington transistor driver for each latch, and CMOS control circuitry for the common CLEAR, STROBE, and OUTPUT ENABLE functions. The bipolar/MOS combination provides an extremely low-power latch with maximum interface flexibility. The UCN-4401A contains four latch/drivers while the UCN-4801A contains eight latch/drivers.

The CMOS inputs are compatible with standard CMOS, PMOS, and NMOS circuits. TTL or DTL circuits may require the use of appropriate pull-up resistors. The bipolar outputs are suitable for use with relays, solenoids, stepping motors, LED or incandescent displays, and other high-power loads.

Both units feature open-collector outputs and integral diodes for inductive load transient suppression. The output transistors are capable of sinking 500 mA and will sustain at least 50 V in the OFF state. Because of limitations on package power dissipation, the simultaneous operation of all drivers at maximum rated current can only be accomplished by a reduction in duty cycle. Outputs may be paralleled for higher load current capability.

The UCN-4401A 4-latch device is furnished in a standard 14-pin dual in-line plastic package. The UCN-4801A 8-latch device is furnished in a 22-pin dual in-line plastic package with lead centers on 0.400" (10.16 mm) spacing. All outputs are pinned opposite their respective inputs to simplify circuit board layout.

FUNCTIONAL BLOCK DIAGRAM

UCN-4805A and UCN-4806A BiMOS LATCHED DECODER/DRIVERS

FEATURES

- High-Voltage Source Outputs
- CMOS, PMOS, NMOS, TTL Compatible Inputs
- Low-Power CMOS Latches
- Hexadecimal Decoding
- Internal Pull-Up/Pull-Down Resistors
- Wide Supply Voltage Range

DESIGNED for use in high-voltage vacuum fluorescent display driver applications, the UCN-4805A and UCN-4806A latched decoder/drivers combine CMOS logic with bipolar source outputs. Both devices consist of eight high-voltage bipolar sourcing outputs with internal pull-down resistors and CMOS input latches, hexadecimal decoder, and control circuitry (strobe and blanking).

The UCN-4805A BiMOS latched decoder/driver is intended to serve as the segment driver with standard 7-segment displays incorporating a colon or decimal point. The UCN-4806A modification is designed for use with centered "1" (9-segment) displays. It has an I/O input to permit interrogating the input latches for error-checking purposes. Both ICs use hexadecimal decoding to display 0-9, A, b, C, d, E, and F.

Both BiMOS latched decoder/drivers have sufficient speed to permit operation with most microprocessor/LSI-based systems. The CMOS input latches provide operation over the supply voltage range of 5 to 15 volts with minimum logic loading. Internal output pull-down resistors eliminate the need for external components usually required for fluorescent display applications. When used with standard TTL or low-speed TTL logic, both devices may require employment of input pull-up resistors to insure a proper input logic high.

Information present at an input is transferred to its latch when the STROBE (ST) is low. The latches will continue to accept new data as long as the STROBE is held low. Applications where the latches are bypassed (STROBE tied low) ordinarily require that the BLANKING input be low between digit selection because of possible non-synchronous decoding.

When the BLANKING (BL) input is low, all of the output buffers are disabled (OFF) without affecting the information stored in the latches. With the

BLANKING input high, the outputs are controlled by the latch/decoder circuitry.

With the I/O input control (UCN-4806A only) held high, the BCD data terminals function as inputs and allow information to be transferred to the latches. With the I/O input control held low, the BCD data terminals function as high-impedance latch outputs and allow the latches to be interrogated for error-checking purposes. While I/O is low, the STROBE line must be held high.

TYPICAL INPUT CIRCUITS

TYPICAL OUTPUT DRIVER

UCN-4810A BiMOS 10-BIT SERIAL-INPUT, LATCHED DRIVER

FEATURES

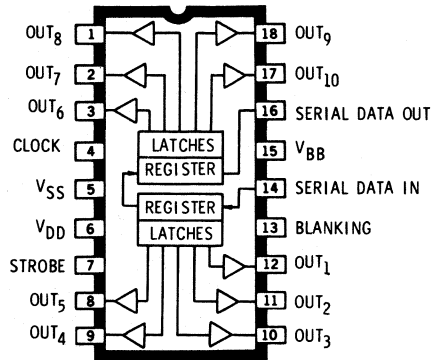

- High-Voltage Source Outputs
- CMOS, PMOS, NMOS, TTL Compatible Inputs
- Low-Power CMOS Logic & Latches
- Internal Pull-Down Resistors
- Wide Supply Voltage Range

COMBINING low-power CMOS logic with bipolar source drivers, the UCN-4810A BiMOS 10-bit serial-input, latched driver will simplify many display systems. Primarily designed for use with vacuum fluorescent displays, it can also be used with LED and incandescent displays within its output limitations of 60 V and 40 mA per driver.

The CMOS 10-bit shift register and associated latches are designed for operation over a supply voltage range of 5 V to 15 V. They also provide for minimum loading and are compatible with standard CMOS, PMOS, and NMOS logic. When used with standard TTL or low speed TTL logic the use of appropriate pull-up resistors may be required to insure a proper input logic high. A CMOS serial data output allows cascading these devices for interface requiring many drive lines (dot matrix, alphanumeric, bargraph, etc.).

The ten bipolar outputs are used as segment or digit drivers in vacuum fluorescent displays. Under normal operating conditions, these devices will sustain 25 mA per output at 50°C and a duty cycle of 85%. Other combinations of number of outputs conducting and duty cycle are shown in the specifications.

The UCN-4810A driver, combined with the UCN-4805A or UCN-4806A latched hexadecimal decoder/drivers or the UCN-4815A 8-bit latched source driver, comprises a minimum component display subsystem, requiring few, if any, discrete components.

TIMING CONDITIONS
 (Logic Levels are V_{DD} and V_{SS})

$V_{DD} = 5.0\text{ V}$ $V_{DD} = 15\text{ V}$

A. Minimum Data Active Time Before Clock Pulse (Data Set-Up Time)	250 ns	150 ns
B. Minimum Data Pulse Width	500 ns	300 ns
C. Minimum Clock Pulse Width	1.0 μs	250 ns
D. Minimum Time Between Clock Activation and Strobe	1.0 μs	400 ns
E. Minimum Strobe Pulse Width	500 ns	300 ns
F. Typical Time Between Strobe Activation and Output Transition	1.0 μs	1.0 μs

SERIAL DATA present at the input is transferred to the shift register on the logic "0" to logic "1" transition of the CLOCK input pulse. On succeeding CLOCK pulses, the registers shift data information towards the SERIAL DATA OUTPUT. The SERIAL DATA must appear at the input prior to the rising edge of the CLOCK input waveform.

Information present at any register is transferred to its respective latch when the STROBE is high (serial-to-parallel conversion). The latches will con-

tinue to accept new data as long as the STROBE is held high. Applications where the latches are bypassed (STROBE tied high) will require that the BLANKING input be high during serial data entry.

When the BLANKING input is high, all of the output buffers are disabled (OFF) without affecting the information stored in the latches or shift register. With the BLANKING input low, the outputs are controlled by the state of the latches.

UCN-4815A

BiMOS LATCH/SOURCE DRIVER

FEATURES

- High-Voltage Source Outputs
- CMOS, PMOS, NMOS, TTL Compatible Inputs
- Low-Power CMOS Latches
- Internal Pull-Down Resistors
- Wide Supply Voltage Range

DESIGNED primarily for use with high-voltage vacuum fluorescent displays, the UCN-4815A BiMOS latch/source driver consists of eight NPN Darlington source drivers with pull-down resistors, a CMOS latch for each driver, and common strobe, blanking, and enable functions.

The CMOS inputs provide for minimum loading and are compatible with standard CMOS, PMOS, and NMOS logic commonly found in microprocessor designs. The use of CMOS latches also allows operation over a supply voltage range of 5 V to 15 V. When employed with either standard TTL or low speed TTL logic, the UCN-4815A may require the use of appropriate pull-up resistors.

The bipolar outputs may be used as segment, dot (matrix), bar, or digit drivers in vacuum fluorescent displays. All eight outputs can be activated simultaneously at ambient temperatures up to 60°C. To simplify circuit board layout, all outputs are pinned opposite their respective inputs.

A minimum component display subsystem, requiring few or no discrete components, may be realized by using the UCN-4815A BiMOS Latch/Source Driver with either a UCN-4805A or UCN-4806A latched hexadecimal decoder/drivers or a UCN-4810A serial-to-parallel latch/driver.

4

A. Minimum Data Active Time Before Strobe Enabled (Data Set-Up Time)	100 ns
B. Minimum Data Active Time After Strobe Disabled (Data Hold Time)	100 ns
C. Typical Strobe Pulse Width For Power-Up Clear Disable	500 ns
Minimum Strobe Pulse Width After Power-Up Clear Disabled	300 ns
D. Typical Time Between Strobe Activation and Output On to Off Transition	1.0 μ s
E. Typical Time Between Strobe Activation and Output Off to On Transition	1.0 μ s
F. Minimum Data Pulse Width	500 ns

Information present at an input is transferred to its latch when the STROBE and ENABLE are high. The latches will continue to accept new data as long as both STROBE and ENABLE are held high. With either STROBE or ENABLE in the low state, no information can be loaded into the latches.

When the BLANKING input is high, all of the output buffers are disabled (OFF) without affecting the information stored in the latches. With the

BLANKING input low, the outputs are controlled by the state of the latches.

On first applying V_{DD} to the device, all latch outputs assume a low state (Power-Up Clear) resulting in all outputs being OFF. The latches will remain in the low condition until the Clear is disabled by a STROBE high input. Data may be entered into the latches during Power-Up Clear disable if the ENABLE input is also high.

SERIES UCN-4820A

BiMOS 8-BIT SERIAL-INPUT, LATCHED DRIVERS

FEATURES

- High-Voltage Current-Sink Outputs
- CMOS, PMOS, NMOS, TTL Compatible
- Low-Power CMOS Logic and Latches
- Internal Pull-Up/Pull-Down Resistors
- 16-Pin Dual In-Line Plastic Packages

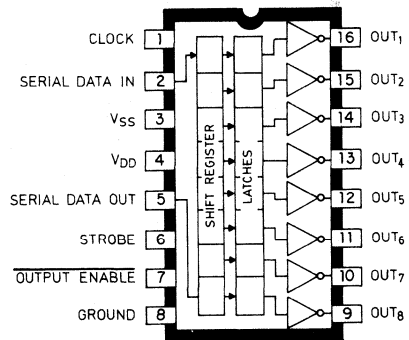

A COMBINATION of bipolar and MOS technology gives Sprague's Series UCN-4820A an interface flexibility beyond the reach of standard logic buffers and power driver arrays.

The three devices in this series each have eight bipolar current-sink Darlington drivers, a CMOS data latch for each of the eight open-collector outputs, an eight-bit CMOS shift register and CMOS control circuitry. Except for maximum driver voltage ratings, Types UCN-4821A, UCN-4822A and UCN-4823A are identical.

The bipolar outputs can drive multiplexed LED displays, incandescent lamps, thermal print heads, and (with appropriate clamping techniques) relays, solenoids and other high-power inductive loads.

The CMOS shift register and latches, which operate over a 5- to 15-volt supply range, minimize loading and are compatible with CMOS, PMOS and NMOS logic. Use of the drivers with TTL and DTL may require a pull-up resistor to ensure an input logic high. By using the serial data output, the drivers can be cascaded for interface applications requiring additional drive lines.

These devices are also available in industrial-grade ceramic packages (Series UCQ-4820R) and in military side-brazed, hermetically sealed packages (Series UCS-4820H).

Caution: Sprague CMOS devices have input static protection but are still susceptible to damage when exposed to extremely high static electrical charges.

SERIES UCN-4820A
BiMOS 8-BIT SERIAL-INPUT LATCHED DRIVERS

Dwg. No. A-10,990A

TIMING CONDITIONS

(Logic Levels are V_{DD} and V_{SS})

$V_{DD} = 5.0V$ $V_{DD} = 15V$

A. Minimum Data Active Time Before Clock Pulse (Data Set-Up Time)	250 ns	150 ns
B. Minimum Data Pulse Width	500 ns	300 ns
C. Minimum Clock Pulse Width	1.0 μs	250 ns
D. Minimum Time Between Clock Activation and Strobe	1.0 μs	400 ns
E. Minimum Strobe Pulse Width	500 ns	300 ns
F. Typical Time Between Strobe Activation and Output Transition	1.0 μs	1.0 μs

SERIAL DATA present at the input is transferred to the shift register on the logic '0' to logic '1' transition of the CLOCK input pulse. On succeeding CLOCK pulses, the registers shift data information towards the SERIAL DATA OUTPUT. The SERIAL DATA must appear at the input prior to the rising edge of the CLOCK input waveform.

Information present at any register is transferred to its respective latch when the STROBE is high (serial-to-parallel conversion). The latches will con-

tinue to accept new data as long as the STROBE is held high. Applications where the latches are bypassed (STROBE tied high) will require that the ENABLE input be high during serial data entry.

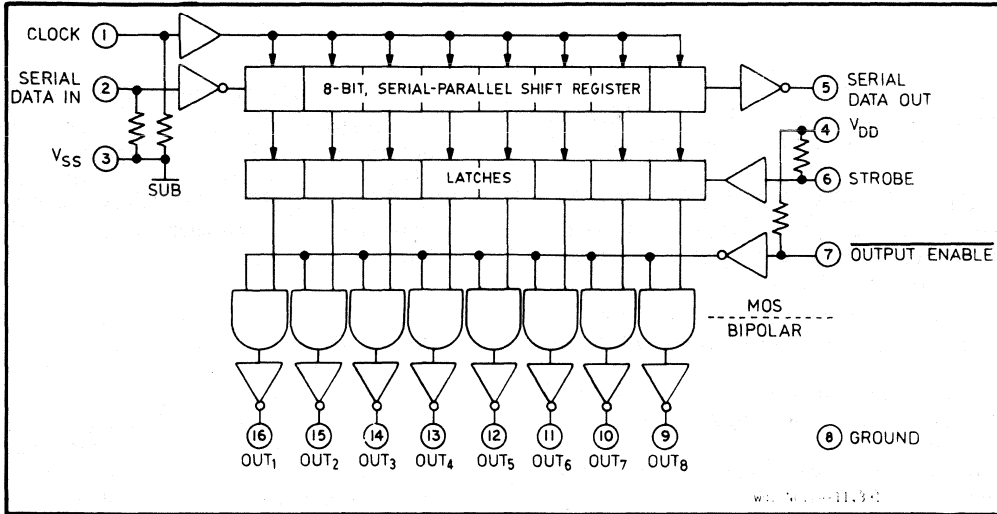

When the ENABLE input is high, all of the output buffers are disabled (OFF) without affecting the information stored in the latches or shift register. With the ENABLE input low, the outputs are controlled by the state of the latches.

Figure 3

Figure 4

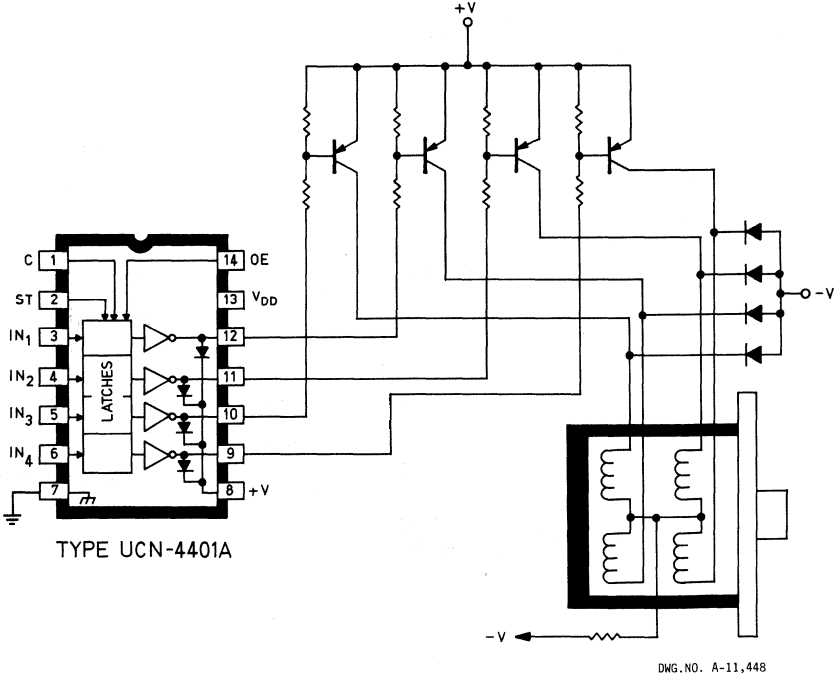

Figure 5

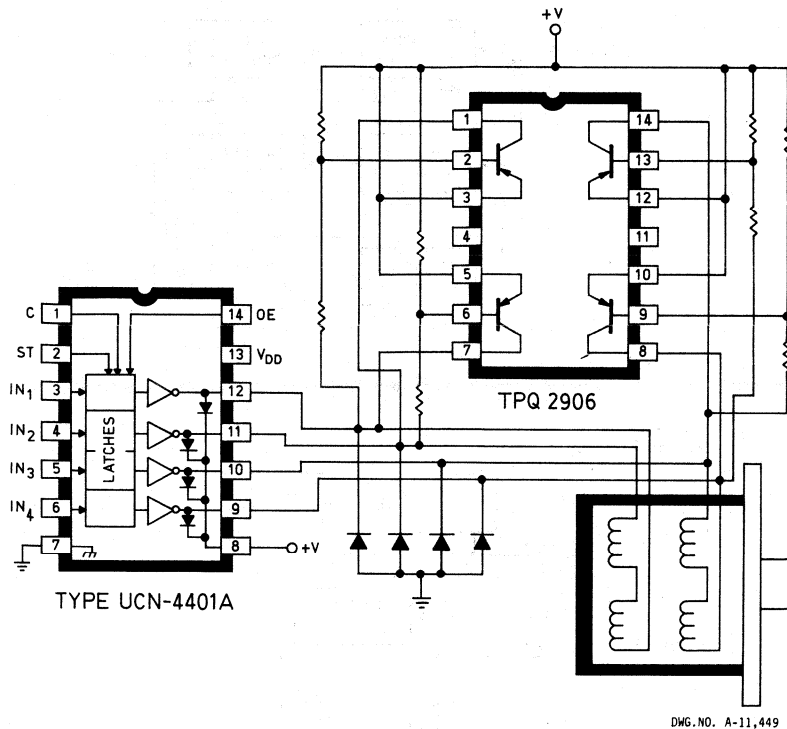

Figure 6

UCN-4810A

This integrated circuit functionally replaces a 10-bit serial-in, parallel-out shift register, a 10-bit data latch, and 10 high-voltage buffers (including output pull-down resistors). It is designed for use with vacuum fluorescent displays, but has been put to many other uses, including control of thermal print heads.

Connecting a data-out line from one device to a data-in pin of a second device minimizes the number of input/output lines required for a system. A 20-character 5×7 vacuum fluorescent dot matrix display, for instance, requires only six Type UCN-4810As (two as grid drivers and four as dot drivers). An example of cascaded data control is given in Figure 7. The arrangement cascades two devices for grid selection and four as dot drivers.

Data sent to the four dot drivers can be loaded in less than $80 \mu\text{s}$ using this configuration. The shift-rate limit of the dot drivers is 500 kHz at $V_{DD} = 5 \text{ V}$.

The two units that function as grid drivers are loaded with a single "1" during each scan cycle. The minimum recommended scan frequency is 30 Hz per character (a clock frequency of 2 kHz for 20-character display).

Since blanking ($20 \mu\text{s}$ minimum) is required between characters, and since the minimum ON time for each digit or character is $100 \mu\text{s}$, the maximum number of characters in a display is 80 (8 kHz clock, $125 \mu\text{s}$ ON and blanking time per character).

The typical ON time for vacuum fluorescent characters is $200 \mu\text{s}$ (40-character panel) to $500 \mu\text{s}$ (20-character display). Failure to provide proper blanking time can cause ghosting or flicker.

A faster method of loading matrix data, shown in Figure 8, requires more I/O lines. This technique loads shift registers during a blanking period (greater than $20 \mu\text{s}$). Each dot driver has a separate data-input line, but uses common clock, strobe and blanking lines. A second clock is used with the grid drivers.

A typical data-input timing chart for this configuration is shown in Figure 9. With a 20-character vacuum fluorescent display having a 2 kHz scan frequency, 10 bits of data are loaded during the first blanking period; succeeding 10-bit data blocks are loaded during blanking periods at $400 \mu\text{s}$ intervals.

A more unusual application of Type UCN-4810A is shown in Figure 10: The device is used with a thermal printer. In production, the drivers (in chip form) were built into a hybrid assembly.

TIMING CONDITIONS UCN-4810A

DWG. NO. A-11,452

Figure 9

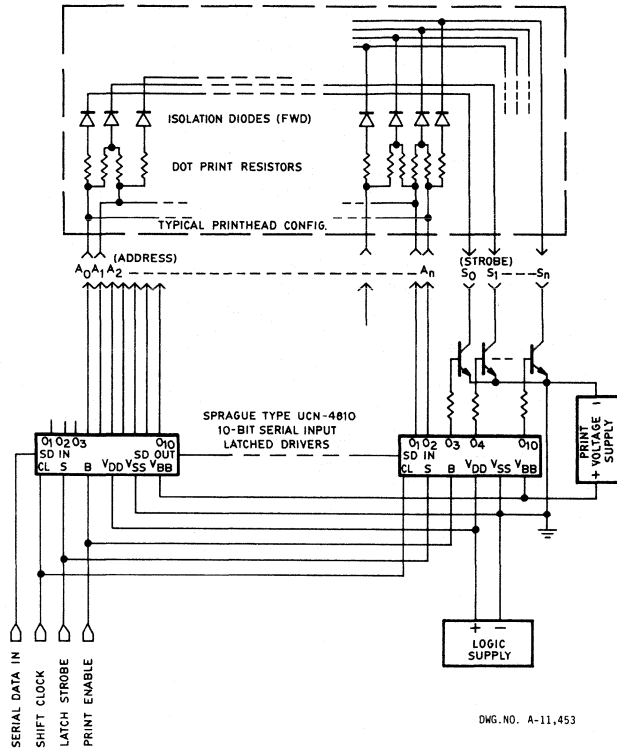

Figure 10

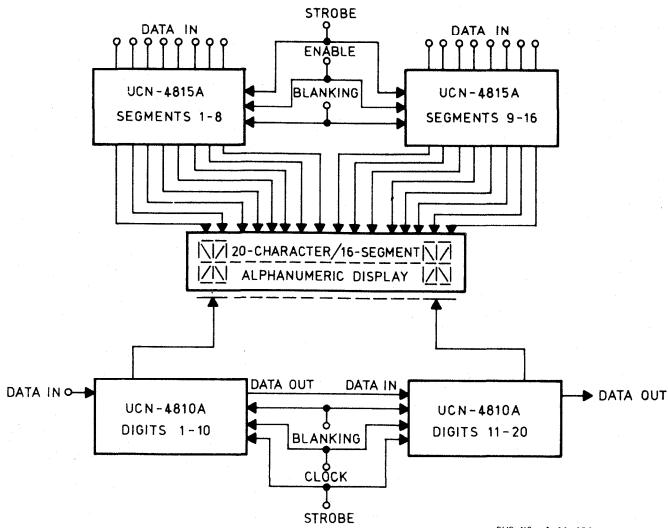

Figure 11

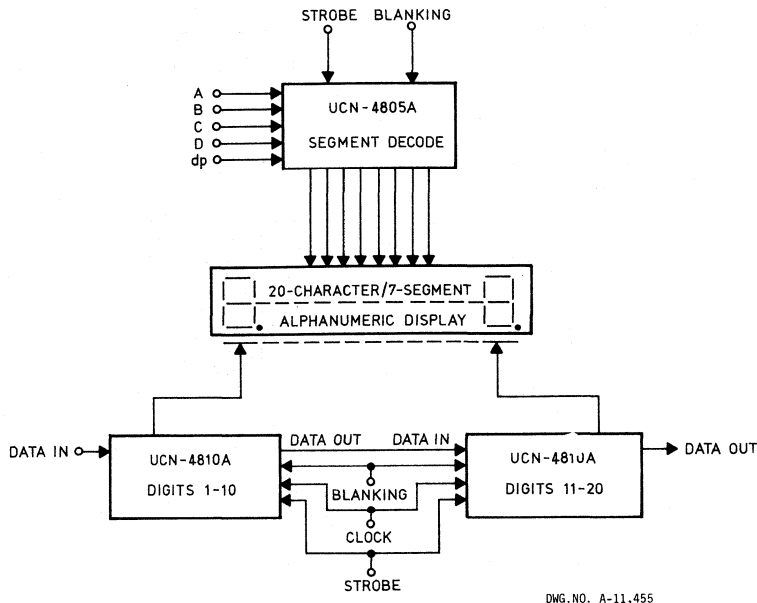

Figure 12

UCN-4815

Type UCN-4815A provides an eight-bit parallel-in, parallel-out interface for vacuum fluorescent displays. A typical application appears in Figure 11. A pair of Type UCN-4810As are used for grid control. The two Type UCN-4815As drive a 16-segment alphanumeric display.

UCN-4805A and UCN-4806A

Each of these devices has eight high-voltage source outputs, latched inputs, and both the hexadecimal decoding and speed capabilities for microprocessor-based designs.

Type UCN-4805A is used to decode and drive seven-segment displays. Its eighth source output is used to generate a colon or decimal point.

Type UCN-4806A is used with nine-segment (centered "1") displays. It has an I/O input that can be used to check for errors by interrogating input data latches.

A typical application with a 20-character vacuum fluorescent display is shown in Figure 12. Type

UCN-4805A is used as a seven-segment decoder/driver. A pair of Type UCN-4810As is used for grid-select.

SERIES UCN-4820A

The drivers in this series were designed for use in printers. Each integrated circuit has an eight-bit serial-input shift register, an eight-bit data latch, and eight NPN Darlington-pair outputs. The data entry rate for this series is 500 kHz (minimum) at $V_{DD} = 5V$.

A typical application appears in Figure 13; although the drawing depicts use with an electro-sensitive printer, the device can also control inductive loads such as print hammers and solenoids, or thermal print heads.

Use of Types UCN-4823A and UCN-4810A-1 is combined in the planar gas-discharge display application shown in Figure 14. Type UCN-4810A-1 signal inputs are level-shifted (floated to the V_{BE} supply level). The application requires external segment limiting and pull-up resistors and use of Zener diodes.

SERIES 400, 400-1 and 500

HERMETICALLY SEALED POWER and RELAY DRIVERS

FEATURES

- 500mA Output Sink Current Capability
- DTL/TTL Compatible Inputs
- Transient Protected Outputs on Relay Drivers
- High Voltage Output — 100V Series 500, 70V Series 400-1, and 40V Series 400
- Hermetically Sealed Packages to MIL-M-38510
- High-Reliability Screening to MIL-STD-883, Class B

Description

These Series 400, 400-1, and 500 hermetically sealed power and relay drivers are bipolar monolithic circuits incorporating both logic gates and high-current switching transistors on the same chip. Each device contains four drivers capable of sinking 500mA in the ON state. In the OFF state, Series 400 devices will sustain 40V, Series 400-1 devices will sustain 70V, and Series 500 devices will sustain 100V.

All devices are available in either a 14-pin hermetic flat-pack package (Types UHC-) or a 14-pin hermetic dual in-line package (Types UHD-). These packages conform to the dimensional requirements of Military Specification MIL-M-38510 and meet all of the processing and environmental requirements of Military Standard MIL-STD-883, Method 5004 and 5005. These devices are also furnished in a plastic 14-pin dual in-line package (Types UHP-) for operation over a limited temperature range.

Applications

The UHC- and UHD- Series 400, 400-1, and 500 power and relay drivers are ideally suited for driving incandescent lamps, relays, solenoids, and other interface devices with up to 1A output current per package. Hermetic sealing and an operating temperature range of -55°C to $+125^{\circ}\text{C}$ recommend them for military and aerospace applications as well as commercial and industrial control applications where severe environments may be encountered.

SERIES ULS-2000H and ULQ-2000R HIGH-VOLTAGE, HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

FEATURES

- TTL, DTL, PMOS, or CMOS Compatible Inputs
- Peak Output Current to 600 mA
- Transient Protected Outputs
- Side-Brazed Hermetic Package, or
- Cer-DIP Package
- High-Reliability Screening Available
- Wide Operating Temperature Ranges

COMPRISED of seven silicon NPN Darlington power drivers on a common monolithic substrate, the Series ULS-2000H and ULQ-2000R arrays are ideally suited for driving relays, solenoids, lamps, and other devices with up to 3.0 A output current per package. The side-brazed, hermetically sealed Series ULS-2000H devices are rated for operation over the temperature range of -55°C to $+125^{\circ}\text{C}$, recommending them for military and aerospace applications. The Cer-DIP, industrial-grade hermetic Series ULQ-2000R devices are rated for use over the operating temperature range of -40°C to $+85^{\circ}\text{C}$, allowing their use in commercial and industrial applications where severe environments may be encountered.

The twenty-five integrated circuits permit the circuit designer to select the optimum device for his application. There are two packages, five input characteristics, two output voltages, and two output currents covered by the listings. The appropriate part for use in specific applications can be determined from the Device Type Number Designation chart. Note that the high-voltage devices ($BV_{CE} \approx 95\text{ V}$) are available in the Series ULS-2000H only. All units feature open collector outputs and integral diodes for inductive load transient suppression.

All Series ULS-2000H arrays are furnished in a 16-pin side-brazed dual in-line hermetic package

DPG. NO. A-9594

that conforms to the dimensional requirements of Military Specification MIL-M-38510 and meets the processing and environmental requirements of Military Standard MIL-STD-883, Methods 5004 and 5005.

ULS-2064H through ULS-2077H 1.25 A QUAD DARLINGTON SWITCHES

FEATURES

- TTL, DTL, PMOS, or CMOS Compatible Inputs
- Transient-Protected Outputs
- Hermetically Sealed Package to MIL-M-38510
- High-Reliability Screening to MIL-STD-883, Class B

INTENDED FOR MILITARY, aerospace, and related applications, ULS-2064H through ULS-2077H high-voltage high-current integrated circuit switches will interface from low-level logic to a variety of peripheral loads such as relays, solenoids, d-c and stepping motors, multiplexed LED and incandescent displays, heaters, and similar loads up to 400 W (1.25 A per output, 80 V, 12.5% duty cycle, +50°C).

The devices are specified with a minimum output breakdown of 50 volts, and $V_{CE(SUS)}$ minimum of 35 volts measured at 100 mA, or a minimum output breakdown of 80 volts, $V_{CE(SUS)}$ minimum of 50 volts, and an output current specification of 1.25 A (saturated).

Types ULS-2064H, ULS-2065H, ULS-2068H and ULS-2069H are designed for use with TTL, DTL, Schottky TTL, and 5 V CMOS logic.

Types ULS-2066H, ULS-2067H, ULS-2070H and ULS-2071H are intended for use with 6 V to 15 V CMOS and PMOS input circuits.

All eight of these devices include integral transient suppression diodes for use with inductive loads.

Types ULS-2068H and ULS-2069H incorporate a pre-driver stage requiring a 5 V supply rail. Types ULS-2070H and ULS-2071H include an added gain stage requiring a 12 V (nominal) supply rail. The input drive requirements for these devices are reduced, while the output can switch currents up to 1.5 A.

Types ULS-2074H through ULS-2077H are intended for use in emitter-follower or similar isolated Darlington applications where common-emitter versions cannot be used. These circuits are identical with the ULS-2064H through ULS-2067H types except for the isolated Darlington pin-out and the omission of the suppression diodes.

All twelve Quad Darlington Switches are supplied in 16-pin hermetic dual-in-line packages. They meet the processing and environmental requirements of MIL-STD-883 Methods 5004 and 5005, and the dimensional requirements of MIL-M-38510.

ULS-2071H	80 V	50 V	30 V	and PMOS
ULS-2074H	50 V	35 V	30 V	General Purpose
ULS-2075H	80 V	50 V	60 V	
ULS-2076H	50 V	35 V	30 V	6 to 15 V CMOS
ULS-2077H	80 V	50 V	60 V	and PMOS

Notes:

1. For allowable combinations of output current, number of outputs conducting, and duty cycle, see graphs following.
2. Input voltage is with reference to the substrate (no connection to any other pins) for the ULS-2074/75/76/77H, reference is ground for all other types.
3. Input current may be limited by maximum allowable input voltage.

SERIES ULS-2800H and ULQ-2800R HIGH-VOLTAGE, HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

FEATURES

- TTL, DTL, PMOS, or CMOS Compatible Inputs
- Peak Output Current to 600 mA
- Transient Protected Outputs
- Side-Brazed Hermetic Package, or
- Cer-DIP Package
- High-Reliability Screening Available
- Wide Operating Temperature Ranges

DESIGNED for interfacing between low-level logic circuitry and high-power loads, the Series ULS-2800H and ULQ-2800R arrays consist of eight silicon NPN Darlington power drivers on a common monolithic substrate. The choice of five input characteristics, two output voltage ratings (50 or 95 V), two output current ratings (500 or 600 mA), and two package styles (suffix 'H' or 'R') allow the circuit designer to select the optimum device for any specific application.

The side-brazed, hermetically sealed Series ULS-2800H devices are rated for operation over the temperature range of -55°C to $+125^{\circ}\text{C}$, recommending them for military and aerospace applications. The cer-DIP, industrial grade hermetic Series ULQ-2800R devices are rated for use over the operating temperature range of -40°C to $+85^{\circ}\text{C}$, permitting their use in commercial and industrial applications where severe environmental conditions may be encountered.

The appropriate specific part number for use in standard logic applications can be determined from the Device Type Number Designation chart. Note that the high-voltage devices ($BV_{CE} \approx 95\text{ V}$) are available in the Series ULS-2800H only. All units feature open collector outputs and integral diodes for inductive load transient suppression.

All Series ULS-2800H Darlington power drivers are furnished in an 18-pin side-brazed dual in-line

D·G. NO. A-10.322

hermetic package that meets the processing and environmental requirements of Military Standard MIL-STD-883, Methods 5004 and 5005.

UDQ-2956R and UDQ-2957R

HIGH-VOLTAGE, HIGH-CURRENT SOURCE DRIVERS

EACH OF THESE SOURCE-DRIVER arrays has five NPN Darlington-pair outputs and five PNP common-base inputs controlled by a single ENABLE stage.

Types UDQ-2956R and UDQ-2957R are typically used to switch the ground ends of loads such as telephone relays, PIN diodes, LEDs and similar devices directly connected to negative supplies. Internal transient-suppression diodes allow use of the drivers with inductive loads.

Each output stage of both integrated circuits will withstand output OFF voltages of -80 V and load currents as high as -500 mA. Under normal operating conditions, the five drivers will simultaneously handle load currents of -170 mA at ambient temperatures of up to $+70^{\circ}\text{C}$.

Type UDQ-2956R is designed for use with PMOS or CMOS logic input levels operating with supply voltages of 6 V to 16 V. Type UDQ-2957R has input current-limiting resistors that permit its operation with TTL, Schottky TTL, DTL and 5 V CMOS.

Both devices are supplied in industrial-grade, hermetically sealed 14-pin dual in-line ceramic packages rated for use over the temperature range of -40°C to $+85^{\circ}\text{C}$. Input connections are on one side of the packages, output connections on the other, to simplify applications designs.

The substrate of Type UDQ-2956R and Type UDQ-2957R should be tied to the most negative supply available in order to maintain isolation between drivers.

ABSOLUTE MAXIMUM RATINGS **at 25°C Free-Air Temperature** **(reference pin 7)**

Supply Voltage, V_{EE}	-80 V
Input Voltage, V_{IN} (UDQ-2956R)	$+20$ V
(UDQ-2957R)	$+10$ V
Output Current, I_{OUT}	-500 mA
Power Dissipation, P_D (any one driver)	1.0 W
(total package)	1.67 W*
Operating Temperature Range, T_A	-40°C to $+85^{\circ}\text{C}$
Storage Temperature Range, T_S	-65°C to $+150^{\circ}\text{C}$

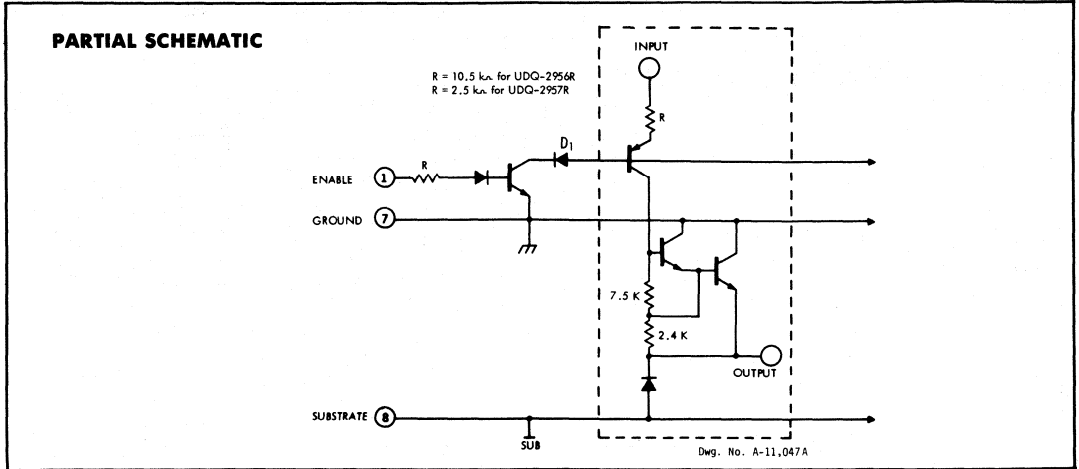

*Derate at the rate of 13.3 mW/ $^{\circ}\text{C}$. above $+25^{\circ}\text{C}$.

**UDQ-2956R and UDQ-2957R
HIGH-VOLTAGE, HIGH-CURRENT SOURCE DRIVERS**

**ALLOWABLE PEAK OUTPUT CURRENT
AS A FUNCTION OF DUTY CYCLE**

**INPUT CURRENT AS A FUNCTION OF INPUT VOLTAGE
at $T_A = +25^\circ\text{C}$**

SERIES UDS-2980H HERMETICALLY SEALED HIGH-VOLTAGE, HIGH-CURRENT SOURCE DRIVERS

FEATURES:

- TTL, DTL, PMOS or CMOS Compatible Inputs
- -500 mA Output Source Current Capability
- Transient-Protected Outputs
- High-Reliability Screening to MIL-STD-883, Class B
- Operating Temperature -55°C to +125°C

SERIES UDS-2980H HERMETICALLY SEALED source drivers interface between standard low-power digital logic, and relays, solenoids, stepping motors, LEDs, lamps, etc., in applications requiring separate logic and load grounds, load supply voltages to +80V, and/or load currents to 500 mA.

Under normal operating conditions these devices will sustain 50 mA continuously on each of the eight outputs, at an ambient temperature of +85°C, with a supply of +15 V. All four devices incorporate input current limiting resistors and output suppression diodes.

UDS-2981H and UDS-2983H drivers are intended for use with +5 V logic systems (TTL, Schottky TTL, DTL and 5 V CMOS). UDS-2982H and UDS-2984H drivers are intended for MOS interface (PMOS and CMOS) operating from supply voltages of from +6 to +16 V.

UDS-2981H and UDS-2982H drivers will sustain a maximum output OFF voltage of +50 V; UDS-2983H and UDS-2984H drivers a maximum output OFF voltage of +80 V.

In all cases the output is switched ON by an active high input level.

Note that the maximum current rating may not be obtained at -55°C because of beta fall-off, or at +125°C because of package power limitations.

5

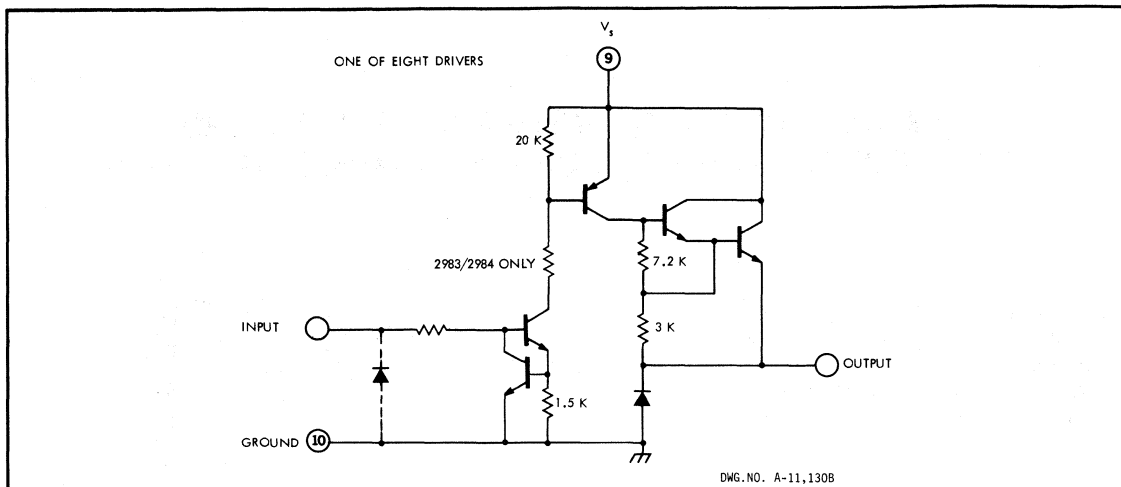

Series UDS-2980H drivers are furnished in 18-pin hermetic dual-in-line packages, and are processed to the requirements of MIL-STD-883, Methods 5004 and 5005.

SERIES UDS-3600H DUAL 2-INPUT PERIPHERAL and POWER DRIVERS
— Hermetically Sealed

FEATURES

- Four Logic Types
- DTL/TTL/PMOS/CMOS Compatible Inputs
- Low Input Current
- Sustaining Voltage of 80 V
- Hermetically Sealed Package
- High-Reliability Screening to MIL-STD-883, Class B

Description

These “mini-DIP” dual 2-input peripheral and power drivers are bi-polar monolithic integrated circuits incorporating AND, NAND, OR, or NOR logic gates, and high-current switching transistors on the same chip. The two output transistors are capable of simultaneously sinking 250 mA continuously at an ambient temperature of +75°C. In the OFF state, these drivers will sustain at least 80 V.

Applications

The Series UDS-3600H dual drivers are ideally suited for interface between low-level or high-level logic and high-current/high-voltage loads. Typical applications include driving peripheral loads such as incandescent lamps, light-emitting diodes, memories, and heaters.

With appropriate external diode transient suppression, the Series UDS-3600H drivers can also be used with inductive loads such as relays, solenoids, and stepping motors.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}	7.0 V
Input Voltage, V_{in}	30 V

NOTES:

1. Typical values are at V_{CC} = 5.0 V, T_A = 25°C.
2. Per package.
3. Capacitance values specified include probe and test fixture capacitance.

UCS-4401H and UCS-4801H BiMOS LATCHED DRIVERS — Hermetically Sealed

FEATURES

- High-Voltage, High-Current Outputs
- Output Transient Protection
- CMOS, PMOS, NMOS, TTL Compatible
- Internal Pull-Down Resistors
- Low-Power CMOS Latches

HIGH-VOLTAGE, HIGH-CURRENT interface for military, aerospace and related applications is supplied by these latched drivers. Type UCS-4401H contains four pairs of latches and drivers; Type UCS-4801H has eight pairs of latches and drivers.

The integrated circuits' CMOS inputs work with standard CMOS, PMOS and NMOS logic levels and (with appropriate pull-up resistors) with TTL or DTL circuits. The bipolar open-collector outputs can be used with relays, solenoids, motors, LED or incandescent displays, and other high-power loads.

The output transistors can sink 500 mA and will withstand a V_{CE} of 50 V in the OFF state. Outputs can be paralleled for higher current capability. Because of limitations on package power dissipation, simultaneous operation of all drivers at maximum rated current can only be accomplished with a reduction of duty cycle.

Type UCS-4401H, the four-latch device, is furnished in a standard 14-pin side-brazed hermetic package. Type UCS-4801H, the eight-latch device, is furnished in a 22-pin side-brazed hermetic package with row centers 0.400-inch (10.16 mm) apart.

Both devices meet all processing and environmental requirements of Military Standard MIL-STD-883, Methods 5004 and 5005.

Note: Operation of these devices with standard TTL or DTL may require the use of appropriate pull-up resistors to insure the minimum logic "1".
*Pulsed test.

TIMING CONDITIONS

$T_A = +25^\circ\text{C}$; Logic Levels are V_{DD} and V_{SS}

DWG. NO. A-10,895A

- A. Minimum data active time before strobe enabled (data set-up time) 100 ns
- B. Minimum data active time after strobe disabled (data hold time) 100 ns
- C. Minimum strobe pulse width 300 ns
- D. Typical time between strobe activation and output on to off transition 500 ns
- E. Typical time between strobe activation and output off to on transition 500 ns
- F. Minimum clear pulse width 300 ns
- G. Minimum data pulse width 500 ns

Information present at an input is transferred to its latch when the STROBE is high. A high CLEAR input will set all latches to the output OFF condition regardless of the data or STROBE input levels. A high OUTPUT ENABLE will set all outputs to the OFF condition regardless of any other input conditions. When the OUTPUT ENABLE is low, the outputs depend on the state of their respective latches.

t = present output state

SERIES UDS-5700H QUAD 2-INPUT PERIPHERAL and POWER DRIVERS — Hermetically Sealed

FEATURES

- Four Logic Types
- DTL/TTL/PMOS/CMOS Compatible Inputs
- Low Input Current
- Sustaining Voltage of 80 V
- Hermetically Sealed Package to MIL-M-38510
- High-Reliability Screening to MIL-STD-883, Class B

Description

These 16-Lead quad 2-input peripheral and power drivers are bi-polar monolithic integrated circuits incorporating AND, NAND, OR, and NOR logic gates, high-current switching transistors, and transient suppression diodes on the same chip. The four output transistors are capable of simultaneously sinking 150 mA continuously at an ambient temperature of +70°C. In the OFF state, these drivers will sustain at least 80 V.

Applications

The Series UDS-5700H quad drivers are ideally suited for interface between low-level or high-level logic and high-current/high-voltage loads. Typical applications include driving peripheral loads such as incandescent lamps, light-emitting diodes, memories, and heaters.

The integral transient suppression diodes allow their use with inductive loads such as relays, solenoids, or stepping motors without the need for discrete diodes. For non-inductive loads, the diode common bus can be used as a convenient lamp test.

SERIES UDS-5710H DUAL PERIPHERAL and POWER DRIVERS — Hermetically Sealed

FEATURES

- Four Logic Types
- DTL/TTL/PMOS/CMOS Compatible Inputs
- Low Input Current
- Sustaining Voltage of 80 V
- Transient-Protected Outputs
- High-Reliability Screening to MIL-STD-883, Class B

Description

These dual peripheral and power drivers are bipolar monolithic integrated circuits incorporating AND, NAND, OR, or NOR logic gates, high-current switching transistors, and transient suppression diodes on the same chip. The two output transistors are capable of simultaneously sinking 200 mA continuously at ambient temperatures of up to +85°C. In the OFF state, these drivers will sustain at least 80 V. Units are supplied in 8-pin hermetically sealed mini-DIP packages.

Applications

The Series UDS-5710H dual drivers are ideally suited for interface between low-level or high-level logic and high-current/high-voltage loads. Typical applications include driving peripheral loads such as incandescent lamps, light-emitting diodes, memories, and heaters with a load current of up to a 500 mA peak value.

The integral transient suppression diodes allow the use of these drivers with inductive loads such as relays, solenoids, or stepping motors without the need for discrete diodes. When not required for transient suppression, the diode common bus can be used to perform the "lamp test" function.

UDS-5790H and UDS-5791H QUAD PIN DIODE POWER DRIVERS

FEATURES

- Inverting or Non-Inverting
- Low Input Current
- TTL, DTL, MOS Compatible
- Wide Operating Voltage Range
- High Output Breakdown Voltage

CONSISTING of four high-voltage NPN output stages and associated logic and level shifting, these monolithic, planar integrated circuits offer an easy solution to many PIN diode driving applications.

The UDS-5790H and UDS-5791H quad power drivers are designed to replace discrete or hybrid PIN diode drivers. They provide significant reductions in cost and space with improved reliability. The UDS-5790H driver uses a grounded-base input stage for non-inverting operation while the UDS-5791H driver uses a common-emitter input stage for inverting operation. Both devices are capable of sustaining OFF voltages of 120V and will switch currents to 500 mA.

The input buffer circuitry has been designed to utilize external discrete resistors. The one-resistor-per-driver effectively reduces total package power dissipation and junction temperature while allowing user selection of output base drive current, power supply voltages, and output current.

All devices are rated for operation over an extended temperature range of -55°C to $+125^{\circ}\text{C}$. They are customarily supplied in 16-pin hermetic dual in-line packages. All units are subjected to the 100% production screen tests specified in MIL-STD-883, Method 5004, Class B, paragraphs 3.1.1 through 3.1.6. On special order, 160 hours of burn-in to Method 1015, Condition A, can also be performed.

UDS-5790H

UDS-5791H

DMG. NO. A-10.655

GENERAL DESIGN NOTES

$$I_{RX} = \frac{I_{ON}}{B}$$

$$R_X = \frac{B(V_{CC} - V_{EE} - V_X)}{I_{ON}}$$

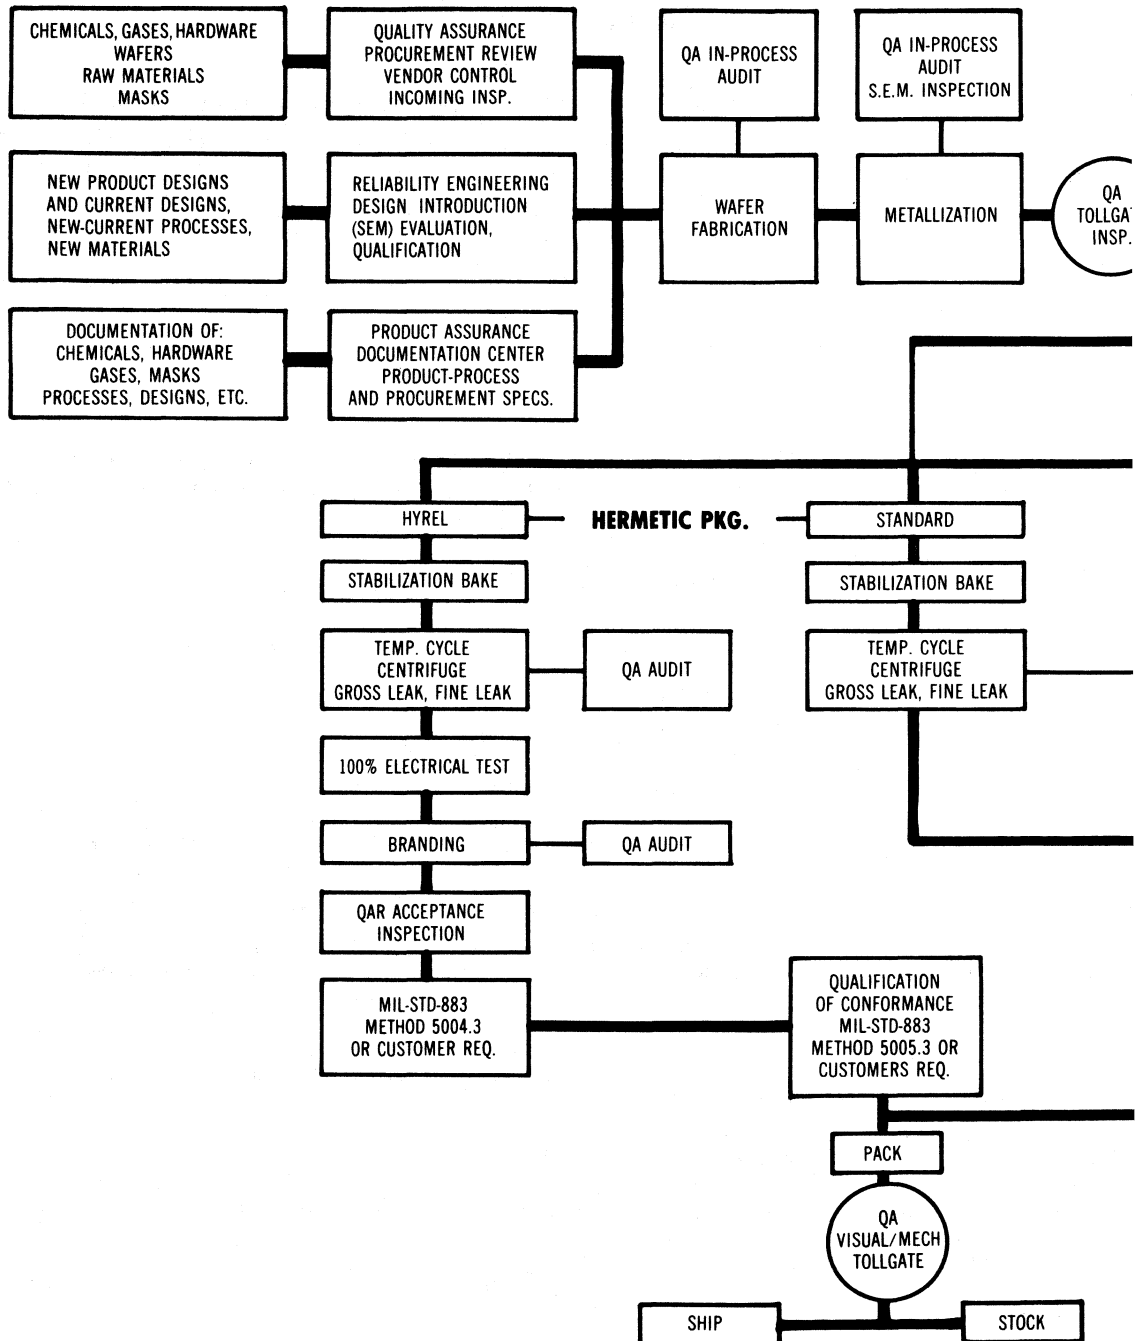

where

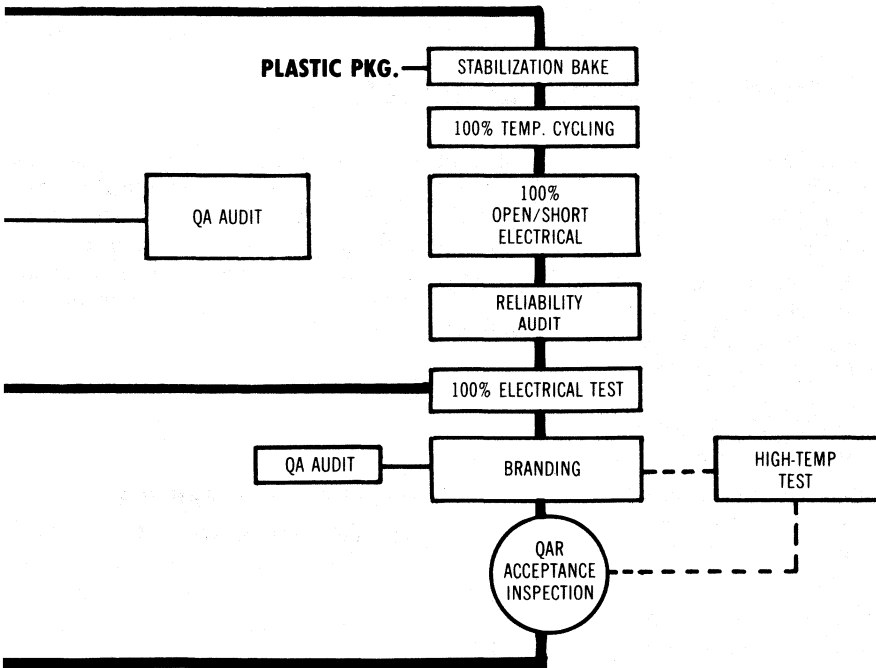

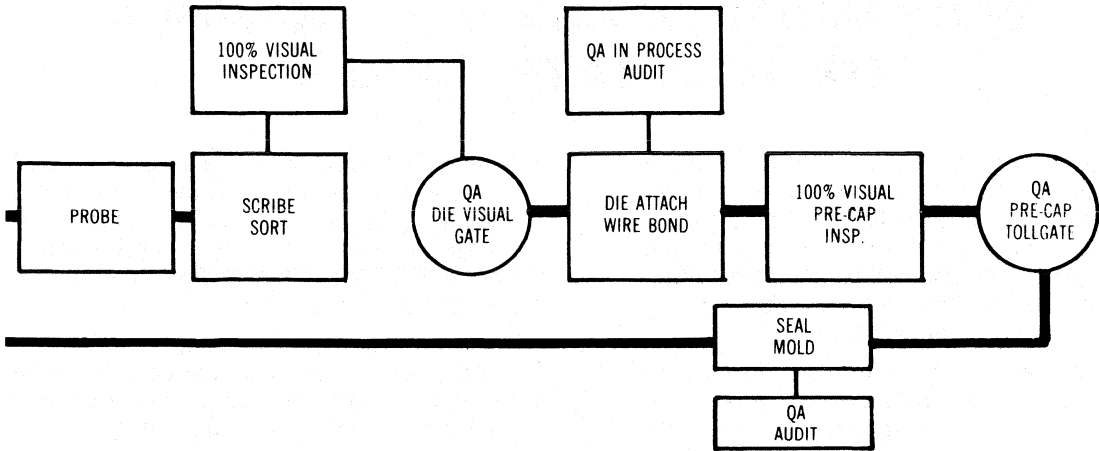

B = 30, the minimum output current gain over the operating temperature range

V_X = 1.5, the maximum predriver voltage

It is recommended that a minimum overdrive of 25% to be used (1.25 I_{RX} or 0.8R_X).

QUALITY ASSURANCE FLOW CHART

THE SPRAGUE ELECTRIC 'DOUBLE-DEUCE' BURN-IN PROGRAM FOR INTEGRATED CIRCUITS

THE EXPENSE OF DEVICE FAILURE is more than the time and money spent locating and replacing a defective integrated circuit. The total cost can include the price of assembly rework, system downtime, service calls, warranty claims and lost customer goodwill.

Costs of \$25 for each in-house failure and \$250 for each field failure are not uncommon. At a relatively low cost, Sprague

Electric Company's "Double-Deuce" screening program removes marginal devices before shipment. Improved customer satisfaction with performance and reliability is an immeasurable but certain bonus of the program.

"Double-Deuce" screening is done during the last stage of production. Because Sprague does the screening, only qualified devices are received by the user.

QUALITY AND RELIABILITY

Quality and reliability are terms that are often used interchangeably. Quality implies reliability, but a product's merit should always be defined by both.

Quality is the extent to which a device conforms to specifications when it is shipped to the user. Quality is verified by testing. Inspections at every step of production of Sprague integrated circuits ensure the devices meet demanding standards for workmanship and materials.

Inspections of integrated circuits under the "Double-Deuce" program have been made even more stringent to secure a higher level of quality.

Reliability is the measure of an integrated circuit's ability to meet specifications over time. Reliability is a product of design and process control. Accelerated-life tests provide the manufacturer and user with an indication of the reliability of a device. Normally, a small number of integrated circuits exhibit signs of early failure or infant mortality. This statistic, taken from the steepest part of the IC

lifetime probability curve, is often used to project time-to-failure for integrated circuits. Because the "Double-Deuce" program eliminates early failures, Sprague integrated circuits delivered after the screening process have a higher degree of reliability.

PROBABILITY OF FAILURE
AS A FUNCTION OF TIME

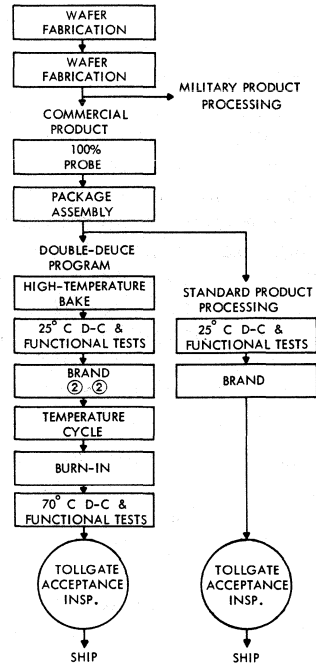

Dwg. No. A-11,417

OUTLINE OF THE 'DOUBLE-DEUCE' PROCESS

The "Double-Deuce" burn-in program uses high stress levels to accelerate the failure mechanisms associated with infant mortality. These normally occur within the first few hours of user application. Although typically less than 1 per cent of a lot will be rejected, user confidence in lot integrity is greatly improved. The screening program is designed to eliminate the following failure modes:

Stress	Failure Mode
High-Temp. Bake	Contamination
Temp. Cycling	Package-Related
Burn-In	Process-Related
High-Temp. Testing	Electrical Degradation

The majority of early integrated circuit failures (infant mortality or ionic contamination) can be attributed to manufacturing defects, package or assembly defects, or final test escapes. The "Double-Deuce" program is designed to eliminate weaker parts, reduce or eliminate user shipment inspection, assembly rework, system checkout, and warranty returns.

5

TEST PROCEDURES

The "Double-Deuce" burn-in program includes five test procedures:

1. High-Temperature Bake

This is a process designed to stabilize electrical drift and to accelerate chemical degradation such as surface contamination. It is a four-hour bake at +175°C without electrical stress (similar to MIL-STD-883, Method 1008).

2. Temperature Cycling

This is a screening process designed to mechanically stress the integrated circuit by alternately heating and cooling it.

Potential failures are seal or bond failure, cracked packages or chips.

The process has 10 cycles with 10 minutes of dwell at -65°C and 10 minutes of dwell at +150°C (air to air), with a maximum transfer time of five minutes (MIL-STD-883, Method 1010, Condition C). At Sprague's option, this process may be changed to thermal shock (liquid to liquid) for 10 cycles, five minutes at 0°C and five minutes at +100°C with a transfer time of 10 seconds (MIL-STD-883, Method 1011, Condition A).

TEST PROCEDURES

3. Burn-In

The burn-in, or accelerated-life test, is performed to screen out marginal devices, those with inherent defects, or defects resulting from manufacturing deviations that can cause time-dependent or stress-dependent failures. Without this conditioning, marginal circuits that initially meet all specifications could exhibit early lifetime failures under normal operating conditions. The test is conducted for 96 hours at a junction temperature of +150°C under electrical stress conditions (similar to MIL-STD-883, Method 1015) such as:

Type of Device	Electrical Stress
Bipolar Interface	Steady-State Reverse Bias
Linear Devices	Steady-State Forward Bias
PL and MOS Logic	Clocked

The burn-in conditions (96 hours at $T_J = +150^\circ\text{C}$) are equivalent to 525 hours at

$T_J = +125^\circ\text{C}$ for ionic contamination ($E_A = 1.0\text{ eV}$) or for 192 hours at $T_J = +125^\circ\text{C}$ for infant mortality defects ($E_A = 0.4\text{ eV}$).

4. High-Temperature Test

Every device is subjected to complete electrical tests at +70°C for function and d-c parameters (similar to MIL-STD-883, Methods 3001 through 3014 and 4001 through 4007, as applicable). Relaxed +25°C limits or published high-temperature limits, are used to remove devices with circuit anomalies such as beta mismatch, high leakage current, and intermittent bonds, which may only affect the circuit at higher temperatures.

5. Outgoing Quality Control Inspection

All "Double-Deuce" product is inspected to an outgoing sampling plan which guarantees that the product will meet an acceptable quality level of 0.25%.

HOW TO ORDER

All standard Sprague integrated circuits are branded with the Sprague registered trademark, (D).

Integrated circuits screened to the added requirements of the "Double-Deuce" program are marked:

(D) (D)

The double "circle-deuce" identifies a

part subjected to the screening program for extra reliability.

Devices processed in the "Double-Deuce" burn-in program are specified by adding the suffix "BU" to the end of the part number. For example, to order ULN-2023A with this processing, specify ULN-2023ABU; to order UDN-6116R-2, specify UDN-6116R-2BU.

INTERFACE DRIVERS WITH MIL-STD-883 HIGH-RELIABILITY SCREENING

Interface drivers with high-reliability screening can be ordered by adding the suffix "MIL" to the part number, for example, ULS-2064H-MIL. If marking with the customers part number is necessary in place of the Sprague Electric part number, this must be stated on the purchase order with the marking desired.

ULN-2111A F-M I-F AMPLIFIER/LIMITER and QUADRATURE DETECTOR

FEATURES

- Good Sensitivity
- Excellent A-M Rejection
- Low Harmonic Distortion
- Single-Adjustment Tuning
- High Gain to 50 MHz
- 500 mV Recovered Audio at 10.7 MHz
- Wide Operating Voltage Range
- Direct Replacement for ULN-2113A, MC1357, SN76643
- 14-Pin Dual In-Line Plastic Package

PROVIDING a multi-stage wideband amplifier/limiter, an F-M quadrature detector, and an emitter-follower audio output stage, the Type ULN-2111A is designed for use in F-M receivers or in the sound I-F of TV receivers.

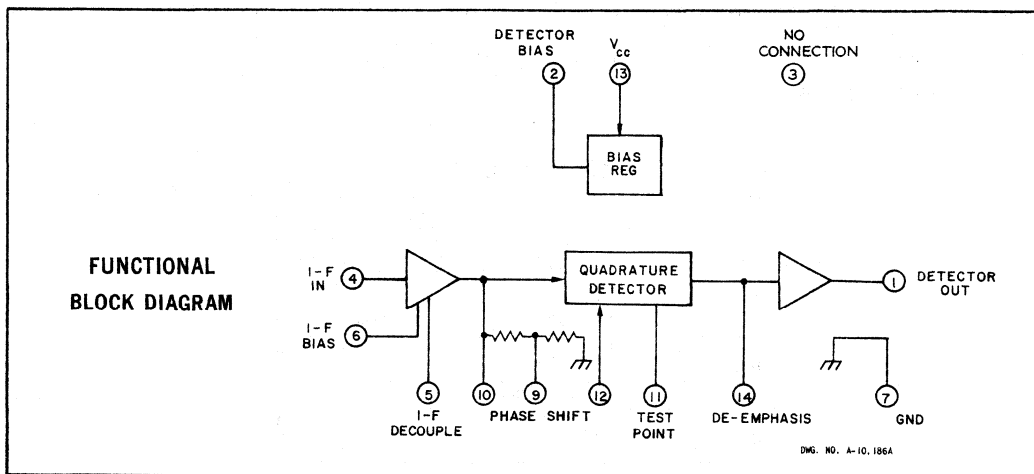

The Type ULN-2111A amplifier/limiter and quadrature detector is a Sprague-originated design. This circuit was the original monolithic integrated circuit F-M detector and was the first integrated circuit to be used in entertainment electronics. Its outstanding feature is that only a single low-cost tuned circuit is required instead of the previous triple-winding transformer.

TYPICAL APPLICATION

DNG. NO. A-6360

GENERAL DESIGN NOTES

- Phase shift network is aligned by applying F-M signal through decoupling network to pin 4 ($V_4 = 5 \text{ mV}_{\text{rms}}$). Tune for maximum recovered audio at pin 1 or maximum I-F voltage at pin 11.
- A d-c path of less than 100Ω must be provided between pins 2 and 12. No other biasing provisions are required.
- A d-c path of less than 300Ω must be provided between pins 4 and 6. No other biasing provisions are required.
- The maximum a-c load current can be increased by adding an external resistor between pin 1 and ground. The minimum value for this resistor is 800Ω , giving a maximum load current of $4 \text{ mA}_{\text{rms}}$.
- All decoupling capacitors should be of the ceramic type with minimum inductance at the operating frequency.
- Decoupling capacitor leads at pins 2, 5, and 6 should be as short as possible.
- Keep appropriate distance between the input (pin 4 and the input network) and the phase shift network (pins 9, 10, and 12, and the phase shift inductor).
- If a high impedance power supply is used (voltage dropping resistor), decouple pin 13 for the lowest audio frequency.
- The linear detection mode (low signal level at pin 12), as shown, is preferred for communications and other commercial applications, due to the preservation of the tuned circuit bandwidth and better rejection of Gaussian noise. The combination of coupling capacitor (C_2) and I-F amplifier output (pin 9) was chosen for optimum quieting. The bandwidth of the phase shift network (peak separation) is primarily defined by the Damping resistor (R). A higher value resistor will decrease bandwidth, increase the recovered audio output, reduce the capture ratio, and increase harmonic distortion.
- The switching detection mode (high signal level at pin 12) features a greater linear range, increased insensitivity to amplitude variations, and is recommended for AFC applications or where side responses must be avoided. Limiting in the quadrature detector will produce slightly more audio output, but will increase the noise bandwidth and degrade quieting.

ULN-2136A F-M I-F AMPLIFIER/LIMITER and QUADRATURE DETECTOR

FEATURES

- Single Tuning Coil Design
- Good Line and Load Regulation
- Low Harmonic Distortion
- Good Sensitivity
- Excellent A-M Rejection
- 400 mV Recovered Audio at 10.7 MHz
- Pin-for-Pin Replacement for MC1356P, LM1841, SN76669

FEATURING improved detector temperature stability, the Type ULN-2136A F-M, I-F amplifier/limiter and quadrature detector is used wherever AFC stability and off-station noise are important considerations. These devices consist of a three-stage I-F amplifier/limiter, a quadrature F-M detector, an emitter-follower audio output stage, and a regulated power supply capable of furnishing up to 20 mA to external circuitry. Except for the voltage regulator, the Type ULN-2136A is similar to the original Type ULN-2111A amplifier/limiter and detector.

The Type ULN-2136A is housed in a standard 14-pin dual in-line plastic 'A' package.

A-M Rejection	AMR	1	3	$V_{in} = 10\text{ mV}_{rms}$	—	40	—	dB	2

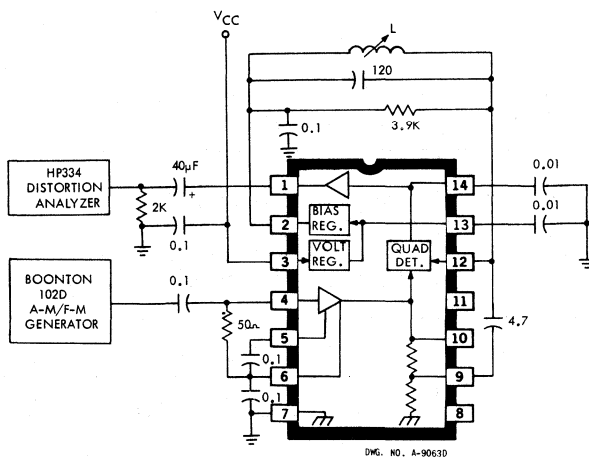

NOTES:

- The input limiting threshold is the F-M input voltage for a recovered audio output which is 3 dB less than the recovered audio output for an F-M input voltage of 200 mV $_{rms}$.
- The amplitude modulation rejection is determined by: $AMR_{dB} = 20 \log \frac{V_{out} \text{ for } 100\% \text{ F-M } V_{in}}{V_{out} \text{ for } 30\% \text{ A-M } V_{in}}$

TEST FIGURE 4

GENERAL DESIGN NOTES

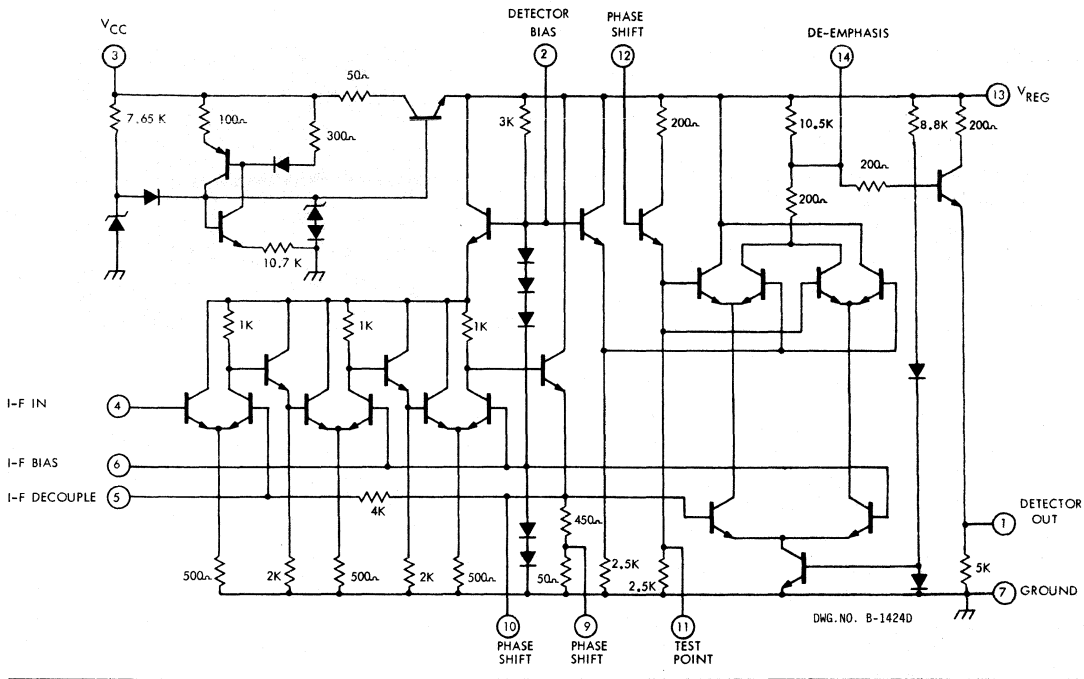

- Phase shift network is aligned by applying F-M signal through decoupling network to pin 4 ($V_4 = 5 \text{ mV}_{\text{rms}}$). Tune for maximum recovered audio at pin 1 or maximum I-F voltage at pin 11.
- A d-c path of less than 100Ω must be provided between pins 2 and 12. No other biasing provisions are required.
- A d-c path of less than 300Ω must be provided between pins 4 and 6. No other biasing provisions are required.
- The maximum a-c load current can be increased by adding an external resistor between pin 1 and ground. The minimum value for this resistor is 800Ω , giving a maximum load current of $4 \text{ mA}_{\text{rms}}$.
- All decoupling capacitors should be of the ceramic type with minimum inductance at the operating frequency.
- Decoupling capacitor leads at pins 2, 5, and 6 should be as short as possible.
- Keep appropriate distance between the input (pin 4 and the input network) and the phase shift network (pins 9, 10, and 12, and the phase shift inductor).
- If a high impedance power supply is used (voltage dropping resistor), decouple pin 13 for the lowest audio frequency.
- The linear detection mode (low signal level at pin 12), as shown, is preferred for communications and other commercial applications, due to the preservation of the tuned circuit bandwidth and better rejection of Gaussian noise. The combination of coupling capacitor (C_2) and I-F amplifier output (pin 9) was chosen for optimum quieting. The bandwidth of the phase shift network (peak separation) is primarily defined by the Damping resistor (R). A higher value resistor will decrease bandwidth, increase the recovered audio output, reduce the capture ratio, and increase harmonic distortion.
- The switching detection mode (high signal level at pin 12) features a greater linear range, increased insensitivity to amplitude variations, and is recommended for AFC applications or where side responses must be avoided. Limiting in the quadrature detector will produce slightly more audio output, but will increase the noise bandwidth and degrade quieting.

SCHEMATIC

ULN-2204A A-M/F-M RADIO SYSTEM

FEATURES

- Low Harmonic Distortion
- Wide Operating Voltage Range
- Low Power Drain
- D-C A-M/F-M Switching
- 30 μ V Limiting Threshold
- Excellent A-M Rejection
- Interchangeable With HA12402, TA7613, TDA1083, U417B

PROVIDING ALL radio functions except VHF tuning, Type ULN-2204A A-M/F-M radio system excels in low-cost applications requiring a minimal parts count and high performance.

In the A-M mode of operation, the device is a complete single-conversion superheterodyne broadcast or shortwave receiver with AGC and peak envelope detection. In the F-M mode, Type ULN-2204A operates as a high-gain I-F amplifier/limiter and phase-shift detector. A simple d-c switch is used to change mode of operation.

A single external capacitor at pin 16 provides the A-M AGC time constant, the F-M AFC time constant, and R-F decoupling. A single resistor at the same pin will adjust the A-M gain for optimal system performance.

The audio power amplifier will work into any speaker load of 8 Ω or greater. Class B operation of the audio power amplifier yields high efficiency at rated output with very low quiescent power drain. The amplifier exhibits little crossover distortion. Its output impedance is significantly less than one ohm.

Type ULN-2204A will work with a wide range of supply voltages, and is suitable for use in a-c powered table radios and in battery-powered (6 or 9 V) portable radios.

This system will operate at supply voltages as low as 2 V at reduced volume without significant increase in distortion. Brown-outs or weak batteries need no longer be a major concern.

Type ULN-2204A is housed in a 16-pin dual in-line plastic package with a copper lead frame that eliminates many decoupling problems and allows maximum power dissipation.

ULN-2204A VARIATIONS FOR OPTIMAL SYSTEM PERFORMANCE

The receiver system's performance can be kept within tighter performance limits by matching bias groupings and appropriate external resistors (R_8 and R_{16}). With proper matching of parts and lots, consistent device performance can be obtained. Bias groups for Type ULN-2204A are shown in the table below. There are three selections for each mode of operation and nine possible combinations.

Sprague Electric Company recommends that customers do not specify particular selections except in unusual circumstances. All parts manufactured with Sprague part numbers are branded with appropriate part-number suffixes. Any shipment to a customer will consist of parts from a single selection (single suffix).

The first digit of the suffix (the "3" in ULN-2204A-31) refers to F-M performance. It indicates F-M gain and pin 16 output voltage as functions of the pin 16 load resistance. (See graph on next page.)

F-M circuit stability is inversely related to gain or sensitivity and is affected by source and load impedances, decoupling, and printed wiring board layout. After an optimal F-M I-F gain is determined for a particular circuit design, that gain can be attained by matching the part-number suffix and the pin 16 load.

In addition, some system designs derive the F-M tuner supply, tuner bias, or AFC voltage from pin 16 output of Type ULN-2204A. For example, if the tuner design requires 2.4 V at 2.0 mA (an equivalent R_{16} of 1200Ω), the graph below indicates a Type ULN-2204A-1X is required. A -2X or -3X device could also be used by paralleling the equivalent 1200Ω tuner load with a fixed resistance for an 830Ω load or a 520Ω load, respectively. For AFC applications, note that as frequency increases, V_{16} voltage decreases. The amount of change is a factor of load impedance, detector coil characteristics, and part grouping.

In A-M operation, stability is seldom a problem. However, large-signal overload can be optimized (to typically 30 mV) by matching the particular part group with an appropriate load resistor at pin 8. The A-M grouping of a device is identified by the second digit of the part-number suffix (the "1" in ULN-2204A-31).

- For -X1, R_8 should be ∞ .
- For -X2, R_8 should be 47 k Ω .
- For -X3, R_8 should be 33 k Ω .

Additional loading may raise the overload point slightly, but AGC and sensitivity will be compromised. For any fixed value of R_8 , -X3 parts will exhibit slightly higher A-M gain, while -X1 parts will have slightly lower A-M gain.

TYPICAL F-M I-F GAIN CHARACTERISTIC

DWG. NO. A-11.354

TYPICAL APPLICATION

An A-M/F-M radio using the ULN-2204A receiver system, designed for a usable F-M sensitivity of about $4 \mu\text{V}$ and an A-M sensitivity of $350 \mu\text{V/m}$, appears on the next page.

The two-stage F-M tuner is operated at about 4 V. Reducing the pin 16 voltage to 1.8 V (by changing R_{16}) reduces interstation noise and the F-M I-F gain. An inductor at pin 12 (L6) prevents the wide-band audio amplifier from

radiating R-F noise in the A-M spectrum.

The tuning indicator below may be added to the radio circuit to provide an LED indication when the received signal strength exceeds $7 \mu\text{V}$ in the F-M mode or $700 \mu\text{V/m}$ in the A-M mode. The tuning indicator circuit reduces the I-F gain by about 2 dB. The sensitivity may be adjusted by changing the value of C1 or C2.

SCHEMATIC

ULN-2240A A-M/F-M SIGNAL PROCESSOR

FEATURES

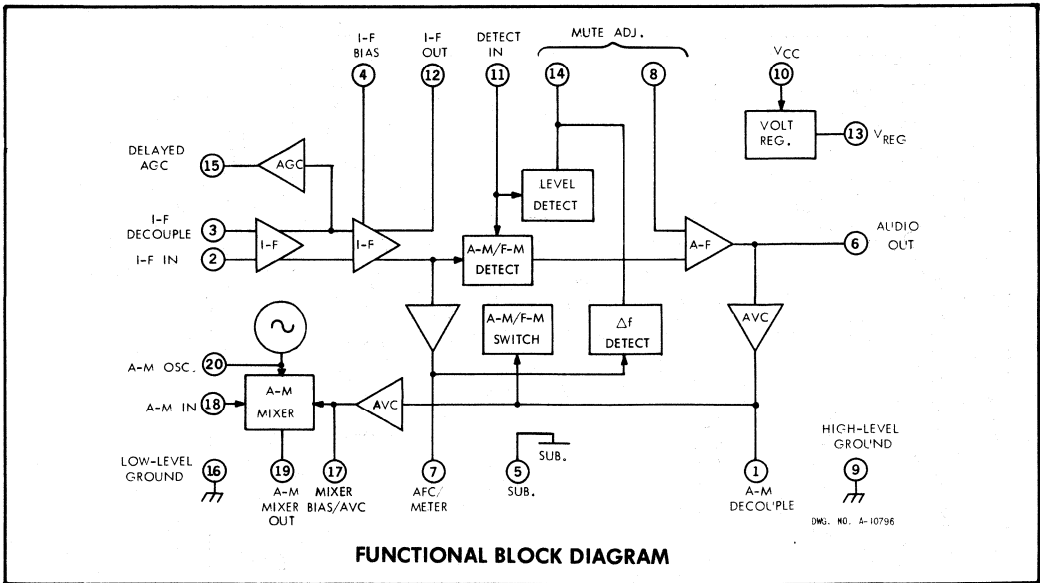

- 12 μ V Limiting Threshold
- Tuning-Error and Signal-Level Muting
- Zero-Tune Meter Drive
- Balanced A-M Mixer
- 5 μ V A-M Sensitivity
- D-C Mode Switching
- Internal Voltage Regulator
- Meets Dolby® Noise Requirements
- 20-Pin Dual In-Line Plastic Package

PREMIUM PERFORMANCE features such as delayed AGC for the R-F stage, an AFC drive circuit, interstation (signal level) muting, and off-channel (tuning error) muting, are offered by Type ULN-2240A.

The signal processor combines F-M I-F receiver functions and all A-M radio functions in a single monolithic integrated circuit. The system's audio output stage uses low-noise biasing that meets Dolby® receiver noise requirements.

®Registered Trademark, Dolby Laboratories, Inc.

The A-M mixer is a balanced low-current analog multiplier with very low local oscillator feed-through, high I-F rejection and freedom from spurious responses. It can be used in the long, medium, and shortwave bands.

A balanced four-stage differential I-F amplifier is used in both A-M and F-M modes. It gives maximum gain without common-mode interference and noise. The delayed AGC output (pin 15) can be used for a discrete R-F stage or for stereo switching logic.

In the F-M mode of operation, the detector is a high-level, four-quadrant analog multiplier. In the A-M mode, the detector is operated as a balanced peak detector.

The low-level audio output is common to both operating modes and can be used to drive an audio

power amplifier (ULN-3701Z) or stereo decoder (ULN-3810A).

A-M gain is controlled with AVC to the I-F and delayed AVC to the mixer. Switching between modes is done with a single-pole d-c switch.

Type ULN-2240A signal processor excels in signal-seeking or scanning applications. False triggers on adjacent channels or strong mistuned signals are eliminated since off-tune mute voltage changes are more pronounced than the usual signal-level voltage changes. In standard F-M radio applications, tuning-error muting eliminates the low-frequency "thump" and noise-tail associated with tuning through a strong signal.

Internal voltage regulators assure consistent performance with wide variations in supply voltage (8.5 to 16 V) and temperature.

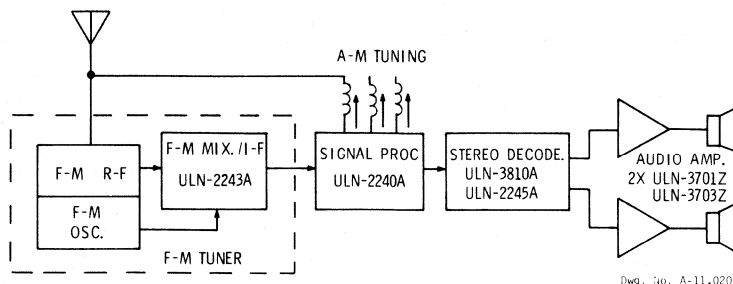

ABSOLUTE MAXIMUM RATINGS

F-M TUNING-ERROR DETECTOR RESPONSE

ULN-2240A A-M/F-M SIGNAL PROCESSOR

SCHEMATIC

ULN-2241A A-M/F-M SIGNAL PROCESSING SYSTEM

FEATURES

- Low External Parts Count
- D-C A-M/F-M Switching
- 12 μ V Limiting Threshold
- 5 μ V A-M Sensitivity
- Low Harmonic Distortion
- Balanced A-M Mixer
- Internal Regulator
- 16-Pin Dual In-Line Plastic Package

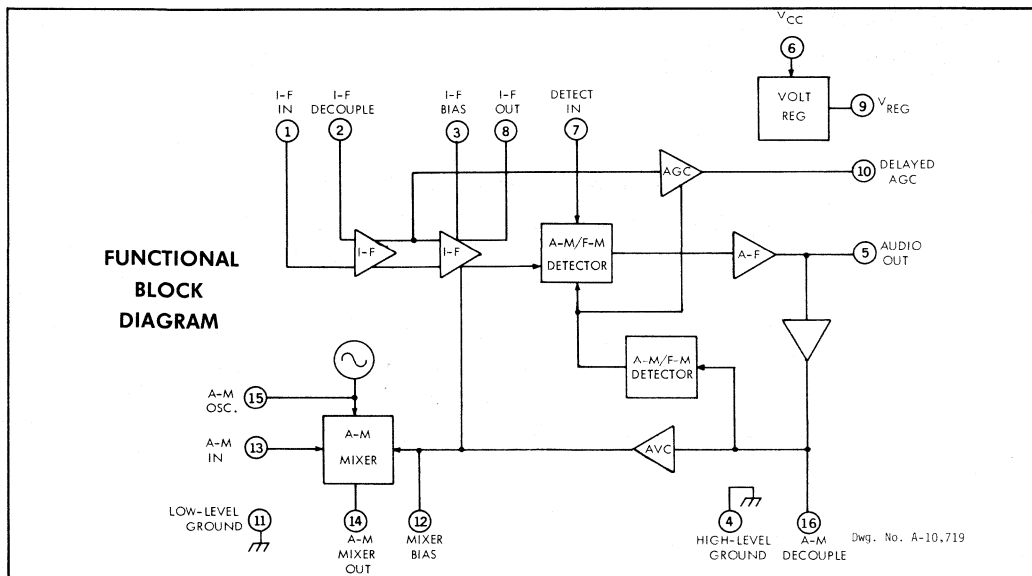

THIS SIGNAL PROCESSING SYSTEM was designed with careful attention to the total system costs and performance requirements of modern automotive and high-quality home entertainment broadcast receivers. All F-M I-F functions and all A-M functions are provided by Sprague Type ULN-2241A with a minimal external parts count.

The use of an analog multiplier as a balanced low-current mixer results in freedom from spurious responses and gives the system high tweed rejection, low feedthrough (I-F rejection), and low noise, as well as very low local oscillator feedthrough.

6

(Continued on next page)

Although primarily intended for use in A-M broadcast reception, the A-M mixer is also suitable for use at long-wave or shortwave frequencies. Delayed AGC is available for use with an optional discrete R-F stage.

A fully-balanced, four stage differential I-F amplifier gives maximum gain with freedom from interference and noise. It is used in both the A-M and F-M modes of operation with approximately 82 dB gain in the F-M mode and controlled AGC gain of 26 dB in the A-M mode.

The detector in the F-M mode is a four-quadrant analog multiplier operating in the high-level injection mode. Again, interference and noise are rejected through the use of balanced current-mirror outputs.

The delayed AGC output provides a d-c voltage for control of signal level-related func-

tions. The detector is biased to a no-signal value of 4.7 V, that approaches 0 V with increasing signal input.

In the A-M mode of operation, the detector is configured as a balanced peak detector resulting in low audio distortion. A-M gain control is achieved with AVC applied to the I-F and with delayed AVC applied to the mixer.

Switching between modes can be accomplished with a simple single-pole d-c switch. The common low-level audio output can be used to drive any suitable audio power amplifier or stereo decoder (e.g. Sprague Types ULN-3701Z and ULN-3810A, respectively).

Internal voltage regulators and bias supplies assure premium performance despite variations in external supply voltage (8.5 to 16 V) or temperature (-20°C to +85°C). Separate ground leads minimize possible decoupling problems.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}	18 V
Regulator Current, I_{REG}	5.0 mA
Package Power Dissipation, P_D (see note)	640 mW
Operating Temperature Range, T_A	-20°C to +85°C
Storage Temperature Range, T_S	-65°C to +150°C

NOTE: P_D is derated at the rate of 8.0 mW/°C above $T_A = +70°C$.

ULN-2242A/TDA1090 A-M/F-M SIGNAL PROCESSING SYSTEM

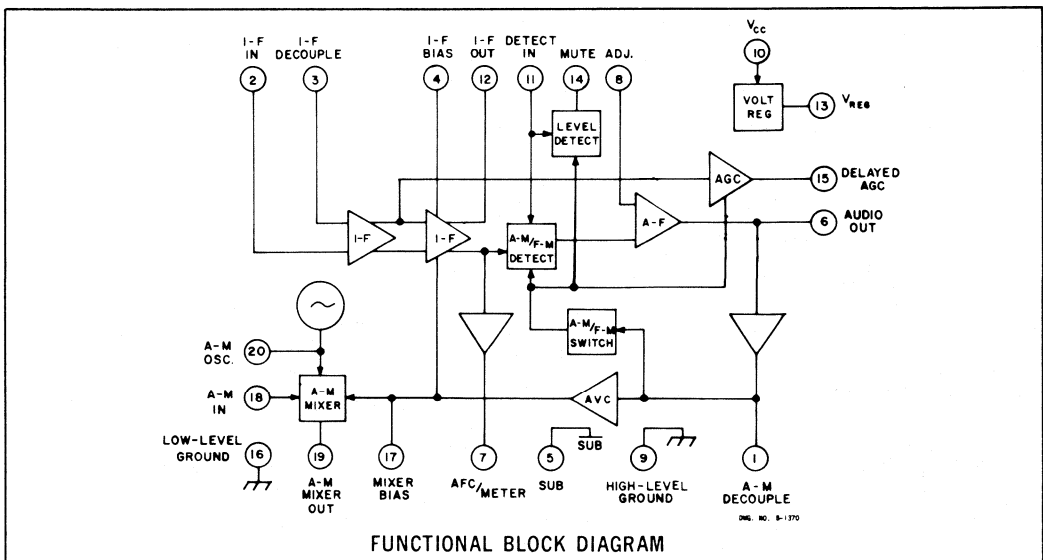

FEATURES

- Low External Parts Count
- D-C A-M/F-M Switching
- 12 μ V Limiting Threshold
- 5 μ V A-M Sensitivity
- Low Harmonic Distortion
- Balanced A-M Mixer
- Meter Drive
- Internal Regulator
- Self-Contained Muting (Squelch)

SUBSTANTIAL SIMPLIFICATION of A-M/F-M receiver design is possible with Type ULN-2242A signal processing system with improved system performance and a minimal external parts count. All F-M I-F functions and all A-M functions are provided by this monolithic integrated circuit.

The use of an analog multiplier as a balanced mixer results in freedom from spurious responses, high tweet rejection, low feedthrough (I-F rejection), and low noise, as well as very low local oscillator radiation.

Although primarily intended for use in A-M broadcast reception, the A-M mixer is also suitable for use at long-wave or short-wave frequencies. Delayed AGC is available for use with an optional, discrete R-F stage.

A fully-balanced, four-stage differential I-F amplifier gives maximum gain with freedom from common-mode signals. It is used in both the A-M and F-M modes of operation with approximately 82 dB gain in the F-M mode and controlled AGC gain of 26 to 82 dB in the A-M mode.

The detector in the F-M mode is a four-quadrant analog multiplier operating in the high-level injection mode. Interference and noise are rejected. AFC and meter-drive signals (pin 7) are generated for use with any reference voltage between V_{CC} and ground, with AFC gain determined by the choice of load resistor.

The mute and delayed AGC outputs provide d-c voltages for control of signal-level-related functions. Both detectors are biased to a no-signal value of

4.7 V and approach zero with increasing signal input.

In the A-M mode of operation, the detector is configured as a balanced peak detector for low audio distortion. A-M gain control is achieved with AVC applied to the I-F and delayed AVC applied to the mixer.

Switching between modes can be accomplished with a simple single-pole d-c switch. The common low-level audio output can be used to drive any suitable audio power amplifier or stereo decoder (Sprague Type ULN-3703Z and ULN-3810A, respectively).

Internal voltage regulators and bias supplies assure premium performance despite variations in external supply voltage (8.5 to 16 V) or temperature (-20°C to $+85^{\circ}\text{C}$). Separate ground leads minimize possible decoupling problems.

Type ULN-2242A A-M/F-M signal processing system is housed in a 20-pin dual in-line plastic package. Parts are marked with the Sprague Electric part number (ULN-2242A) unless the Pro-Electron marking (TDA1090) is requested.

ULN-2243A MIXER/I-F FOR F-M RADIO APPLICATIONS

FEATURES

- Doubly-Balanced Linear Mixer
- Very-High I-F Rejection
- 32 mmho (millisiemens) Conversion Gain at 100 MHz
- 330 Ω I-F Input/Output Impedance
- 46 dB I-F Gain at 10.7 MHz
- AGC Detector for MOSFET R-F Stage
- Low External Component Count
- 16-Pin Dual In-Line Plastic Package

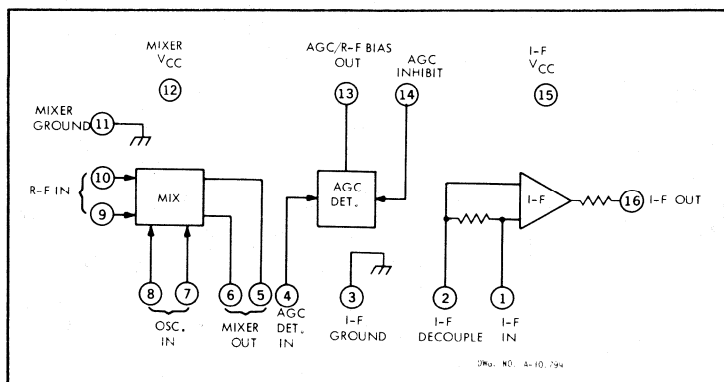

PROVIDING AN IMPORTANT basic building block for use in F-M radio applications, the ULN-2243A mixer/I-F minimizes spurious responses from strong off-channel signals while providing an excellent noise figure, maximum desired signal gain and very-high I-F rejection.

The linear fully-balanced mixer is an analog multiplier which will outperform discrete mixers. The low local oscillator and received frequency feed-through greatly reduces the outband rejection requirements.

I-F gain is furnished by a 2-stage amplifier with the

gain set at typically 46 dB. Input and output impedances are 330 Ω to allow the use of inexpensive ceramic filter coupling.

Both bias and AGC voltages, for use with a dual-gate MOSFET R-F stage, are provided by the wide-band AGC detector. An inhibit connection (pin 14) allows for maximum wide-band R-F gain up to the signal level at which the AGC action of the following narrow-band I-F amplifier/limiter and detector (ULN-3840A or ULN-3889A) starts operating. For strong on-channel signal levels, the wide-band R-F gain is determined by the strongest in-band signal.

APPLICATION INFORMATION

The ULN-2243A mixer/I-F performs a variety of functions especially suitable for automobile radios and other receivers required to handle an extremely wide range of input signal levels. It has been designed to use some of the inherent advantages of an integrated circuit to improve F-M front end designs instead of simply attempting to replace discrete devices with integrated ones. This allows the tuner designer to select an R-F amplifier and oscillator circuit best-suited to the particular application.

The double-balanced mixer (Q_1 through Q_7 , Figure 4) is internally biased so that all inputs can be capacitively coupled. This mixer possesses several advantages over discrete devices.:

1. High inherent I-F rejection,
2. Good I-F/2 rejection,
3. Less oscillator drive required than with FET mixers,
4. Low oscillator feed through,
5. Less oscillator modulation with large signals, and
6. Balanced inputs eliminate ground loops which can cause stray coupling paths in discrete mixers.

Note that the oscillator input can be to either pin 7 or pin 8, the R-F input to either pin 9 or pin 10, to suit the circuit board layout.

The I-F transformer used with the ULN-2243A has been made to utilize both outputs of the mixer and was wound on a bobbin type coil form (Toko Type 10EZ) to maintain close couplings between windings. This eliminates the high cost of a bifilar-wound transformer. A conventional tuner with two R-F tuned circuits will typically have an I-F/2 rejection of at least 100 dB and a low noise figure. A single-ended output from either pin 5 or pin 6 could have been used (with degradation in rejection and noise figure) with the remaining output connected directly to V_{CC} .

The limiting amplifier consists of transistors Q_8 through Q_{15} and has about 46 dB of gain at 10.7 MHz. The input and output impedances are 330 Ω for easy ceramic filter connection. The differential input again avoids the low-impedance ground loops associated with discrete common emitter I-F input stages. This makes the construction of a stable amplifier much easier. Since the I-F amplifier is an independent element, various combinations of filters before and after the amplifier are possible.

The relatively high gain of the ULN-2243A I-F amplifier allows the circuit designer to use surface wave or cascaded ceramic filters between it and the

amplifier/detector integrated circuit. The resistive matching pad between ceramic filter elements prevents interactions which can cause undesirable group delay variations.

The AGC detector between pins 4, 13, and 14 has some unique properties which can be used in different ways. If the R-F amplifier is a dual-gate MOSFET (Figure 5), only the minimum in external discrete components is required.

The AGC detector input (pin 4) is connected through a small coupling capacitor to the mixer output. Internally is an R-F peak detector (Q_{20}) and d-c amplifier (Q_{21} through Q_{24}). If the AGC inhibit voltage (pin 14) is greater than approximately 1 volt, the AGC output voltage (pin 13) will change from typically 7.7 V with no applied signal to 0.5 V if an R-F signal of more than 150 mV is present at the input. This allows the tuner designer several design possibilities:

1. Connecting the AGC inhibit to the meter drive output of the limiter/detector (pin 13, ULN-3840A or ULN-3889A), the R-F stage will be AGC'd when tuned to a strong signal or when tuned to a weak signal with a strong adjacent channel signal, or
2. Pin 14 can be connected to a fixed bias voltage (typically +5 V). The R-F stage would then be AGC'd by any signal falling within the mixer coil bandpass, or
3. Combinations of fixed bias and signal-dependent levels (AFC, deviation mute, or delayed AGC) will then allow almost an unlimited number of AGC possibilities.

The AGC characteristics of the ULN-2243A mixer/I-F can be used with many other types of R-F amplifier. By adding a discrete transistor amplifier at pin 13, the AGC signal can be inverted and/or amplified to drive a bipolar R-F stage into forward AGC or to drive a PIN diode attenuator. A simplified graphical illustration of the most common AGC characteristic is shown in Figure 6.

A typical application of the ULN-2243A mixer/I-F in an F-M tuner was shown in Figure 5. Note that an output from the high-frequency oscillator has been provided with no increase in cost. This is one advantage to having the oscillator external to the integrated circuit. Also, by not including the R-F amplifier within the device, a wide variety of R-F amplifiers can be used depending on the wishes of the designer or the particular constraints of the application.

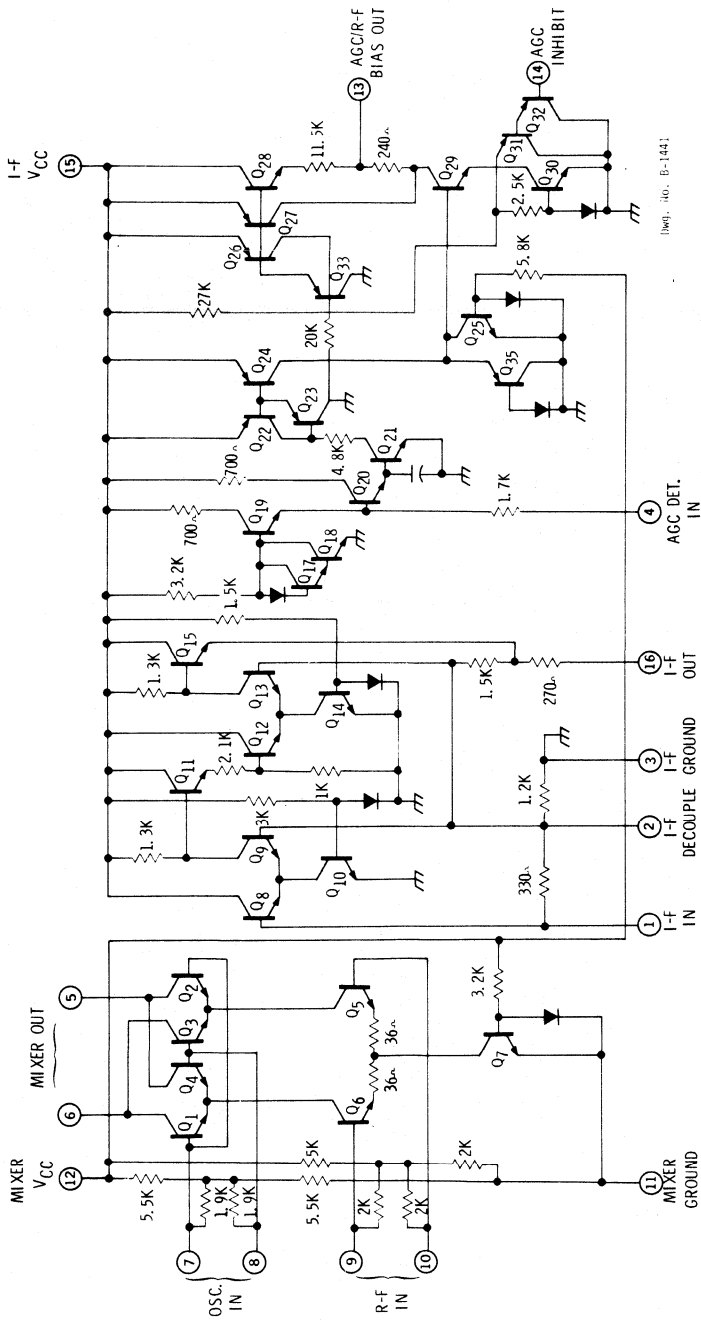

Figure 4
SCHEMATIC

ULN-2245A PHASE-LOCKED LOOP STEREO DECODER

FEATURES

- Excellent Channel Separation
- Low Total Harmonic Distortion
- Power Supply Decoupling
- VCO Frequency Stable
- High Gain
- Operating Voltage — 10.5 to 16 V
- 70 dB SCA Rejection
- 16-Pin Dual In-Line Plastic Package

STEREO multiplexed F-M signals are decoded by Sprague Type ULN-2245A without the use of tuning coils required for operation of previous stereo processors in F-M receivers.

The monolithic integrated circuit creates a signal in phase with and exactly twice the frequency of the 19 kHz pilot signal provided by stereo transmissions. This 38 kHz subcarrier is used to demodulate F-M stereo broadcast information.

The stereo portion of the circuit is disabled during reception of weak signals or monaural broadcasts.

Additional features include emitter-follower outputs for driving low impedance loads and a voltage regulator for increased stability. Type ULN-2245A is suitable for both line-operated and automotive

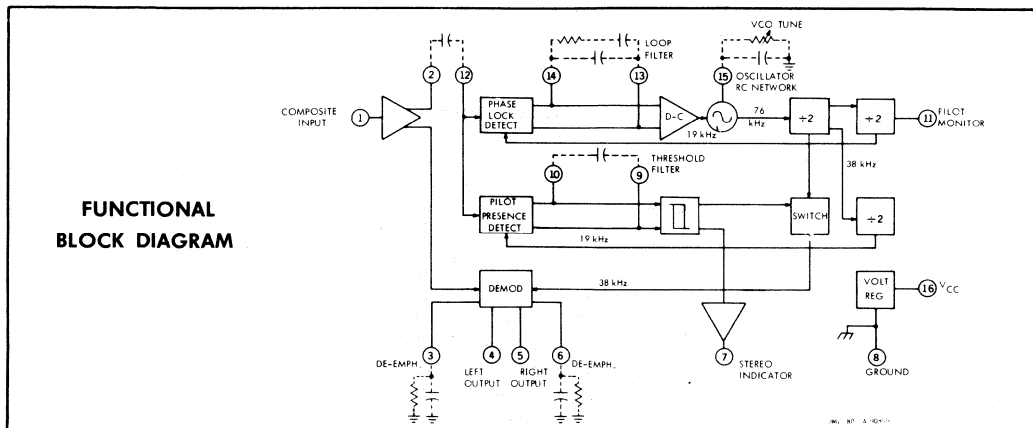

F-M stereo receivers.

Except for a reduced audio output impedance, Type ULN-2245A is interchangeable with Type ULN-2244A, μ A758, LM1800, and MC1311.

SCHEMATIC

ULN-2249A A-M RADIO SYSTEM FOR AUTOMOTIVE APPLICATIONS

FEATURES

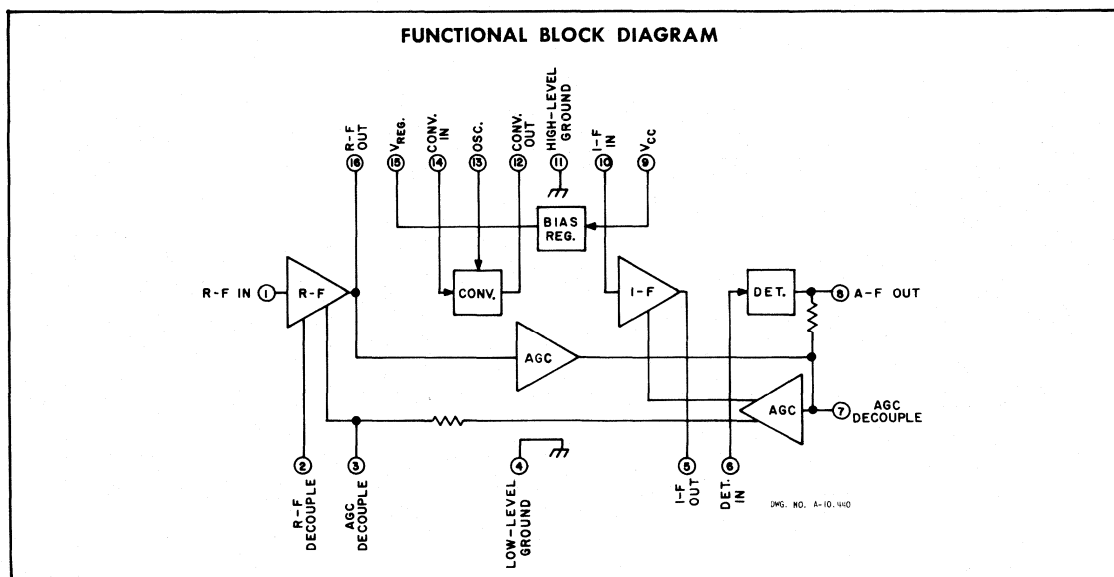

- Low External Parts Count
- Internal Bias Regulator
- High AGC Ratio
- Low Distortion
- Good Sensitivity
- Direct Replacement for HA1199

SPECIFICALLY DESIGNED for automotive A-M radio applications, the ULN-2249A A-M radio system consists of an R-F amplifier, converter, I-F amplifier, A-M detector, AGC amplifier, and bias voltage regulator. The low-level audio output can be used to drive a standard audio power amplifier, such as the Sprague Type ULN-3701Z.

Of particular significance in automotive applications is the ability of this integrated circuit to perform

satisfactorily under wide variations in signal level. A typical AGC ratio of 63 dB, a usable sensitivity of approximately $8 \mu\text{V}$, and an overload point in excess of 3 V, all contribute to the excellent performance of these devices under real conditions. Moreover, the ULN-2249A A-M radio system is rated for operation over the broad supply voltage range of 10.8 V to 15.6 V although the self-contained local oscillator will continue to function at much lower voltages.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}	18 V

ULX-3804A A-M/F-M SIGNAL PROCESSOR

FEATURES

- Good Sensitivity
- Low Harmonic Distortion
- Wide Operating Voltage Range
- Excellent A-M Rejection
- Low Power Drain
- D-C A-M/F-M Switching
- 30 μ V Limiting Threshold
- 16-Pin Dual In-Line Plastic Package

DESIGNED for use in battery-powered portable radios or line-driven table radios, Type ULX-3804A works well in low-cost applications requiring high performance with few external parts. An entire A-M/F-M stereo receiver can be built with a Type ULX-3804A, a Type ULN-3809A stereo decoder, and two Type ULN-2283B audio amplifiers, for operation over a supply range of 4.5 to 12 V.

The signal processor includes the A-M oscillator and mixer and the A-M/F-M I-F amplifier and detector from the popular radio system, Sprague Type ULN-2204A. Radio designs using Type ULN-2204A can be revised for greater power output or for stereo operation (without reworking the printed wiring board layout) by replacement of Type ULN-2204A with Type ULX-3804A and addition of appropriate stereo decoders and audio power amplifiers.

In the A-M mode of operation, Type ULX-3804A provides all high-frequency circuitry, including AGC and envelope peak detection, for a single-conversion superheterodyne broadcast or shortwave receiver. In the F-M mode, the signal processor operates as a high-gain amplifier/limiter and phase-shift detector. A d-c switch is used to change modes.

A single external capacitor at pin 16 provides the A-M AGC time constant, the F-M AFC time constant, and R-F decoupling.

ABSOLUTE MAXIMUM RATINGS

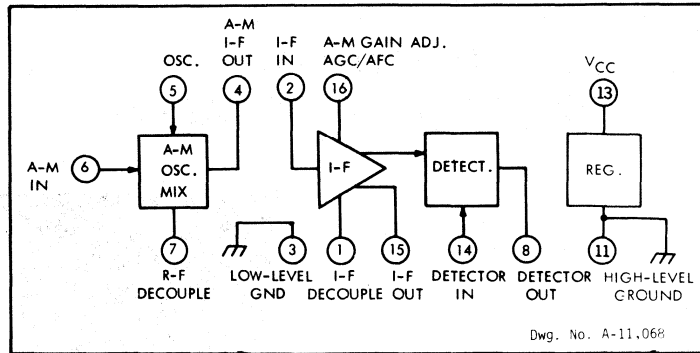

Supply Voltage, V_{CC}	16 V

Device Classification and Design Considerations

The A-M/F-M receiver system's operation can be kept within tighter performance limits by matching bias groupings and appropriate external resistors (R8 and R16). With proper matching of parts and lots, consistent device performance can be obtained. The groupings, shown in the table below, are based on A-M and F-M operation. There are three selections for each mode and nine possible combinations:

PIN 16 OUTPUT VOLTAGE, V_{16}

A-M Operation	Complete Part Number Including Suffix		
	F-M Operation		
	2.20 — 2.65 V	2.55 — 3.05 V	2.95 — 3.40 V
1.40 — 1.75 V	ULN-3804A-11	ULN-3804A-21	ULN-3804A-31
1.65 — 2.00 V	ULN-3804A-12	ULN-3804A-22	ULN-3804A-32
1.90 — 2.25 V	ULN-3804A-13	ULN-3804A-23	ULN-3804A-33

Sprague recommends that customers not specify particular selections except in unusual circumstances. All parts manufactured with the Sprague part number will be marked with the complete number, including the appropriate suffix. In addition, any one shipment to a customer will consist of a single selection (single suffix).

The first digit of the suffix (such as the '3' in '-31') applies to F-M performance. It indicates the F-M gain and pin 16 output voltage as functions of the pin 16 load resistance, as shown in the graph on the next page.

F-M circuit stability is inversely related to gain or sensitivity and is also affected by source and load impedances, decoupling, and printed wiring board layout. After an optimal F-M I-F gain is determined for a particular circuit design, the gain can be controlled with proper matching of the suffix and the pin 16 load.

Design Considerations (Continued)

In addition, certain system designs derive the F-M tuner supply, tuner bias, or AFC voltage at pin 16 of Type ULN-3804A. As an example, if the tuner design requires 2.4 V at 2.0 mA (an equivalent R16 of 1200Ω), Type ULN-3804A-1X is required. A -2X or -3X device can also be used by paralleling the equivalent 1200Ω tuner load with a fixed resistor to present an 830Ω load or a 520Ω load.

For AFC applications, note that as the frequency is increased, the V_{16} voltage will decrease. The amount of change is a function of load impedance, detector coil characteristics, and part grouping.

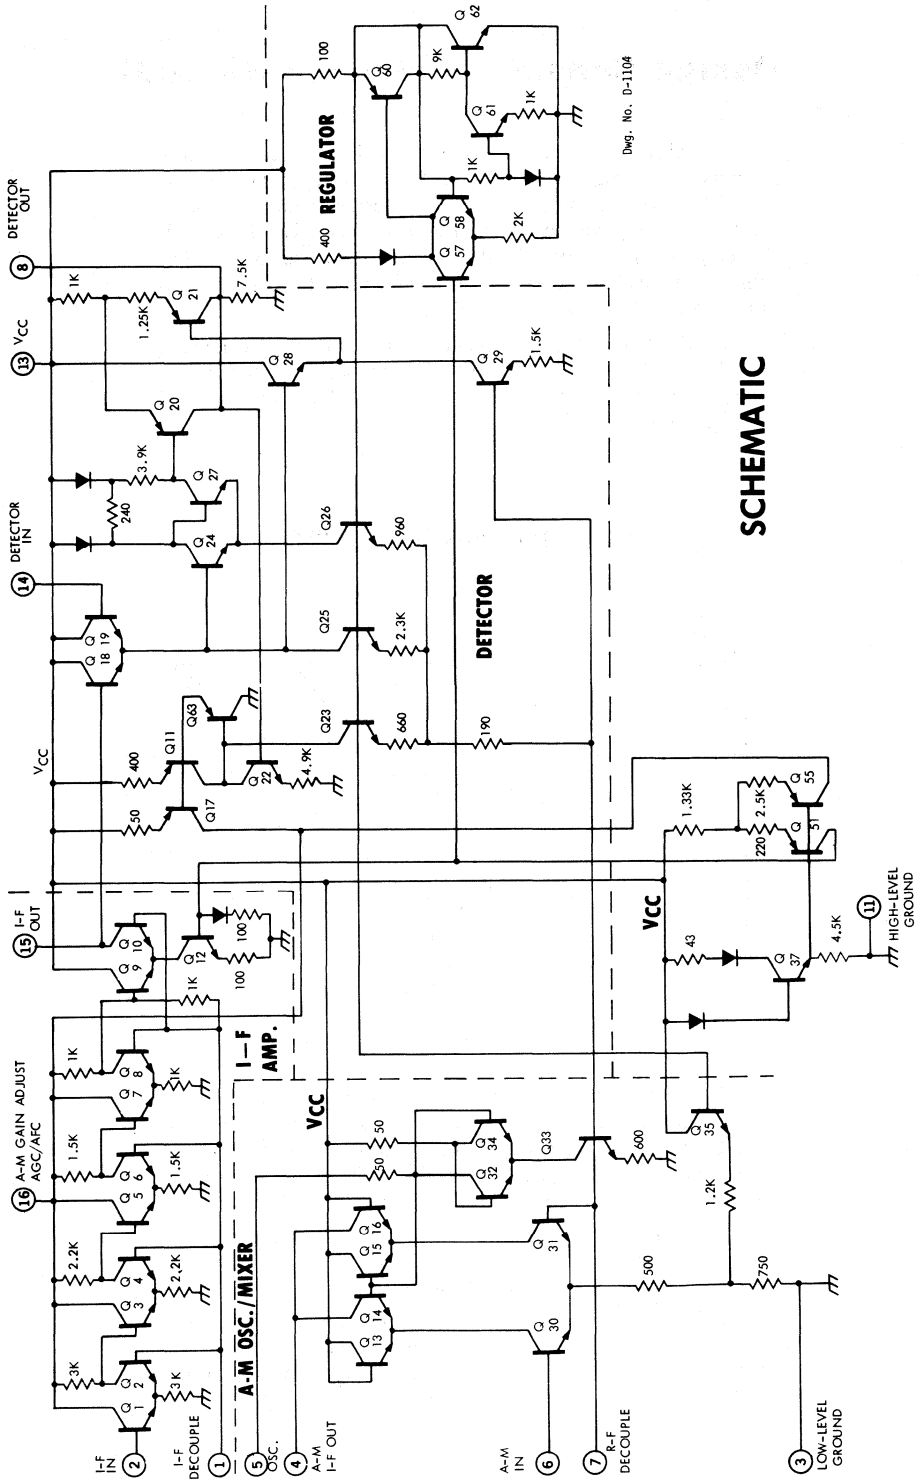

TYPICAL F-M I-F GAIN CHARACTERISTICS

Stability is seldom a problem with A-M operation. However, large-signal overload can be held to typically 30 mV by matching the particular part group with an appropriate load resistor at pin 8. The A-M grouping is identified by the second digit of the part number suffix (such as the "2" in "-32").

- For -X1, R8 should be an open circuit;
- for -X2, R8 should be 47 kΩ;
- for -X3, R8 should be 33 kΩ.

Additional loading may raise the overload point slightly, but AGC and sensitivity will be compromised. For any fixed value of R8, the -X3 parts will exhibit slightly higher A-M gain, the -X1 parts slightly lower A-M gain.

Desig. No. D-1104

SCHEMATIC

ULN-3809A PHASE-LOCKED LOOP STEREO DECODER

FEATURES

- Unity Voltage Gain
- I^2L and Ion Implant Technology
- Wide Dynamic Range
- Low Distortion
- Excellent Channel Separation
- No Tuning Coils
- Automatic Stereo/Mono Switching
- Stereo Indicator Lamp Driver
- Direct Replacement for MC1309
- 14-Pin Dual In-Line Plastic Package

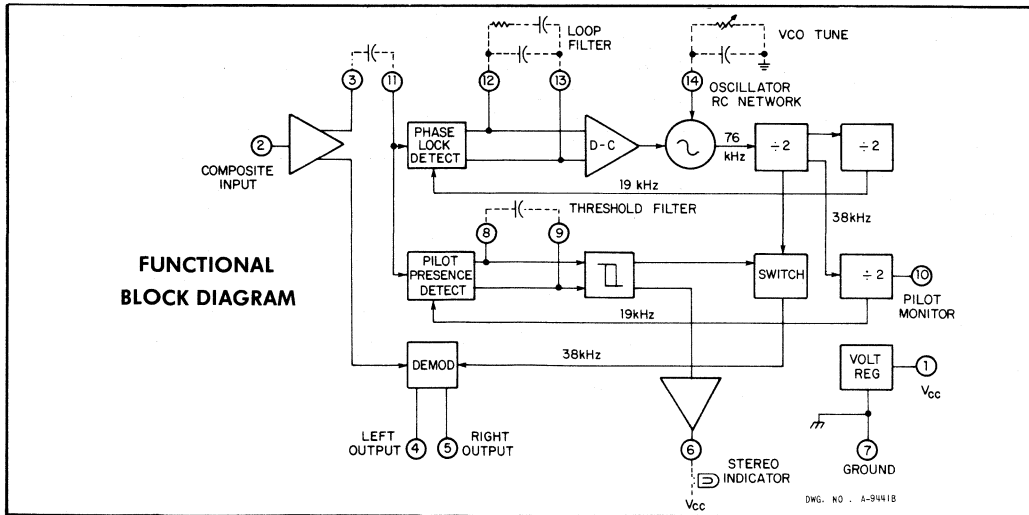

SPRAGUE Type ULN-3809A phase-locked loop decoder demodulates standard composite F-M stereo input signals within the range of 0.25 to 1.7 Vpp without the use of tuning coils.

Integrated circuit design allows tuning with a single resistive adjustment. The decoder automatically switches between stereo and monaural operation by detection and evaluation of the 19-kHz pilot carrier signal.

Type ULN-3809A exhibits 35 dB suppression of the 19-kHz pilot and 45 dB rejection of the regenerated 38-kHz subcarrier at demodulator output terminals. Stereo channel separation is typically 47 dB. With a composite input signal of 850 mV, total harmonic distortion for the unit is typically 0.06%.

Type ULN-3809A is designed to work within a range of supply voltages from 4.5 to 16 V.

ULX-3840A HIGH-PERFORMANCE A-M/F-M SIGNAL PROCESSING SYSTEM

FEATURES

- 12 μ V Limiting Threshold
- Tuning-Error/Level Muting
- Meter Drive
- Balanced A-M Mixer
- 5 μ V A-M Sensitivity
- D-C Mode Switching
- Internal Voltage Regulator
- Meets Dolby® Noise Requirements
- 20-Pin Dual In-Line Plastic Package

Dwg. No. A-11,462

IDEALLY SUITED FOR TOP-NOTCH

A-M/ F-M radios, Type ULX-3840A provides sophisticated operating features highly desired by the modern consumer at a price that allows it to be used in budget receivers.

A combination of inter-station (signal-level) muting and off-channel (tuning-error) muting is useful in signal-seeking or scanning applications. The circuit design eliminates annoying low-frequency thump and noise tail when the system is manually tuned through a strong signal.

Outputs are available for directly driving a peak reading meter and a zero-tune meter. The peak meter output also is useful in controlling external system functions, such as blending multiplexers, stereo decoders, noise blankers, or in providing positive-going AGC for the tuner.

All standard F-M I-F functions and all A-M functions are provided by this single monolithic integrated circuit. The low-level audio output stages have been designed to meet stringent Dolby® noise requirements.

The A-M mixer is a balanced low-current analog multiplier with very-low local oscillator feedthrough, high I-F rejection, and freedom from spurious responses. This mixer can be used in the long-wave, medium-wave, and shortwave bands.

A fully-balanced, four-stage differential I-F amplifier gives maximum gain with freedom from common mode signals. It is used in both the A-M and F-M modes of operation with approximately 82 dB of gain in the F-M mode and controlled AGC gain of 26 dB in the A-M mode.

The detector in the F-M mode is a four-quadrant analog multiplier operating in the high-level injection mode. Common mode signals are rejected through the use of balanced current-mirror outputs.

In the A-M mode of operation, the detector is configured as a balanced peak detector for low audio distortion. A-M gain control is achieved with AVC applied to the I-F and delayed AVC applied to the mixer.

The ULX prefix to the part number denotes an integrated circuit presently in development and undergoing engineering evaluation. If and when the device becomes a production item, the prefix will be changed to ULN. Sprague Electric assumes no obligation for future manufacture of any products presently in development unless such obligation is specifically undertaken in writing by authorized Sprague personnel.

ULX-3840A
HIGH-PERFORMANCE A-M/F-M SIGNAL PROCESSING SYSTEM

Switching between modes can be accomplished with a simple single-pole d-c switch. The common low-level audio output can be used to drive an audio power amplifier (Type ULN-3703Z) or stereo decoder (Type ULN-3810A).

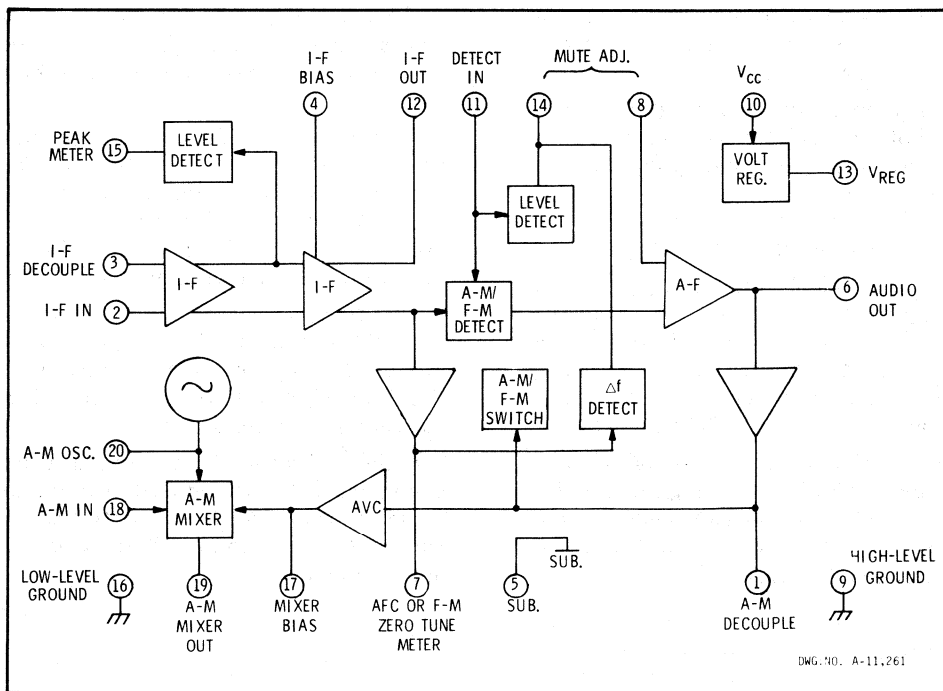

Internal voltage regulators and bias supplies assure premium performance despite variations in external supply voltage (8.5 to 16 V) or temperature (-20°C to +85°C). Separate ground leads minimize decoupling problems.

ULN-3859A F-M COMMUNICATIONS I-F SYSTEM

FEATURES

- Dual Conversion
- Low Current Drain
- Wide Operating Voltage Range
- High Sensitivity
- Replaces MC3359P
- 18-Pin Dual In-Line Plastic Package

THIS low-power, narrow-band F-M I-F system provides the second converter, second I-F, demodulator and squelch circuitry for communications and scanning receivers.

Type ULN-3859A's double-balanced mixer permits low-noise operation while eliminating spurious responses, effectively rejecting tweet and I-F feedthrough, and reducing local oscillator radiation. The mixer's high input impedance matches popular 10.7 MHz crystal filters while its output impedance matches most 455 kHz ceramic filters. Although designed for use with a 10.7 MHz first I-F and a 455 kHz second I-F, the mixer operates at other R-F or I-F input frequencies through 30 MHz.

A multi-stage 1 MHz differential amplifier/limiter following the second I-F filter operates as

a high gain stage with excellent common-mode rejection.

Audio is recovered by a quadrature F-M detector that requires only a single low-cost tuned circuit.

Type ULN-3859A has both a low-impedance emitter-follower audio output and an AFC output. Few external components are needed for operation with noise-activated or tone squelch.

This communications I-F system meets the stability requirements of many automotive applications, and also meets the low-power demands of portable radio design. Internal voltage regulators and bias supplies ensure stable performance despite variations in external supply voltage (4 to 9 V) or temperature (-20°C to $+85^{\circ}\text{C}$).

TEST CIRCUIT

Dwg. No. A-11,372

APPLICATION INFORMATION

1. In a typical application, with a 3.6 kΩ crystal filter source, Type ULN-3859A will give 23 dB conversion gain.

2. Because crystal filters are extremely sensitive to reactive loading, radio designers frequently have added a coil and/or capacitor at pin 18 to cancel the input reactance component. This practice is not required with Type ULN-3859A, since its input is designed to match typical 10.7 MHz crystal filters. However, if an external reactive component is used, it is important to adjust it for optimal passband shape and not simply to peak it for maximum sensitivity.

3. Pin 11 provides AFC. If AFC is not required, pin 11 should be grounded, or tied to pin 9 to double the available recovered audio.

4. Pin 10 may require an external resistor (2 kΩ minimum) to ground to prevent audio rectification with some capacitive loads.

ULN-3889A/TDA3189 I-F SYSTEM FOR F-M RECEIVER APPLICATIONS

FEATURES

- Tuning-Error Muting
- Improved A-M Rejection
- Signal-Level Muting
- Direct Tuning-Meter Drives
- Single Coil Tuning
- Isolated AFC Output
- Internal Voltage Regulator
- Programmable AGC Output
- Direct Replacement for CA3189E.
- 16-Pin Dual In-Line Plastic Package

EQUIPPED WITH FEATURES such as programmable delayed AGC for the R-F tuner, an AFC drive circuit, outputs for tuning meters and stereo switching logic, signal-level and tuning-error muting, Type ULN-3889A is a comprehensive F-M I-F system.

This monolithic integrated circuit excels in signal-seeking and scanning applications. False triggers on adjacent channels and strong mistuned signals are eliminated by its off-tune muting, which exhibits a greater voltage change than that of commonly used signal-level muting. In standard F-M radio applications, tuning-error muting eliminates the low-frequency thump and the noise tail associated with tuning through a strong signal.

Three balanced stages of I-F amplification and limiting, each with its own level detector, and a double-balanced quadrature detector give the system high gain and effective common-mode rejection.

In automotive and communications applications,

low-level injection (with the mute detector disabled) permits operation of the F-M detector as an analog multiplier. This mode of operation dramatically reduces off-station noise without sacrificing gain.

The I-F system's audio amplifier, with muting or squelch, can directly drive an audio power amplifier (such as Sprague Type ULN-3703Z) or a stereo decoder (such as Sprague Type ULN-3810A).

An internal voltage regulator and bias supply ensures reliable operation with supply variation between 8.5 and 16 V and temperature variations between -20°C and $+85^{\circ}\text{C}$.

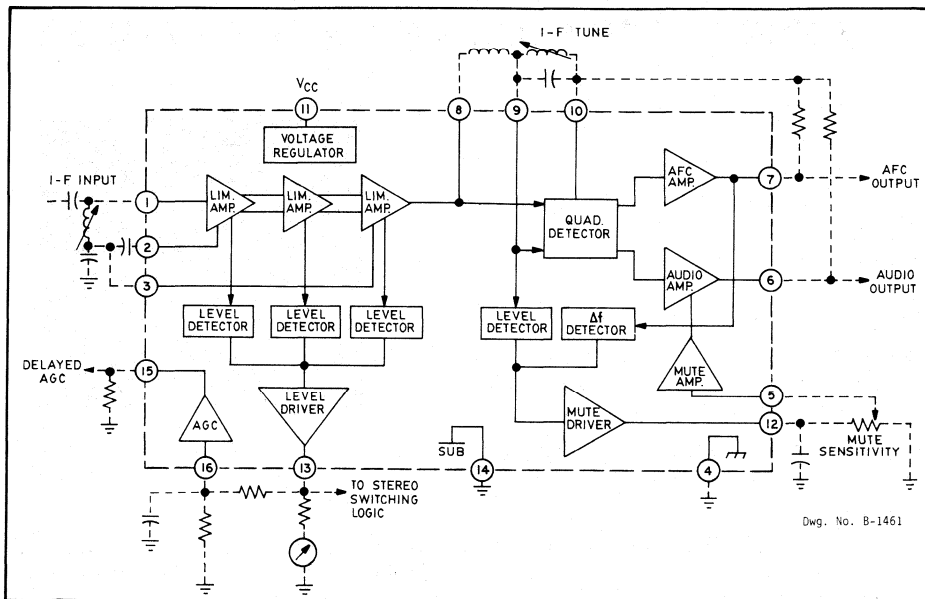

ABSOLUTE MAXIMUM RATINGS

PHASE SHIFT NETWORKS

DWG. NO. A-9438A

Figure 2A

L is selected to resonate with C at 10.7 MHz and has an unloaded Q of approximately 75. R (approximately 3.9 k Ω) is selected for a voltage across L of 160 mV with an input signal of 100 μ V.

Dwg. No. A-9439B

Figure 2B

L is selected to resonate with C at 10.7 MHz and has an unloaded Q of approximately 75. R (approximately 8.2 k Ω) is selected for a voltage across L_p of 150 mV with an input signal of 100 μ V; kQ, or per cent of critical coupling (approximately 70%), is adjusted for minimum output distortion.

GENERAL DESIGN NOTES

1. The phase shift network is aligned by applying an F-M signal through a decoupling network to pin 1 and tuning for maximum recovered audio at pin 6.
2. A low-resistance path must be provided between pins 9 and 10. No other biasing provisions are required.
3. A low-resistance path must be provided between pins 1 and 3. No other biasing provisions are required.
4. Keep appropriate distance between the input (pin 1 and the input network) and the phase shift network (pins 8, 9, and 10, and the phase shift inductor).
5. If a high-impedance power supply is used (voltage dropping resistor), decouple pin 11 for the lowest audio frequency.
6. The level of recovered audio increases with higher values of loaded Q and higher values of resistance between pins 6 and 10. It decreases with lower values of loaded Q and lower values of resistance between pins 6 and 10.
7. Mute bandwidth decreases with higher values of loaded Q and higher values of resistance between pins 7 and 10. It increases with lower values of loaded Q and lower values of resistance between pins 7 and 10.

SCHEMATIC

ULN-2204A A-M/F-M RECEIVER SYSTEM — TYPICAL APPLICATIONS AND OPERATION

Introduction

Through the relatively short history of bipolar monolithic circuits, several revolutionary new circuits have been developed for a-m/f-m receiver design. A. Bilotti pioneered the original monolithic f-m-quadrature detector/I-F gainblock in the form of the Sprague ULN-2111A.

Subsequent devices have included gain-control stages, output drivers, and voltage regulators. During this same period a-m integrated circuitry showed far less inspiration. Numerous a-m circuits were developed which in essence attempted to combine the active elements of a discrete bipolar a-m receiver in a monolithic circuit. To no surprise, the resulting chips were *at best* capable of performance no better than the parent discrete design, and with the uneconomical displacement of three discrete transistors with one integrated circuit. In addition to the a-m-only circuits and f-m-only circuits, a-m/f-m circuits were also attempted using the same design approaches used for the a-m-only circuit, that of combining an existing discrete receiver circuitry in a monolithic device. The results were much like the a-m only efforts, a bewildering collection of economically unattractive circuits of modest performance.

To achieve useful cost and performance objectives, the ULN-2204A was designed with careful attention to the cost and performance objectives of the modern portable and table model broadcast receiver. Concern for low external component count, low power consumption, wide supply voltage range, and versatility remained foremost as design objectives.

Power Amplifier

To achieve the desired performance objectives of high power output and efficiency from a 2 to 12 V supply requires that the power amplifier be capable

of peak-to-peak voltage swings approaching the available supply. To meet these performance objectives a new power amplifier design was required having no more than one V_{BE} of swing restriction.

As shown in Figure 1, the output stage is comprised of 2 NPN transistors (Q42 and Q49) plus a phase inverter (Q54). Quiescent operating current is set up by the current source (I).

Figure 1

Assuming $V_{Oq} = V_{CC}/2$ then the collector current of Q54 = I, ignoring base currents, and if Q54 is matched to Q49 as is possible in a monolithic circuit, then the collector current of Q49 equals the collector current of Q54. The circuit in Figure 1 achieves an excellent voltage swing capability of $V_{CC} - V_{BE} - 2V_{CE(SAT)}$. This totally NPN configuration also has good freedom from the high-frequency problems that often occur with quasi-complementary composite NPN-PNP configurations.

Although the circuit in Figure 1 has been incorporated in production monolithic circuits in essentially the form shown, in practice it has unacceptable design restrictions. Since I is also the base drive current for Q42, the ratio of available base drive current I to idling current is proportional to the ratio of the emitter areas of Q49 to Q54. For practical values of $1Q54/1Q49$, i.e. one, the circuit has a serious implementation problem; it requires three output transistors (Q42, Q49, and Q54).

To reduce the size of Q54, an additional transistor (Q48) is added to the circuit as shown in Figure 2. Transistor Q48 divides I by its $\beta + 1$ allowing Q54 to be reduced in area by a similar value. In the practical realization of the ULN-2204A, Q54 is chosen as $1/5$ the emitter area of Q49 with a typical β for Q48 of 6.

Figure 2

Figure 3 illustrates other refinements in the practical realization of the output circuit. The drive and idling current I is derived from a V_{CC} dependent source allowing maximum drive under maximum supply conditions while affording reduced drive and associated current conservation under minimum supply conditions. In addition, the Q48 divider circuit is refined to reduce PNP β dependence. Finally with the addition of an input emitter follower (Q53) and a local negative feedback loop (R36), the output is completed as it appears in the ULN-2204A.

The input stage of the power amplifier (Figure 4) is comprised of a PNP differential pair (Q44 and Q45) preceded by a PNP emitter follower (Q43) which allows d-c referencing of the source signal to ground. This eliminates the need for an input coupling

Figure 3

capacitor. Overall negative feedback, set by the ratio of R33 to R32, is applied to the inverting input Q45 through an NPN emitter follower (Q46) which also provides d-c level shifting.

Figure 4

The $V_{CC}/2$ output tracking is achieved by summing the current flow through R33 and R32, with the current through R41 "reflected off of ground". Thus $V_{CC}/2$ tracking is maintained by the voltage drop across 2 resistors. This allows the current from R41 to be bypassed at Pin 10, thereby combining the ripple bypass capacitor with the audio feedback capacitor.

Figure 5 illustrates the complete power amplifier as realized in the ULN-2204A, including the external components. The remarkably-low external component count, (only two capacitors including the output coupling) reflects concern for simplicity in implementation, yet the device achieves excellent performance. Typical output power can be as high as 850 mW from a 9 volt supply and useful output power at supply voltages of as low as 2 volts, with minimum of distortion as the curves in Figure 6 illustrate.

Figure 6

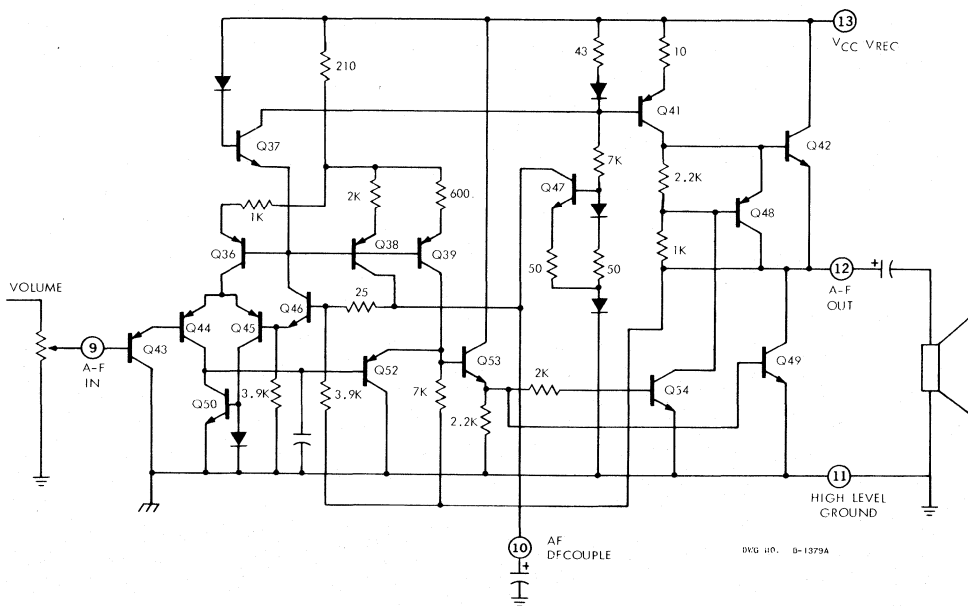

Figure 5

Receiver

The a-m signal is processed from the antenna to the detector output via the traditional blocks of mixer, I-F, and detector enclosed in a reverse A-G-C loop. However, closer examination reveals certain very important advantages that can be afforded only by the monolithic design.

The a-m mixer is a fully-balanced mixer based on a four-quadrant multiplier as shown in Figure 7. This affords rejection of both the oscillator and input signal as observed at the output. In addition, an analog multiplier is (as the name implies) a true linear device. Balanced operation of the mixer provides typically 25 dB of I-F rejection at the input, with a similar rejection of the associated noise passband. Also, the linear operation of the circuit affords good freedom from intermodulation product responses.

I-F gain is provided for both a-m and f-m by a common I-F amplifier (Figure 8) using "stacked" selectivity. In f-m operation the gain of stages 1, 2, 3, and 4 (Q1 thru Q8) is set at typically 76 dB providing a typical limiting threshold of 40 μ V.

For a-m the gain is lowered by reducing stage current. This is accomplished by reducing the current applied to the I-F amplifier by the current source Q17. The fifth I-F stage (Q9 and Q10) is operated at maximum gain and current to provide full signal to the a-m and f-m detector.

A-M/F-M Detector

The detector is also a combination circuit. It recovers a-m audio by peak detection and f-m audio by phase discrimination.

The a-m signal from the I-F output appears at Pin 15 across T_2 as shown in Figure 9. The signal is applied to the base of Q18 and after phase inversion by T_2 is applied also to the base of Q19. Full wave detection occurs at the emitter of Q18 and Q19, utilizing the on-chip junction capacity for integration. This requires only that the stage current be chosen at a low value (typically 1 μ A) to produce the desired integration.

The f-m detection process relies on the phase/frequency relationship of a tuned external circuit for demodulation. The device converts phase

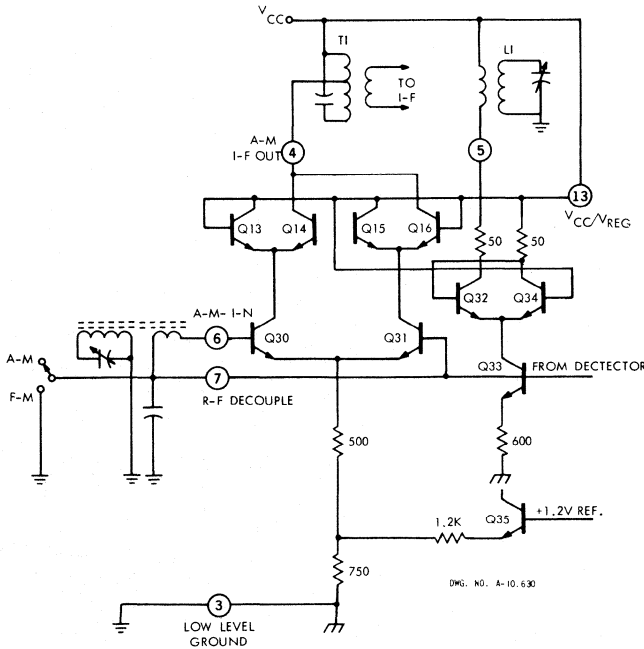

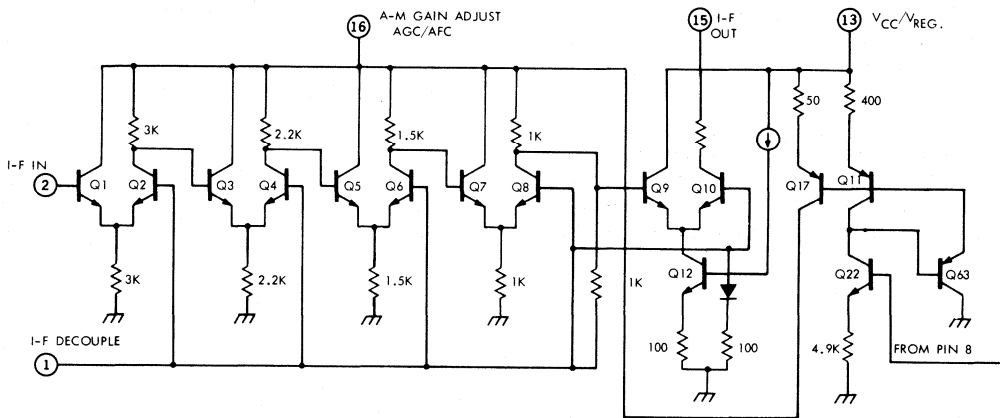

Figure 7

RADIO INTEGRATED CIRCUITS (Continued)

variation, as observed across the tuned network, to a proportional voltage. The basic phase detection process combines the positive-going portions of the quadrature and reference signals (Pin 14 and 15, respectively), and evaluating the duty cycle of the resulting waveform as shown in Figure 10. The combining action occurs at the emitters of Q18 and Q19 resulting in the waveform shown. Subsequent processing involves squaring up the signal in a limiter, comprised of Q24 and Q27, resulting in the constant-amplitude pulse train which is also shown. This pulse train is then applied to a PNP gain stage which, owing to the PNP's low f_T of typically 1 MHz, integrates the pulse train into an average d-c

voltage which appears at Pin 8, the detector audio output. Figure 11 illustrates the complete a-m/f-m detector of the ULN-2204A, including the external components.

To complete the circuit, the a-m stages also require A-G-C. This is implemented in the ULN-2204A by internally setting the I-F supply voltage (Pin 16) equal to the voltage at the detector audio output. As carrier appears, a corresponding reduction in the d-c voltage occurs at the audio output terminal and at Pin 16, where an external bypass capacitor from the A-G-C line and sets the time constant.

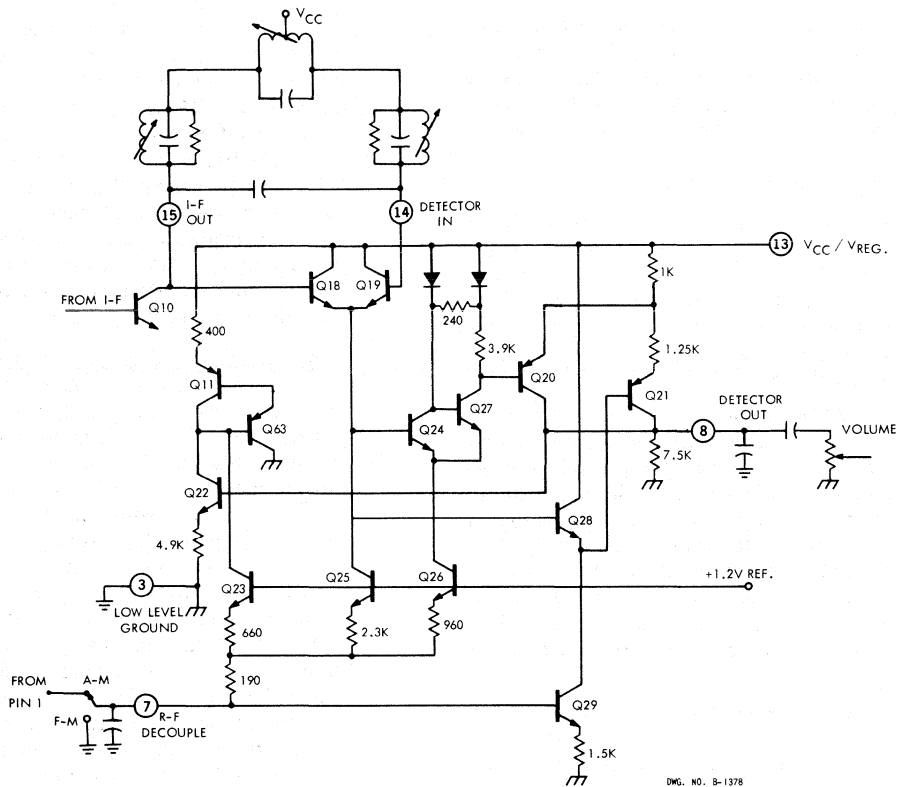

Figure 11

Application

The primary application, but certainly not the only application, for the ULN-2204A is the broadcast band a-m/f-m table or portable radio as illustrated in Figure 12.

Power Amplifier

Selection of power supply voltage and speaker impedance allow the designer to choose audio power levels up to almost 1 watt as the curves in Figure 6 illustrated. No unique precautions are necessary when designing with the ULN-2204A power amplifier. The device is stable and short-circuit immune.

External component choice for the power amplifier involves only two capacitors; one for the speaker coupling and one for the feedback and ripple bypassing. The coupling capacitor value should be

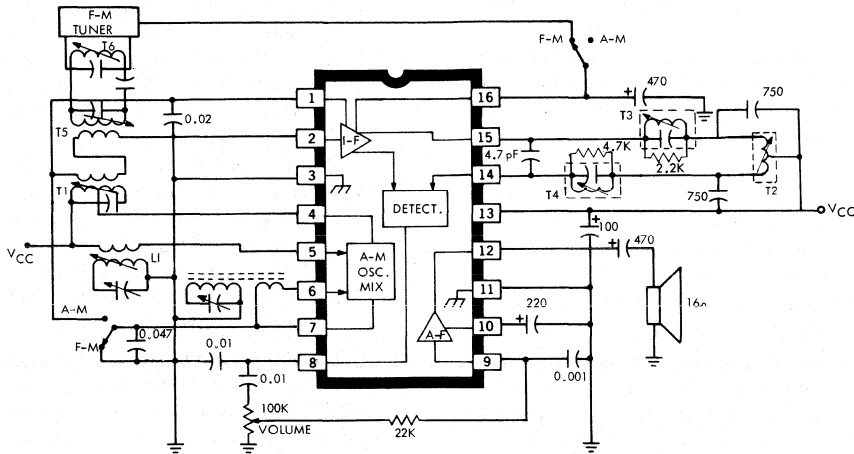

selected to provide the desired low-frequency cutoff with the chosen speaker impedance. The feedback and ripple bypass capacitor at Pin 10 should be chosen for both low-frequency audio rolloff and supply ripple rejection.

Ripple rejection is not practical to calculate due to the large number of mechanisms involved. The 220 μ F capacitor indicated in Figure 12 achieves typically 35 dB rejection.

The high gain of typically 43 dB and the high input impedance (200 k Ω) of the power amplifier allow utilization of this stage for other applications such as ceramic cartridge phono amplifiers.

Typical ceramic phono cartridges develop approximately 400 mV. However, the recommended

Figure 12

proximately 90 in the circuit, and the second transformer T_2 as 70 with virtually no load presented by the circuit. Impedances are selected based on two constraints: a-m gain and overload. One additional point to consider is the behavior of the a-m component when the receiver is in the f-m mode.

The available I-F current at Pin 15 is 200 μA peak, 100 μA at its quiescent point. (See Figure 9). Maximum permissible swing at Pins 14 and 15 is limited to 0.5 volt positive with respect to Pin 13. This restricts peak voltage swing at Pin 15 to $1 V_{pp}$, considering the inverting action of T_2 . This restricts the impedance of T_2 , as seen by the I-F output, to values greater than 15 k Ω to permit maximum dynamic range. Including all worst case conditions, a value of 18k Ω is chosen for T_2 in the example. Considered were temperature variations and internal device tolerances. In addition, a 470 pF capacitor has been added to assure an adequate a-c return for the f-m coil.

Transformer T_1 (Figure 7) is chosen for the correct overload characteristics of the mixer. It also features a 100 μA quiescent state and a 0.5 volt peak swing restriction for primary impedance considerations, and the secondary winding chosen as the lowest practical impedance for desired system gain. Unlike T_2 which is not loaded to any degree by the circuit, T_1 is loaded by both the mixer output impedance of approximately 50 k Ω and the I-F input impedance of approximately 30 k Ω . Both must be taken into consideration in calculating the loaded Q of the transformer. In addition, the effect of the a-m components on the f-m I-F stability must be considered — the device must be stable at both the intermediate frequencies in both modes of operation. Although no practical method exists for evaluating stability criteria for an integrated circuit as is commonly done for discrete circuits, the practical ground rules are much the same — mismatching of the input at the first transformer to achieve stability.

The oscillator coil (L_1) has a secondary impedance selected to be approximately 800 Ω at resonance. This provides typically 150 millivolts of injection voltage to the mixer driving the upper differential pairs of the four-quadrant multiplier into hard limiting. The oscillator is also restricted to a $1 V_{pp}$ swing and operates with a quiescent current of 0.5 mA.

Printed Wiring Board Layout and Special Considerations

Special on-chip considerations for minimizing tendencies towards instabilities of all types were taken in the design of the ULN-2204A. However, like all

complex high-gain circuits, considerable care and forethought should still be given to a printed wiring board layout to avoid undesirable effects. Inputs and outputs should be well separated and should avoid common mode impedances wherever possible. Much of the signal-processing circuitry is referenced off of the supply line, and this should avoid being in a common mode loop caused by current drain of the power amplifier through Pin 13. Reference points for the local oscillator, a-m mixer, and the detector coils should be connected to Pin 13 very close to the device and away from the V_{CC} connection to the power supply bypass capacitor.

The Pin 13 common mode resistance will also interfere with device operation in a socket. In the f-m mode of operation, current drawn by the power amplifier will cause the Pin 13 voltage to drop slightly with respect to the reference for Pin 14 and 15. This will cause a variation in gain of the f-m detector. The effect also causes an apparent increase in distortion when the power amplifier is loaded, with distortion figures approaching several percent under worst case conditions. The effect is negligible, however, when the device is soldered into a printed wiring board.

Connections between Pins 14, 15, and transformers T_2 , T_3 , and T_4 should be kept as short as possible as should connections for Pins 1 and 2, those associated with the transformers. The ground return for the audio bypass at Pin 10 should be kept reasonably close to the volume control ground as Pin 9 and 10 represent the inverting and non-inverting inputs to the amplifier and enjoy about 40 dB of common mode rejection.

Other Applications — TV Sound Channel

Beyond the obvious applications of the ULN-2204A as an a-m/f-m receiver it has much to offer as a sound system for television. The device offers exceptionally-low current consumption and a wide operating supply voltage range. Its high a-m rejection and low external component count will make it

practical for use in many power conscious applications. Most of the comments which apply to the f-m application of the ULN-2204A also apply to its application at 4.5 MHz or 5.5 MHz with suitable adaptations of the external selectivity components. (See Figure 13)

Multiband Receiver

The ULN-2204A A-M circuitry is not restricted to conventional broadcast band applications. The

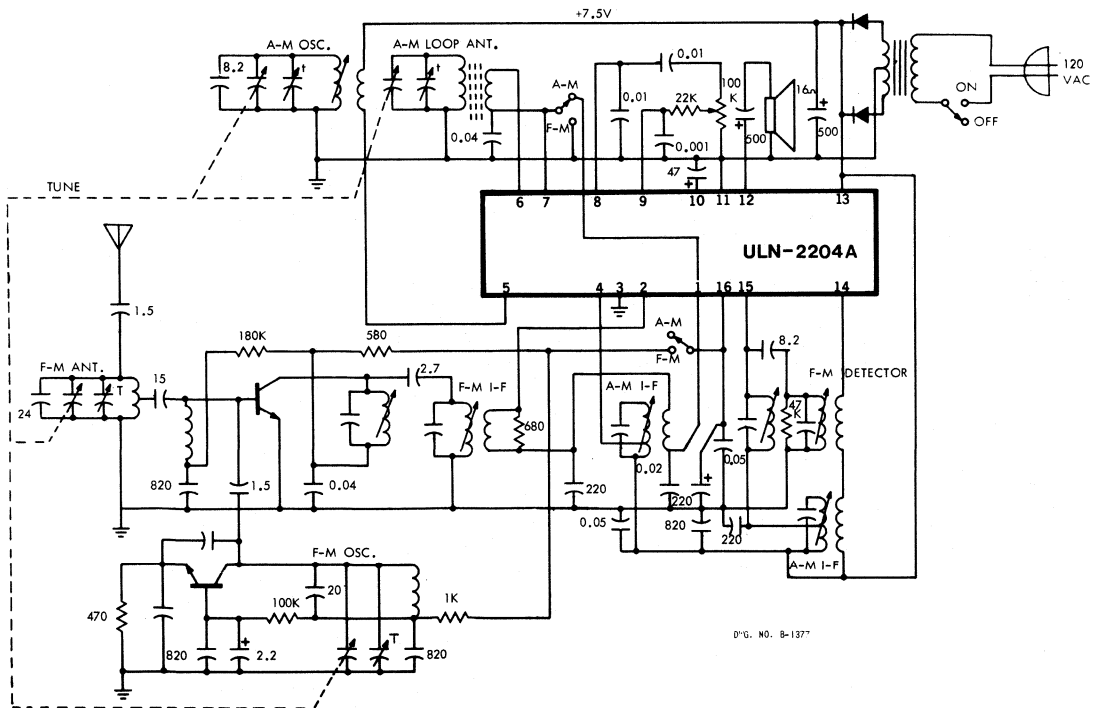

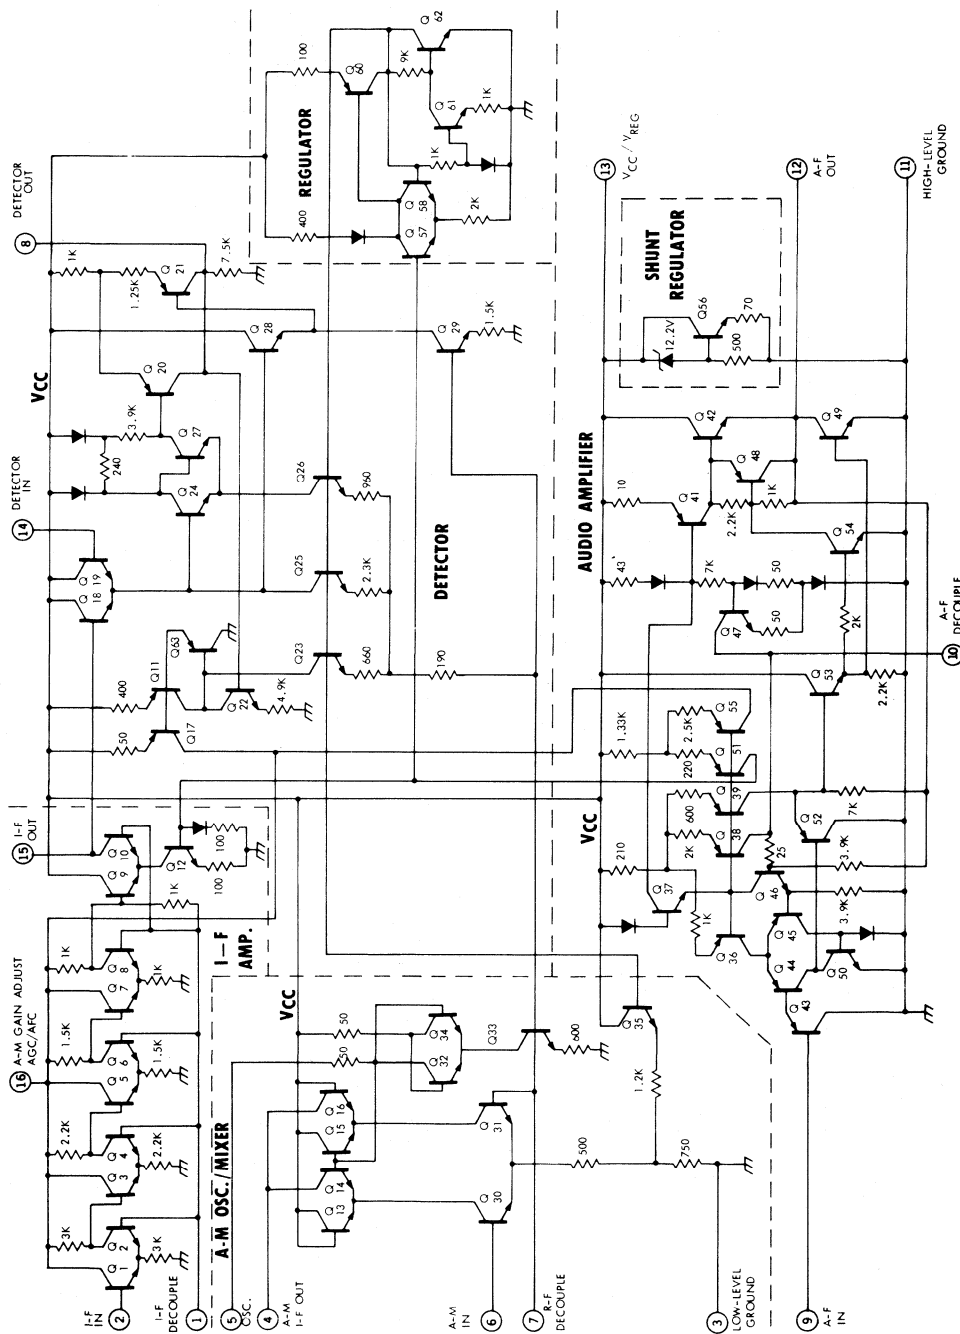

Figure 13

ULN-2204A mixer and oscillator are both capable of operation from the very-long wave band to well above the medium wave bands. Only the antenna and oscillator coils need to be switched or adapted

for use at other frequencies. The useful limits of the mixer-oscillator combination extend to approximately 50 MHz with excellent performance up through and including the citizens' band at 28 MHz.

Figure 15

A-M/F-M RECEIVER DESIGNS USING ULN-2240A, ULN-2241A, and ULN-2242A INTEGRATED CIRCUITS

THREE MONOLITHIC INTEGRATED circuits, Types ULN-2240A, ULN-2241A and ULN-2242A, each contain all the active circuit elements required for the A-M tuner, F-M I-F amplifier and detector functions. Only an F-M tuner, filter elements, and a minimum of additional external components are necessary for a complete A-M/F-M receiver.

This Application Note discusses several circuits and options for a number of A-M/F-M receiver applications. Each of the three Sprague integrated circuits used provides performance characteristics equivalent to or better than systems using discrete components for A-M and F-M functions.

The circuits are ideal for special receivers such as scanners which must be able to detect A-M and F-M signals at one I-F frequency. Also, the three devices lend themselves to shortwave receiver designs because of the simplicity of their A-M oscillator systems.

The various receiver designs covered here include an A-M tuner using a ferrite antenna, and a permeability-tuned automobile radio. Enhanced sensitivity and overload performance is obtained with the addition of an R-F amplifier, easily accomplished using the AGC voltage for the A-M mixer to control an R-F amplifier stage. The discussion covers a table model receiver with a ferrite antenna and R-F stage, and an R-F stage for an automobile receiver. The concept is extended to varactor-tuned automobile radios with the addition of an FET-bipolar cascode R-F stage and an AGC driver.

ULN-2241A

General Performance Considerations

Internal voltage regulators and bias supplies assure consistent performance despite variations in external supply voltage (8.5 to 16 V) or operating temperature (-40°C to $+85^{\circ}\text{C}$). Separate ground leads minimize decoupling problems.

The A-M sections of all three devices are the same. Use of an analog multiplier as a balanced low-current mixer results in freedom from spurious responses, high tweet rejection, low feedthrough, and low noise and very low local oscillator feedthrough. A fully-balanced four-stage differential amplifier gives maximum gain with freedom from common-mode interference

and noise. A-M gain control is achieved with AVC applied to the I-F and delayed AVC applied to the mixer.

The differences in these three circuits are found in the F-M sections, with packaging variations to accommodate the different features. Type ULN-2241A is supplied in a 16-pin plastic dual in-line package. This circuit has no mute, and no AFC/tuning meter output (the audio output can be used for AFC). Type ULN-2242A, in a 20-pin package, incorporates the F-M mute and AFC/tuning meter output. Type ULN-2240A, also in a 20-pin package, adds tuning-error mute, and higher F-M S/N.

Input-Filter Coupling

The common A-M and F-M I-F inputs for all three devices are basically the same. Note that terminals 1, 2 and 3 for Type ULN-2241A correspond to terminals 2, 3 and 4 respectively for Types ULN-2240A and ULN-2242A.

The method of arranging the I-F filters

depends entirely on the type of filters used. For example, coils placed in series may be used for A-M and F-M connected as shown in Figure 1.

A ceramic filter may be used for F-M with an A-M filter incorporating a tuned coil in its output. This arrangement is illustrated in Figure 2.

Figure 1

Dwg. No. A-11,319

Figure 2

Dwg. No. A-11,320

The I-F input impedance is very high (10 k Ω @ 10.7 MHz; 15 k Ω at 455 kHz) and can be ignored when selecting loading resistors for different types of I-F filters. Additionally, the input stage bias currents are very low, therefore a relatively high-value resistor can be connected between pins 1 and 3 of Type ULN-2241A, or pins 2 and 4 of Type ULN-2240A or ULN-2242A, without significantly affecting the limiter balance.

These characteristics simplify the input filter coupling to accommodate ceramic filters used for both A-M and F-M I-Fs as shown in Figure 3.

Most 455 kHz filters are terminated by a 1 to 3 k Ω resistor in parallel with a capacitor of less

than 50 pF. The 10.7 MHz filter requires a 330 Ω termination. If the capacitance of the 455 kHz filter is high at 10.7 MHz, the circuit will work properly as shown. However, if the capacitance of the 455 kHz filter is low, it would be advantageous to add an inductance in series with the 330 Ω resistor to form a series resonant circuit with the output capacitance of the 455 kHz filter. Such a modification is shown in Figure 4.

If the inductance required is very small, it might be possible to incorporate it as an integral part of the printed wiring board.

Figure 3

Dwg. No. A-11,321

Figure 4

Dwg. No. A-11,322

A-M Detector Considerations

Passive diode detectors are still used in many low-cost receiver designs. The A-M detector functions of Types ULN-2240A, ULN-2241A and ULN-2242A, however, are entirely self-contained. Several drawbacks to the passive diode detector design are overcome; the load presented to the detector coil does not change with signal level, the detected output is not distorted at low signal levels, and the detector coil is not loaded down, so overall receiver selectivity is unaffected.

The self-contained detector design produces excellent A-M performance without external filtering elements. There is virtually no 910 kHz and 1365 kHz tweet. Distortion at 30% modula-

tion is only 0.3%, and at 80% modulation the distortion is still under 1%.

The design of the detector coil is strictly dependent on the type of receiver desired. The detector input impedance is about 250 k Ω . For optimum detector operation, the coil should present an impedance of 4.7 k Ω . An inexpensive detector coil can be loaded with an external resistor or tapped to obtain the 4.7 k Ω impedance.

It should be noted that the A-M detector works very well at 455 kHz and also at 10.7 MHz. Switching from A-M to F-M is as simple as grounding one pin of the integrated circuit.

F-M Detector Options

The F-M detector functions in these three integrated circuits are very similar to those of Type ULN-3889A and the same type of circuit arrangements may be used. For low-cost receivers where distortion up to 0.4% at 100% modulation can be tolerated, the single-tuned coil detector illustrated in Figure 5 is most appropriate.

Figure 5

Note that terminals 7, 8 and 9 of Type ULN-2241A correspond respectively to terminals 11, 12 and 13 for both Type ULN-2240A and Type ULN-2242A.

Types ULN-2240A and ULN-2242A require 165 mV injection level at pin 11 to insure proper mute detector operation.

Lower interstation noise levels can be obtained in applications using Type ULN-2241A by using a lower value resistor than the 220 Ω I-F load resistor shown (typically 82 Ω) and thus reducing the injection level.

The double-tuned detector shown in Figure 6 provides signal distortion levels as low as 0.1%. In addition, the double-tuned detector minimizes distortion as a function of tuning, when the receiver is tuned away from a strong signal.

Dwg. No. A-11,324

Figure 6

Usually the primary coil is adjusted for the maximum audio output while the secondary coil is adjusted for minimum distortion. Perfect detector balance at minimum distortion is desirable; however, a signal lag caused by excess parasitic capacitance from the I-F output to ground could prevent this.

The parasitic capacitance of the A-M detector coil may effectively compensate for this signal lag or it can be eliminated by placing a small inductance (0.1 to 1.0 μH) in series with the 220 Ω load resistor.

Any of the three signal processing systems can be used as phase-locked F-M detectors. An external, voltage-controlled oscillator signal must be applied to the F-M detector. If the audio output is used, the phase detector constant $K_D = 4.8$ volts/radian. If the AFC output is used, then:

$$K_D = 785 \times 10^{-6} \times R_L$$

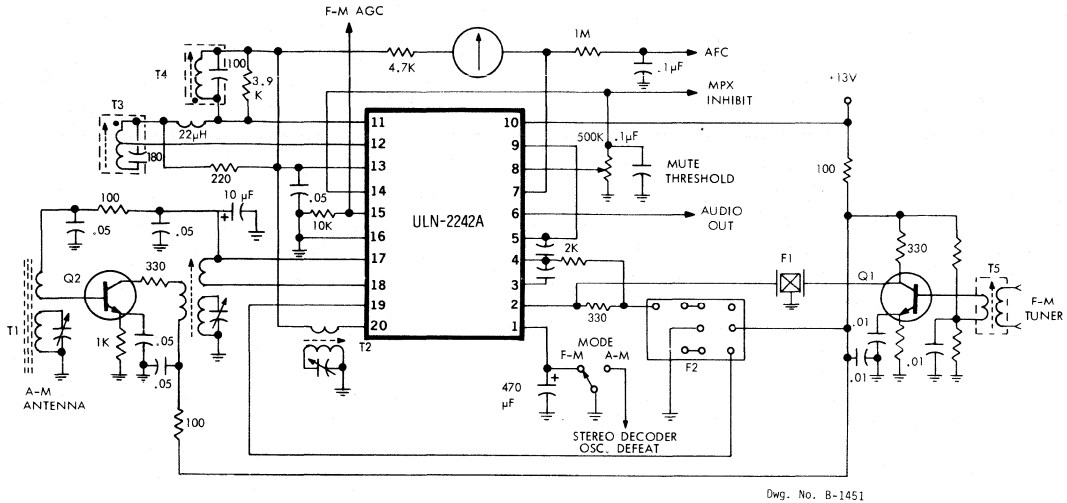

R_L is the value of the resistor connected to V_{REG} .

The AFC output is preferred because the audio can then still be muted without affecting the loop operation. More detailed information can be found in a paper published by Jon P. GrosJean. See Reference 2.

High-Performance A-M/F-M Tuner

A high-performance A-M/F-M tuner illustrated in Figure 7 uses an R-F stage controlled by the mixer bias on pin 17. This is 1.7 V with no

input signal and 0.6 V with large input signals. The circuit also includes mute, a tuning meter, and an AFC output to the F-M tuner.

Low-Cost Receiver Design

A simplified receiver design illustrated in Figure 8 can produce excellent performance at very low cost using Type ULN-2241A. This simple A-M/F-M system uses a Type ULN-2283B audio amplifier and a Toko CY2-22124 PT Polyvaricon type of tuning capacitor.

The A-M section tunes from 540 to 1610 kHz. The ferrite antenna T1 has an inductance of 571 μ H, and 6 turns on the secondary. Twenty dB quieting sensitivity is 180 μ V/m and the maximum signal is about 1.0 V/m. The A-M oscillator is a negative resistance type needing only an impedance greater than 1.5 k Ω across pins 9 and 15 to oscillate. The oscillator coil T2 has been designed for a secondary impedance of about 5 k Ω .

In order to obtain good A-M selectivity, a low-cost ceramic I-F filter F2 and a relatively high-Q detector coil T3 are used. The tap impedance T3 is 4.7 k Ω .

The CFZ455C filter F2 contains a tuned circuit and ceramic resonator and has sufficient input impedance for a good mixer gain. It must be loaded with 2 k Ω . The output capacitance of 250 pF at 10.7 MHz is large enough to terminate the F-M I-F filter F1 through 330 Ω . A slightly better termination for F1 can be produced using a small inductance (0.88 μ H) placed in series

with the output of F2, the 455 kHz filter. At 10.7 MHz, this inductance will form a series resonant circuit with the F2 output capacitance.

The single-tuned detector coil T4 is easily aligned by simply tuning for maximum audio output. Note that AFC has been included even though Type ULN-2241A has no AFC output pin. It is only necessary to filter the audio output at pin 5 with a 1 M Ω resistor and a 0.05 μ F capacitor for AFC.

The F-M tuner design is relatively straightforward, except: the autodyne converter is designed so that the F-M oscillator signal does not appear across the primary of the mixer coil T5, and the oscillator coil is grounded. This circuit configuration prevents the F-M oscillator signal from coupling across T5 through F1 into the ULN-2241A (pin 1). Excessive oscillator input would cause the limiters to be driven by the oscillator producing undesirable offsets with weak signals.

Note the AGC output of Type ULN-2241A is used to drive the R-F amplifier Q1. This eliminates any problems with large signals overdriving the converter Q2. Consequently, the oscillator frequency in this tuner will not change even when the input voltage rises as high as 300,000 μ V.

Low-Cost Automobile Radio

Automobile radios usually have two tuned R-F circuits in addition to the local oscillator. In this case Type ULN-2242A can be used in an A-M/F-M automobile radio without an A-M R-F amplifier. The R-F circuit can be double-tuned with minimal loss in sensitivity. The inductive tuning circuit is easily connected to the mixer of Type ULN-2242A as shown in Figure 9.

Note that L51 and L53 are not tapped and only the oscillator coil L55 needs a secondary winding. The 150 μ H coil L54 forms an inductive tap with L53 to provide a desired sensitivity and

overload level. The A-M sensitivity of the tuner with the 30 pF/30 pF dummy antenna shown is 10 μ V for 10 dB (S + N)/N, and the maximum input at 80% modulation is 300 mV.

The I-F uses a ceramic filter and a single-tuned high-Q detector coil. The I-F collector load resistor of 150 Ω on pin 13 has been reduced from the usual 220 Ω (pin 9, Figure 8) to reduce the interstation noise and to increase the limiting level for better tuning feel. An F-M tuner of the designer's choice can be added to this circuit to form a complete A-M/F-M tuner.

6

Automobile Tuner With A-M R-F Stage

Improved sensitivity and excellent overload performance with the radio tuner illustrated in Figure 9 may be obtained by adding the R-F stage of Figure 10. A secondary winding has been added to L53 to couple it to the mixer of Type ULN-2241A. The emitter of the R-F stage is biased up to 0.5 V when it is turned OFF to im-

prove the overload. This condition causes the R-F stage to be turned OFF at a lower R-F level. Large signals are not rectified in the R-F stage.

This circuit will handle input signals to 1 volt into the 30 pF/30 pF dummy antenna.

Dwg. No. A-11,325

Figure 10

Varactor-Tuned Automobile Radio

The tuner in Figure 11 was specifically designed for a digital synthesized A-M/F-M automobile radio. A large area, low-noise JFET, Q1, provides a reasonable broad-band match to the antenna. Tuning the antenna with a varactor diode would require a capacitance change of 9 times the total of antenna, input cable, minimum diode and stray capacitance. Because Q1 has about 5 pF feedback capacitance, Q3 is added to form a cascode input.

Q2 provides the interface between the AGC of Type ULN-2242A and Q1, reducing the g_m of Q1 by dropping the drain current as the signal level increases. This arrangement produces excellent large-signal and cross-modulation characteristics. L1 and R1 provide a static current discharge path for the antenna while L2 reduces interference from VHF signals.

T1, T2 and L4 form a double-tuned R-F circuit, an arrangement with several advantages over single-tuned circuits. The bandwidth is greater, especially at the low end of the band, so that receiver bandwidth is not determined by the R-F stages and image rejection is maintained. Mistracking caused by the matched tuning diodes is much less of a problem with the wider R-F bandwidth. The primary voltage of T1 increases as the receiver is tuned off a station, producing better local AGC action.

As the receiver is tuned off a strong station, the AGC supplied by Q2 is normally removed from the R-F stage Q1. Large signals applied to the diodes will cause oscillations heard as whistles when the receiver is tuned in and out of a strong station. Local AGC is therefore required, and is provided by Q4 and associated components.

Q4 is coupled to T1 by C2 and C3 so minimum additional capacitance is added to T1. The output of Q4 is rectified by a voltage doubler and filtered to remove audio frequencies produced by the voltage doubler. This arrangement coupled with the very good AGC characteristics of Type ULN-2242A, results in a receiver with large-signal capabilities better than most conventional automobile radios.

An A-M oscillator signal of about 200 mV at pin 20 can be used to drive a synthesizer if desired. Most synthesized radios mute the audio when changing stations. Since A-M and F-M are common in Type ULN-2242A, the mute works for both. A 3 to 4-volt signal applied to pin 8 will mute either A-M or F-M.

The A-M AGC and F-M mute signals applied to Q5 provide a stop signal for use with signal-seeking receivers. The collector of Q5 goes high when a signal is reached and is limited to 6.5 V to interface with 5 V digital logic circuits.

THE ULN-2242A, A COMPLETE AM/FM SIGNAL PROCESSING SYSTEM

Introduction

This paper describes a monolithic integrated circuit which makes possible substantial simplification of AM/FM receiver design, while at the same time improving system performance.

Prior attempts at monolithic implementation started with the quadrature detector/IF gain block which was first described by A. Bilotti in 1967.¹ Other devices were developed for AM circuits which in essence attempted to combine the active elements of a discrete bipolar AM receiver. The resulting monolithic devices were capable of performance no better than the original discrete design, and with the very uneconomical displacement of three discrete transistors with one integrated circuit.

To achieve useful cost and performance objectives, a new monolithic AM/FM signal processing system² was designed with careful attention to the total system costs and performance objectives of modern

automotive and high quality home entertainment broadcast receivers. In addition to providing state-of-the-art receiver performance, this "one-chip" receiver also provides for meter drive, interstation muting, delayed AGC (for control of external AM and FM RF stages), and simple AM/FM switching.

Circuit Description-AM Mixer

An analog multiplier is used for the AM mixer. It substantially outperforms discrete mixers in the areas of noise and spurious response rejection. As an AM mixer this circuit provides both local oscillator and received frequency rejection. The local oscillator is suppressed by approximately 40 dB and the intermediate frequency feedthrough is down by 26 dB. Spurious response suppression is important as a receiver performance objective, and also the receiver's ability to reject undesired noise passbands. The mixer's freedom from oscillator signal in

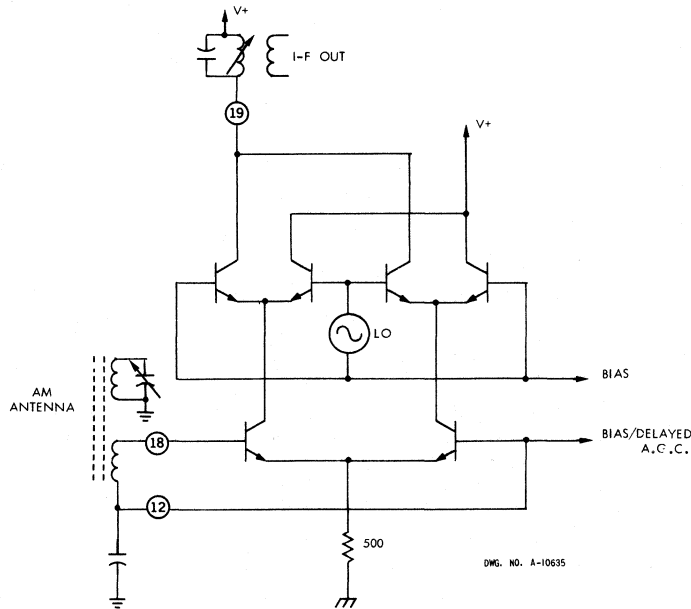

Figure 1

NOTE: This paper was originally presented at the IEEE Fall Conference on Broadcast and Television Receivers in Chicago, December 1977.

the IF also reduces the outband rejection requirement for the IF selectivity elements, simplifying the use of low-cost ceramic filters. The mixer current is chosen to provide 20 mmho of gain with an acceptable output overload capability.

The AM Detector

The AM signal is peak detected, recovering audio and a d-c voltage to control AGC. Low audio distortion of 1% is achieved by maintaining a relatively constant current and resistance load, presented by the emitter-base junction of Q82 as shown in Figure 2. The recovered audio is taken off in a balanced configuration and summed at a node to cancel stage current.

AM AGC

AM gain control is achieved by reverse AGC of the first IF by cutting off stage current to the first IF stage. AGC to the mixer is by the same method, but with a 14 dB delay to optimize gain distribution for noise considerations, and allow a better match to the input to the mixer. Gain reduction as a function of signal level is shown in the graph of Figure 3.

Combined AM/FM IF

Stacking of the AM and FM selectivity components allows the use of a common IF amplifier.

The IF (Figure 5) is a fully-balanced amplifier having each stage differentially coupled to the succeeding stage. In addition to providing a 6 dB per stage increase in gain over single-ended coupling, this maintains constant stage and emitter follower currents to prevent signal current from appearing in on-chip grounds or supplies. Attendant signals or noise appearing on ground or supplies will be rejected as common mode by the balanced stages.

The differential coupling approach also balances capacitive effects to minimize phase delay modulation with various signal levels. To further control AC effects and reduce device input capacitance, the first IF stage is a cascode configuration to reduce Miller effect.

In the FM configuration, the IF stages are operated as limiters and provide 76 dB of gain with a corner frequency of 36 MHz. Coupled with the detector section, the combination achieves a 3 dB limiting threshold of 15 μ V.

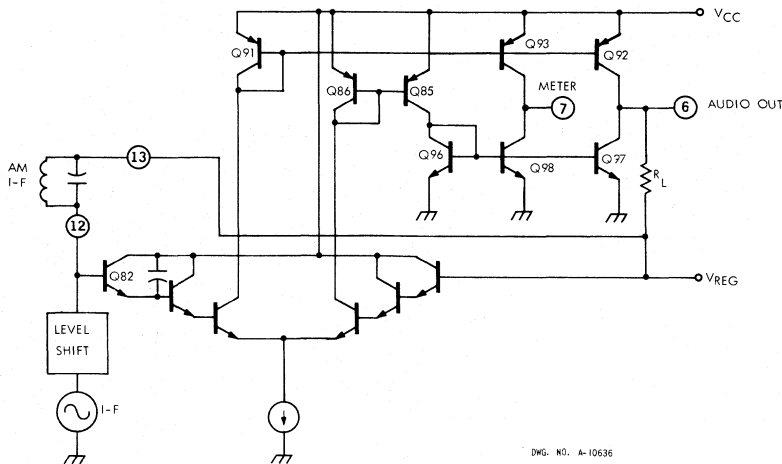

Figure 2

DWG. NO. A-10637

Figure 3

DWG. NO. B-1369

Figure 4

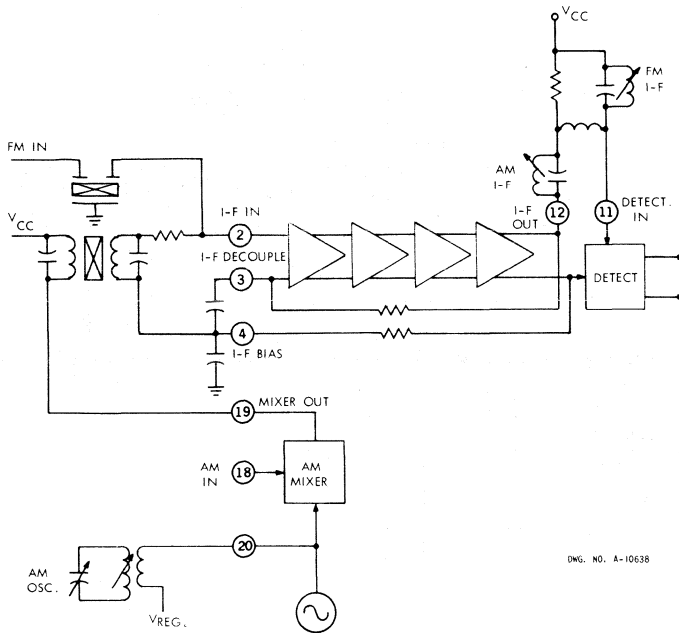

Figure 5

AM operation utilizes the same IF section as used for FM with a gain reduction and redistribution. To accomplish this, stage current is reduced in the second, third, and fourth IF stages. This puts 20 dB of gain in the first, and only 6 dB total in the remaining three stages, and also maintains a reasonably low input impedance to the IF.

The FM Detector

The FM detector (Figure 6) is an analog multiplier operating in the high-level injection mode. In this mode, a multiplier provides high recovered audio with low audio distortion. Like the IF, the detector is also driven differentially. In addition, the inphase and quadrature signals are passed through the same number of stages. This assures good freedom from a-c offset, i.e. detector d-c offset caused by unequal phase delay in the two applied signals.

Recovered audio is processed through the same current mirrors, summing resistor, and output pin as was used for AM. AFC and meter information is provided open collector for use with an external load. This allows the AFC to be used with any reference voltage between V+ and ground, and also permits adjustment of AFC gain by the choice of load resistor value.

FM Mute and AGC Detectors

The mute and AGC provide d-c voltages for control of signal level related functions. The basic detector (Figure 7) is biased as a triple Darlington current source, with a quiescent state value of 10 μ A. Detector operation is accomplished by applying an a-c signal to C3 which forms a voltage doubler with the emitter-base junctions of Q61 and Q62 plus the smoothing Miller capacitors of convenient size for integration.

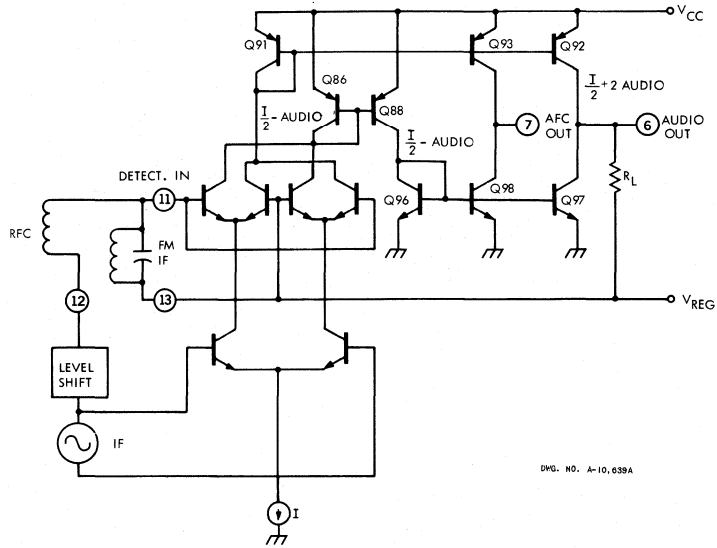

Figure 6

Figure 7

Signal for the mute detector is taken out of the quadrature coil to limit bandwidth and allow mute detector operation at the approximate limiting threshold of the device. The mute attenuation is obtained by cutting off the current mirrors to the audio. This achieves greater than 60 dB of attenuation with a minimum disturbance in d-c levels.

The AGC detector is basically the same as the mute detector, with the exception of the source of the a-c signal. This detector responds with a 2 mV signal input. Both detectors are biased to a no-signal value of 4.7 volts, and approach zero with increasing signal input as shown in Figure 8.

Typical Application

Figure 9 illustrates a typical home entertainment receiver application for this new AM/FM signal processing system.

Sufficient FM IF gain is provided by the device to eliminate the need for any additional external gain besides that of the tuner. A 3 dB limiting sensitivity of about $2 \mu\text{V}$ is easily achieved.

All AM signal processing is performed within the device. The gain AGC and noise performance of the device in the AM mode is sufficient to achieve a useable sensitivity of $150 \mu\text{V}/\text{m}$ while featuring an overload capability of 2 V/m with a 15 cm ferrite antenna.

Conclusion

Much of the original design for this new device was to define its operation as a system rather than as a simple component. To achieve the same revolutionary impact in AM/FM radio receivers as the design by A. Bilotti did for FM only, the new device required more than simple assembly of discrete components into an integrated circuit. Despite the integrated circuit's limitations on pin count and component values, the monolithic process with ion implantation is capable of fabricating superior circuit implementations such as fully-balanced mixers, multi-rate AGC systems, linear AM detectors, etc. at costs comparable to inferior circuits constructed with discrete components.

Figure 8

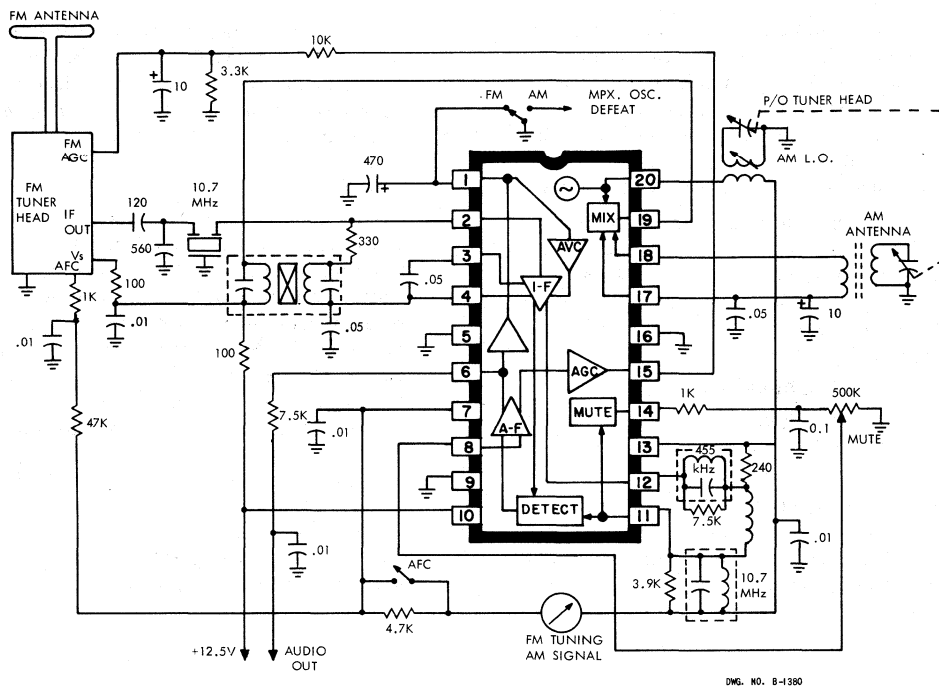

Figure 9

The device is most often specified in a standardized test fixture, eliminating as many variables as possible including AM antenna and FM tuner characteristics. Typical overall performance in such a fixture is illustrated in the following curves.

This new monolithic AM/FM signal processing system which has been described, provides the radio designer with a modern cost-effective approach to

the "one-chip" radio receiver without the performance tradeoffs so common with previous AM/FM integrated circuits.

6

DEVELOPMENT OF HIGH-QUALITY RECEIVERS FOR A-M STEREO

Introduction

Almost all current designs for A-M receivers or tuners use a ferrite antenna and/or a tuned R-F stage with one or two separate tuned R-F circuits. These are basically just slight modifications of the old five-tube radio. Because of this, almost all literature written on the subject of A-M receiver design was written when large tube-type receivers were popular.

When a receiver must have an audio-frequency response greater than about 4 kHz, this arrangement is not satisfactory and a new approach is required. This does not, however, necessitate the design of new integrated circuits for the R-F and I-F portions of high-quality A-M stereo tuners. Presently available integrated circuits can be used (with minor circuit variations) to produce A-M tuners with performance that compete with that of the receiver's F-M section.

Design Parameters

A-M stereo testing of many different types of A-M receivers indicates that receivers performing well with monophonic signals also perform well with stereophonic signals. A good criterion appears to be total harmonic distortion and audio frequency response. In addition to the usual requirements of good sensitivity, selectivity, image rejection, and the ability to handle large signals, distortion, signal-to-noise ratio, and audio fidelity are important parameters when designing A-M receivers for stereo or mono. Fortunately, if the I-F filter response can be kept symmetrical, current A-M integrated circuits will give very low distortion for a large range of signal levels. In addition, most of them have also had their gains apportioned properly so that under AGC conditions, signal-to-noise ratios are not degraded and high ultimate S+N/N ratios can be reached. This eliminates some problems for the designer, but does not solve all of the possible problems.

As a guide, the following receiver parameters have been chosen: (The modulation is 30% at 1 kHz unless otherwise noted.)

1. 20 dB S+N/N \approx 200 μ V/M
2. Adjacent Channel Attenuation \approx 35 dB
3. Image Rejection \approx 50 dB
4. Maximum Input Signal 1 V/M
5. THD < 0.5% and 1% at 80% Modulation
6. Maximum S/N \approx 50 dB
7. Audio Response: 20 Hz - 15 kHz

Unfortunately, items 2 and 7 are incompatible with channel spacings of 10 kHz, so either a dual-bandwidth I-F or poorer frequency response must be accepted.

I-F Filters

The audio distortion and receiver selectivity are essentially determined by the I-F filter of a receiver. (Some other factors degrading the audio frequency response will be discussed under R-F circuits.) The traditional approach of using LC networks in a good quality receiver becomes very difficult because of Q limitations.

As an example, consider a transitional filter with a 40 dB bandwidth of 20 kHz and center frequency of 455 kHz.

Number of Sections	Max. 3 dB BW	Min. Coil Q
3	3.2 kHz	211
4	5.0 kHz	180
5	6.7 kHz	238
6	8.0 kHz	322
7	9.1 kHz	411
8	10.5 kHz	483

The maximum available coil Q is only about 140, so it is almost imperative that the I-F filter be a ceramic filter designed specifically for that purpose. Suitable communications ceramic filters are available, but at a cost 3 to 10 times greater than that of standard I-F transformers. There is, however, a good compromise available. Reasonably priced ceramic ladder filters with zeros in their transfer function are available with the following response (Figure 1):

Figure 1

The zeros can be selected to fall at ± 10 kHz for narrow-band I-Fs, and at ± 20 kHz for wide-band I-Fs. The minimum attenuation beyond the zeros of only 27 dB is too small, but this falls within a range where supplemental inductive filters can be used. This requires buffers between the coil and ceramic filters, but, as we shall see later, some integrated circuit designs easily accommodate this arrangement.

It has been found by experiment that a full 20 kHz or even 15 kHz audio response is not necessarily desirable in a high quality A-M tuner, and might even be undesirable. So much background noise and interference from other stations is present even during local daytime listening that a narrower bandwidth is more acceptable. A good compromise appears to be about 20 kHz for 3 dB bandwidth. This is degraded by other filtering in the set plus the necessary 10 kHz notch filter in the audio output to give an overall audio frequency response of about 7 to 8 kHz. In the narrow bandwidth mode for nighttime listening, the ± 10 kHz attenuation must be greater than 40 dB, restricting the audio response to about 4 kHz. It should be noted that this is considerably better than the 1.6 kHz to 3 kHz audio response of current receivers.

R-F Circuits

The R-F circuits of a high-quality A-M tuner present difficult challenges. The first occurs because the R-F stage bandwidth should not degrade the audio

frequency response. A few calculations will demonstrate the problem:

If the R-F circuit loaded Q is 60:

$$1400 \text{ kHz} - 3 \text{ dB BW} = 23 \text{ kHz, Audio} = 12 \text{ kHz}$$

$$\text{At } 600 \text{ kHz} - 3 \text{ dB BW} = 10 \text{ kHz, Audio} = 5 \text{ kHz}$$

$$600 \text{ kHz Image rejection} = 48 \text{ dB}$$

If the Q of the ferrite antenna or R-F tuned circuit is reduced to improve the audio response, the image rejection suffers. In the case of the ferrite antenna, the sensitivity also suffers:

$$E_g = \frac{n\mu Af}{60} E \quad V = QE_g$$

V = Voltage Across Antenna Circuit

n = Number of Turns

μ = Antenna Permeability

A = Antenna Cross Sectional Area

f = Received Frequency

Q = Antenna Q

E = Electric Field Strength

E_g = Induced Voltage

This situation can be improved by using a large loop of a few turns of wire. In this case, the formula is the same with μ being replaced with μ_o . This antenna must, however, be very large in cross-sectional area (typically 1 m²) before it is effective. It is also directional.

The only other alternative is the old-fashioned wire antenna which turns out to be much better in terms of signal reception. For this type:

$$E_g = \frac{\ell}{2} E \quad V = QE_g$$

ℓ = Antenna Length

Now, the received signal can be increased to offset reduced Q simply by making the wire longer.

This still leaves the problem of how to deal with the loss in image rejection when the R-F circuit Q is reduced. The most obvious solution is to use a double-tuned R-F circuit. This can be manipulated to have constant bandwidth with different center frequencies so almost any desired result (without severe loss in image rejection) can be obtained. Additionally, the wider R-F bandwidth reduces tracking problems which are not usually serious for A-M mono signals, but which will cause problems with A-M stereo signals because of the group delay variations they produce.

This leaves two possibilities for antenna input circuits:

1. Couple the antenna directly to the double-tuned circuit and suffer a 6 dB insertion loss.
2. Use an untuned FET input and put the double-tuned circuit between the FET and the mixer.

Option 2 also eliminates the need for an antenna trimming capacitor. This can be a significant cost savings in automobile receivers. In both cases, however, the Q of the antenna circuit will be quite low at the low end of the A-M band, and the receiver will have somewhat poor I-F rejection. This can easily be solved by using an integrated circuit with a double-balanced mixer.

Receiver Designs

Illustrations of two high quality A-M tuned designs which use currently available parts are shown in Figures 2 and 3.

Both achieve the following performance levels.

$$20 \text{ dB } \frac{S+N}{N} \quad 100 \text{ } \mu\text{V/m}$$

(depends on antenna length)

Image Rejection = 55 dB

— 3 dB audio frequency response from 550 to 1600 kHz:

wide — 7.5 kHz

narrow — 4 kHz

THD < 0.5% at 30% modulation

Maximum signal level > 1V/m

Max signal-to-noise at 30% modulation = 47 to 50 dB

The first design shown in Figure 2 uses a combination A-M/F-M integrated circuit (1) with a balanced mixer for A-M. A junction FET must be used for the R-F stage to obtain a reasonable sensitivity (MOSFETs are very noisy at these low frequencies), but since it has a high feedback capacitance, a transistor is also used to form a cascode stage. AGC is derived from the IC and is used to reduce the current of the R-F stage. Since the IC has enough gain, the R-F stage gain can be kept low to reduce overloading. The ceramic filters in the IF stage are separated by low-cost buffer transistor stages which also perform the bandwidth switching. Added to the ceramic filters are double-tuned input (pin 14) and output coils (pin 1) to suppress the spurious responses of the filters.

The audio output terminal (pin 4) includes a 10 kHz notch filter and a 15 kHz low-pass filter to reduce unwanted noise in wideband operation. Note the simplicity of the double-tuned R-F filter. The two coils are identical and a mutual coupling capacitor is used to give greater coupling at low frequencies.

The second tuner shown in Figure 3 uses a very popular A-M-only integrated circuit (2). This IC, while not having a balanced mixer, has a separate I-F stage perfectly suited to driving the ceramic I-F filter. The R-F stage is slightly different here but retains the double-tuned interstage filter. The required R-F gain is higher because of the lower overall gain of the IC.

Instead of two double-tuned I-F filters, a 3-section filter is used and transistors are again used for bandwidth switching. The lowpass and notch filters are also retained in the audio output.

Conclusion

It has been shown that high-quality A-M tuners using existing monolithic integrated circuits can be designed and their cost is reasonable. They are suitable for driving A-M stereo decoders and should produce very good A-M mono or stereo results. In the case of the first tuner, the 455 kHz signal to the decoder can be taken from the last I-F collector, or from a secondary winding on the detector coil. A 455 kHz signal of high-enough level is somewhat harder to obtain from the second tuner. The easiest approach appears to be to amplify the approximately 5 mV detector input signal. The internal detector then serves to generate AGC signals.

The advent of A-M stereo may hopefully serve as a catalyst for the re-development of good A-M tuners which died out when the "all-American" five-tube table radio was first introduced.

ULN-2211B TV SOUND CHANNEL — 2-WATT OUTPUT

FEATURES

- Low Limiting Threshold
- Low External Parts Count
- Wide Operating Voltage Range
- 70 dB Limiter Gain
- 70 dB D-C Volume Control Range
- Automatic Thermal Shutdown
- Output Current Limiting
- 20 dB Ripple Rejection

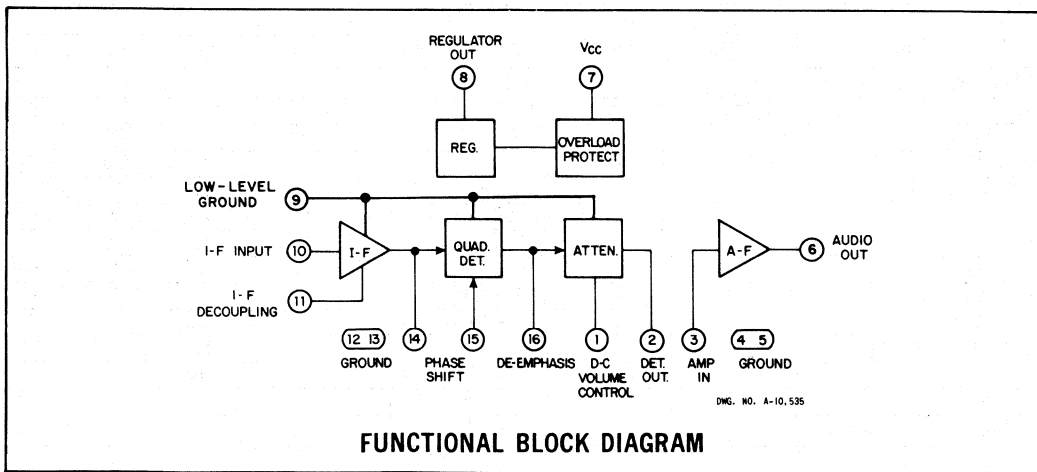

DESIGNED for use as the entire sound function in television receivers or F-M table radios, the ULN-2211B sound channel will directly drive a 16 ohm speaker with more than 2 watts output. This monolithic integrated circuit will operate from a single 18 V to 28 V power supply and can also function (with reduced power output) with supplies as low as 12 V if additional decoupling is provided.

The ULN-2211B is supplied in an improved 16-lead plastic dual in-line package with heat-sink contact tabs. A copper alloy lead frame allows maximum

power dissipation with standard cooling methods. The unique lead configuration allows easy attachment of a heat sink and yet permits the use of a standard I.C. socket or printed wiring board layout.

ULN-2224A CHROMA DEMODULATOR WITH RGB OUTPUT

FEATURES

- Luminance and Blanking Inputs
- Good Chroma Sensitivity
- 3 mV/°C Typical Temperature Stability
- 600 mV Maximum Offset Voltage
- 10 V_{pp} Typical Blue Output Voltage
- Output Short-Circuit Protection
- Pin-for-Pin Replacement for MC1324P

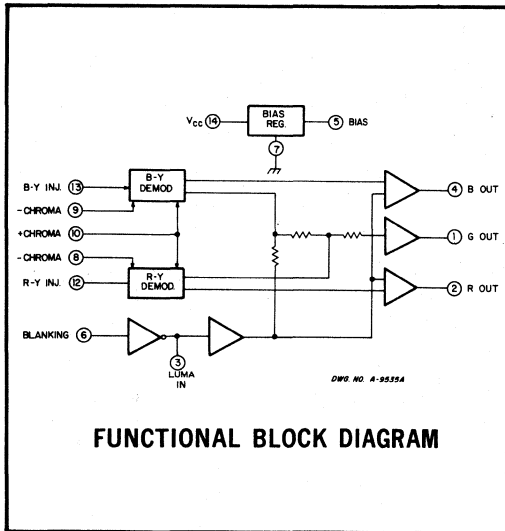

PROVIDING direct red-green-blue (RGB) outputs, the Sprague ULN-2224A Chroma Demodulator contains two doubly-balanced demodulators, a resistor matrix to derive the G-Y signal, luminance and blanking stages, and three high-level output emitter follower stages.

The ULN-2224A Chroma Demodulator is supplied in a 14-pin dual in-line plastic 'A' package.

ABSOLUTE MAXIMUM RATINGS at T_A = +25°C

Relative Output Phase (B to R)	4-2	B output = 5.0 V_{PP}	101	106	111	Degrees	5
Relative Output Phase (B to G)	4-1	B output = 5.0 V_{PP}	248	256	264	Degrees	5
Demodulator Unbalance Voltage	1, 2, 4	No chroma input voltage and normal reference signal input voltage	—	250	500	mV $_{PP}$	6
Residual Carrier and Harmonics	1, 2, 4	With input signal voltage, normal reference signal voltage and B = 5.0 V_{PP}	—	0.7	1.5	V_{PP}	7
Reference Input Resistance	12, 13	Chroma input = 0	—	2.0	—	k Ω	
Reference Input Capacitance	12, 13	Chroma input = 0	—	6.0	—	pF	
Chroma Input Resistance	9, 10		—	1.0	—	k Ω	
Chroma Input Capacitance	9, 10		—	2.0	—	pF	
Luma Input Resistance	3		100	—	—	k Ω	

NOTES:

1. With chroma input signal voltage = 0 and normal reference input signal voltage = 1.0 V_{PP} , all output voltages will be within specified limits and will not differ from each other by greater than 600 mV.
2. With normal reference input signal voltage, adjust chroma input signal voltage to 1.2 V_{PP} .
3. With normal reference input signal voltage, adjust chroma input signal voltage until the B output voltage = 5 V_{PP} : The chroma input voltage at this point should be equal to or less than 700 mV $_{PP}$.
4. With normal reference input signal voltage, adjust the chroma input signal until the B output voltage = 5 V_{PP} . At this point, the R and G voltages will fall within the specified limits. Luma voltage = 23 V.
5. Tested with B output = 5.0 V_{PP} , luma voltage = 23 V.
6. No chroma input voltage and normal reference signal input voltage.
7. Tested with input signal voltage, normal reference signal voltage and B output = 5.0 V_{PP} .

ULN-2260A AGC CONTROL, SYNC SEPARATOR and SCAN PROCESSOR

FEATURES

- Excellent AGC Noise Immunity
- High Output Sync Level
- Balanced Phase Detector
- Stable Master Oscillator
- 16-Pin Dual-In-Line Plastic Package

TELEVISION-CIRCUIT SIMPLIFICATION and high performance are primary advantages of designs using Type ULN-2260A. NTSC or PAL television receivers, color or monochrome, with countdown or conventional synchronization, can be flexibly and efficiently partitioned through use of this device.

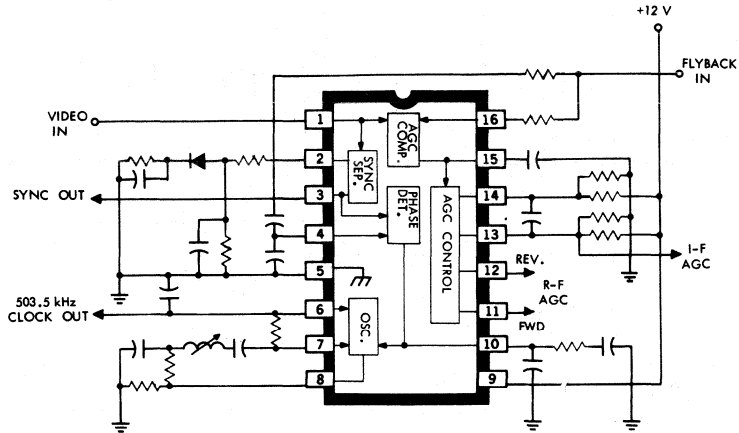

The AGC detector of Type ULN-2260A employs a coincidence gate approach that minimizes noise effects. The circuit maintains constant AGC levels despite temporary losses of synchronization and temporary horizontal timing disturbances. The AGC-synchronization loop has both the high gain and high slew rate needed for fast channel-to-channel gain equalization and reduction of airplane flutter. Both forward and reverse delayed AGC currents are developed.

The sync separator uses an external passive network. The designer chooses the sampling level and time constants. The 10 V_{pp} output is short-circuit limited at approximately 25 mA.

The phase detector of Type ULN-2260A compares the sync separator's output to the integrated horizontal flyback pulse. Its output is a voltage proportional to the phasing error. Static phase error attributable to detector imbalance is minimized.

The designer is able to define the free-running frequency, control sensitivity and temperature compensation of the integrated circuit's oscillator. A wide range of frequencies can be generated, accommodating any of several TV or video display terminal deflection systems.

SCHEMATIC

ULN-2261A LUMINANCE PROCESSOR

FEATURES

- Luma/Chroma Tracking
- Automatic Beam Limiter
- D-C Restoration
- Luma/Chroma Vertical Blanking
- Single D-C Gain Control
- Low External Component Count
- Direct Replacement for CA3135
- 16-Pin Dual In-Line Plastic Package

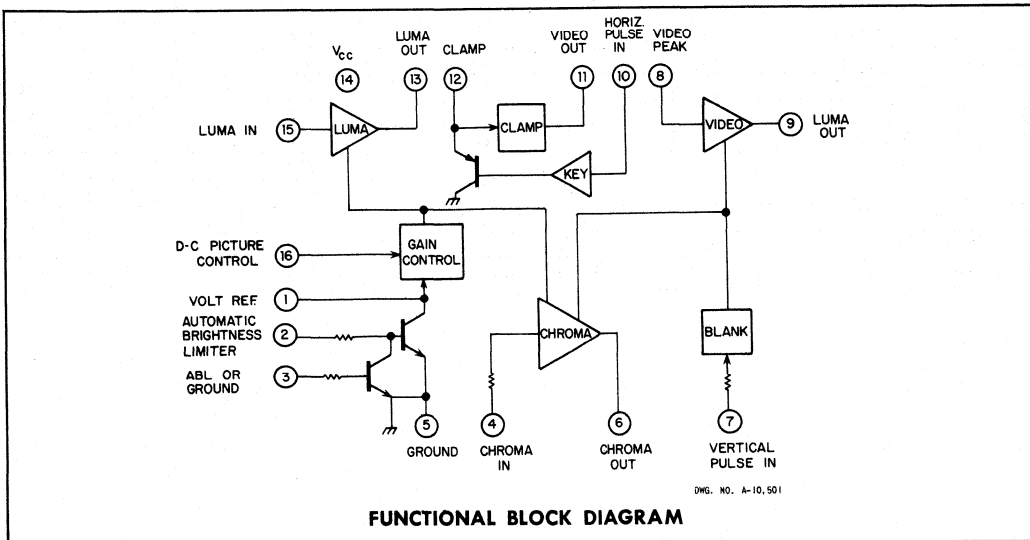

A SINGLE d-c picture control adjusts the gain of both the low-level video and chroma amplification in color TV receivers which employ the ULN-2261A Luminance Processor. Automatic brightness limiting (ABL) and vertical blanking also take place on both channels while maintaining a constant black level. During the horizontal blanking interval, the black level is determined by clamping the black-level reference (the "back porch"). This allows for 100% d-c restoration.

TYPICAL APPLICATION

ULN-2270B AND ULN-2270Q/TDA1170 VERTICAL DEFLECTION SYSTEM

FEATURES

- Internal Reference
- Positive or Negative Sync Input
- Vertical Ramp Generator
- Vertical Driver
- Flyback Generator
- Single-Supply Operation

AS A SINGLE DEVICE containing a vertical oscillator, a flyback generator and a power amplifier, this vertical deflection system can greatly simplify design of black-and-white and small-screen color television receivers.

The oscillator of Types ULN-2270B and ULN-2270Q is directly synchronized by positive or negative sync pulses. A current feedback loop makes yoke current independent of yoke resistance changes caused by operating temperature variations. The flyback generator develops the high voltage required by the yoke for short flyback time and high efficiency.

Type ULN-2270B is supplied in a 16-pin dual in-line plastic package with heat sink contact tabs. Its copper alloy lead frame gives enhanced power dissipation ratings with standard cooling methods. Greater package power dissipation is available with attachment of an external heat sink to the webbed center leads of the device. The lead configuration makes possible easy attachment of a heat sink and

use of a standard integrated circuit socket or printed wiring board layout.

Type ULN-2270Q/TDA1170 is supplied in a 16-pin quad in-line plastic package. It uses the printed wiring board on which it is mounted as a heat sink. Small heat sinks can also be attached to the center tabs of the device. The device carries the Sprague Electric Company part number (ULN-2270Q) unless the Pro-Electron marking (TDA1170) is requested.

ULN-2290B and ULN-2290Q TV SOUND CHANNEL (TDA3190 and TDA1190Z) — 4 WATT OUTPUT

FEATURES

- High Sensitivity
- High A-M Rejection
- D-C Volume Control
- High Power Output
- Low Distortion
- Wide Operating Voltage Range (9 to 28 V)
- Low Quiescent Current Drain

CAPABLE OF CARRYING OUT all of the functions of a TV sound channel, the ULN-2290 silicon monolithic integrated circuit consists of a six-stage I-F amplifier/limiter, low-pass filter, differential peak detector, d-c volume control, regulated power supply, audio preamplifier and output stage.

The audio power amplifier will deliver 4 W of low-distortion audio to a 16Ω load with a supply of 4 V. When used with a 12 V supply, such as is found in many portable TV sets, these ICs will furnish 1.5 W to an 8Ω loud speaker.

This TV sound channel is available in either of two package configurations. Type ULN-2290Q is supplied in a quad in-line plastic package with a copper lead frame. This device is designed to use the printed wiring board on which it is mounted for heat dissipation and is identical to European Type TDA1190Z. It is marked with its Pro-Electron registration unless otherwise specified on production orders.

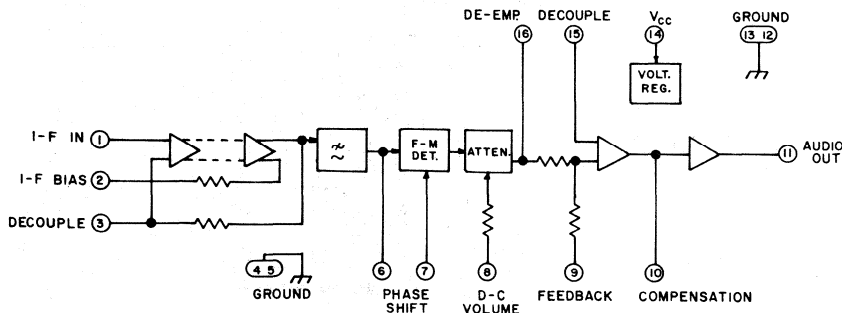

Type ULN-2290B is furnished in an improved 16-lead plastic dual in-line package with heat-sink contact tabs. The webbed lead configuration, originated by Sprague Electric, allows an inexpensive heat sink to be easily attached for increased power dissipation capability and yet permits the use of a standard IC socket or printed wiring board hole layout. This device is identical to European Type TDA3190.

Pro-Electron	1	2	3	TAB	TAB	4	5	6	7	8	9	TAB	TAB	10	11	12

Applications Information

1. Types ULN-2290B and ULN-2290Q have high input impedances, allowing them to be used with a ceramic filter or tuned circuit to provide the necessary input selectivity.

2. The electrical characteristics of these devices will remain relatively constant over the I-F frequency range of 4.5 MHz to 10 MHz. They can therefore be used with all common television standards.

3. The a-c gain of the audio amplifier is determined by the resistor ratio at pin 9. The gain should be defined in relation to the frequency deviation at which the output stage of the audio amplifier begins clipping.

4. The resistor between pins 9 and 11 can be replaced with various combinations of resistance and capacitance to provide bass boost or treble attenuation.

5. De-emphasis is determined by the capacitor connected at pin 16 and an internal 10 kΩ resistor. This pin can also be used to provide a treble-cut type of tone control.

6. The high-frequency audio cutoff is determined by the capacitors connected at pin 10. To increase the audio bandwidth, reduce the values of these capacitors, keeping their ratio constant.

- RGB Outputs
- 10 to 14 V Operation
- Internal Bias Supplies
- 28-Pin Dual In-Line Plastic Package

IMPROVED performance, reliability, manufacturing economy, and elimination of a substantial number of discrete components are among advantages offered by this NTSC chrominance/luminance television subsystem.

This monolithic integrated circuit replaces four devices — the chroma amplifier, chroma demodulator, oscillator and luma processor.

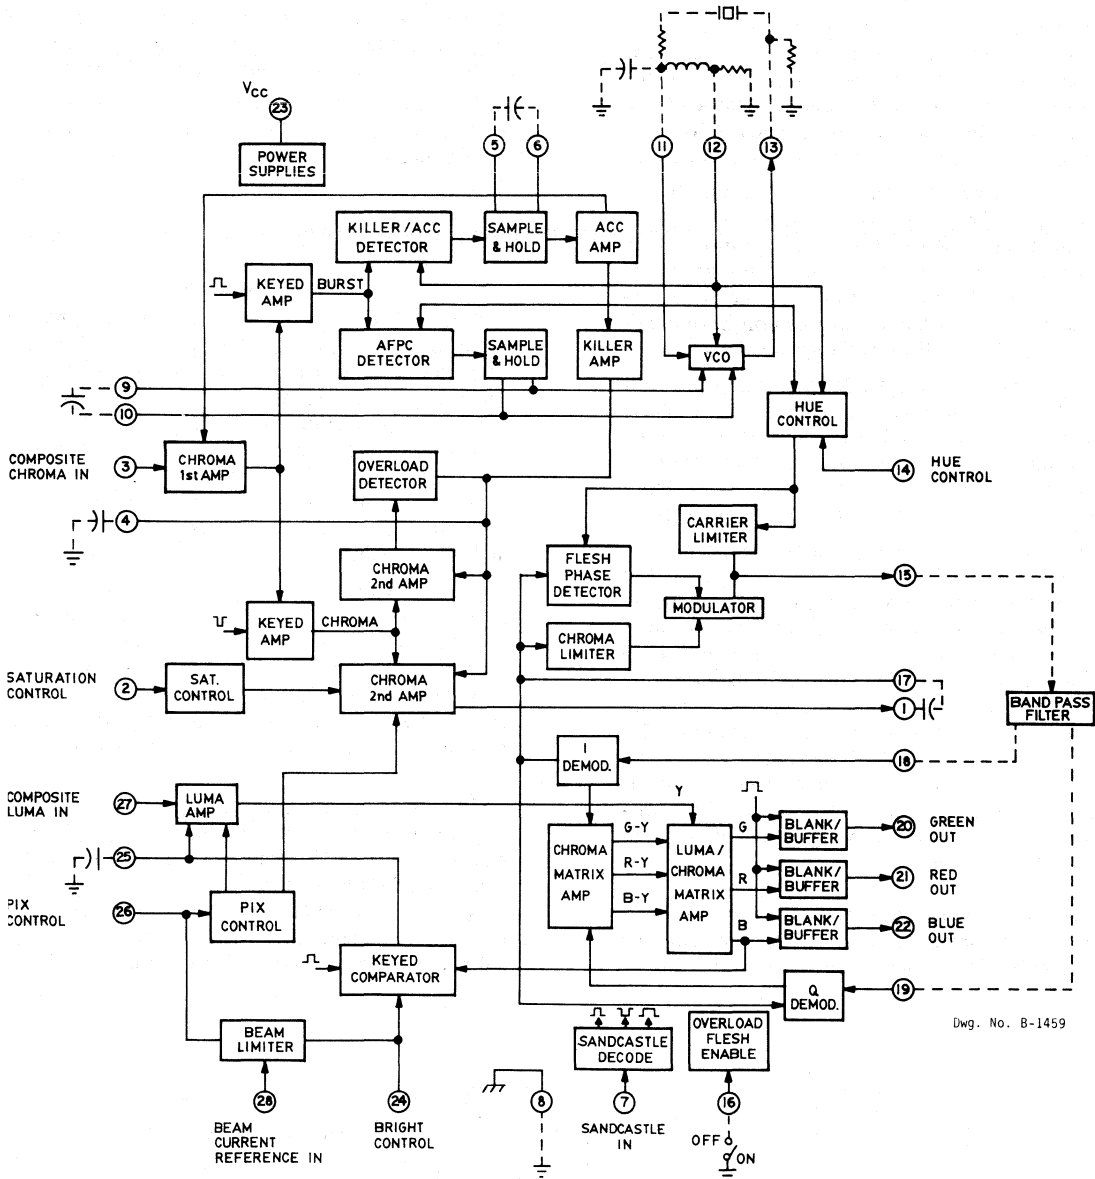

Type ULN-3914A derives the three color signals (RGB) from the composite video signal. Viewer

operated controls such as picture control, tint, saturation and brightness remain accessible although feedback loops are employed to eliminate the need for frequent viewer adjustments. The feedback loops provide standard automatic chroma control (ACC), dynamic flesh-color correction, beam limiting and gated black level control.

FUNCTIONAL BLOCK DIAGRAM

THE ULN-2211 TV — FM SOUND SYSTEM

Introduction

The sound section of the typical home television receiver has had several stages of development. The earliest vacuum-tube receivers used either a discriminator or a ratio detector. Later, because of cost and ease of tuning, the one-tube locked oscillator (or so-called quadrature detector) came into wide use.

With the advent of linear integrated circuits for the consumer market, methods of performing the F-M detector function, theretofore cost-prohibitive, were utilized to significant advantage. Although phase-locked systems have been introduced, the more classical approaches to the sound function have dominated both TV and F-M radio applications.

In the present monolithic detector, the phase-shift network is a simple one-winding coil. The full task of balancing the output has been taken over by monolithic circuitry. This makes the best use of the integrated components in keeping external components as simple as possible, and lowering costs.

The basic F-M sound system comprises five functional blocks. The first is the limiting amplifier that, together with certain detector characteristics, determines the sensitivity or threshold of the system. The small-signal gain of the limiting amplifier is typically 60 to 80 dB. The volume-control function has usually consisted of a potentiometer for varying the voltage ratio. The electronic attenuator or d-c volume control has gained popularity due to its simplicity in monolithic form and its economic advantages. The audio preamplifier usually has sufficient voltage gain to fully drive an output amplifier at 30% F-M modulation.

In the past, the output power amplifier consisted of a transformer-coupled discrete transistor or vacuum-tube class A design, although some class B

designs have also been used. Type ULN-2211 sound system includes a quasi-complementary audio power amplifier. Internal biasing and feedback is provided to set the closed loop gain at about 28 dB.

Type ULN-2211 is completely fault-protected by short-circuit current limiting and by thermal overload protection.

System Description

Type ULN-2211 sound system is designed to satisfy all requirements of the sound-channel portion of a television receiver. In addition, it has adequate sensitivity and, with the addition of a tuner and power supply, can function as a complete monaural F-M receiver. The device features a high output-power capability of four W (with adequate heat sinking), a wide supply-voltage range (12 to 28 V d-c), a minimum number of required external components, and high reliability at low cost.

A block diagram of Type ULN-2211 is shown in Figure 2. The limiting amplifier and true quadrature detector have been designed to provide more than adequate sensitivity (typically 150 μ V). Excellent A-M rejection has been achieved by the use of balanced differential gain stages, interstage decoupling networks, and balanced differential quadrature inputs.

The d-c volume control is capable of providing high attenuation for a low system play-through (typically less than 5 mV_{rms}). Its circuit design permits the use of standard linear taper controls in a wide range of resistance values (1 k Ω to 100 k Ω). The attenuation is independent of any match between the external control and internal device parameters.

Figure 1
FM SOUND SYSTEM BLOCK DIAGRAM

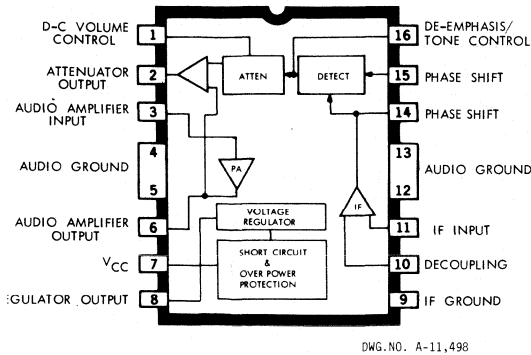

Figure 2
ULN-2211 BLOCK DIAGRAM

An internal voltage regulator provides more than 10 dB of isolation to external signals on the supply line. The regulator also permits device operation over the wide supply-voltage range with virtually no change in characteristics, other than the output-power rating. The regulated output-voltage is available for possible use in external biasing or as a low level (less than 10 mA) regulated supply.

The audio power amplifier provides adequate gain and drive capability to produce 4 W of power into a 6Ω load with a 27 V power supply. A special bias circuit gives a power supply rejection of better than 5 dB without the use of expensive high-value capacitors. Bias voltage is removed from the output amplifier if any overload condition causes the chip temperature to exceed a preset value. This feature, with the emitter-ballasted output-current limiters, permits complete a-c short-circuit protection under any load condition without damage to the device. D-C short-circuits can be tolerated under less severe conditions of supply voltage and drive.

Type ULN-2211 sound system is normally applied in a modified 16-pin dual in-line plastic package. Pins 4, 5, 12, and 13 are common and provide a means for attaching an external heat sink. The use of a copper-alloy lead frame permits a high pitch to tab thermal resistance of about 15°C/W.

Limiting-Amplifier Description

The limiting-amplifier consists of three differential stages. A fourth stage is used to provide balanced quadrature signals, as well as additional threshold sensitivity. The first two stages have a gain of 24 dB each; the gain of the third is 17 dB; the fourth adds approximately 10 dB more for a total of 75 dB before limiting. The gain characteristic is flat to at least 0 MHz to permit the device to function at either of the standard F-M I-F frequencies (4.5 MHz or 0.7 MHz).

The stages are d-c coupled via emitter followers. These are returned to the supply to keep low-level A-M signals from detector-biasing circuits. The third stage is single-ended. Its output is buffered and level shifted by Q_{13} and D_3 to provide the proper d-c feedback via R_{14} and pin 11. This arrangement allows the use of only a single decoupling capacitor, saving a capacitor and resistor and requiring one pin less than other approaches.

The feedback reference for the first stage is set by diodes D_1 and D_2 which also serve as the bias source for Q_5 , Q_6 , and Q_{14} .

Resistors R_1 , R_2 , and R_3 form a T-connection to define the collector loads of the first stage and adjust the output d-c level of the next stage. Similar functions are performed by R_7 , R_8 , R_9 , and R_{12} , R_{13} . Resistors R_3 , R_9 , and R_{13} also serve a decoupling function with the low impedance at the emitters of Q_{15} and Q_{16} that suppresses any feedback between stages, which would degrade AM rejection, particularly at low levels.

The limiter output at diode D_3 is coupled through resistor R_{15} to the quadrature amplifier (Q_{24} and Q_{25}) and to the detector. Resistor R_{15} compensates for base-current drops in R_{14} and, together with the input capacitance of Q_{24} provides higher order harmonic suppression in the detector. The primary function of the quadrature amplifier is to provide balanced, symmetrical inputs to the quadrature network. This improves performance and simplifies board layout, since spurious pickup by the quadrature network is greatly reduced due to the common-mode nature of the circuit. This stage also supplies additional limiting since its output will not be reduced until the limiter output falls below that required to reduce the differential output of Q_{24} and Q_{25} .

F-M Detector Description

Type ULN-2211 uses a quadrature detector as shown in Figure 4. Transistors Q_{27} through Q_{32} form the actual detector. They are biased by the stabilized voltage regulator to prevent any ripple from the supply from appearing in the recovered audio. The limiter output drives the bottom pair (Q_{31} and Q_{32}), while the upper pairs are used as the quadrature inputs.

The detector output is developed across the balanced loads, R_{28} and R_{29} . A direct audio output is available from this point via pin 16. The impedance is set at 10 kΩ, which provides a suitable point for de-emphasis and a tone-control function, if desired.

7

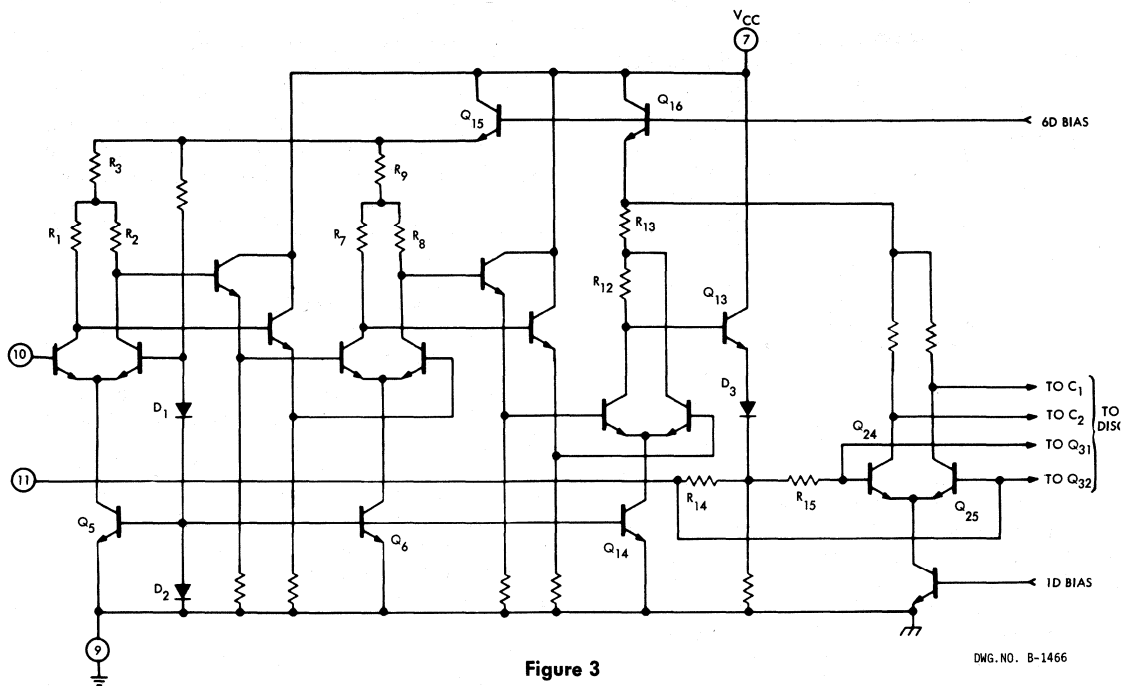

Figure 3
LIMITING AMPLIFIER

The audio signal is directly coupled to the attenuator circuitry via the d-c level shift circuit consisting of Q_{35} , Q_{36} , and R_{39} .

D-C Volume Control

The primary requirements of an attenuator, or d-c volume control, are: A dynamic range of better than 70 dB, temperature stability, and independence of external component tolerances.

The d-c volume control consists of two current-steering differential pairs (Q_{38} through Q_{41}). The left pair is driven by current source Q_{37} from the level-shifted detector output. Current source Q_{47} acts as a d-c reference to maintain the output Q-point. Attenuator output is obtained from the attenuator load resistor, R_{40} , which is returned to the regulated supply. The other side of the attenuator is returned to V_{CC} to minimize play-through. Transistor Q_{65} forms a simple emitter-follower buffer to give a low impedance output at pin 2.

The current-steering attenuator is controlled by a d-c control voltage applied to the bases of Q_{38} through Q_{41} . The signal output of the attenuator follows the relation:

$$I_o = \frac{I_s}{1 + e^{-\frac{V_{BB}}{KT/q}}}$$

(1)

where KT/q is equal to 0.026V. As can be seen 6 dB of attenuation occurs at $V_{BB} = 0$. Also, 70 dB of attenuation requires a V_{BB} of $8KT/q$. This is minimum figure, which more typically would be $9KT/q$ or 234 mV.

All d-c volume controls now in use have some form of this attenuator to control the audio gain. The configuration provides the required 70 dB attenuation. The derivation of the control voltage (V_{BI}) requires careful consideration, since it will directly determine the terminal characteristics of the device.

Many designs use an external resistance to control an internal bridge configuration and produce the control voltage. In spite of the problems introduced because of the wide attenuation spreads of these devices in production (15 to 20 dB), they have been widely used. This attests to the value of the function itself. Some designs have derived the control voltage completely externally, relying on external component tolerances to control gain spreads and reduce thermal interactions.

The shape of the control curve has been the subject of much debate. Resistor-divider controls vary the attenuation as a logarithmic function of the control voltage while other techniques yield linear relationships.

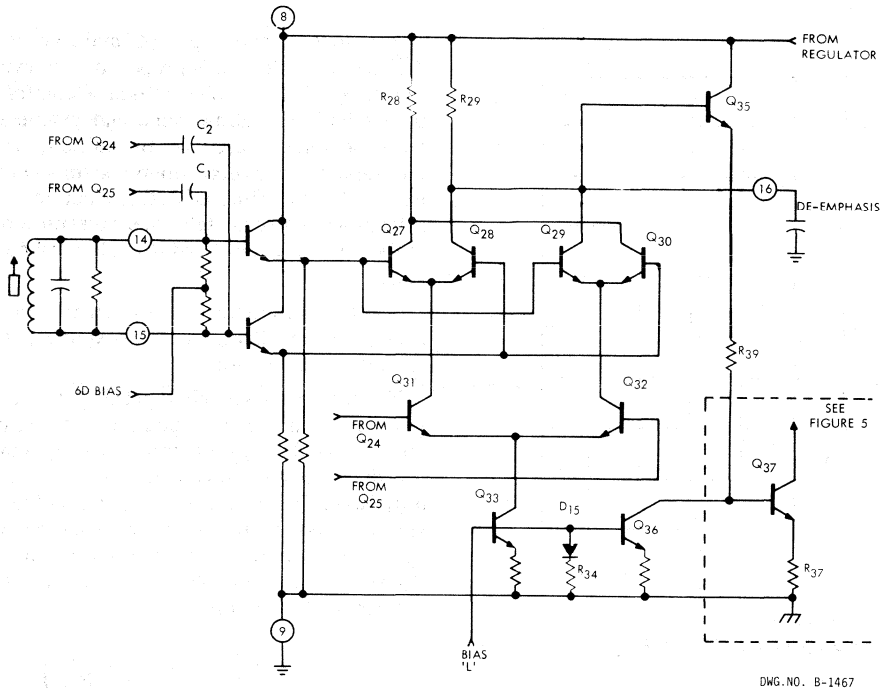

Figure 4
QUADRATURE DETECTOR

Figure 5
D-C VOLUME CONTROL

DWG. NO. A-11,504

Figure 8
D-C VOLUME-CONTROL CHARACTERISTIC

Inserting the resistor values, this simplifies to

$$V_{OQ} = 0.45 V_{CC} + 1.6 V_{BE}$$

(21)

The unique input biasing (pat. U.S. 3,896,383) provides internal ripple rejection without the use of a separate large external decoupling capacitor. Supply ripple voltage appears at the amplifier input via divider R_{48} and R_{50} and divider R_{49} and $C_C + R_{OUT}$, where R_{OUT} is the output impedance of the attenuator at pin 2. The amplifier input therefore sees only a greatly attenuated ripple component. The following expressions define the ripple rejection.

The input ripple voltage is:

$$V_{r_i} \approx V_r \left(\frac{R_{50}}{R_{48} + R_{50}} \right) \left(\frac{R_{OUT}^2 + (1/\omega C_C)^2}{R_{49}} \right)^{1/2}$$

(22)

The output ripple voltage is:

$$V_{r_o} = V_{r_i} A_{VCL}$$

(23)

The ripple rejection is:

$$S_{rr} = 20 \log \frac{V_r}{V_{r_o}}$$

(24)

Assuming

$$R_{OUT} \ll \frac{1}{\omega_r C_C}$$

(25)

and

$$R_{48} \gg R_{50}$$

(26)

then

$$\frac{V_r}{V_{r_o}} = \frac{R_{48} R_{49} \omega_r C_C}{25 R_{50}}$$

(27)

Inserting the component values and simplifying, the ripple rejection at 120 Hz becomes

$$S_{rr} = 20 \log 39.8 = 32 \text{ dB}$$

(28)

and at 60 Hz

$$S_{rr} = 20 \log 19.9 = 26 \text{ dB}$$

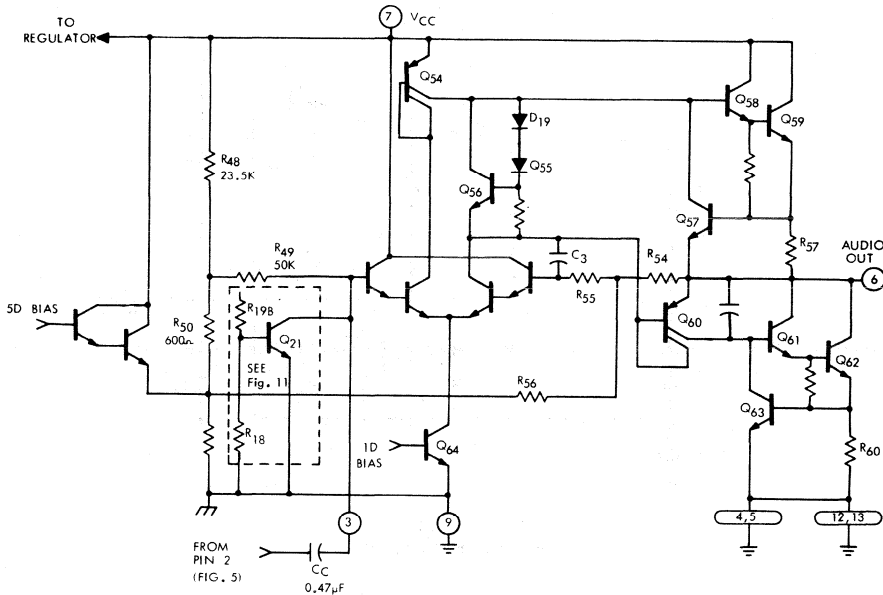

(29)

The amplifier input stage is a Darlington differential stage biased by Q_{64} . A diode-connected current mirror (Q_{54}) converts the differential output of Q_{51} and Q_{52} to a single-ended output for the final amplifier. The final amplifier's idling current is set by a $3V_{BE}$ diode network consisting of D_{19} , Q_{55} , and Q_{56} .

The output stage is a quasi-complementary class B design. The drivers are Q_{58} and Q_{61} , while the output power transistors are Q_{59} and Q_{62} . Transistor Q_{60} is a unity gain PNP that provides the phase reversal function. The internal closed loop gain is set by R_{54} and R_{56} . A dominant pole is introduced in the amplifier's open-loop response by means of R_{55} , C_3 , and C_4 . This pole can be determined by

$$f_d = \frac{1}{2\pi A_{VOL} C_3 R_{55}}$$

(30)

DWG. NO. B-1468

Figure 9
OUTPUT AMPLIFIER

This puts the pole at approximately 500 Hz, limiting the amplifier's closed-loop response (f_{th}) to about 50 kHz.

The low-frequency pole (f_L), defined by the input coupling capacitor and R_{49} , is specified as:

$$f_L = \frac{1}{2\pi C_C R_{49}} \quad (31)$$

It should be noted that the output-load coupling capacitor will also influence the low-frequency response.

A plot of the output amplifier's frequency response is shown in Figure 10.

Overload protection for the output amplifier is accomplished by limiting the output-transistor current and by removing the bias from the amplifier input when chip temperature exceeds 150°C. Transistors Q_{57} and Q_{63} perform the current-limiting function while Q_{21} senses chip temperature and acts to ground the input to the amplifier, removing bias from the output devices.

DWG. NO. A-11,500

Figure 10
OUTPUT-AMPLIFIER FREQUENCY RESPONSE

Current limiting is defined by the emitter ballast resistors (R_{57} and R_{60}) as simply

$$I_{sc} = \frac{V_{BE}}{R} \quad (32)$$

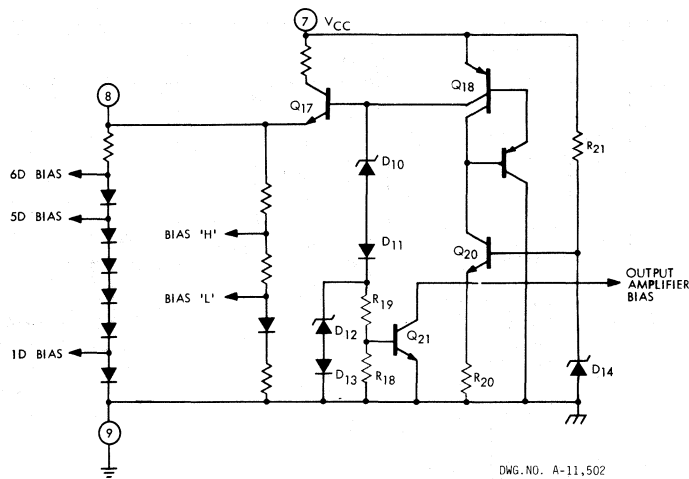

Figure 11
INTERNAL REGULATOR

The short-circuit current is typically 1 A at +25°C, decreasing by approximately 3500ppm/°C due to the reduction of V_{BE} and the increase of R_{57} and R_{60} with temperature. At the maximum chip temperature (150°C), the short-circuit current will be about 560 mA.

Thermal shutdown is programmed by the voltage divider, R_{18} and R_{19} . The base-emitter bias of transistor Q_{21} is related to the shutdown temperature as

$$T_s \approx T_A \left(2 - \frac{V_{BEs}}{V_{BEA}} \right) \quad (33)$$

where:

T_s = chip shutdown temperature in °K;

T_A = reference temperature (293 °K);

V_{BEs} = shutdown bias voltage;

V_{BEA} = bias at reference temperature (600 mV).

If T_s is 423 °K (150°C), then V_{BEs} is equal to 334 mV. The circuit design actually requires a temperature of about 180°C to produce complete shutdown. This ensures a smooth, stable transition.

Internal Regulator Description

The internal voltage regulator in Type ULN-2211 provides bias stabilization necessary for critical input, detector, and control functions. In addition, the regulator provides stabilization of the output bias currents and provides bias for the thermal shutdown

circuit. The first stage of the regulator consists of resistor R_{21} and diodes D_{14} and D_{21} to provide a stable voltage for current source Q_{20} . The emitter resistor (R_{19}) is tapped to establish the thermal shutdown reference. The current source is mirrored in Q_{18} , which drives diodes D_{10} through D_{13} to set the regulator output voltage. Transistor Q_{17} is the series-pass output of the regulator. It is capable of driving all of the internal bias loads and is available at pin 8 for driving up to 10 mA (at 15 V) into an external load.

Characteristics and Applications

A typical application of Type ULN-2211 is shown in Figure 12. The input selectivity network can be any of several types. However, the total network impedance (pin 10-pin 11) must be less than 500 ohms to guarantee stable operation. The bypass capacitor on pin 11 should be as close to the pin as possible to assure good bypassing. It is also advisable to keep the input grounds (pin 9) separate from the output grounds (tabs) to prevent ground-current interaction at low input levels.

The detector characteristics can be varied by changing the values of R, L, and C in the quadrature tuning network. The output level and THD of the detector will depend on the Q of the network. The loaded Q (Q_L) of the network can be found from

$$Q_L = \frac{Q_C}{1 + \frac{\omega_o L Q_C}{R}} \quad (34)$$

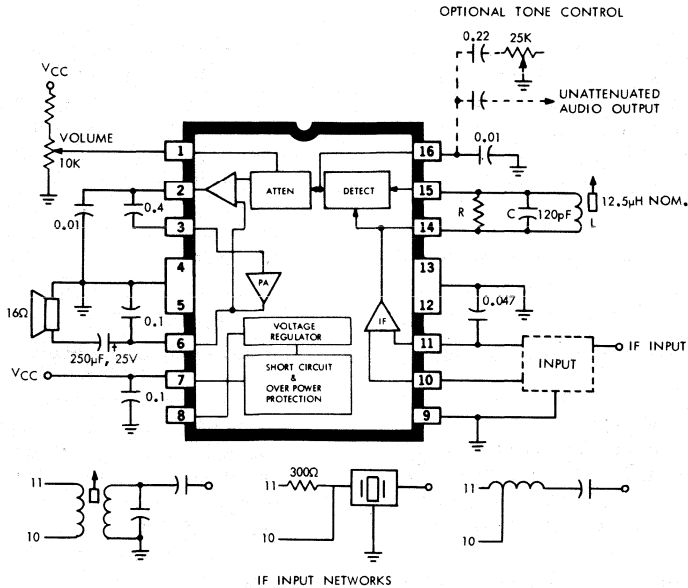

Figure 12
TYPICAL APPLICATION

where:

Q_c = the unloaded coil Q ;

R = the parallel combination of the equivalent 20 kΩ internal resistance and any additional external resistance.

Lower Q results in lower THD and recovered audio. The output of the detector is given by:

$$V_o = \frac{2}{\pi} \arctan\left(\frac{2Q_L f_d}{f_o}\right) \quad (35)$$

The detector THD is given by:

$$THD \approx 8.4 \left(\frac{2Q_L f_d}{f_o}\right)^2 \quad (36)$$

By substituting and solving for $Q_c = 50$ ($R = 20$ kΩ, $f_o = 4.5$ MHz, and $f_d = 25$ kHz), $Q_L = 30$ and $THD \approx 1\%$. By adding an external resistor to reduce Q_L to 20, the THD is reduced to about 0.4% and the detector output is reduced by about 35%.

The capacitor at pin 16 provides system de-emphasis. The internal impedance at pin 16 is 10 kΩ. A 0.01 μF capacitor sets de-emphasis at 100 μs or 1.6 kHz. A high-cut (low-pass) tone control can be added at pin 16. Typical values would be 25 kΩ and 0.22 μF. Alternatively, the tone control can be added between the attenuator output and the audio input with some degradation in ripple rejection, as discussed previously.

A volume-control value between 10 kΩ and 100 kΩ is recommended. The control can be returned to V_{CC} or returned to the regulated output on pin 8. In the former case, some decoupling may be necessary to prevent ripple feedthrough.

The output amplifier requires only the output load capacitor and a 0.1 μF output bypass to suppress any tendency for the composite output current-sinking transistor to oscillate with inductive loads.

The input coupling capacitor (C_c) is selected in accordance with previous discussions. A small capacitor, typically 0.01 μF, is used at pin 2 to remove any residual high-frequency content.

7

The supply voltage for Type ULN-2211 may range from 12 to 27 V. However, in order to obtain a nominal 2 W output with the recommended 24 V supply, the supply impedance must be kept below 25 Ω (19 V minimum full-load supply voltage).

The most important typical characteristics of the sound system are summarized in Table I.

Figure 13 shows the input-limiting threshold and signal-to-noise performance for the entire system (IF input to audio output). As shown, the typical limiting threshold is at $V_m = 150 \mu V$.

Figure 14 shows the excellent A-M rejection characteristics of the sound system over three decades of input signal variation. The performance for the entire system is shown. The output level is set by the volume control to produce 4 V across the 16 Ω load (1 W) with an input voltage of 10 mV_{rms}.

Figure 15 shows the output volume-control characteristic with 30% F-M modulation.

The three curves in Figure 16 show the system's residual output under conditions of 30% A-M signal, continuous unmodulated carrier, and no-input signal as a function of the volume-control voltage. The curves are very similar to that of the volume-control characteristic shown in Figure 8, illustrating the uniform A-M rejection and signal-to-noise performance of the sound system as the control is varied over its full range.

Figures 17 and 18 illustrate the output capabilities of Type ULN-2211 over a wide variety of supply voltage and load conditions. As shown, a power output of up to 4 W can be obtained with a 27 V supply while a more nominal 24 V supply will allow up to 3.6 W at 10% total harmonic distortion. Care should be taken to allow for supply-voltage sag when calculating maximum output power. For example, the typical 24 V supply, with an equivalent impedance of 25 Ω , will sag to 19.5 V at full audio power output (approximately 2 W). Figure 19 shows device dissipation and efficiency curves for the nominal 24 V supply.

16-LEAD DUAL IN-LINE 'B' PACKAGE

Package Design

Type ULN-2211 is furnished in a modified 16-lead plastic dual in-line 'B' package shown in Figure 20. The tabs (pins 4, 5, 12, and 13) allow easy attachment of various inexpensive heat sinks or can be directly soldered into the printed wiring board for low power applications.

The power dissipation of the package is ultimately limited by the chip-to-tab thermal resistance (Θ_{JT}) of approximately 15°C/W, and the absolute maximum chip temperature of +150°C. The allowable power dissipation can be determined from the following equation:

$$P_D = \frac{T_J - T_A}{\Theta_{JT} + \Theta_{TA}} \tag{37}$$

Figure 21 shows the allowable power dissipation as a function of ambient temperature for various tab-to-ambient thermal resistances (Θ_{TA}). The two extremes are for an infinite heat sink, which is ideal but impossible to attain, and normal unsunked printed wiring board mounting.

In practice, an intermediate condition usually exists. This is illustrated with the Staver Type V-8 heat sink. An approximate equivalent can be constructed by allowing about two square inches of excess ground foil on the printed wiring board in close proximity to the tabs.

Figure 21
POWER DISSIPATION vs AMBIENT TEMPERATURE

Reliability

Extensive reliability testing has been performed on the single-chip sound system. These tests have included pressure-cooker, temperature, dynamic operation, and power cycling at elevated ambient temperatures. These tests have shown an excellent reliability for use in all expected environments.

Conclusion

Type ULN-2211 sound system is designed to provide all functions required for consumer television and FM radio applications. It combines high performance with the lowest possible cost in both manufacture and application. It is capable of operating over a broad range of supply and load conditions, including repeated output short-circuits. The device has a highly stable remote d-c volume control and a superior front end performance. The output stage provides more-than-adequate power output and high ripple rejection, without the need for a separate bypass capacitor and pin.

THE ULN-2260A SIGNAL, SYNC, and SCAN PROCESSOR

Introduction

The monolithic integrated circuit provides high performance by careful selection of circuit techniques, and efficient partitioning of the AGC, sync separator, and master-scan phase-locked loop.

This grouping of circuit functions is particularly efficient. Since the video input is common to both AGC and sync separator, the separated sync can be internally coupled to the phase detector of the scan phase-locked loop; the flyback waveform is required for AGC gating and the phase detector.

DWG. NO. A-11,484

Figure 1
RECEIVER PARTITIONING

DWG. NO. A-11,485

Figure 2

AGC

When the scan is synchronized, current is supplied to the AGC detector (comparator) during the separated sync. The negative-going sync video waveform at pin 1 is compared with a 4.0 V level during this time. As a result of the AGC loop, the tip of the sync is clamped to 4.0 V.

DWG. NO. A-11,486

Figure 3
AGC DETECTOR

The AGC detector is a high gain comparator with an asymmetrical active load (Figures 3 and 4). The active load provides approximately 3.2 mA of primary filter capacitor charge current and 1.0 mA of discharge current.

DWG. NO. A-11,487

Figure 4
AGC DETECTOR CHARACTERISTICS

The high AGC-loop gain provides the high slew rate necessary for fast channel-to-channel gain equalization and response to airplane flutter variations.

The AGC detector is gated ON by a pulse defined by coincidence of horizontal flyback and sync. Coincidence-gating provides improved AGC noise immunity over systems only are flyback-gated. Coincidence-gating maintains AGC levels in the event of temporary loss of horizontal sync or disturbance of horizontal timing.

Coincidence-gating demands the use of two additional internal circuits to compensate for two extremes of video input level at pin 1. The first is a sync recovery system (Figure 5).

Figure 5
SYNC RECOVERY SYSTEM

Extremes occur in the transition from a strong to a weak signal. The AGC loop requires time to respond to new signal level. In the meantime, system gain is too low, and the video amplitude at pin 1 is too low for the sync separator to provide sync pulses for coincidence-gating. The resulting condition would be lockout of the signal. However, a threshold detector composed of Q_{35} and Q_{36} senses sync-separator (pin 2) voltages less than 3.8 V. When this occurs, the AGC detector is gated by flyback only, allowing the AGC system to respond to the new signal level. As the video amplitude at pin 1 increases to its nominal value, the AGC detector returns to the coincidence-gating mode.

The second extreme of video input level occurs in the transition from a weak to a strong signal. In the transition, the I-F amplifier overloads, resulting in a low d-c level at pin 1, Figure 6. The sync separator at pin 2 charges to a higher d-c level, and no sync pulses are generated for coincidence-gating. Lockout of the signal is again possible, being dependent on both AGC-loop response and sync-separator time constants.

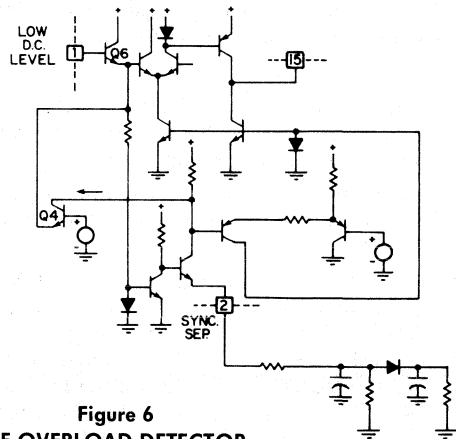

Figure 6
I-F OVERLOAD DETECTOR

DWG. NO. A-11,489

The threshold detector, Q_6 and Q_4 , senses when the d-c level at pin 1 is below 3.4 V. When this occurs, the AGC detector is gated by flyback only, allowing the AGC system to respond to the new signal level. As the video level at pin 1 decreases to its nominal value, the AGC detector returns to the coincidence-gating mode.

The AGC primary filter at pin 15 integrates the AGC-detector output into a d-c voltage, which drives the AGC control circuit. A low d-c level at pin 15 corresponds to a low received-signal level. Conversely, a high d-c level at pin 15 corresponds to a high received-signal level.

Figure 7 is a simplification of the I-F portion of the AGC control circuit. As is common practice, the I-F amplifier is gain-reduced prior to the tuner under increasing signal levels.

Figure 7
I-F AGC CONTROL CIRCUIT

DWG. NO. A-11,490

The maximum-gain voltage of the AGC primary filter is defined by the circuit designer as

$$V_{14} - 0.7 \text{ V}$$

since this level is internally clamped by Q_{18} . Under gain reduction, Q_{16} and Q_{17} force the voltage at pin 14 to follow 1.4 V below the primary filter voltage.

Produced by a series of emitter-followers, the I-F AGC output has a gain of 1, referenced to the AGC primary filter.

Choice of the external voltage-divider level, V_X , at pin 13 (I-F AGC output) defines the maximum I-F gain-reduction level, or AGC delay point, at which the tuner is called upon for further gain reduction. As there is a finite dead zone in the cross-over between I-F AGC and tuner AGC, a capacitor between pin 14 (a buffered primary AGC filter a-c voltage source) and pin 13 will decrease AGC recovery time in the transition between I-F and tuner AGC.

At the maximum I-F AGC level, V_X , the values of resistors R_{27} and R_{30} are such that the voltage at the base of Q_{27} is 1.4 V (Figure 8). This defines the point at which tuner AGC action is initiated. The collector current of Q_{27} is mirrored to provide forward-tuner AGC with a trans-conductance gain of 2.1 mA/V, referenced to the AGC primary filter. The emitter current of Q_{27} is mirrored to provide reverse-tuner AGC with a gain of 3.1 mA/V.

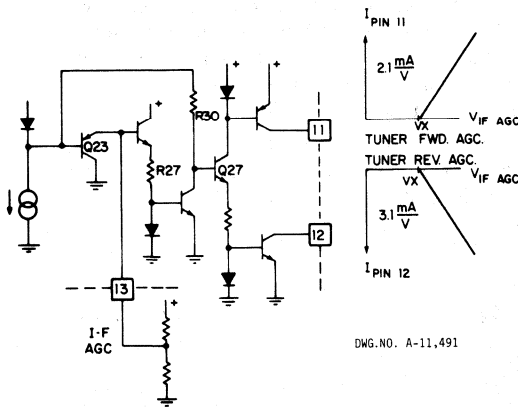

Figure 8
TUNER CONTROL CIRCUIT

Sync Separator

Since Q_4 , (Figure 6), clamps the video waveform to 0.5 V below the level of the sync tip, noise accompanying the incoming video is prevented from severely altering the sampling level of the sync separator.

The negative-going sync video waveform at pin 1 is inverted and amplified by 6 dB. This waveform is

buffered and applied to the base of Q_{33} , which has as its emitter load a dual time-constant sync-separator network (Figure 9). Since this network is external to the device, the circuit designer has freedom to choose the sampling level and sync-separator time constants.

Figure 9
SINGLE PIN SYNC SEPARATOR

The separated sync-voltage waveform at the collector of Q_{33} is clamped to 7.3 V by Q_{38} , and is amplified by approximately 20 dB (Figure 10). Complementary emitter-followers buffering the sync waveform have an amplitude of 10 V_{pp}. The sync output is provided at pin 3, protected by short-circuit current-limiting of approximately 25 mA. It is internally coupled to the scan-phase detector. In addition to protecting the device against accidental shorts, grounding pin 3 also provides a convenient method of adjusting the oscillator's free-run frequency.

Figure 10
SYNC OUTPUT CIRCUIT

Scan Processing

The scan-phase detector consists of a differential amplifier that is gated ON by separated sync. An integrated flyback waveform is applied to the input of the differential amplifier (Figure 11). The differential amplifier has an active load, providing single-ended output of the phase-detector currents.

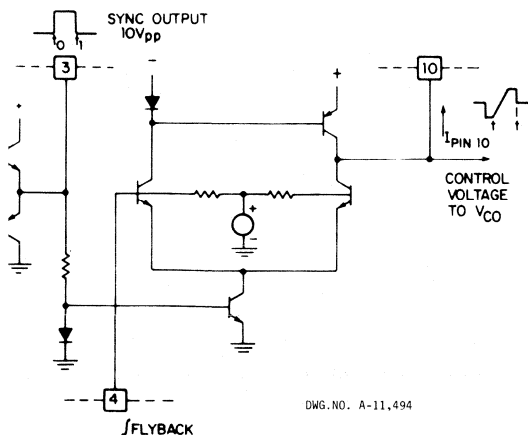

Figure 11
PHASE DETECTOR CIRCUIT

The positive and negative-output currents ($500 \mu\text{A}$) of the phase detector are internally balanced to within approximately 5% of the absolute value of these currents. This limits the static phase-error attributable to phase-detector imbalance. Since the phase-detector output filter is external to the device, pull-in characteristics can be defined by the choice of external filter components at pin 10.

A simplification of the master-scan VCO of Type ULN-2260A is shown in Figure 12. The VCO is designed to minimize the effects of device parameter variations on free-run frequency and VCO characteristics. Components defining phase-shift and filter

Figure 12
MASTER SCAN VCO

functions are external to the device. This provides the circuit designer with freedom to define the characteristics of the oscillator: Free-run frequency, control sensitivity and temperature compensation. Control of free-run frequency allows operation of the circuit in both countdown-synchronized and conventionally synchronized receivers.

The oscillator is controlled by weighted summing of quadrature components of feedback-signal current. The quadrature is inherently defined by the external resistor and capacitor of the tank circuit at the input of each of the two differential amplifiers. These external components are series connected. Therefore, the capacitor voltage waveform lags that of the resistor by 90° . VCO characteristics for a 503.5-KHz L-C oscillator, vertical countdown receiver, are shown in Figure 13.

Figure 13
VCO CHARACTERISTICS

Because it is a low-impedance source-point, pin 8 is internally short-circuit current-limited to approximately 70 mA.

Conclusions

The device presented above was designed to provide, with as much flexibility as possible, efficient partitioning of AGC, sync, and scan-control functions. Coincidence AGC-gating was utilized to improve AGC noise immunity. The circuit provides a high-level separated-sync output for sync integrators. The scan-phase detector is accurately balanced internally. The scan VCO was chosen to minimize the effects of device-parameter variations on oscillator characteristics, and is adaptable to both countdown-synchronized and conventionally synchronized receivers.

ULN-2231A DUAL PREAMPLIFIER

FEATURES

- Single Power Supply Operation
- Wide Supply Voltage Range
- Matched Open Loop Voltage Gain
- Turn-On Delay
- Low External Parts Count

OFFERING OUTSTANDING VALUE in low-noise amplification of low-level signals, Type ULN-2231A is a reliable performer in consumer and industrial products such as stereo tape players, microphone amplifiers, phonograph preamplifiers and stereo receivers.

This dual preamplifier has an internal voltage regulator. Internal feedback resistors are provided for NAB equalization.

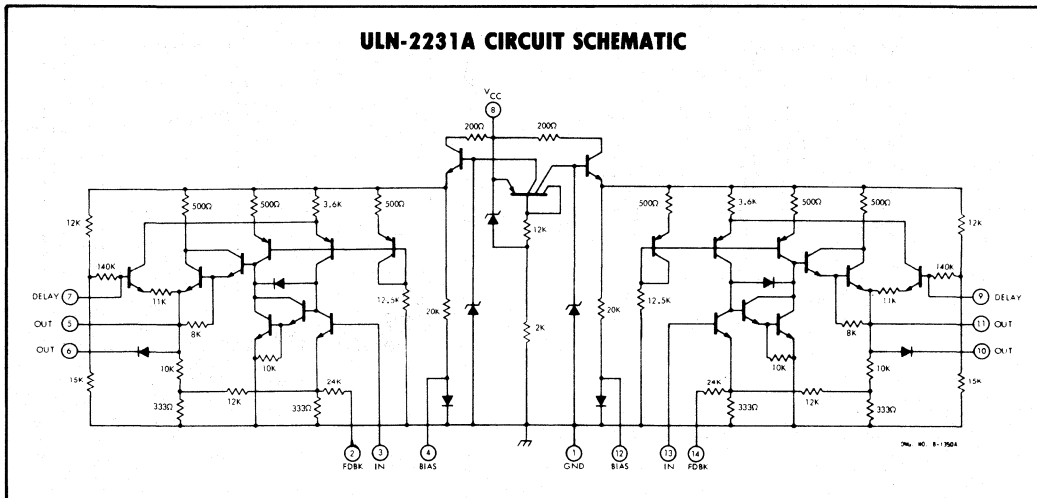

Type ULN-2231A is supplied in a 14-pin dual in-line plastic package.

ULN-2280B AUDIO POWER AMPLIFIER

FEATURES

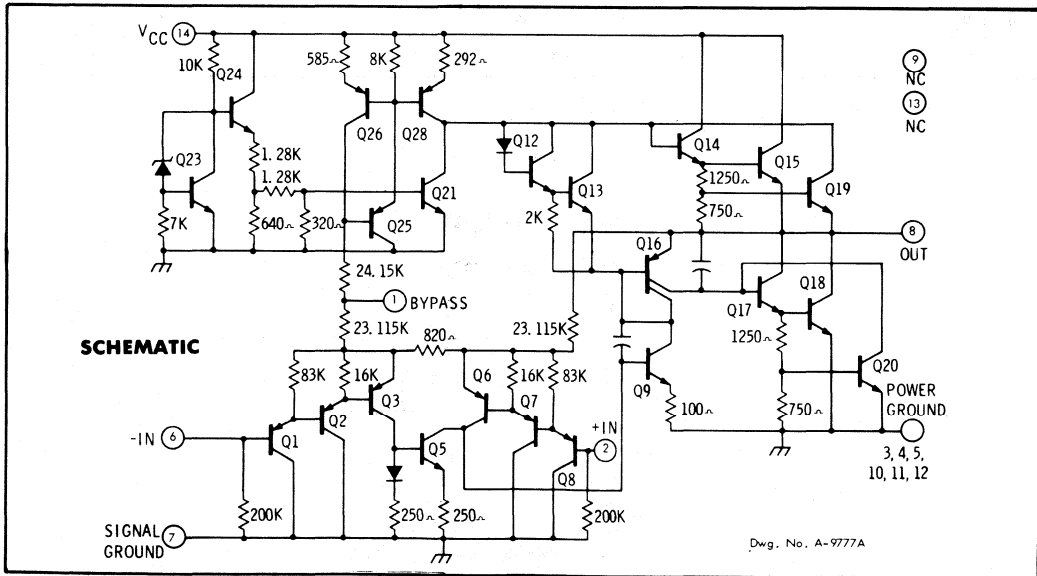

- Low Distortion
- Low Quiescent Current
- A-C Short-Circuit Protection
- 34 dB Internally Fixed Gain
- High Input Impedance
- Thermal Overload Protection
- Replaces LM380N

FEW SUPPLEMENTAL discrete components are needed to use Sprague Type ULN-2280B audio power amplifier in automotive, communication and consumer designs.

With an 18 V supply, the amplifier delivers 2.5 W of low-distortion audio into an 8Ω load. Output power with a 24 V supply is 2.5 W into a 16Ω load.

The audio amplifier is supplied in an improved 14-pin dual in-line plastic package with heat sink contact tabs. The webbed lead configuration, originated by Sprague Electric, permits attachment of an inexpensive heat sink for increased power dissipation capability and use of a standard integrated circuit socket or printed wiring board layout.

THERMAL FACTORS AND ULN-2280B OPERATION

Thermal factors must be considered in achieving reliable operation of Type ULN-2280B. Guidelines given here provide the circuit design engineer with information on maintaining IC junction temperature below safe limits when the audio power amplifier is operated at maximum ambient temperature and power dissipation.

The graphs below show package power dissipation as a function of output power over a wide range of supply voltage with a load resistance of 8Ω or 16Ω . Lines indicating 3% distortion and 10% distortion are shown as guides to trade-offs between supply voltages, package power dissipation and upper-limit distortion.

As the power supply voltage increases for any output power requirement, distortion decreases and package power dissipation increases. Package power dissipation figures must be taken from the highest point on the supply voltage curve.

**DISSIPATION AS A FUNCTION
OF OUTPUT POWER (8Ω LOAD)**

**DISSIPATION AS A FUNCTION
OF OUTPUT POWER (16Ω LOAD)**

CIRCUIT DESIGN

If design values of audio output power, distortion and maximum ambient temperature have been selected, optimal speaker impedance and supply voltage, as well as heat-sink requirements, can be determined from curves below and on page 4.

For an output of 2.5 W with 3% distortion and a maximum ambient temperature of +50°C:

R_L	8Ω	16Ω
THD	3%	3%
P_{OUT}	2.5 W	2.5 W
V_{CC}	16.7 V	22 V
P_D (max)	1.9 W	1.75 W
$P_D + P_{OUT}$	4.4 W	4.25 W
I_{CC}	263 mA	193 mA

The preceding appears to indicate the best choice is an output impedance of 16Ω with a 22 V supply. However, if an unregulated supply is used, the designer may prefer an 8Ω load with a 16 V supply, since the absolute maximum V_{CC} rating of Type ULN-2280B is 26 V and since maximum package dissipation must be calculated using the no-load voltage level.

The graph below (left) shows that the Staver V-8 heat sink would be just adequate for design conditions outlined above at an ambient temperature of 50°C. The Staver V-7 heat sink would provide a wider margin of safety.

ULN-2283B LOW POWER AUDIO AMPLIFIER

FEATURES

- Wide Operating Voltage Range (3 to 18 V)
- Low Quiescent Current Drain
- A-C Short Circuit Protected
- Low External Parts Count
- Low Distortion
- 42 dB Voltage Gain

DESIGNED primarily for use in low-cost phonographs and radio receivers, the ULN-2283B audio power amplifier is well-suited for use in battery-operated portable equipment. It will function with supply voltages as low as 2 volts (at reduced volume) without any significant increase in distortion. Weak batteries need no longer be a major concern for users in sets with this device. The class AB audio amplifier also features low quiescent current drain for maximum battery life.

The ULN-2283B is rated for operation over the supply voltage range of 3.0 to 15 volts. Selected devices, for operation with supply voltages of up to 18 volts, are available as ULN-2283B-1. Except for the maximum allowable supply voltage specification, the ULN-2283B and the ULN-2283B-1 are identical.

The ULN-2283B audio power amplifier is supplied in an improved 8-lead dual in-line plastic package with two webbed tabs. A copper alloy lead frame results in maximum power dissipation without need for an external heat sink. Lead configuration is compatible with standard IC sockets or printed wiring board hole layouts.

CIRCUIT DESCRIPTION

To achieve the desired performance objectives of high power output and efficiency from a 2 to 18 V supply requires that the amplifier be capable of peak-to-peak voltage swings approaching the available supply. To meet these performance objectives, a power amplifier design is required having no more than one V_{BE} of swing restriction.

As shown in Figure 1, the output stage is comprised of 2 NPN transistors (Q17 and Q18) plus a phase inverter (Q15). Quiescent operating current is set up by the current source (I).

Assuming $V_{oq} = V_{CC}/2$ then the collector current of Q15 = I, ignoring base currents, and if Q15 is matched to Q18 as is possible in a monolithic circuit, then the collector current of Q18 equals the collector current of Q15.

The circuit in Figure 1 achieves an excellent voltage swing capability of $V_{CC} - V_{BE} - 2V_{CE(SAT)}$. This totally NPN configuration also has good freedom from the high-frequency problems that often occur with quasi-complementary composite NPN-PNP configurations.

Figure 1

Although the circuit in Figure 1 has been incorporated in production monolithic circuits in essentially the form shown, in practice it has unacceptable design restrictions. Since I is also the base drive current for Q17, the ratio of available base drive current I to idling current is proportional to the ratio of the emitter areas of Q18 to Q15. For practical values of I_{Q15}/I_{Q18} , i.e. one, the circuit has a serious implementation problem; it requires three output transistors (Q15, Q17, and Q18).

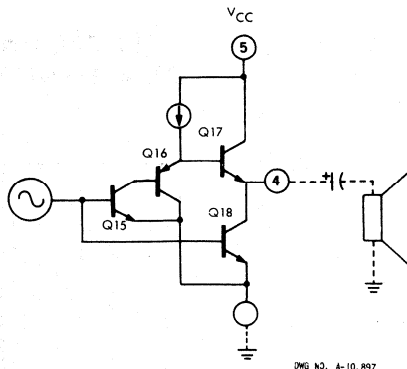

Figure 2

To reduce the size of Q15, an additional transistor (Q16) is added to the circuit as shown in Figure 2. Transistor Q16 divides I by its beta + 1 allowing Q15 to be reduced in area by a similar value. In the practical realization of the ULN-2283B, Q15 is chosen as 1/5 the emitter area of Q18 with a typical beta for Q16 of 6.

Figure 3

Figure 3 illustrates other refinements in the practical realization of the output circuit. The drive and idling current I is derived from a V_{CC} dependent source allowing maximum drive under maximum supply conditions while affording reduced drive and associated current conservation under minimum supply conditions. In addition, the Q16 divider circuit is refined to reduce PNP beta dependence. Finally with the addition of an input emitter follower (Q11) and a local negative feedback loop (R8), the output is completed as it appears in the ULN-2283B.

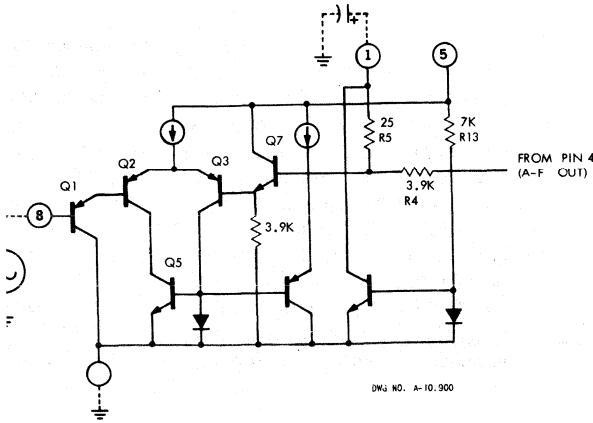

Figure 4

The input stage of the power amplifier (Figure 4) is comprised of a PNP differential pair (Q2 and Q3) preceded by a PNP emitter follower (Q1) which allows d-c referencing of the source signal to ground. This eliminates the need for an input coupling capacitor. Overall negative feedback, set by the ratio of R4 to R5, is applied to the inverting input Q3 through an NPN emitter follower (Q7) which also provides d-c level shifting.

The $V_{CC}/2$ output tracking is achieved by summing the current flow through R4 and R5, with the current through R13 "reflected off of ground." Thus $V_{CC}/2$ tracking is maintained by the voltage drop across 2 resistors. This allows the current from R13 to be bypassed at Pin 1, thereby combining the ripple bypass capacitor with the audio feedback capacitor.

Figure 5 illustrates the complete power amplifier as realized in the ULN-2283B, including the external components. The remarkably-low external component count, (only two capacitors including the output coupling) reflects concern for simplicity in implementation, yet the device achieves excellent performance. Typical output power can be as high as 2.1 W from a 12 volt supply and useful output power at supply voltages of as low as 2 volts.

APPLICATIONS

Selection of power supply voltage and speaker impedance allow the designer to choose audio power levels. No unique precautions are necessary when designing with the ULN-2283B power amplifier. The device is stable and a-c short-circuit immune.

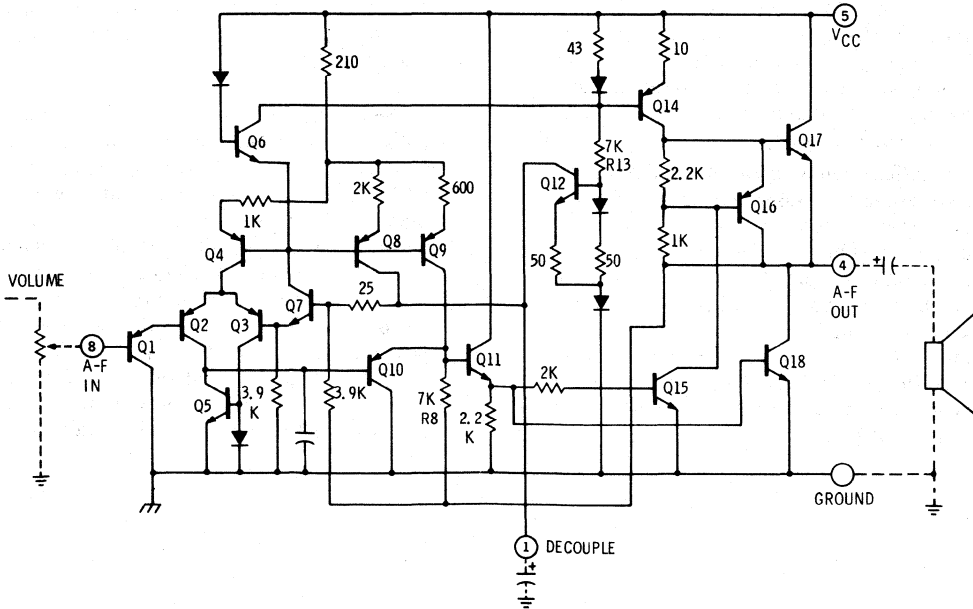

Figure 5

External component choice for the power amplifier involves only two capacitors; one for the speaker coupling and one for the feedback and ripple by-passing. The coupling capacitor value should be selected to provide the desired low-frequency cutoff with the chosen speaker impedance. The feedback and ripple bypass capacitor at Pin 1 should be chosen for both low-frequency audio rolloff and supply ripple rejection.

Ripple rejection is not practical to calculate due to the large number of mechanisms involved. A 500 μF capacitor at Pin 1 achieves typically 34 dB rejection.

The high gain of typically 42 dB and the high input impedance (250 $\text{k}\Omega$) of the power amplifier allow utilization of this device for applications such as ceramic cartridge phono amplifiers.

Typical ceramic phono cartridges develop approximately 400 mV. However, the recommended load impedance for the most economical cartridges is usually 1 $\text{M}\Omega$. This poses no problem with the 250 $\text{k}\Omega$ input impedance of the ULN-2283B since the cartridge manufacturer specifies the load impedance for full low-frequency response to less than 40 Hz. Decreasing the load impedance produces an increased low end cutoff frequency.

In a ULN-2283B based application employing a cost and space conscious loudspeaker, 40 Hz program material capability is not only unnecessary but undesirable, and therefore a mismatch of the cartridge to increase the lower cutoff frequency to a value more in keeping with the other components of the system is recommended.

The ULN-2283B audio amplifier stage has other input considerations to be taken into account for best results. The input is referenced to ground for internal biasing and must be provided with a d-c path to ground. A current of typically 0.1 μA flows from Pin 8 through the volume control producing an IR drop which is multiplied by the closed loop d-c gain of the amplifier (1), and appears as an error in output centering at Pin 4. This recommends a value of 200 $\text{k}\Omega$ or less for the volume control, with values of less than 100 $\text{k}\Omega$ preferred.

The selection of amplifier load impedance involves more consideration than just the desired power output. Ideally a low speaker impedance would produce the highest power outputs for any one supply voltage as the curves illustrated. However, operation with a 16 Ω load can produce as much power as with an 8 Ω load. The higher impedance load will also furnish a significant reduction in harmonic distortion and improvement in overall repeatability in power output capacity. In applications which allow the selection of the power supply voltage it is therefore recommended that a 16 Ω load impedance be utilized in applications up to 1.2 watt.

PRINTED WIRING BOARD LAYOUT & SPECIAL CONSIDERATIONS

Special on-chip considerations for minimizing tendencies towards instabilities of all types were taken in the design of the ULN-2283B. However, like all high-gain circuits, care and forethought should still be given to a printed wiring board layout to avoid undesirable effects. Input and output should be well separated and should avoid common mode impedances wherever possible. The ground return for the audio bypass at Pin 1 should be kept reasonably close to the volume control ground as Pins 1 and 8 represent the inverting and non-inverting inputs to the amplifier and enjoy about 40 dB of common mode rejection.

Device dissipation vs. output power and supply voltage for 4, 8, and 16 ohm loads is shown in the curves on page 4. With no heat sinking (free air), the ULN-2283B audio power amplifier will withstand the worst case conditions (4 Ω at 9 V) for ambient temperatures to +42.5°C. For conditions not shown for higher ambient temperatures, or for improved device reliability, a minimum heat sink is recommended. As illustrated in the allowable package power dissipation curves, with the heat sink tab (Pins 2, 3, 6, and 7) soldered into a 2.5 square inch (16.13 cm^2) copper area of a printed circuit board adequate heat sinking is easily obtained.

ULN-3701Z/TDA2002 5- to 10-WATT AUDIO POWER AMPLIFIER

FEATURES

- Low External Parts Count
- Low Distortion
- Class B Operation
- Short-Circuit Protected
- Thermal Overload Protected
- Low Noise
- High Output-Voltage Swing
- TO-220 Style Package
- Direct Replacement for LM383 and CA2002

DESIGNED specifically for driving low-impedance loads down to 1.6Ω , the ULN-3701Z/TDA2002 audio power amplifier is ideal for automotive radio, tape player, and CB applications and can deliver 15 W of audio in the bridge configuration or 5 W to 10 W single-ended. Operating in the extremely harsh automotive environment, these devices are capable of withstanding high ambient temperatures, output overloads, and repeated power supply transient voltages without damage.

The ULN-3701Z/TDA2002 is supplied in a modified 5-lead JEDEC Style TO-220 plastic package. The heat sink tab is at ground potential and therefore no insulation is required. Lead forming for either vertical or horizontal mounting (suffix letter "V" or "H," respectively) is available on special order.

These integrated circuits will be marked with their U.S. part number unless the European TDA number is specified on production orders.

ULN-3702Z/TDA2002A 12-WATT AUDIO POWER AMPLIFIER

FEATURES

- Low External Parts Count
- Low Distortion
- Class B Operation
- Short-Circuit Protected
- Thermal Overload Protected
- Low Noise
- TO-220 Style Package

THE ABILITY TO DRIVE high-power loads in consumer and industrial electronics expands the field of application for Type ULN-3702Z/TDA2002A.

The high-gain power amplifier can be used as a vertical output driver in television receivers and video terminals or as a linear d-c motor driver. Its operational-amplifier configuration, with high input impedance and low output impedance, makes it adaptable to many input, output and feedback arrangements.

One modification sets this audio power amplifier apart from Sprague Type ULN-3701Z/TDA2002: The integrated circuit's internal high-voltage shut-down has been disabled. The change allows continuous operation with supply voltages of up to 26 V. With a d-c load current rating of 2.5 A, Type ULN-3702Z/TDA2002A can handle up to 60 watts of power with an appropriate heat sink. It is able to withstand high ambient temperatures, output overloads, and repeated power supply transients without damage.

The amplifier is supplied in a modified five-lead JEDEC Style TO-220 plastic package. The heat sink tab is at ground potential; no insulation is required.

Special lead configurations for vertical mounting (ULN-3702ZV) and for horizontal mounting (ULN-3702ZH) are available on special order. Parts are branded with the Sprague Electric part number (ULN-3702Z) unless Pro-Electron marking (TDA2002A) is requested.

SCHEMATIC

ULN-3703Z / TDA2003 10-WATT AUDIO POWER AMPLIFIER

FEATURES

- Low External Parts Count
- Low Distortion
- Class B Operation
- Short-Circuit Protected
- Thermal Overload Protected
- Low Noise
- High Output-Voltage Swing
- TO-220 Style Package

DESIGNED to drive low-impedance loads down to 1.6Ω , Type ULN-3703Z/ TDA2003 audio power amplifier is ideal for automotive radio, tape player, and CB applications and can deliver 15 W of audio in the bridge configuration or 5 W to 10 W single-ended.

Operating in the harsh automotive environment, this device is capable of withstanding high ambient temperatures, output overloads, and repeated power supply transient voltages without damage. It is protected against a-c/d-c short-circuits, polarity inversions, or open grounds.

Type ULN-3703Z/TDA2003 is supplied in a modified five-lead JEDEC Style TO-220 plastic package. The heat sink tab is at ground potential; no insulation is required. Lead forming for either vertical or horizontal mounting (suffix letter "V" or "H," respectively) is standard.

These integrated circuits will be marked with their Pro-Electron registrations (TDA2003H or TDA2003V) unless U.S. part-number marking is specified on production orders.

ULX-3777W DUAL 10-WATT AUDIO POWER AMPLIFIER

Preliminary Information

FEATURES

- High-Voltage Protection
- Operating Voltage Range: 8 to 18 V
- Thermal Shutdown
- Low Distortion
- Excellent Channel Separation
- Replacement for HA1377A

Dwg. No. A-11,332

DELIVERING up to 10 watts per channel into low impedance loads, Type ULX-3777W is designed for the demanding domain of automobile stereo sound systems.

This monolithic integrated circuit carries built-in protection from temporary high voltages, automotive transients and excessive power dissipation.

An internal voltage regulator allows amplifier operation with power supply levels between 8.0 and 18 V. As supply voltages exceed that maximum, a protective circuit shuts down the device until the supply level falls below the 18 V limit.

Frequency response of Type ULX-3777W is flat from 40 Hz to 25 kHz. Channel separation is typically 58 dB.

Type ULX-3777W is supplied in a 12-pin single in-line power tab plastic package that permits dissipation of up to 18 W.

The ULX prefix to the part number denotes an integrated circuit presently in development and undergoing engineering evaluation. If and when the device becomes a production item, the prefix will be changed to ULN. Sprague Electric assumes no obligation for future manufacture of any products presently in development unless such obligation is specifically undertaken in writing by authorized Sprague personnel.

TEST CIRCUIT AND TYPICAL APPLICATION

DWG. NO. A-11, 373

ULX-3788W 20-WATT AUDIO POWER AMPLIFIER

Preliminary Information

FEATURES

- Operating Voltage Range: 8 to 18 V
- Short Circuit Protected — Outputs and Speaker
- High-Voltage Protection
- Thermal Shutdown
- Minimal External Circuitry
- Low Distortion
- Replacement for HA1388

Dwg. No. A-11,332

DEVELOPED to meet demanding performance standards in automotive applications, this monolithic integrated circuit offers high-power, low-noise, low-distortion audio with a minimum of external circuitry.

When used in automobile sound systems, Sprague Type ULX-3788W delivers up to 18 W of output power to a 4Ω load and up to 11 W into an 8Ω load impedance. Audio output of 20 W is available with higher levels of supply voltage.

The amplifier's frequency response is flat from 20 Hz to 25 kHz.

Type ULX-3788W has built-in protection against damage by automotive transients, temporary surges in supply voltage and excessive power dissipation levels. Its internal voltage regulator ensures stable operation with variations in supply voltage (8 to 18 V) and temperature (-20°C to +85°C).

The audio amplifier is supplied in a 12-pin single in-line plastic package with a power dissipation rating of 18 W.

The ULX prefix to the part number denotes an integrated circuit presently in development and undergoing engineering evaluation. If and when the device becomes a production item, the prefix will be changed to ULN. Sprague Electric assumes no obligation for future manufacture of any products presently in development unless such obligation is specifically undertaken in writing by authorized Sprague personnel.

UGN-3013T SOLID-STATE ULTRA LOW-COST HALL EFFECT DIGITAL SWITCHES

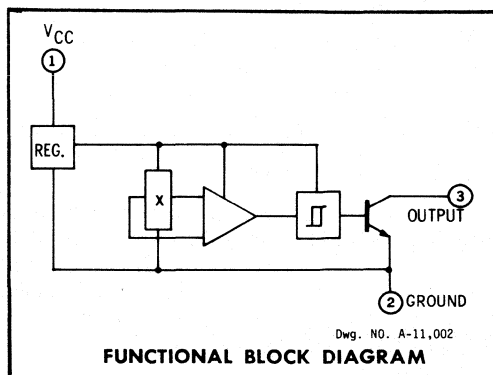

FEATURES

- Operate from 4.5 V to 16 V D-C Power Source
- Activates With Small, Commercially Available Permanent Magnets
- Solid-State Reliability — No Moving Parts
- Small Size
- Constant Amplitude Output
- Output Compatible With All Digital Logic Families

THE SPRAGUE TYPE UGN-3013T is a low-cost magnetically-activated electronic switch. Each device consists of a voltage regulator, a Hall voltage generator, amplifier, Schmitt trigger, and an open collector output stage integrated in a single monolithic silicon chip.

The on-board regulator permits operation over a wide variation of supply voltages. The circuit output can be interfaced directly with bipolar or MOS logic circuits.

UGN-3013T integrated circuits are packaged in the miniature 3-pin single output plastic "T" pack.

OPERATION

The output transistor is normally "off" when the magnetic field perpendicular to the surface of the chip is below the threshold or "operate point." When the field exceeds the "operate point," the output transistor switches "on" and is capable of sinking 25 mA of current.

The output transistor switches "off" when the magnetic field is reduced below the "release point" which is less than the "operate point." This is illustrated graphically in the transfer characteristics curve. The hysteresis characteristic provides for unambiguous or non-oscillatory switching.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and $0.032'' \pm 0.002''$ (0.81 ± 0.05 mm) below the branded surface of the T package and $0.012'' \pm 0.002''$ (0.30 ± 0.05 mm) below the branded surface of the U package.

For reference purposes, both an Alnico VIII magnet, $0.212''$ (5.38 mm) in diameter and $0.187''$ (4.75 mm) long and a samarium cobalt magnet, $0.100''$ (2.54 mm) square and $0.040''$ (1.02 mm) thick, are approximately 1200 gauss at its surface.

The flux density decays at a high rate as the distance from a pole increases.

As an example, using the Alnico VIII magnet referenced above in good alignment and the pole surface in contact with the branded surface of the package, the flux density at the active Hall sensing area of the device would be approximately 850 gauss.

The flux density would drop to approximately 600 gauss with an air-gap between the package and the magnet of $0.031''$ (0.79 mm).

TRANSFER CHARACTERISTICS SHOWING HYSTERESIS

Dwg. No. A-11.003

These Hall effect devices are also available in a miniature 3-pin plastic "U" package. The "T" package is 0.080" (2.03 mm) thick; the "U" package is 0.061" (1.54 mm) thick. All other dimensions are identical.

UGN-3019T and UGS-3019T SOLID-STATE LOW-COST HALL EFFECT DIGITAL SWITCHES

FEATURES

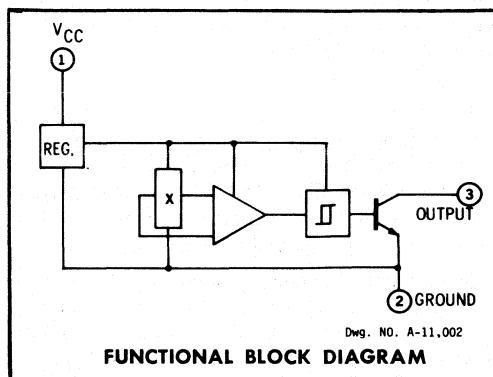

- Operate from 4.5 V to 16 V D-C Power Source
- Operable With a Small Permanent Magnet
- High Reliability—Eliminates Contact Wear, Contact Bounce
- No Moving Parts
- Small Size
- Constant Amplitude Output
- Output Compatible With All Digital Logic Families

THE TYPE UGN-3019T and UGS-3019T are low-cost magnetically-activated electronic switches utilizing the Hall effect for sensing a magnetic field. Each circuit consists of a voltage regulator, Hall cell, signal amplifier, Schmitt trigger, and current sinking output stage integrated into a monolithic silicon chip.

The circuit output can be interfaced directly with bipolar or MOS logic circuits. The on-board regulator insures stable operation over a wide range of supply voltages. Operation over an extended temperature range is made possible by the careful matching of components which can be done economically only on a monolithic chip.

These devices are packaged in the 3-pin single output plastic "T" package.

The UGN-3019T was originally introduced as the ULN-3006T.

ABSOLUTE MAXIMUM RATINGS

		$V_{CC} = 12 \text{ V}$, output open	—	12	16	mA
Output Rise Time	t_r	$V_{CC} = 12 \text{ V}$, $R_L = 820 \Omega$, $C_L = 20 \text{ pF}$	—	15	—	ns
Output Fall Time	t_f	$V_{CC} = 12 \text{ V}$, $R_L = 820 \Omega$, $C_L = 20 \text{ pF}$	—	100	—	ns

Note: Magnetic flux density is measured at most sensitive area of device. This area is located 0.032" \pm 0.002 (0.81 \pm 0.05 mm) below the branded face of the T package and 0.012" \pm 0.002" (0.30 \pm 0.05 mm) below the branded surface of the U package.

OPERATION

The output transistors are normally "off" when the magnetic field perpendicular to the surface of the chip is below the threshold or "operate point." When the field exceeds the "operate point," each output transistor switches "on" and is capable of sinking 25 mA of current. Selections to 50 mA are available.

The output transistors switch "off" when the magnetic field is reduced below the "release point" (which is less than the "operate point"). This is illustrated graphically in the transfer characteristics curve. The hysteresis characteristic provides for unambiguous or non-oscillatory switching.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and $0.032'' \pm 0.002''$ (0.81 ± 0.05 mm) below the branded surface of the T package and $0.012'' \pm 0.002''$ (0.30 ± 0.05 mm) below the branded surface of the U package.

For reference purposes, both an Alnico VIII magnet, 0.212" (5.38 mm) in diameter and 0.187"

(4.75 mm) long and a samarium cobalt magnet, 0.100" (2.54 mm) square and 0.040" (1.02 mm) thick, are approximately 1200 gauss at its surface.

The flux density decays at a high rate as the distance from a pole increases.

As an example, using the Alnico VIII magnet referenced above in good alignment and the pole surface in contact with the branded surface of the package, the flux density at the active Hall sensing area of the device would be approximately 850 gauss.

The flux density would drop to approximately 600 gauss with an air-gap between the package and the magnet of 0.031" (0.79 mm).

Switching point variations with temperature should be considered in applications covering a wide temperature range.

TRANSFER CHARACTERISTICS SHOWING HYSTERESIS

SWITCHING POINT VARIATION WITH TEMPERATURE

These Hall effect devices are also available in a miniature 3-pin plastic "U" package. The "T" package is 0.080" (2.03 mm) thick; the "U" package is 0.061" (1.54 mm) thick. All other dimensions are identical.

UGN-3020T and UGS-3020T SOLID-STATE LOW-COST HALL EFFECT DIGITAL SWITCHES

FEATURES

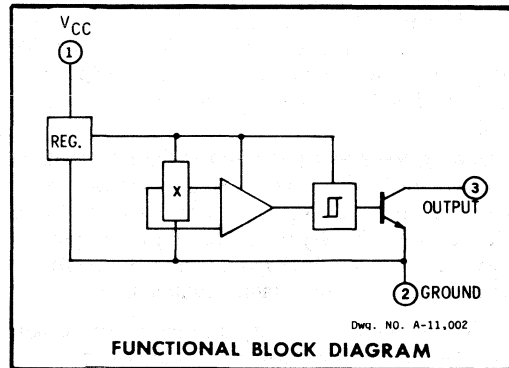

- Operate from 4.5 V to 24 V D-C Power Source
- Operable With a Small Permanent Magnet

- Constant Amplitude Output
- Output Compatible With All Logic Families

THE TYPE UGN-3020T and UGS-3020T are low-cost magnetically-activated electronic switches utilizing the Hall effect for sensing a magnetic field. Each circuit consists of a voltage regulator, Hall cell, signal amplifier, Schmitt trigger, and current sinking output stage integrated in a single monolithic silicon chip.

The on-board regulator permits stable operation over a wide variation of supply voltages. Operation over an extended temperature range is made possible by the careful matching of components which can be done economically only on a monolithic circuit.

Both devices will typically operate up to a 100 kHz repetition rate.

The circuit output can be interfaced directly with bipolar or MOS logic circuits.

These devices are packaged in the 3-pin single output plastic "T" pack.

These devices were originally introduced with ULN and ULS prefixes.

OPERATION

The output transistor is normally "off" when the magnetic field perpendicular to the surface of the chip is below the threshold or "operate point." When the field exceeds the "operate point," the output transistor switches "on" and is capable of sinking 25 mA of current. Selections to 50 mA are available.

The output transistor switches "off" when the magnetic field is reduced below the "release point" which is less than the "operate point." This is illustrated graphically in the transfer characteristics curve. The hysteresis characteristic provides for unambiguous or non-oscillatory switching.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and $0.032'' \pm 0.002''$ (0.81 ± 0.05 mm) below the branded surface of the T package and $0.012'' \pm 0.002''$ (0.30 ± 0.05 mm) below the branded surface of the U package.

For reference purposes, both an Alnico VIII magnet, $0.212''$ (5.38 mm) in diameter and $0.187''$

(4.75 mm) long and a samarium cobalt magnet, $0.100''$ (2.54 mm) square and $0.040''$ (1.02 mm) thick, are approximately 1200 gauss at the pole surfaces.

The flux density decays at a high rate as the distance from a pole increases.

As an example, using the Alnico VIII magnet referenced above in good alignment and the pole surface in contact with the branded surface of the package, the flux density at the active Hall sensing area of the device would be approximately 850 gauss.

The flux density would drop to approximately 600 gauss with an air-gap between the package and the magnet of $0.031''$ (0.79 mm).

Note: Switching point variations with temperature should be considered in applications covering a wide temperature range.

SWITCHING POINT VARIATION WITH TEMPERATURE

TRANSFER CHARACTERISTICS SHOWING HYSTERESIS

These Hall effect devices are also available in a miniature 3-pin plastic "U" package. The "T" package is 0.080" (2.03 mm) thick; the "U" package is 0.061" (1.54 mm) thick. All other dimensions are identical.

UGN-3030T and UGS-3030T LOW-COST BIPOLAR HALL EFFECT DIGITAL SWITCHES

FEATURES

- Operable With Inexpensive Multi-Pole Ring Magnets
- High Reliability — Eliminates Contact Wear, Contact Bounce
- No Moving Parts
- Small Size
- Constant Amplitude Output — Compatible With All Digital Logic Families

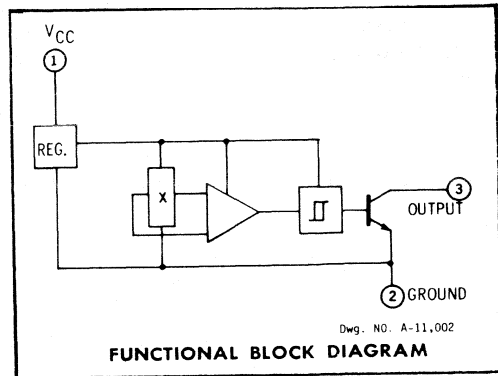

TYPE UGN-3030T and UGS-3030T solid-state switches are designed for use with inexpensive multi-pole ring magnets. Both switches operate within the magnetic field range of +250 to -250 Gauss.

The UGN-3030T operates over the temperature range of 0°C to +70°C with supply voltages (V_{CC}) of 4.5 to 24 V.

The UGS-3030T, intended for more severe automotive environments, operates from -40°C to +125°C.

Circuit output can be interfaced directly with bipolar or MOS logic circuits. These switches provide a constant amplitude output at frequencies to 100 MHz.

Type UGN-3030T and UGS-3030T switches are supplied in a rugged 3-pin plastic 'T' pack.

The output transistor switches OFF when the magnetic field is reduced below the "release point" which is less than the "operate point." This is illustrated graphically in the transfer characteristics curve. The hysteresis characteristic provides for unambiguous or non-oscillatory switching.

TRANSFER CHARACTERISTICS SHOWING HYSTERESIS

Dwg. No. A-11,040

The simplest form of magnet which will operate the Hall effect bipolar digital switch is a multiple pole ring magnet as shown. Such magnets are commercially available and are quite inexpensive.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and 0.032" \pm 0.002" (0.81 \pm 0.05 mm) below the top surface of the T package and 0.012" \pm 0.002" (0.30 \pm 0.05 mm) below the top surface of the U package. The magnetic circuit must provide a +250 Gauss to -250 Gauss magnetic flux density range at this point for all conditions to insure reliable operation; + Gauss indicates the South pole is toward the branded face of the package; - Gauss indicates the North pole is toward the branded package face.

DWG. NO. A-11,041

BASIC MODES OF ACTIVATION USING A MULTIPLE-POLE RING MAGNET

NOTE: A rotary magnet may be constructed with poles either on the rim (axial) or on the face (radial) but not both.

UGN-3040T

ULTRA-SENSITIVE HALL EFFECT DIGITAL SWITCHES

FEATURES

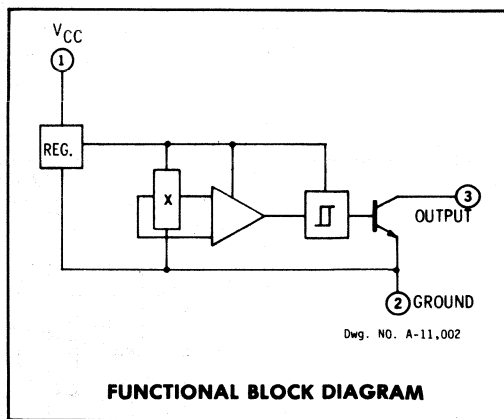

- Operate from 4.5 V to 24 V D-C Power Source
- Operable With Small Permanent Magnets
- Solid-State Reliability — No Moving Parts
- Small Size
- Constant Amplitude Output
- Output Compatible With All Digital Logic Families

THE SPRAGUE TYPE UGN-3040T is a magnetically-activated electronic switch with extreme sensitivity for use with small, inexpensive magnets, or with relatively large magnet-to-switch distances.

Each circuit consists of a voltage regulator, Hall voltage generator, signal amplifier, Schmitt trigger circuit, and an open collector output driver integrated in a single silicon chip.

The on-board regulator permits operation over a wide range of supply voltages. Circuit output can be interfaced directly with bipolar or MOS logic circuits, and will typically operate up to a 100 kHz repetition rate.

The UGN-3040T is packaged in a miniature 3-pin single-output plastic "T" pack.

GUIDE TO INSTALLATION

1. All Hall effect integrated circuits are susceptible to mechanical stress effects. Caution should be exercised to minimize the application of stress to the leads or the epoxy package.
2. To prevent permanent damage to the Hall cell, heat sink the leads during hand soldering. For wave soldering, the part should not experience more than 230°C for more than five seconds and solder should be no closer than 0.125" to the epoxy package.

**SWITCHING POINT
AS A FUNCTION OF TEMPERATURE**

These Hall effect devices are also available in a miniature 3-pin plastic "U" package. The "T" package is 0.080" (2.03 mm) thick; the "U" package is 0.061" (1.54 mm) thick. All other dimensions are identical.

OPERATION

The simplest form of magnet which will operate the Hall Effect digital sensor is a bar magnet as shown. Other methods are possible.

In the illustration, the magnet's axis is on the center line of the packaged device and the magnet is moved toward and away from the device. Also, note the orientation of the magnet's south pole in relation to the branded face of the package.

BASIC 'HEAD-ON' MODE OF OPERATION

TRANSFER CHARACTERISTICS SHOWING HYSTERESIS

OPERATION (Continued)

The output transistor is normally "off" when the magnetic field perpendicular to the surface of the chip is below the threshold or "operate point." When the field exceeds the "operate point," the output transistor switches "on" and is capable of sinking 25 mA of current. A 50 mA unit is available upon special order.

The output transistor switches "off" when the magnetic field is reduced below the "release point" which is less than the "operate point." This is illustrated graphically in the transfer characteristics curve. The hysteresis characteristic provides for unambiguous or non-oscillatory switching.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located $0.032" \pm 0.005"$ ($0.81 \pm 0.127\text{mm}$) below the branded surface of the T package and $0.012 \pm 0.005"$ ($0.30 \pm 0.127 \text{mm}$) below the branded surface of the U package.

A variety of magnets are commercially available, each exhibiting unique field characteristics. The curves presented below are flux density values for the magnets measured for switch activation in a head-on mode (along the magnet axis). The curves are also pertinent for peak flux density for a given clearance in the slide-by mode of actuation.

FLUX DENSITY AS A FUNCTION OF AIR GAP

UGN-3201M and UGN-3203M DUAL OUTPUT HALL EFFECT DIGITAL SWITCHES

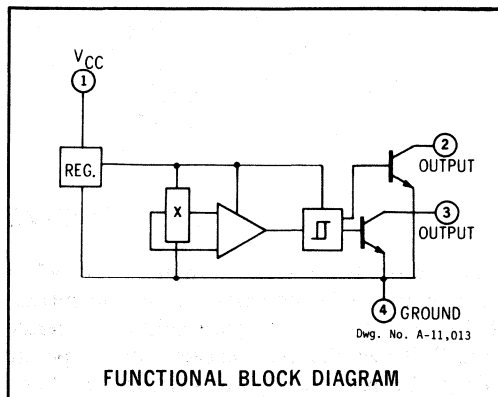

FEATURES

- Operate from 5 V to 16 V D-C Power Supply
- Operate With a Small Permanent Magnet
- High Reliability — No Contact Wear or Bounce
- Small Size — 8-Pin DIP
- Constant Amplitude Output
- Dual Open-Collector Outputs

INTEENDED for use in position sensing and contact-less switching applications, the Types UGN-3201M and UGN-3203M switches utilize the Hall Effect for detecting a magnetic field.

Both devices feature identical electrical and environmental characteristics. However, the UGN-3201M has a typical Operate Point of 450 gauss and Release Point of 300 gauss; the UGN-3203M is more sensitive, with a typical Operate Point of 235 gauss and Release Point of 100 gauss. The UGN-3203M may be activated by smaller magnets, or at a greater magnet-device spacing.

The UGN-3201M and UGN-3203M Hall Effect digital switches are supplied in 8-pin dual in-line plastic packages. These switches were originally introduced as device numbers ULN-3006M and ULN-3007M, respectively.

GUIDE TO INSTALLATION

1. All Hall effect integrated circuits are susceptible to mechanical stress effects. Caution should be exercised to minimize the application of stress to the leads or the epoxy package.

2. To prevent permanent damage to the Hall cell I.C., heat sink the leads during hand soldering. For wave soldering, the part should not experience more than 230°C for more than 5 seconds and no closer than 0.125" to the epoxy package.

'M' PACKAGE

DIMENSIONS IN INCHES

DIMENSIONS IN MILLIMETRES

Based on 1 in. = 25.4 mm

OPERATION

The output transistors are normally "off" when the magnetic field perpendicular to the surface of the chip is below the threshold or "operate point." When the field exceeds the "operate point," the output transistors switch "on" and will each typically sink 20mA.

The output transistors switch "off" when the magnetic field is reduced below the "release point" which is less than the "operate point." This is illustrated graphically in the transfer characteristic curves. The hysteresis characteristic provides for unambiguous or non-oscillatory switching regardless of the rate of change of the magnetic field.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and $0.037'' \pm 0.001''$ (0.94 ± 0.05 mm) below the top surface of the package.

For reference purposes, both an Alnico VIII magnet, 0.212'' (5.38 mm) in diameter and 0.187'' (4.75 mm) long and a samarium cobalt magnet, 0.100'' (2.54 mm) square and 0.040'' (1.02 mm) thick, are approximately 1200 gauss at its surface.

The flux density decays at a high rate as the distance from a pole increases.

As an example, using the Alnico VIII magnet referenced above in good alignment and the pole surface in contact with the branded surface of the package, the flux density at the active Hall sensing area of the device would be approximately 850 gauss (0.032'' below the package surface).

The flux density would drop to approximately 600 gauss with an air-gap between the package and the magnet of 0.031'' (0.79 mm).

BASIC 'HEAD-ON' MODE OF OPERATION

UGN-3501M SOLID-STATE LINEAR OUTPUT HALL EFFECT SENSORS

FEATURES

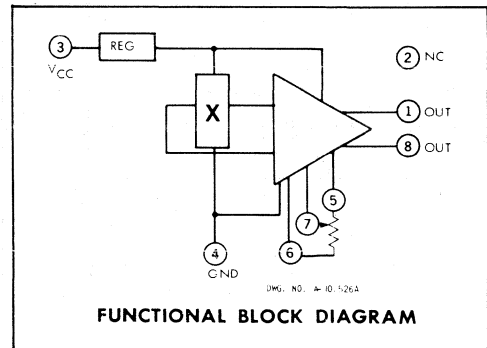

- Excellent Sensitivity
- Flat Response to 25 kHz (typ.)
- Internal Voltage Regulation
- Excellent Temperature Stability

UTILIZING THE HALL EFFECT for sensing a magnetic field, Type UGN-3501M ICs provide a linear differential output which is a function of magnetic field intensity.

These devices are intended for applications requiring accurate measurement and/or control of position, weight, thickness, velocity, etc.

The Type UGN-3501M Hall Effect IC includes a monolithic Hall cell, linear differential amplifier, differential emitter follower output, and a voltage regulator. Integrating the Hall cell and the amplifier into one monolithic device minimizes problems related to the handling of millivolt analog signals.

Provisions are included for output offset null. This sensor is supplied as a 8-pin dual in-line plastic package and is rated for continuous operation over the temperature range of 0°C to +70°C and a voltage range of 8 to 16 volts d-c.

GUIDE TO INSTALLATION

1. All Hall Effect integrated circuits are susceptible to mechanical stress effects. Caution should be exercised to minimize the application of stress to the leads or the epoxy package.

2. To prevent permanent damage to the Hall cell IC, heat sink the leads during hand soldering. For wave soldering, the part should not experience more than 230°C for more than 5 seconds and no closer than 0.125" to the epoxy package.

3. If a zeroing potentiometer is used, minimize lead lengths from it and isolate these leads from out-

put leads if possible. In some cases, it may be more practical to limit the frequency response with an output RC network to prevent oscillation:

UGN-3501T SOLID-STATE LINEAR OUTPUT HALL EFFECT SENSORS

FEATURES

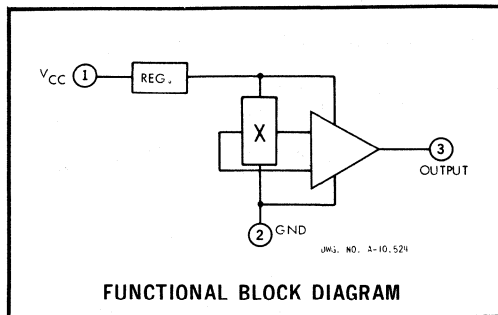

- Excellent Sensitivity
- Flat Response to 25 kHz (typ.)
- Internal Voltage Regulation
- Excellent Temperature Stability

UTILIZING THE HALL EFFECT for sensing a magnetic field, Type UGN-3501T integrated circuits provide a linear single-ended output which is a function of magnetic field intensity.

These devices are used principally to sense relatively small changes in a magnetic field — changes which are too small to operate a Hall effect switching device. They are customarily capacitively coupled to an amplifier, which boosts the output to a higher level.

The Type UGN-3501T Hall Effect IC includes a monolithic Hall cell, linear amplifier, emitter follower output, and a voltage regulator. Integrating the Hall cell and the amplifier into one monolithic device minimizes problems related to the handling of millivolt analog signals.

This sensor is supplied a 3-pin plastic package and is rated for continuous operation over the temperature range of 0°C to +70°C and a voltage range of 8 to 12 volts d-c.

For reference only – an Alnico VIII permanent magnet, 0.212" (5.38 mm) in diameter and 0.187" (4.75 mm) long is approximately 800 gauss at the surface. A samarium cobalt perma-

nent magnet, 0.100" (2.54 mm) square and 0.040" (1.02 mm) thick is approximately 1200 gauss at its surface.

GUIDE TO INSTALLATION

1. All 'Hall Effect' integrated circuits are susceptible to mechanical stress effects. Caution should be exercised to minimize the application of stress to the leads or the epoxy package.

2. To prevent permanent damage to the Hall cell IC, heat sink the leads during hand soldering. For wave soldering, the part should not experience more than 230°C for more than 5 seconds and no closer than 0.125" to the epoxy package.

UGN-3604M and UGN-3605M HALL EFFECT SENSORS

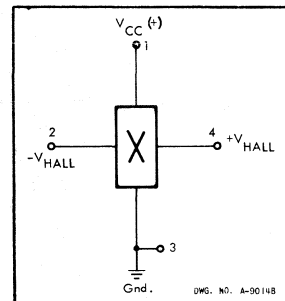

THE MOST BASIC Hall Effect magnetic field sensors are the Type UGN-3604M and UGN-3605M. The differential output of the devices is a function of the magnetic flux density present at the sensor. Sensitivity is a function of the control current: sensitivity increases as the control current increases.

The UGN-3604M and UGN-3605M are most often used for magnetic circuit design, analysis, testing and alignment, and for calibrating magnetic sensing devices.

The UGN-3604M is supplied in an 8-pin DIP package, with a calibration chart. The UGN-3605M is the same device without the calibration chart.

Each Type UGN-3604M Hall Effect sensor is individually calibrated at a temperature of +25°C using a supply voltage of 5-volts. The calibration chart supplied indicates differential output values for a magnetic flux density range from 0 gauss to 1000 gauss. Sensitivity at this supply voltage level is typically 40 mV per 1000 gauss.

Since the differential output voltage is a linear function of the magnetic flux density, other readings are easily interpolated.

The UGN-3605M is intended to be used primarily as a sensing device. When operated from a constant current source of 3 mA the device provides a typical sensitivity of 60 mV per 1000 gauss. This is the preferred biasing method, to achieve the most stable output voltage vs. temperature.

ABSOLUTE MAXIMUM RATING

Supply Voltage, V_{cc} +7 V
 Supply Current, I_{cc} 10 mA
 Magnetic Flux Density, B No Limit
 Operating Temperature Range, T_A 0°C to +70°C
 Storage Temperature Range, T_S -65°C to +150°C

ELECTRICAL CHARACTERISTICS at $T_A = +25^\circ\text{C}$

Characteristic	Symbol	Test Condition	Min.	Typ.	Max.	Notes
Control Current	I_{cc}	—	—	3 mA	7 mA	1, 2
Control Resistance	R_{1-3}	—	1 k Ω	2.2 k Ω	4.5 k Ω	
Control Resistance vs. Temperature	$\Delta R_{1-3}/\Delta T$	—	—	+ .8%/°C	—	
Differential Output Resistance	R_{2-4}	—	2 k Ω	4.4 k Ω	9 k Ω	
Output Offset Voltage	V_{OFF}	$B = 0$ Gauss	—	≤ 5 mV	—	
Output Offset Voltage vs. Temperature	$\Delta V_{OFF}/\Delta T$	$B = 0$ Gauss	—	$\leq (\pm 30 \mu\text{V}/^\circ\text{C})$	—	
Sensitivity	$\Delta V_{OUT}/\Delta B$	$I_{cc} = 7\text{V}/R_{1-3}$	—	60 mV/1000 Gauss	—	
Sensitivity vs. Temperature	$\frac{\Delta V_{OUT}/\Delta B}{\Delta T}$	$I_{cc} = 1.5$ mA	—	+ .1%/°C	—	
Product Sensitivity	$V/A \times \text{kG}$	$I_{cc} = 7\text{V}/R_{1-3}$	—	20	—	

1. I_{cc} is limited to a maximum value which produces a 7-volt drop across the Control Resistance R_{1-3} .
2. Terminal 1 must always be positive in relation to terminal 3.

APPLICATION NOTES

1. All Hall effect integrated circuits are susceptible to mechanical stress effects. Caution should be exercised to minimize the application of stress to the leads or to the epoxy package.

2. To prevent permanent damage to a Hall cell I.C., heat sink the leads during hand soldering. For wave soldering, the part should not experience more than 230°C for more than 5 seconds and no closer than 0.125" (3.28 mm) to the epoxy package.

3. The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and 0.037" ± 0.001" (0.94 ± 0.03 mm) below the top surface of the package.

4. For reference purposes, an Alnico VIII magnet, 0.212" (5.38 mm) in diameter and 0.187" (4.75 mm) long or a samarium cobalt magnet, 0.100" (2.54 mm) square and 0.040" (1.02 mm) thick, is approximately 1200 gauss at its surface.

Note that the flux density decays at a high rate as the distance from a pole increases. In most cases, this is a relatively linear decrease in the region of interest, and it may range from 5 to 20 gauss/mil.

Hall Effect IC Application Guide

SPRAGUE ELECTRIC uses the latest linear integrated circuit technology in combination with the 100+ year old Hall Effect to produce Hall Effect ICs. These are magnetically activated switches and sensors with the potential to simplify and improve systems designed for switch and sensor applications.

Simplified Switching At Low Cost

Simplified switching is a Hall switch feature. Sprague Hall Effect ICs combine Hall voltage generators, signal amplifiers, Schmitt trigger circuits and transistor output circuits on an IC chip. Output is clean, fast, and switched with no bounce, an inherent problem in mechanical contact switches. A Sprague Hall Effect IC switch costs less than many common electromechanical switches.

Efficient, Effective Low-Cost Sensors

A Hall Effect sensor detects the motion, position, or change in field strength of an electromagnet, a permanent magnet, or a ferromagnetic material with an applied magnetic bias. Output is linear and temperature stable. Energy consumption is significantly low. Response is independent of the velocity of the field being sensed.

A Sprague Hall Effect IC sensor can be more efficient and effective than inductive or optoelectronic sensors and at lower cost.

Sensitive Circuits For Rugged Service

The Hall Effect IC is virtually immune to environmental contaminants, is particularly rugged, and is suitable for use under severe service conditions. These circuits are very sensitive, providing reliable, repetitive operations in close tolerance applications. The Hall Effect IC can "see" precisely through dirt and darkness.

Sprague Hall Effect IC switches and sensing systems cost less than most optoelectronic switch and sensor circuits.

HALL EFFECT SWITCH OUTPUT WAVEFORM

REED RELAY OUTPUT WAVEFORM

HALL EFFECT SENSOR LINEAR OUTPUT

HISTORY AND THE HALL EFFECT

E. H. Hall, at Johns Hopkins University in 1879, first noted the effect that bears his name. A magnetic field applied to a conductor carrying current produces a voltage across the conductor as shown in Figure 6.

The effect is caused by electron deflection within the solid, concentrating the negative charges to one side or the other depending on the influence of the magnetic lines of force. The difference in potential is called the Hall voltage.

The ratio V_t/IH is the Hall Coefficient. (V is the Hall voltage, t the material thickness, I the primary current flow, and H the magnetic field.) This ratio is a constant for a given material.

H. A. Lorentz and Paul Drude developed theories of conduction which apparently accounted for the Hall Effect early in this century. Subsequently the Hall Effect was widely used to study conductivity of materials, with a Hall Coefficient assigned as a means of classification.

Attempts to classify some specific materials such as lead sulphide and silicon produced baffling, contradictory data. The introduction of quantum mechanics in 1926 provided a means for clarification of these problems and other difficulties associated with semiconductor materials.

A proper understanding of semiconductor theory, impurity conduction, junction theory and the fundamental approaches to semiconductor device design did evolve out of studies using the Hall Effect.

The Hall voltage is proportional to the cross-product $I \times H$ (Current x Field). A device that exhibits the Hall Effect is a multiplier: if current flow is constant, the Hall voltage will be proportional to the magnetic field applied; if the magnetic field is constant, the Hall voltage will be proportional to the current flow.

Early Hall Effect devices found limited application as wattmeters or gaussmeters. Such devices were complex, expensive, and susceptible to noise and temperature variations. It was difficult to achieve useful Hall voltage levels.

Production of Hall Effect integrated circuits have eliminated the problems associated with discrete component circuit designs. The Hall Effect ICs are simple, inexpensive, virtually immune to noise, and are temperature stable. Amplifier circuits integral to the devices produce useful electrical output levels.

A MAGNETIC FIELD IS APPLIED TO THE CONDUCTOR CARRYING CURRENT. THE NEGATIVE CHARGES ARE DEFLECTED BY THE MAGNETIC FIELD PRODUCING A DIFFERENCE IN POTENTIAL CALLED THE HALL VOLTAGE (V_{HALL}). THIS PRINCIPLE IS APPLIED IN HALL EFFECT IC'S TO PRODUCE MAGNETICALLY ACTIVATED SWITCHES AND SENSORS.

TYPICAL APPLICATIONS

What Does A Hall Effect Switch Do?

Switch designers have obtained high performance switching characteristics with the use of photoelectric switching, capacitive circuits, mercury wetting switches, proximity devices and magnetic pickup techniques. Such designs have unique characteristics suitable for one or more specific applications. In general these designs are usually more complex and more expensive than Hall Effect IC switches performing similar functions.

Snap-action or reed switches have been used wherever the switch life, speed and reliability per-

mitted, primarily because of their low cost. Some applications require performance standards not available in electro-mechanical switches.

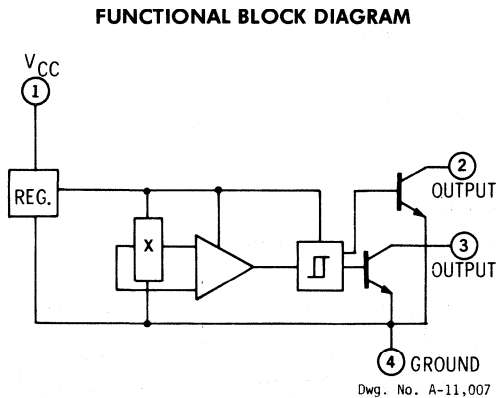

Sprague Electric Hall Effect IC switches provide high-performance switching characteristics at costs comparable with snap-action or reed switches.

The devices are very small. The 3-lead "T" pack units are 0.18" x 0.18" x 0.08". The cost is as low as the devices are small.

Whatever Turns Them On . . .

The application of Hall Effect switches is not very different from other switching methods. A means for mounting and making electrical connections must be provided. Supply voltage, load, environment and ambient temperature range must fall within limits specified in the applicable engineering bulletin.

Hall Effect switches incorporate a voltage regulator, a Hall voltage generator, a signal amplifier, trigger circuits and output drivers on a single silicon chip.

Switching is dependent on the proximity of an external magnet whose field passes perpendicularly through the Hall voltage generator on the chip face. The Hall generator produces an analog voltage amplified and converted by the trigger circuit to a digital output.

Hall Effect IC switches feature such characteristics as high-speed response and very high cycle rates. Typical rise time (turn-on) is 15 nanoseconds, fall time (turn-off) 100 nanoseconds. These units have the capability for cycling at 100,000 Hz (cycles-per-second).

Hall Effect IC switches feature constant amplitude output without the bounce characteristics of electromechanical switches. Hall Effect ICs also feature low power consumption: 7 mA is typical.

The magnetic characteristics of the Hall Effect switch are specified in terms of magnetic flux density (in gauss). Typical, maximum, and minimum operate and release points and hysteresis factors are specified.

A built-in hysteresis feature insures that stray magnetic fields from transformers, solenoids, or other associated circuitry will not cause unwanted switch operation. The graph below shows typical hysteresis characteristics for the UGN-3019T switch.

**TRANSFER CHARACTERISTICS
SHOWING HYSTERESIS**

The maximum operate point for the UGN-3019T switch is specified at 500 gauss and the minimum release point at 100 gauss. The maximum hysteresis factor for this switch, however, is 275 gauss. Should the operate point fall near the maximum, the release point will move up as well. Similarly, if the release point falls near the minimum, the operate point will have a correspondingly lower value. The hysteresis factor will remain close to a typical value.

Basic fixed element switch designs will take the maximum and minimum operate and release points into account. However, a configuration which permits adjustment of switch and magnet elements in assembly or operation can take advantage of the closer tolerance hysteresis limits to achieve even more precise switching characteristics.

Head-On Mode of Operation

The simplest form of magnet which will operate the Hall Effect switch is a rod or bar. The curves below illustrate typical flux density (in gauss) as a function of air gap distance for two rod magnets.

In each case, the magnet is oriented with its axis perpendicular to, and on the center line of, a Hall Effect IC switch. Flux density and air gap distance are measured along the magnet axis and switch centerline.

The magnet is moved toward the switch to activate it and away to release it. This method of operation is commonly referred to as the head-on mode.

The switch used is the Sprague UGN-3019T. The typical operate and typical release points are 420 and 300 gauss, respectively.

An ALNICO V rod magnet 0.25" in diameter by 1.25" in length must be 0.18" or less from the switch to insure operation at the 420 gauss typical operate point. The magnet must be moved to a distance 0.25" from the switch to insure release, an "operate-release" distance of 1/16".

The UGN-3019T can be switched with a larger or stronger magnet over greater distances. Or, the device can be switched with a smaller or weaker magnet provided the air gap between the magnet and the switch is properly decreased.

An ALNICO VIII rod magnet 0.212" in diameter by 0.187" in length must be 0.05" or less from the switch to insure operation at the 420 gauss typical operate point. The magnet must be moved to a distance 0.085" from the switch to insure release at the 300 gauss typical release point.

Use of the smaller ALNICO VIII rod magnet reduced the on-to-off motion from approx. 1/16" to 1/32".

MAGNETIC FLUX DENSITY AS A FUNCTION OF AIR GAP
Head-On Mode of Operation

Slide-By Mode of Operation

Hall Effect switches are often activated by means of a slide-by movement of the magnet past the switch as illustrated below.

The axis of the magnet remains perpendicular to the face of the switch, the air gap remains constant, and the magnet passes close enough to the switch to activate it. The maximum flux density is obtained when the magnet axis is on the switch centerline.

The graph at bottom left shows slide-by characteristics for the same magnet used in the previous head-on mode example. The air gap is 0.01". Flux density at the switch is a function of the distance between the magnet axis and the switch centerline.

Movement from the operate point to the release point covers only 0.018". Movement continuing past the switch covers an "operate-release" distance of 0.24", but no change in direction is required.

Dwg. No. A-10,957

Slide-By With Actuator

Magnetic fields may be distorted, interrupted, squeezed, squashed, or focused by various ferromagnetic concentrators, shunts, vanes, flux returns, and actuators. The magnetic circuit improves the efficiency of the magnet by concentrating the magnetic field.

The extent of field distortion can be seen in a comparison of flux density at the switch for a magnet with and without the actuator. Flux density is plotted in a slide-by mode, with a 0.05" air gap for an ALNICO VIII rod magnet 0.188" in diameter by 0.938" in length.

Without the actuator, the flux density across the 0.05" air gap is not sufficient to activate a UGN-3019T, as illustrated in the graph at bottom right. With the actuator, the 420 gauss operate point is obtained with the magnet axis 0.15" from the switch centerline.

Vane Activation

A ferromagnetic plate or vane moved between the magnet and switch will shunt the field, shielding the switch from the magnet. A movable vane, as shown below, is a most practical device for switching a Hall Effect IC.

Vane activation is often accomplished in a fixed assembly incorporating a magnetic conductor to concentrate and focus the magnetic field through the switch. A ferrous vane is used to shunt the flux, turning the switch off. The magnet, switch and magnetic conductor may be molded in place, eliminating alignment problems, and often producing an extremely rugged completed switch.

A fixed assembly designed for vane activation lends itself to a wide variety of possible switch configurations.

Note the curve at bottom left is an approximation. Several factors influence the switching characteristics of a vane activated Hall Effect switch. The relative position of the vane leading and trailing edges and the strength of the magnet used are of primary importance.

The flux density, vane dimensions, and material

all affect the slope of the flux density curve. A steeper curve will minimize the effect of switching point tolerance and temperature and voltage variation. A stronger magnet reduces the vane travel required to switch the Hall Effect switch.

Switch designers have utilized strong magnets with efficient magnetic circuit design in a fixed element molded assembly to provide a very high flux density and a steep curve. This approach minimizes operate-release point variations with changes in temperature.

A different design approach has used an adjustable air gap, permitting use of a smaller magnet in the magnetic circuit design. This design approach produces a shallow flux density curve, and places severe operate-release point restrictions on the Hall switch required. Vane material is typically greater than 1/32" thick to result in a minimum flux density. This leaves little clearance.

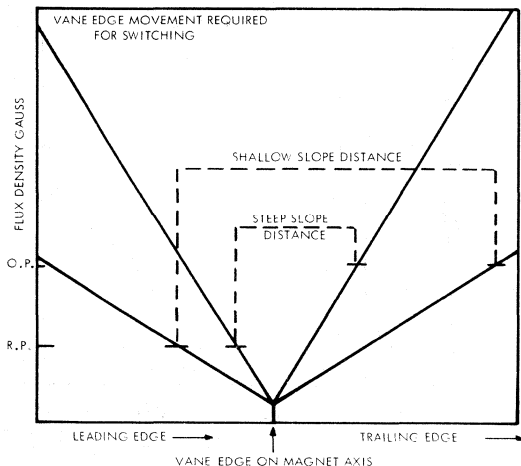

Generally, the physical position of the vane leading and trailing edges, (which determine switch points), the switch characteristics, and the magnet specifications should all be considered as part of an overall switch design. Independent selection of any element can severely restrict the possibilities for designing an effective switch.

The graph at bottom right is a generalization of the principle involved in reducing switching distances and tolerances for vane activated switches. A stronger magnet produces a higher initial flux density and a steeper curve. Note that a steep slope minimizes the effect of temperature changes on the operate point.

FLUX DENSITY AS A FUNCTION OF VANE POSITION

(D) is measured from the point where the vane first effects the flux density at the switch.

Ring Magnets and Bipolar Switches

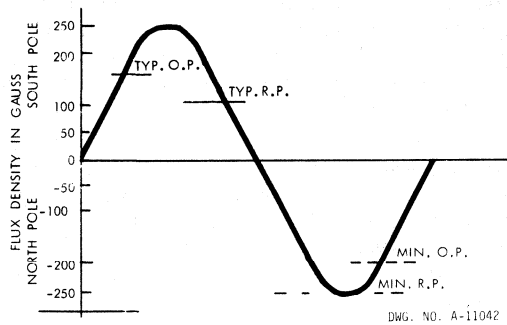

Multiple-pole ring magnets and Hall Effect bipolar switches are used to monitor or measure rotary motion and are especially useful in high-speed applications: speedometer pickups, rpm indicators, angle indicators, etc.

Rugged inexpensive ceramic or plastic ring magnets incorporate up to 20 magnetic pole pairs per inch of ring diameter. The useful field strength available in this type of magnet construction is approximately 250 gauss to 1000 gauss.

Sprague UGN-3030T and UGS-3030T bipolar digital switches operate in the magnetic field range of 250 gauss (South) to -250 gauss (North) and are intended specifically for operation with multiple-pole ring magnets.

Note below that exposure to a single pair of opposite magnetic poles accomplishes a single switching cycle.

A SINGLE SWITCHING CYCLE FOR A MULTIPLE POLE RING MAGNET USING A UGN-3030T SWITCH

The curves shown are approximations. Actual magnetic field exposure at the switch depends on the field strength available and the magnet-to-switch spacing.

Ring magnets are available with radially-oriented poles or with axially-oriented poles.

The output voltage wave form will be determined by the specific distribution of the operate and release points within the switching range. As with other Hall Effect switches, both points move together within the switching range so that the hysteresis factor remains close to the typical value in all cases, as illustrated in the graph at bottom.

RADIAL OR AXIAL ORIENTED POLES FOR SWITCH ACTUATION WITH A RING MAGNET

TRANSFER CHARACTERISTICS SHOWING HYSTERESIS

MODEL OF A MAGNET

An inexpensive commercially available standard ALNICO VIII magnet* is shown in the scale drawing. The solid lines are maximum operate and minimum release points for a Sprague UGN-3019T switch. The field strength levels indicated by dotted lines are maximum operate and minimum release points for other Sprague Hall Effect IC switches.

The field is unique to this magnet, and is a function of the material used and the geometry and dimensions of the magnet. Increasing the diameter would tend to spread the field. Extending the length of the magnet would strengthen the field.

A variety of magnet materials are commercially available, each exhibiting unique field characteristics. A samarium-cobalt magnet only 0.085" square by 0.04" long will produce up to 1200 gauss at its pole surface, more than adequate field strength to operate all Sprague Hall Effect IC switches. The strongest known field available in a permanent magnet is that generated by an ALNICO V magnet capped with a samarium-cobalt rare earth magnet.

The curves below left are flux density values for the magnet measured for switch activation in a head-on mode (along the magnet axis), and for slide-by modes with air gaps of 0.01" and 0.025".

MAGNETIC FIELD MODEL OF AN ALNICO VIII SINTERED ROD MAGNET

Dwg. No. A-11,064

The slide-by curves cross each other, reflecting the fact that the field strength contours are not concentric circles.

The magnetic flux density is indicated for the most sensitive area of the device. This area is centrally located and 0.032" ±0.002" below the branded surface of the T package and 0.012" ±0.002" below the branded face of the U package.

Note that Sprague Hall Effect ICs are designed to be activated by the field generated by a magnetic South pole, applied to the face or branded side of the switch package. The Hall Effect switches will operate with a magnetic North pole of sufficient strength applied to the back of the switch.

A magnetic South pole at the face, and a magnetic North pole at the back of the switch at the same time produce a concentrated field through the switch. A magnetic South pole applied to the reverse side of the switch will offset the effects of a South pole applied to the switch face. Conversely, a North pole may be applied to the back side of the switch so the device is normally on, and a North pole approaching the switch face will turn it off.

LOW-COST HALL EFFECT DIGITAL SWITCHES

Sprague offers 10 different Hall Effect switches from its automated high-volume production, packaging and test facilities in Concord, N.H. These rugged solid-state switches operate with small low-cost commercially available permanent magnets.

The devices feature "no-bounce" contactless switching to 100,000 Hz, circuit operation over a wide range of specified supply voltages (4.5 to 25 V), and constant amplitude output. Output stages are easily interfaced with a variety of output loads.

Each Hall Effect switch is a plastic-packaged monolithic integrated circuit: a voltage regulator, a

Hall voltage generator, signal amplifier, trigger circuit and output transistors on a single silicon chip.

Output transistors are normally OFF until a magnetic activating field exceeds a specified operate point. Switched ON the transistors will sink up to 25 mA. See Electrical Characteristics below.

The output transistors switch OFF when the activating field drops below a specified release point that is a lower value than the operate point. This switching hysteresis characteristic insures unambiguous, non-oscillatory switching.

*Dual Outputs

SUGGESTED OUTPUT LOADS FOR HALL EFFECT SWITCHES

The output of each Sprague Hall Effect switch is a grounded-emitter, open-collector structure. In the absence of a magnetic field the output transistor is OFF and switches ON when the proper field is applied to the associated Hall voltage generator.

With a simple external resistor network the output can be interfaced with transistors, triacs, SCRs or common DTL, TTL, RTL and MOS logic circuits.

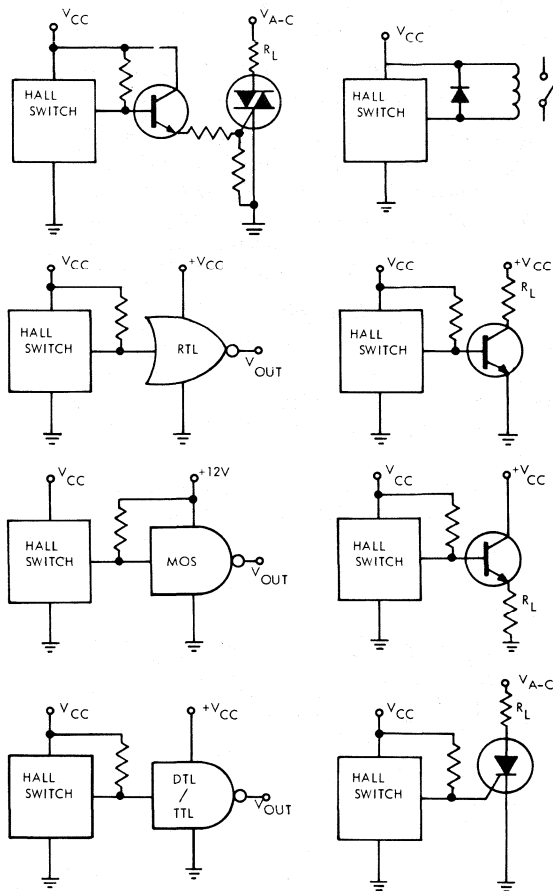

Any type of load within specified current and voltage limitations is possible. Transient suppression may be required on all inductive loads.

Output is specified in the engineering bulletins in terms of positive logic: low or ON voltage level = 0; high or OFF voltage level = 1. In the logic '1' state, the output is guaranteed to sustain a specified voltage level. The UGN-3019T is capable of sinking up to 15 mA with a voltage drop of less than 400 mV.

The graph at bottom left illustrates the typical output ON voltage level as a function of temperature for the UGN-3019T.

Below are some suggested interfacing approaches. Many techniques can be used and are discussed in the following pages.

Specific device type numbers are referenced in this section in discussion of applications, loads and interfacing techniques. However, all Sprague Hall Effect switches may be used in the same way provided the total sink current and maximum OFF voltage levels do not exceed values specified for each device.

Switching Common Loads With The UGN-3020T

The UGN-3020T is supplied in a 3-pin plastic "T" Pack. The branded side of the package is the face. Terminals are, from left-to-right facing the package, the input (V_{CC}) terminal, common ground and output terminals.

Supply voltage is any value between +4.5 and +24 volts applied between the V_{CC} terminal and common ground. The absolute maximum output terminal sink current is 25 mA. Voltage drop at 25 mA is typically 0.2 volts.

Note that the voltage on the output terminal must always be positive (+).

The South pole of the magnet shown below will activate the UGN-3020T in a head-on mode, at a typical distance of 0.12" from the switch face (typical operate point is 220 gauss). The switch is turned OFF by removing the magnet to a distance of 0.16" from the switch (typical release point is 165 gauss).

Light-Emitting-Diode

Let's connect a load, a light-emitting-diode. We have a +12 volt supply. We must connect a current-limiting resistor in series with the diode to keep the ON current under 50 mA maximum, as illustrated below.

If the LED drops 1.4 volt, we need a resistor of $\frac{12\text{ V} - 1.4\text{ V}}{.05\text{ A}} = 212\text{ ohms}$. The closest standard value is 220 ohms.

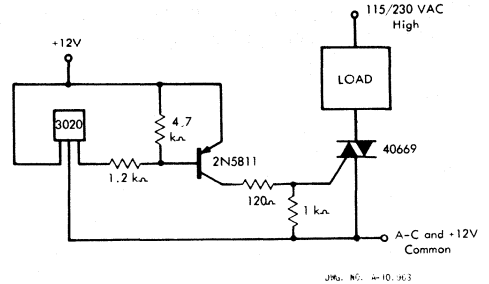

40669 Triac

The RCA 40669 triac is often used to control a-c loads up to 8 amperes rms maximum. We must add a current gain stage between the UGN-3020T and the 40669 triac.

When the Hall switch is turned on, it supplies 9 mA of base current to the 2N5811 which turns on and supplies 80 mA of drive to the triac. Note that

the +12 volt supply common ground is connected to the low side of the a-c line. Be careful. If the high and low are mixed up the Hall switch could be hot!

D-C Load 4 Amperes

When the UGN-3030T is activated, base drive is pulled away from the 2N5812. Collector current then flows to the base of the 2N3055. A 4 ampere load can be activated.

TTL/DTL

The popular TTL 7400 series is quite simple to drive. The UGN-3020T, switched ON, will sink the 1.6 mA maximum to operate the 7400.

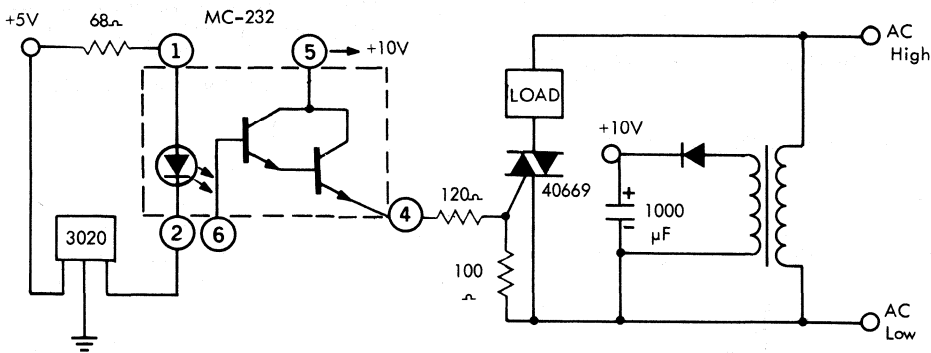

Isolating The Switch From The A-C Line

It is desirable to isolate the Hall Effect switch from the a-c line for many control applications driving line-operated loads. A Fairchild MC-232 photo-isolator may be used to accomplish this design.

The activated UGN-3020T will draw current through the LED. The current must be limited to 50 mA. A 5-volt supply is used. The calculation is

$$R = \frac{V_{CC} - V_F(LED)}{I} = \frac{5 V - 1.4 V}{.05 A} = 72 \text{ ohms.}$$

The resistor selected is the closest standard value — 68 ohms. The LED drives the detector which supplies 70 mA to drive the triac. Note that the 10 volt power supply, consisting of the 6.3-volt transformer, diode and capacitor, can supply detector bias for several of these control circuits.

DWG. NO. A-10.961

Types UGN-3013T, UGN-3019T, UGS-3019T, UGN-3020T, UGS-3020T, UGN-3030T, UGS-3030T, UGN-3040T, and UGN-3501T are supplied in 3-pin plastic "T" packages 0.080" (2.03 mm) thick. These Hall effect devices are also available in 3-pin plastic "U" packages 0.061" (1.54 mm) thick. The "U" package is specified by replacing the "T" suffix to the part number with a "U" (UGN-3013U).

LINEAR OUTPUT HALL EFFECT SENSORS

TYPE UGN-3501T

Utilizing the Hall Effect for sensing a magnetic field, Type UGN-3501T integrated circuits provide a linear single-ended output which is a function of magnetic field intensity. Integrating the Hall cell and the amplifier into one monolithic device minimizes problems related to the handling of millivolt analog signals.

This sensor, supplied in a 3-pin plastic package, is rated for continuous operation over the temperature range of 0°C to +70°C and a voltage range of 8 to 12 volts d-c.

The functional block diagram for the UGN-3501T is shown below.

FUNCTIONAL BLOCK DIAGRAM

TYPE UGN-3501M

The Type UGN-3501M Hall Effect IC includes a monolithic Hall cell, linear differential amplifier, differential emitter follower output, and a voltage regulator.

Provisions are included for output offset null. This sensor is supplied in an 8-pin dual in-line plastic package and is rated for continuous operation over the temperature range of 0°C to +70°C and a voltage range of 8 to 16 volts d-c.

The figure below shows the functional block diagram for the UGN-3501M Hall Effect Sensor.

FUNCTIONAL BLOCK DIAGRAM

OUTPUT VOLTAGE AS A FUNCTION OF AIR GAP FOR HEAD-ON MODE OF OPERATION

APPLICATIONS FOR TYPE UGN-3501T SENSORS

These devices are used principally to sense relatively small changes in a magnetic field — changes which are too small to operate a ‘Hall Effect’ switching device. They are customarily capacitively coupled to an amplifier, which boosts the output to a higher level.

The UGN-3501T is a single output linear device having a sensitivity of 700 mV/1000 gauss, and output offset which is typically +3.6 volts, at a V_{CC} of -12 volts.

The device will respond to magnetic North and South poles directed to the face or reverse side of the -pin ‘T’ package, as illustrated below.

OUTPUT VOLTAGE AS A FUNCTION OF MAGNETIC FLUX DENSITY

ABSOLUTE MAXIMUM RATINGS

- Supply Voltage, V_{CC} +16V
- Output Current, I_{OUT} 4mA
- Magnetic Flux Density, B No Limit
- Operating Temperature Range, T_A 0°C to +70°C
- Storage Temperature Range, T_S -65°C to +150°C

ELECTRICAL CHARACTERISTICS at $V_{CC} = 12 VDC$, $T_A = +25^\circ C$

Characteristic	Symbol	Test Conditions	Min.	Typ.	Max.	Units	Notes
Operating Voltage	V_{CC}		8.0	—	12	V	—
Supply Current	I_{CC}	$V_{CC} = 12V$	—	10	20	mA	—
Quiescent Output Voltage	V_{OUT}	$B = 0$ Gauss	2.5	3.6	5.0	V	1
Sensitivity	ΔV_{OUT}	$B = 1000$ Gauss	350	700	—	mV	1, 2
Frequency Response	$f(-3dB)$		—	25	—	kHz	—
Broadband Output Noise	e_n	3dB B.W. 10 Hz to 10 kHz	—	0.10	—	mV	—
Output Resistance	R_O		—	100	—	Ω	—

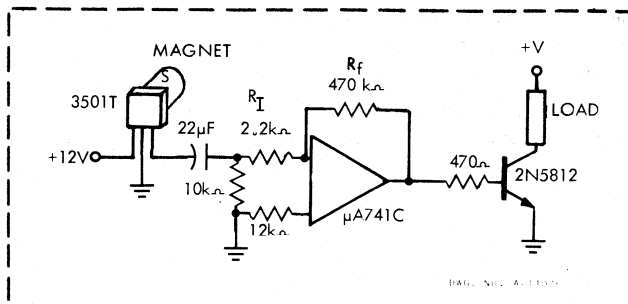

NOTE 1. All output voltage measurements are made with a voltmeter having an input impedance of 10 k Ω or greater.
 NOTE 2. Magnetic flux density is measured at the most sensitive area of the device, which is centered on the branded side of the package: 0.042 \pm 0.001" (1.07 \pm 0.03 mm) below the surface of the T package or 0.022" \pm 0.001" (0.56 \pm 0.03 mm) below the surface of the U package.

Ferrous Metal Detector

Two similar detector designs are illustrated below. One senses the *presence* of a ferrous metal, the other senses an *absence* of the metal. The two sensing modes are accomplished simply by reversing the magnet poles relative to the UGN-3501T. The pole of the magnet is fixed in contact with the reverse side of the UGN-3501T in both cases.

Frequency response characteristics of this circuit are easily controlled by changing the input decoupling capacitor value for the low-frequency breakpoint. If high-frequency attenuation is desired a capacitor may be used to shunt the feedback resistor.

Metal Sensor

The North pole of the magnet is fixed to the reverse side of the UGN-3501T. The sensor is in contact with the bottom of a 3/32" epoxy board. A 20 mV peak output change (decrease) is produced as

the 1" steel ball rolls over the sensor. This signal is amplified by the µA741C to drive the 2N5812 ON to carry a 0.5 A collector current.

Notch Sensor

The South pole of the magnet is fixed to the reverse side of the UGN-3501T. The sensor is 1/32" from the edge of the steel rotor. A 1/16" wide by 1/8" deep slot in the rotor edge passing the sensor causes a 10 mV peak output change (decrease). This signal is amplified by the µA741C to drive the 2N5812 ON, carrying a 0.5 A collector current.

Note that in both examples the branded side of the UGN-3501T faces the material (or lack of material) to be sensed. In both cases the presence (or absence) of the ferrous metal changes the flux density at the Hall Effect sensor so as to produce a negative going output pulse. This pulse is inverted by the amplifier to drive the transistor ON.

Printer Application For The UGN-3501T

The application below is for a sensor that will sense lobes on the character drum. Lobes are spaced

$\approx 3/16''$ apart around the circumference, are $\approx 1/4''$ long and rise 10 to 15 mils from the surface of the drum.

DWG. NO. A-11072

A UGN-3501T Hall Effect linear IC sensor was used with an Indiana General Magnet Products Co. SR8522 magnet. The North pole is fixed to the reverse side of the "T" pack. A flux concentrator is fixed to the branded face of the "T" pack. Though it does not provide a flux return path, a concentrator will "focus" the magnetic field through the switch.

The concentrator "blade" at right is aligned with the drum lobe at an air gap distance of 0.01". The output change is 10 mV peak, amplified as shown to develop a +3 volt output from the operational amplifier, driving the transistor ON.

Sensitivity is so great in this configuration the UGN-3501T output signal base line tracked the eccentricities in the drum quite closely. This affected the lobe resolution, but the lobe position may still be measured.

DWG. NO. A-11.071

DWG. NO. A-11073

APPLICATIONS FOR TYPE UGN-3501M SENSORS

Type UGN-3501M sensors are well-suited for accurate measurement and/or control of position, weight, thickness, velocity, current, etc. The device provides a linear differential output which is a function of magnetic field intensity, with a typical sensitivity of 1.4 volts/1000 gauss.

Either magnetic pole can be used. Pins 1 and 8 are sinking and sourcing terminals for the differential output. Changing poles inverts the output. Connections may be reversed to account for this change.

The figure below shows a 20Ω trimmer potentiometer being used for output offset nulling. Pins 5, 6, and 7 may be shorted if an output offset voltage of up to ±400 mV can be tolerated.

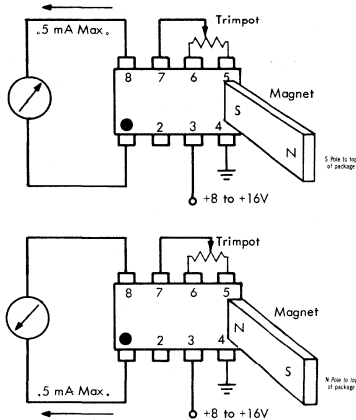

FIG. NO. A-10-072

OUTPUT VOLTAGE AS A FUNCTION OF MAGNETIC FLUX DENSITY

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V _{CC}	+16V
Output Current, I _{O(UT)}	2mA
Magnetic Flux Density, B	No Limit
Operating Temperature Range, T _A	0°C to +70°C
Storage Temperature Range, T _S	-65°C to +150°C

ELECTRICAL CHARACTERISTICS at V_{CC} = 12 VDC, T_A = +25°C (unless otherwise specified)

Characteristic	Symbol	Test Conditions	Min.	Typ.	Max.	Units	Notes
Operating Voltage	V _{CC}		8.0	—	16	V	—

NOTE 1. All output voltage measurements are made with a voltmeter having an input impedance of 10 kΩ or greater and a common mode rejection ratio greater than 60 dB.
 2. Magnetic flux density is measured at the most sensitive area of the device, which is on the top center, 0.037 ± 0.001" (0.94 ± 0.03mm) below the surface.

Motion Measurement With Permanent Magnets

The UGN-3501M, properly biased, will produce the output voltage values shown below when activated in a head-on mode of operation.

Note the output voltage curve is almost linear over the first 0.04" of travel. The change rate here is 10 mV/0.001" air gap change.

The same magnet used in a "slide-by" mode of operation will produce the three curves presented at bottom.

Movement measurements would generate the largest outputs and most accurate readings where they are centered on the steepest portion of each curve, and are confined to the linear segment of that curve. This is the case for the head-on and the slide-by curves.

For example, in a slide-by mode of operation with an 0.03" air gap, movement to be measured could be centered at a "zero" of 0.1" from the centerline. The voltage rate of change would be linear at 5 mV/0.001" movement, for a movement distance of ± 0.02 ".

The rate of change is, of course, a function of the flux density gradient across the magnetic field for the particular magnet used. A samarium-cobalt magnet, with its relatively compact field, can produce voltage change rates to 30 mV/0.001" movement.

UGN-3501M Output Circuit Design

The output current handling capability of the UGN-3501M is 0.5 mA. In the differential connection one output pin sources load current, the other must sink it. A simple method for increasing drive capability is illustrated below.

A 4.3 kΩ resistor is connected from each output pin to ground. The quiescent bias current of the output stage is increased, and the sinking capability is increased to 1 mA.

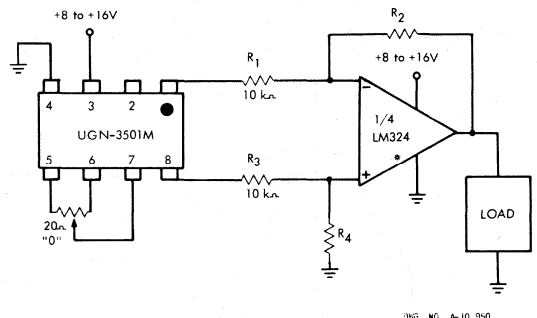

If even higher current drive capability is required, the simplest solution is the addition of a pair of emitter-followers:

Up to 30 mA of load current can be sourced by the circuit as shown, and this can be increased considerably by using Darlington power transistors and lower resistance in the emitter circuits.

Note that the emitter-followers have no voltage gain. The output voltage differential is essentially the same as that of the UGN-3501M.

An operational amplifier will supply a voltage gain and a current gain, and transform the differential output of the UGN-3501M to a single-ended output. (The circuit will drive a load which has one side grounded.)

The LM-324 quad operational amplifier will operate from a single power supply if the output does not swing in the negative direction. Pin 1 of the UGN-3501M does swing negative when a magnetic South pole approaches the device surface. Pin 1, therefore, is connected to the negative or inverting input of the LM-324, and its output swings in the positive direction. Reversing connections to pins 1 and 8 allows the output to respond to a magnetic North pole. If the application requires the output be capable of swing both negative and positive, then a dual ± power supply would have to be used.

$$\text{Voltage amplification} \approx \frac{R_2}{R_1}$$

with

$$R_1 = R_3$$

$$R_2 = R_4$$

The LM-324 can source 40 mA. Other operational amplifiers suitable for single supply operation are MC-3403P, MC-3458P1, CA-3160E.

Current Sensing Applications

The UGN-3501M is ideally suited for current measurement applications. Typical applications are overload detectors for electric motors, current limiters for high-current power supplies, clamp-on current probes for high-current d-c loads, etc.

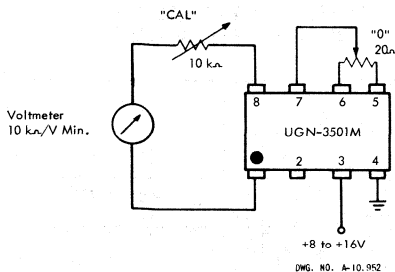

The standard toroid is typical of small commercially-available electromagnetic devices which can be used with the UGN-3501M:

With this toroid, the UGN-3501M, fixed in the gap, would "see" 5.6 gauss per ampere-turn. To "read" from zero to 20 amperes, 9 turns would develop $9 \times 20 \times 5.6 = 1008$ gauss. The UGN-3501M would have a 1.4 volt output with a 20 ampere activating current.

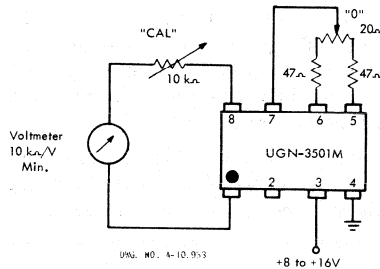

Gaussmeter Applications

A typical UGN-3501M has a differential output of 1400 mV in a 1000 gauss field. Using a 100 μ A movement, with a series calibrating trimmer potentiometer, a simple gaussmeter suitable for many applications can be easily produced:

The UGN-3501M is quite linear to ≈ 1000 gauss. The input differential stage gain must be reduced to maintain linearity beyond this range.

A 47 Ω $\pm 5\%$ resistor in series with pins 5 and 6 extends the useful linear range to 3000 gauss:

Calibrating The UGN-3501M Gaussmeter

Where applications require the differential output voltage at pins 1 and 8 be calibrated, dual precision 100 ohm variable resistors may be used:

A calibration field can be constructed using standard Stancor C-2709 filter chokes, with the pole pieces removed and the center magnetic path completed with a section of the pole piece removed. Brass stock 1/16" x 1/2" x 4 3/8" was used for mechanical support, 2 pieces in the front and 2 pieces in the rear, plus 4 1/4" x 1" No. 6-32 threaded standoffs. The air gap was set at 3/8" as depicted below.

HALL EFFECT DEVICES (Continued)

The chokes are wired in series opposing, and are driven from a constant current source. Initial calibration may be accomplished with a UGN-3600 Hall generator supplied with a calibration curve. The current is fixed at the value which produces 1000 gauss.

The UGN-3501M to be calibrated is "zeroed" and placed in the 1000 gauss field. The dual precision variable resistor is adjusted until the output is 1 volt. The UGN-3501M circuit is re-zeroed out of the field and the calibration rechecked.

The value of the precision variable resistor is then measured. Two 1% resistors of the closest standard value replace these in the final circuit configuration.

Check Oscillation Problems

The UGN-3501M has a relatively wide bandwidth. Oscillation is the most common problem encountered in applications for the device, caused by excessive lead lengths (2') on the zero control, and coupling between the zero control leads and the output leads from pins 1 and 8. (If moving your hand near the zero control changes the output voltage — there are oscillation problems.)

Solutions to oscillation problems are: 1) cut the zero control lead lengths; 2) separate the zero control and output leads; and 3) (in extreme cases) use a low-pass filter on the output:

Sensitivity Variations

Note that the UGN-3501M is specified with a typical sensitivity of 1.4 mV/gauss and a minimum sensitivity of .7 mV/gauss. Unless a special "sort" is ordered, plan on this variation.

Note also that the "0" output varies typically 1 mV/°C, a major factor in determining a minimum detectable long term signal.

The sensitivity varies with temperature and V_{CE} . The output voltage is a function of the load resistance. These factors are illustrated in the graphs at right.

NORMALIZED SENSITIVITY AS A FUNCTION OF TEMPERATURE

NORMALIZED SENSITIVITY AS A FUNCTION OF VCC

RELATIVE OUTPUT VOLTAGE AS A FUNCTION OF LOAD RESISTANCE

Type UGN-3604M/UGN-3605M Hall Cells

The UGN-3604M is a basic Hall voltage generator in an 8-pin DIP package, supplied with a calibration chart. Intended for use as a design or production test aid, the UGN-3604M permits accurate measurement of magnetic field intensity as a means of aligning magnet/Hall switch positions, and for calibrating Hall Effect sensor circuits.

A UGN-3605M is the same Hall voltage generator without a calibration chart. Supply voltage for these units is 5 volts. Below is the terminal pinning diagram for UGN-3605M.

Applications at Sprague Electric Co.
(We use them . . . and love them)

Hall Effect ICs are designed into Sprague's own production and test equipment. Position-sensing digital switches control and monitor high-speed automatic machine operations. Hall Effect switch output provides direct input to a microprocessor-based control unit.

Data is compiled continuously from critical points in the production process. The control informs the machine operator, makes automatic adjustments, indicates manual adjustments which may be necessary, and reports on production.

Hall Effect ICs perform simultaneous control and reporting functions. Extremely reliable precise repetitive operation of these switches helps to achieve and maintain very high levels of process control and product quality.

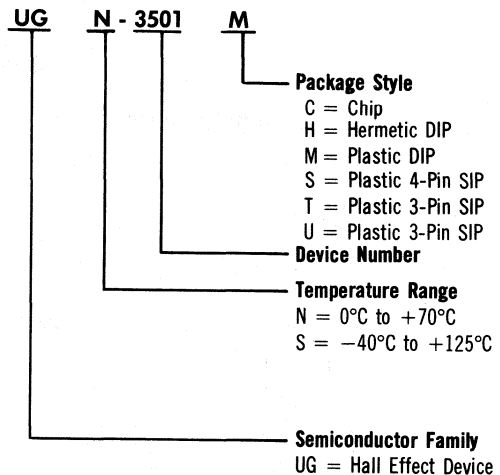

PACKAGE INFORMATION

Sprague's Hall Effect IC's are packaged in a special epoxy material formulated to handle severe service environments. It is impervious to all commercially available consumer and industrial solvents and degreasing compounds, oils and alkaline chemicals. It is susceptible only to hot (+150°C) concentrated fuming red nitric acid applied under pressure.

The material has a continuous thermal rating of +150°C, and a hot-spot rating (100 hours) of +170°C. It is classed by Underwriters' Laboratories, Inc. as a self-extinguishing material. Its resistivity is 10¹⁵ ohms. Thermal coefficient of expansion (T_G) is 30 x 10⁻⁶ppm/°C.

Device leads will meet solderability requirements of Military Standard MIL-STD-202 (95% or better solder-wetting without special preparation).

Magnet Marketplace

A strong field of magnetic components manufacturers can supply parts suitable for use in virtually any conceivable Hall Effect IC application. Comprehensive listings of these suppliers are presented in reference documents such as the Thomas Register.

Many of these firms are familiar with Hall Effect ICs application.

Magnetic components available from these manufacturers include ALNICO, rare-earth, ceramic, and plastic permanent magnets in a variety of form factors such as rods, bars, rings, sheets, etc. Ferromagnetic components for use as electro-magnets, concentrators, actuators, etc. are also available.

ULN-2031A, ULN-2032A, and ULN-2033A HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

SPRAGUE TYPE ULN-2031A, ULN-2032A, and ULN-2033A High-Current Darlington Transistor Arrays are comprised of seven silicon Darlington pairs on a common monolithic substrate. The Type ULN-2031A consists of 14 NPN transistors connected to form seven Darlington pairs with NPN action. The Type ULN-2032A ($h_{FE} = 500$ min.) and the Type ULN-2033A ($h_{FE} = 50$ min.) consist of seven NPN and seven PNP transistors connected to form seven Darlington pairs with PNP action. All devices feature a common emitter configuration.

These devices are especially suited for interfacing between MOS, TTL, or DTL outputs and 7-segment LED or tungsten filament indicators. Peak inrush currents to 100mA are allowable. They are also ideal for a variety of other driver applications such as relay control and thyristor firing.

Type ULN-2031A, ULN-2032A, and ULN-2033A transistor arrays are housed in 16-lead DIP plastic packages which include a separate substrate connection for maximum circuit design flexibility.

ULS-2045H and ULN-2046A TRANSISTOR ARRAYS (Three Isolated Transistors and One Differential Amplifier)

THE ULS-2045H and ULN-2046A are general-purpose transistor arrays each consisting of five silicon N-P-N transistors on a single monolithic chip. Two transistors are internally connected to form a differential pair. Integrated circuit construction provides close electrical and thermal matching between each transistor.

These arrays are well-suited for a wide range of applications such as: DC to VHF signal processing systems; temperature-compensated amplifiers; custom designed differential amplifiers and discrete transistors in conventional circuits.

Two package configurations are available. Type ULS-2045H is supplied in a hermetic 14-lead dual in-line ceramic package and is rated for operation over the military temperature range of -55°C to $+125^{\circ}\text{C}$.

Type ULN-2046A is electrically identical to the ULS-2045H but is supplied in a dual in-line plastic package rated for -20°C to $+85^{\circ}\text{C}$ ambients.

ABSOLUTE MAXIMUM RATINGS at $+25^{\circ}\text{C}$ Free-Air Temperature (unless otherwise noted)

	ULS-2045H		ULN-2046A		UNITS
	EACH TRANSISTOR	TOTAL PACKAGE	EACH TRANSISTOR	TOTAL PACKAGE	
Power Dissipation:					
T_A to $+55^{\circ}\text{C}$	300	750	300	750	mW
T_A to $+75^{\circ}\text{C}$	—	—	—	—	mW
Derating Factor:					
$T_A > +55^{\circ}\text{C}$	—	—	—	6.67	mW/ $^{\circ}\text{C}$
$T_A > +75^{\circ}\text{C}$	—	8	—	—	mW/ $^{\circ}\text{C}$
Collector-Base Voltage, $V_{(BR)CBO}$					30V
Collector-Emitter Voltage, $V_{(BR)CEO}$					20V
Collector-Substrate Voltage, $V_{(BR)CIS}$ (See note 2)					20V
Emitter-Base Voltage, $V_{(BR)EBO}$					6V
Collector Current, I_C					50mA
Operating Temperature Range, T_A :					
Type ULS-2045H					-55°C to $+125^{\circ}\text{C}$
Type ULN-2046A					-20°C to $+85^{\circ}\text{C}$
Storage Temperature Range, T_S :					-65°C to $+150^{\circ}\text{C}$

Notes:

- The maximum ratings are limiting absolute values above which the serviceability may be impaired from the viewpoint of life or satisfactory performance. The breakdown voltages may be far above the maximum voltage ratings. To avoid permanent damage to the transistor, do not attempt to measure these characteristics above the maximum ratings.
- Pin 13 is connected to the substrate. This terminal must be tied to the most negative point in the external circuit to maintain isolation between transistors and to provide for normal transistor action.

ULN-2046A-1 TRANSISTOR ARRAY

TYPE ULN-2046A-1 general-purpose transistor array consists of five silicon NPN transistors, two of which are connected as a differential amplifier. The monolithic construction provides close electrical and thermal matching between all transistors.

Except as shown in the following electrical characteristics, Type ULN-2046A-1 transistor array is identical to Type ULN-2046A.

ELECTRICAL CHARACTERISTICS at $T_A = +25^\circ\text{C}$

NOTE:

Pin 13 is connected to the substrate. This terminal must be tied to the most negative point in the external circuit to maintain isolation between transistors and to provide for normal transistor action.

ULN-2047A TRANSISTOR ARRAY (Three Differential Amplifiers)

TYPE ULN-2047A is a silicon NPN multiple transistor array comprising three independent differential amplifiers. It is specifically intended for use in switching applications such as electronic organ keyboards. All base leads are brought out on one side of the 16-lead plastic dual in-line package to simplify printed wiring board layout. A separate substrate connection permits maximum circuit design flexibility.

Type ULN-2047A is supplied in a 16-pin dual in-line plastic package.

2. Base and collector of associated transistor connected to emitter, all other pins common to base of transistor under test.

10

ULN-2054A TRANSISTOR ARRAY (Dual Independent Differential Amplifiers)

THE ULN-2054A is a transistor array consisting of six silicon NPN transistors on a single monolithic chip. The transistors are internally interconnected to form two independent differential amplifiers.

The ULN-2054A is intended for a wide range of applications requiring extremely close electrical and thermal matching characteristics. Some applications are: cascade limiter circuits; balanced mixer circuits; balanced quadrature/synchronous detector circuits; balanced (push-pull) cascade/sense/IF amplifier circuits; or in almost any multifunction system requiring RF/Mixer/Oscillator, converter/IF functions.

Available in a 14-lead dual in-line plastic package the ULN-2054A is rated for operation over a -20°C to $+85^{\circ}\text{C}$ ambient temperature range.

Other features are:

- Input Offset Voltage – 5mV max.
- Input Offset Current – 2 μA max.
- Voltage gain (single-stage double ended output) – 32 dB typ.
- Common-Mode Rejection Ratio (each amplifier) – 100 dB typ.

ULN-2081A and ULN-2082A GENERAL PURPOSE HIGH-CURRENT TRANSISTOR ARRAYS

SPRAGUE TYPE ULN-2081A and ULN-2082A Transistor Arrays are comprised of seven high-current silicon NPN transistors on a common monolithic substrate. The Type ULN-2081A is connected in a common-emitter configuration and the Type ULN-2082A is connected in a common-collector configuration.

Both arrays are capable of directly driving seven segment displays and LED displays. They are ideal for a variety of other driver applications such as relay control and thyristor firing.

Type ULN-2081A and ULN-2082A are housed in 16-lead DIP plastic packages which include a separate substrate connection for maximum circuit design flexibility.

ULN-2081A

ULN-2082A

ABSOLUTE MAXIMUM RATINGS

Power Dissipation (any one transistor).....	500mW
(total package).....	750mW
Ambient Temperature Range (operating).....	-20°C to +85°C
Individual Transistor Ratings:	
Collector-to-Emitter Voltage, V_{CEO}	16V
Collector-to-Base Voltage, V_{CBO}	20V
Collector-to-Substrate Voltage, V_{CISO}	20V
Emitter-to-Base Voltage, V_{EBO}	5V
Collector Current, I_C	200mA
Base Current, I_B	20mA

NOTE:

The collector of each transistor in the Type ULN-2081A and ULN-2082A is isolated from the substrate by an integral diode. The substrate must be connected to a voltage which is more negative than any collector voltage so as to maintain isolation between transistors, and to provide normal transistor action. Undesired coupling between transistors is avoided by maintaining the substrate terminal (5) at either d-c or signal (a-c) ground. An appropriate bypass-capacitor can be used to establish a signal ground.

ULN-2083A and ULS-2083H TRANSISTOR ARRAYS (Five Independent NPN Transistors)

DESIGNED for use in general purpose, medium current (to 100 mA) switching and differential amplifier applications, the ULN-2083A and ULS-2083H transistor arrays each consist of five NPN transistors on a single monolithic chip. Two transistors are matched at low currents (1 mA) making them ideal for use in balanced mixer circuits, push-pull amplifiers, and other circuit functions requiring close thermal and offset matching.

A separate substrate connection permits maximum circuit design flexibility. In order to maintain isolation between transistors and provide normal transistor action, the substrate must be connected to a voltage which is more negative than any collector voltage. The substrate terminal (pin 5) should therefore be maintained at either d-c ground or suitably bypassed to a-c ground to avoid undesired coupling between transistors.

Two package configurations are available. The Type ULN-2083A is supplied in a 16-lead dual in-line package for operation over the temperature range of -20°C to $+85^{\circ}\text{C}$. This package is similar to

JEDEC style MO-001AC. The Type ULS-2083H is electrically identical to the ULN-2083A but is supplied in a hermetic dual in-line package for operation over the temperature range of -55°C to $+125^{\circ}\text{C}$. This package conforms to the dimensional requirements of Military Specification MIL-M-38510 and can meet all of the applicable environmental requirements of Military Standard MIL-STD-883.

ULN-2086A TRANSISTOR ARRAY

Type ULN-2086A general-purpose transistor array consists of five silicon NPN transistors, two of which are connected as a differential amplifier. The monolithic construction provides close electrical and thermal matching between all transistors.

With the exception of the collector cutoff current specifications listed below and the omission of guaranteed limits on input offset voltage and input offset current, Type ULN-2086A is identical to Type ULN-2046A transistor array.

ELECTRICAL CHARACTERISTICS at $T_A = +25^\circ\text{C}$

ULN-2401A AUTOMOTIVE LAMP MONITOR

FEATURES

- No Standby Power
- Completely Integral to Wiring Assembly
- Monitor 1 to 8 Lamps per Channel
- Fail-Safe
- Reverse Voltage Protected
- 14-Pin Dual In-Line Plastic Package

OFFERING SEVERAL ADVANTAGES for a lamp monitoring system, the ULN-2401A monolithic integrated circuit is versatile, easily connected, and does not affect normal lamp operation. Little additional wiring is required for installation since the system is completely integral to the wiring assembly.

The ULN-2401A electronic lamp monitor was specifically designed for application in the severe automotive environment. Lateral PNP transistors provide high-frequency noise immunity and differential transient voltage protection. Reverse voltage protection, internal voltage regulators, and temperature compensation are all incorporated in the design. A failure within the device will not affect lamp operation. As a quad comparator, the ULN-2401A can also be used to monitor multiple low-voltage power supplies or, with appropriate sensors, industrial processes.

This lamp monitor operates by sensing the voltage drop in the wiring (50 to 100 mV) for each lamp circuit. If any of the four comparators sees a differential input voltage of greater than 26 mV, a failure lamp is turned on. Lamp and wiring tolerances causing differential input voltages of up to 7 mV are permitted. Each comparator is capable of monitoring a mixture of one to eight similar lamps. No standby power is required because the operating voltage is obtained from the sense leads and is energized only when the lamps are turned on.

ULN-2429A FLUID DETECTOR

FEATURES

- High Output Current
- A-C or D-C Output
- Single-Wire Probe
- Low External Parts Count
- Internal Voltage Regulator
- Reverse Voltage Protection
- 14-Pin Dual In-Line Plastic Package

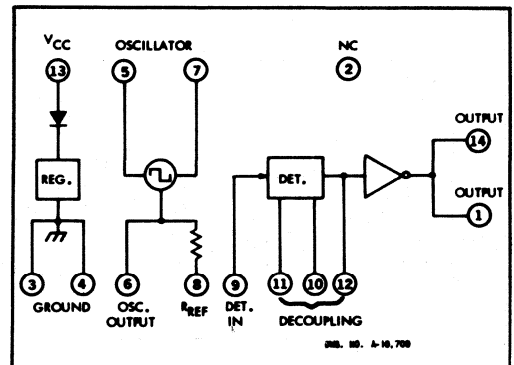

PRIMARILY DESIGNED for use as an automotive low coolant detector, the ULN-2429A monolithic bipolar integrated circuit is ideal for detecting the presence or absence of many different types of liquids in automotive, home, or industrial applications. Especially useful in harsh environments, reverse voltage protection, internal voltage regulation, temperature compensation, and high-frequency noise immunity are all incorporated in the design.

A simple probe, immersed in the fluid being monitored, is driven with an a-c signal to prevent plating problems. The presence, absence, or condition of the fluid is determined by comparing the loaded probe resistance with an internal (pin 8) or external (pin 6) resistance. Typical conductive fluids which can be sensed are tap water, sea water, weak acids and bases, wet soil, wine, beer, and coffee. Non-conductive fluids include most petroleum products, distilled water, dry soil, and vodka. The probe can be replaced with any variable-resistance element such as a photodiode or photoconductive cell, rotary or linear position sensor, or thermistor for detecting solids, non-conducting liquids, gases, etc.

The high-current output is typically a square wave signal for use with an LED, incandescent lamp, or loudspeaker. A capacitor can be connected (pin 12) to provide a d-c output for use with inductive loads such as relays and solenoids.

The ULN-2429A is rated for operation with a load voltage of up to 30 volts. Selected devices, for operation up to 50 V are available as the ULN-2429A-1. In all other respects, the ULN-2429A and the ULN-2429A-1 fluid detectors are identical.

These devices are furnished in an improved 14-lead dual in-line plastic package with a copper alloy lead frame for superior thermal characteristics. However, in order to realize the maximum current-handling capability of these devices, both of the output pins (1 and 14) and both ground pins (3 and 4) should be used.

ULN-2430M TIMER

FEATURES

- Microseconds to Minutes
- Temperature Compensated
- 400 mA Output
- 8-Pin Dual In-Line Plastic Package

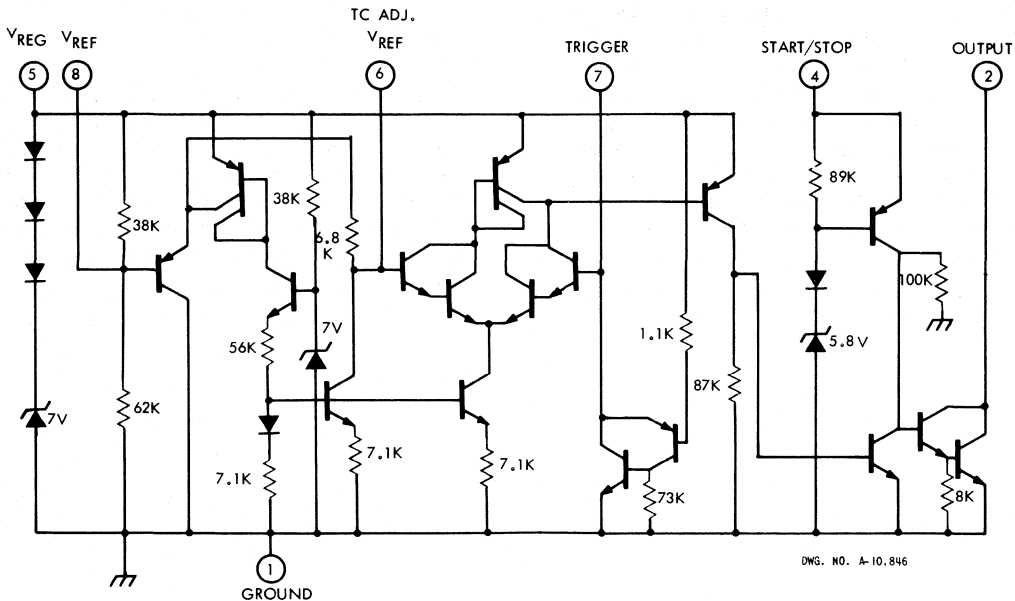

PROVIDING time delays from several micro-seconds to approximately 10 minutes, the ULN-2430M timer was originally designed for use as a rear window heater timer in automotive applications. In typical system designs, this device will meet all of the stringent automotive environmental and transient requirements, including "load dump". The rugged design, the high output current rating, and an internal voltage regulator and reference allow the ULN-2430M timer to be used in many industrial applications.

CIRCUIT OPERATION

The basic system shown in Figure 1 provides power for the timer after the momentary closure of the "rear window heater switch" S_1 . Momentary closure provides an input to pin 4 which turns ON the output driver, energizes the relay, and (through the relay contacts) provides power to the timer and the heater element. Waveforms are shown in Figure 2.

The output remains ON, supplying power to the heater until $V_7 = 62\% V_5$, which occurs at time $t = R_1 \times C_1$. The time delay can be adjusted from several microseconds to approximately 10 minutes by the choice of R_1 and C_1 . When $t = R_1 \times C_1$, the comparator changes state and the relay de-energizes, returning the circuit to the quiescent condition.

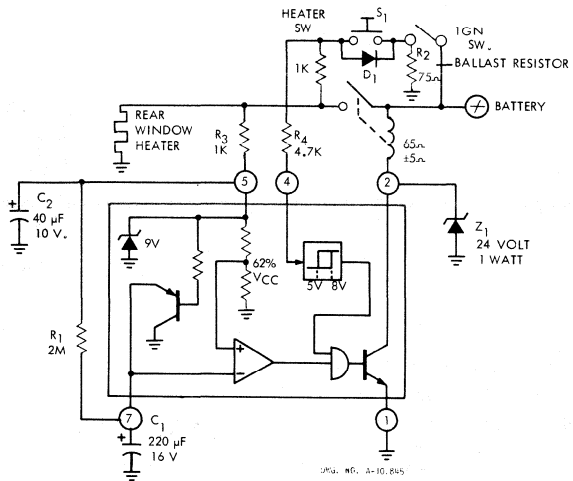

Timing accuracy is primarily a function of capacitor leakage for long time delays. Hard switching of

the comparator necessitates low input bias currents on the comparator and low capacitor leakage current. The worst case comparator input is 200 nA and the charge current at $V_7 = 62\% V_5$ is approximately $1.7 \mu\text{A}$ for $R_1 = 2 \text{ M}\Omega$. For these reasons, it is recommended that R_1 not exceed $2 \text{ M}\Omega$ and C_1 leakage be less than 500 nA.

Diode D_1 and the circuitry associated with pin 4 provide start-stop capability for the timer. When the voltage at pin 4 is larger than 8 V timing is initiated. When less than 5.5 V, timing is stopped. Transient protection against load dump and other automotive environmental hazards is provided by the integrated circuit design and discrete components Z_1 , C_2 , R_3 , R_4 , and D_1 .

ULN-3304M SCHMITT TRIGGER — ZENER CLAMPED OUTPUT

FEATURES

- 2.2 to 6V Supply Voltage Range
- Wide Operating Temperature Range
- Stable Predictable Switching Levels
- Input to Output Isolation
- 10% Hysteresis

DWG. NO. A-9425A

INTENDED for driving inductive loads, the Type ULN-3304M is a threshold detector with a Zener diode clamped output. The high gain circuitry can control a 150mA load with less than 50nA input current. This monolithic integrated circuit is often used as a low voltage relay driver in battery operated consumer electronic equipment. An important feature for these applications is that the Type ULN-3304M Schmitt trigger will sustain battery reversal indefinitely without damage.

Threshold Stability			$T_A = -40^\circ C$ to $+100^\circ C$		± 2	± 5	%

TYPICAL APPLICATIONS

1. Sine Wave To Square Wave Converter

The input is biased to within the hysteresis region. An input with a peak-to-peak voltage greater than

$V_{IN(H)} - V_{IN(L)}$ (typically 70mV) will cause the output to switch ON and OFF producing a square wave. The symmetry of the square wave can be changed by varying the ratio of the input biasing resistors.

TYPICAL APPLICATIONS (Continued)

2. Light-Actuated Switch

Light falling on the photo-sensitive resistor reduces its resistance and lowers the input bias voltage causing the output to switch ON. The sensitivity can be varied by adjusting the value of the fixed resistor. For the output to switch OFF in the presence of light, interchange the two resistors.

3. Automotive Headlight Timer

Switch S_1 controls the headlights in the normal fashion. However, if momentary switch S_2 is operated

prior to opening S_1 , the self-latching contact of the relay will apply power to the headlights for the time determined by the values of R and C . For example, if R is $3.6M\Omega$ and C is $100\mu F$, then t is 6 minutes.

ULN-3305M DUAL SCHMITT TRIGGER — COMPLEMENTARY OUTPUTS

FEATURES

- Stable Predictable Switching Levels
- Input to Output Isolation
- High Output Breakdown Voltage
- 10% Hysteresis

DESIGNED for use as an interface between high impedance networks and digital or resistive loads of up to 75mA, this monolithic dual threshold detector features complementary outputs. The Type ULN-3305M dual Schmitt trigger is especially useful in low-cost consumer battery operated equipment and will sustain battery reversal indefinitely without damage. It is capable of operation over a supply voltage range of 2.2 to 6.0 volts and a temperature range of -40°C to $+100^{\circ}\text{C}$.

Typical applications for this device include level detectors, time delay, photoelectric controls, touch operated switches, sine to square wave converters, temperature sensitive alarms, and thyristor triggering.

ULN-3330Y OPTOELECTRONIC SWITCH

FEATURES

- On-Chip Photodiode
- On-Chip Amplifier
- On-Chip Trigger
- On-Chip Power Driver
- On-Chip Regulator
- Operation to 30 kHz
- TO-92 Clear Plastic Package

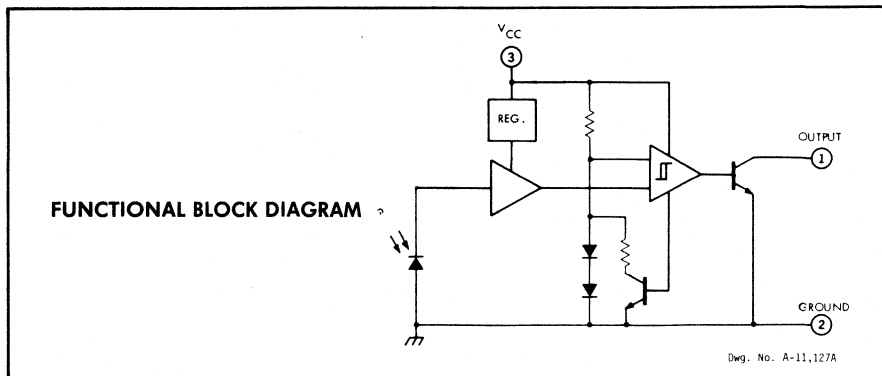

PROVIDING all of the necessary circuitry in a single 3-lead clear plastic package, Type ULN-3330Y Optoelectronic Switch is a monolithic integrated circuit containing a photodiode, low-level amplifier, level detector, output power driver, and voltage regulator. It can be used as a low-cost photo-detector in consumer or industrial applications and requires only the absolute minimum in external components for operation.

The photodiode has an enhanced blue response for improved sensitivity to visible light. The switch typically turns ON as illumination of the device falls below 5 lm/ft². An internal latch provides hysteresis so that the output will not turn OFF until the illumina-

tion increases by approximately 18%. For comparative purposes, twilight is about 1 lm/ft² while an overcast day is about 100 lm/ft². Typical loads include an incandescent lamp, LED, sensitive relay, d-c motor, TTL or CMOS (with appropriate pull-up resistor).

APPLICATIONS INFORMATION

Type ULN-3330Y characteristics are specified at a light wavelength of 555 nm. This wavelength is the peak of the human eye response for normal light levels (photopic or day-vision). At very low light

levels (scotopic or night-vision), the human eye response peaks at 507 nm.

Other light wavelengths will result in usually increased sensitivity (decreased light threshold levels) for silicon photodiode detectors. For example:

Wavelength (nm)	Typical Source	Sensitivity Threshold	
507	Scotopic Vision	0.87	1.14
555	Photopic Reference	1.00	1.00
560	Green (GaP) LED	1.01	0.99
590	Yellow (GaAsP) LED	1.03	0.97
660	Red (GaAsP) LED	1.20	0.84
700	Red (GaP) LED	1.32	0.76
800	Diode Peak Response	1.57	0.64
900	Infrared (GaAs) LED	1.19	0.84

SERIES 8126 (SG3526J, SG2526J AND SG1526J) SWITCHED-MODE POWER SUPPLY CONTROL CIRCUITS

FEATURES

- 8 V to 35 V Operation
- Dual 100 mA Source/Sink Outputs
- Internal Regulator
- Current Limiting
- Temperature-Compensated Reference Source
- Sawtooth Generator
- Low Supply-Voltage Protection
- External Synchronization
- Double-Pulse Suppression
- Programmable Dead-Time
- Programmable Soft-Start

ULQ-8126R/SG2526J
ULS-8126R/SG1526J

THESE INTEGRATED CONTROLLERS of fixed-frequency switching regulators and similar power devices can be used with transformerless or transformer-coupled supplies with single-ended or push-pull, positive or negative output.

Types ULN-8126A/R, ULQ-8126A/R, and ULS-8126R have a temperature-compensated voltage reference, a sawtooth waveform generator, an error amplifier, a pulse-width modulator, pulse metering and steering logic and two 100 mA source/sink drivers. The devices perform housekeeping functions such as soft-start, low-voltage lockout, digital current limiting and double-pulse suppression. Other features include a data latch for single pulse metering, adjustable dead time and provision for symmetry correction.

10

SERIES 8126 SWITCHED-MODE POWER SUPPLY CONTROL CIRCUITS

All digital inputs are TTL and CMOS compatible. Active-low logic allows use of wired-OR connections.

Type ULS-8126R is supplied in an 18-pin glass/ceramic hermetically sealed (cer-DIP) package. It is rated for operation over a temperature range that recommends its use in military and aerospace applications (-55°C to $+125^{\circ}\text{C}$).

Types ULQ-8126A and ULQ-8126R operate over an extended temperature range of -40°C to $+85^{\circ}\text{C}$ that meets the demands of many industrial applications.

Low-cost Types ULN-8126A and ULN-8126R are rated for continuous operation over a temperature range that recommends them for commercial use (0°C to $+70^{\circ}\text{C}$).

Control circuits with commercial and extended temperature ranges are available in both the hermetically sealed cer-DIP package (suffix "R") and a dual in-line plastic package (suffix "A") with a copper alloy lead frame that gives them enhanced power dissipation ratings.

Cer-DIP packaged parts normally are marked with original source part numbers shown below. Sprague part numbers appear on plastic packages. Sprague part numbers should be used on orders and correspondence concerning all Series 8126 devices.

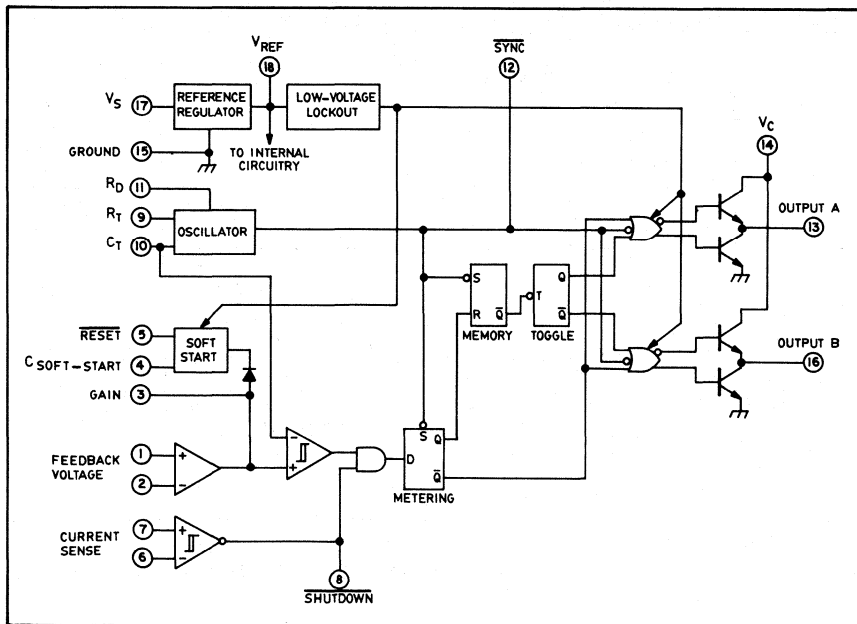

ORDERING INFORMATION

Operating Temperature Range	Package	Original Source Part Number	Sprague Part Number
Commercial 0°C to $+70^{\circ}\text{C}$	Cer-DIP	SG3526J	ULN-8126R
	Plastic	—	ULN-8126A
Extended -40°C to $+85^{\circ}\text{C}$	Cer-DIP	SG2526J	ULQ-8126R
	Plastic	—	ULQ-8126A
Full -55°C to $+125^{\circ}\text{C}$	Cer-DIP	SG1526J	ULS-8126R

RECOMMENDED OPERATING CONDITIONS

Logic Supply Voltage, V_s	8 V to 35 V
Collector Voltage, V_c	4.5 V to 35 V
Output Load Current, I_o	0 to ± 100 mA
Reference Load Current, I_L	0 to 20 mA
Oscillator Frequency, f	1 Hz to 400 kHz
Oscillator Timing Resistance, R_T	2 k Ω to 150 k Ω
Oscillator Timing Capacitance, C_T	0.001 μ F to 20 μ F
Programmed Deadtime	3% to 50%
Operating Temperature Range, T_A	See Ordering Data

ULS-8160R/SE5560F

COMPREHENSIVE CONTROL of state-of-the-art power supplies is offered by Sprague Types ULN-8160A, ULN-8160R and ULS-8160R. Each control circuit has its own temperature-compensated reference source, an internal Zener reference, a sawtooth waveform generator, a pulse-width modulator, an output driver and a variety of protection circuitry.

Type ULN-8160A is supplied in a 16-pin dual in-line plastic package with a copper lead frame that gives the device enhanced power dissipation ratings. It is rated for operation over a temperature range of 0°C to +70°C.

Types ULN-8160R and ULS-8160R are furnished in 16-pin hermetically sealed glass/ceramic packages. These devices will withstand severe environmental contamination. In addition, the extended temperature range of Type ULS-8160R (-55°C to +125°C) recommends it for use in military and aerospace applications.

These devices are normally branded with original source part numbers; however, the Sprague part number should be used on orders and in correspondence.

ULX-8161M (NE5561N) SWITCHED-MODE POWER SUPPLY CONTROL CIRCUIT

Preliminary Information

FEATURES

- Stabilized Power Supply
- Current Limiting
- Temperature-Compensated Reference Source
- Sawtooth Generator
- Pulse-Width Modulator
- Double-Pulse Protection
- Applications in
 - Switched-Mode Power Supplies
 - Motor Controller-Inverters
 - D-C/D-C Converters

Dwg. No. A-11,423

ULX-8161M/NE5561N

DESIGNED AS A CONTROLLER for low-cost switched-mode power supplies, Sprague Type ULX-8161M excels in applications requiring only limited housekeeping functions.

The integrated circuit has its own temperature-compensated reference source, an internal Zener reference, a sawtooth waveform generator, an error amplifier, pulse-width modulator, output driver, current-sensing and low-voltage protection.

Type ULX-8161M is supplied in an 8-pin dual in-line plastic package with a copper lead frame that gives it enhanced power dissipation ratings. It is rated for continuous operation over the temperature range of 0°C to +70°C. Similar devices are available for operation over extended temperature ranges. Control circuits with extensive protective functions (ULN-8160A/R and ULS-8160R) are described in Sprague Engineering Bulletin 27466.

Type ULX-8161M is normally marked with the original-source part number, NE5561N; however, the Sprague part number should be used in orders and correspondence.

The ULX prefix to the part number denotes an integrated circuit presently in development and undergoing engineering evaluation. If and when the device becomes a production item, the prefix will be changed to ULN. Sprague Electric assumes no obligation for future manufacture of any products presently in development unless such obligation is specifically undertaken in writing by authorized Sprague personnel.

SERIES TPP MEDIUM-POWER DARLINGTON ARRAYS

SPRAGUE Series TPP devices are medium-power Darlington arrays, consisting of 1, 2, 3 or 4 discrete Darlington chips in a single 14-pin package. These devices complement Sprague's Series TPQ quad transistor arrays.

All of these devices are furnished in the industry standard T0-116 (or M0-001AA) 14-lead dual in-line plastic package. The molded package is identical to that used in most consumer integrated circuits and offers superior mechanical protection during insertion into printed wiring boards.

TYPICAL RATINGS (Max.)

Power Dissipation, P_D (total package) 2 W*

SERIES TPQ QUAD TRANSISTOR ARRAYS

THE SPRAGUE Series TPQ quad transistor arrays are general-purpose silicon transistor arrays consisting of four independent transistors. Shown are eight NPN types, five PNP types, and nine NPN/PNP dual complementary pairs.

All of these devices are furnished in the industry standard TO-116 (or MO-001AA) 14-lead dual in-line plastic package. The molded package is identical to that used in most consumer integrated circuits and offers superior mechanical protection during insertion into printed wiring boards.

SERIES ULN-3300M

SCHMITT TRIGGER INTEGRATED CIRCUITS

— TYPICAL APPLICATIONS AND OPERATION

Description

Series ULN-3300M Schmitt triggers are monolithic integrated circuits intended for level detection and timing functions.

The three devices making up this series are Type ULN-3304M with a Zener-clamped output, Type ULN-3305M dual Schmitt trigger with complementary outputs, and Type ULN-3306M dual Schmitt trigger with one output Zener-clamped. These three variations of the basic precision threshold detector are shown in Figure 1.

A partial circuit schematic and functional block diagram of the Type ULN-3305M device is shown in Figure 2. Except for the output stage, all other devices in this series are identical.

The differential amplifier (Q_1-Q_6) is a comparator that "trips" when

$$\frac{V_{IN}}{V_{CC}} \geq \frac{R_2}{R_1 + R_2} \approx 0.62$$

As long as V_{IN} is less than $0.62 V_{CC}$, transistor Q_4 will conduct more than Q_3 and thus force Q_5 into saturation. It follows then that transistors Q_7 and Q_8 are cut off while Q_9 and Q_{10} are in saturation.

When V_{IN} becomes greater than $0.62 V_{CC}$, transistor Q_3 will conduct more than Q_4 and Q_5 and transistors Q_7 and Q_8 will be driven into saturation. Positive feedback by way of R_3 will latch the comparator so that it will remain "tripped" until the input drops below $0.55 V_{CC}$. This switching characteristic is illustrated in Figure 3.

TYPICAL OUTPUT VOLTAGE AS A FUNCTION OF
TEMPERATURE, SUPPLY VOLTAGE, AND OUTPUT CURRENT

Figure 5
TYPICAL POWER DISSIPATION (EACH TRIGGER)
AS A FUNCTION OF SUPPLY VOLTAGE

Operating Characteristics

These devices have several important operating characteristics.

One of the most useful of these features is the reverse voltage handling capability of the entire series. These devices will withstand reverse voltages of up to -20 V indefinitely without damage. Where exact timing is not required (± 8 ms), they can be operated directly from a low-voltage a-c supply without rectification or filtering and thus save a considerable amount in circuit cost.

The output load can be of any form: Resistive, inductive, capacitive, tungsten, LED, etc. For switching inductive loads, Type ULN-3304M or ULN-3306M triggers with their internal Zener diode clamps are recommended. Tungsten or capacitive loads can be handled by any of the devices provided the peak (one-cycle) load current is limited to about 300 mA.

Output saturation voltage is customarily specified as a function of load current. However, the Type ULN-3305M Schmitt trigger also incorporates a base-emitter voltage drop and a 500-ohm resistor as part of the non-inverting output. In this case, the output voltage can be shown as:

$$V_{CE(SAT)} \approx 0.7 + \frac{R_L V_{CC}}{500 + R_L}$$

Threshold Detection

Voltage level detection is easily accomplished with any of the Schmitt triggers in the Series ULN-3300M. Shown in Figure 6A is the basic threshold detector. Resistor R_1 or R_2 can be replaced with a transducer such as a thermistor or photocell. The circuit of Figure 6B is used when the input voltage is greater than $0.62 V_{CC}$. The circuit of Figure 6C is

$$\frac{V_{IN}}{R_2} = \frac{V_{CC}}{R_1 + R_2}$$

Figure 6A
BASIC DETECTOR

$$\frac{V_{IN(H)}}{R_1 + R_2} \geq \frac{0.62 V_{CC}}{R_2}$$

$$\frac{V_{IN(L)}}{R_1 + R_2} \leq \frac{0.55 V_{CC}}{R_2}$$

Figure 6B
HIGH V_{IN} DETECTOR

$$\frac{V_{CC} - V_{IN(H)}}{R_1 + R_2} \geq \frac{0.38 V_{CC}}{R_1}$$

$$\frac{V_{CC} - V_{IN(L)}}{R_1 + R_2} \leq \frac{0.45 V_{CC}}{R_1}$$

Figure 6C
LOW V_{IN} DETECTOR

used for input voltages less than $0.55 V_{CC}$. For the case where $R_1 = R_2$ and $V_{CC} = 10$ V, the input voltage switching points for Figure 6B are 12.4 and 11.0 volts and for Figure 6C, 2.4 and 1.0 volts.

Switching errors are caused by component tolerances (including $V_{IN(H)}$ and $V_{IN(L)}$), temperature changes (typically only ± 30 ppm/ $^{\circ}C$), and the effect of I_{IN} . Under worst case conditions this should not be more than 50 nA. If the values of R_1 and R_2 are chosen such that the current through them is at least 5 mA under $V_{IN(H)}$ conditions, the effect of I_{IN} can be ignored. Typical values for R_1 and R_2 are usually between 10 k Ω and 10 M Ω . Resistor R_L is normally between 1 k Ω and 100 k Ω .

Timing

Series ULN-3300M Schmitt triggers can be used in timing applications by connecting an RC integrator to the input as shown in Figure 7. Typical values for R are 10 k Ω to 10 m Ω ; C is between 100 pF and 10 μ F; R_L is between 1 k Ω and 100 k Ω .

Timing accuracy and maximum time delay obtainable are defined by the input characteristics of the device, component tolerances, and the leakage current of the capacitor. Assuming ideal external timing components, the minimum, typical, and maximum switching times are shown as a function of the RC time constant.

S IS OPENED AT $T = 0$

Figure 7
RC INTEGRATING TIMERS

**Figure 8
RC TIME CONSTANTS**

Astable Multivibrators

Positive feedback from the inverting output (V_{OUT}) to the RC network will form a relaxation oscillator or astable multivibrator. This connection is possible with Type ULN-3305M.

The basic astable multivibrator illustrated in Figure 9 can be used for the condition where the period t_1 is less than the period t_2 . In this configuration, the following design equations apply:

$$t_1 = 0.12 R_1 C$$

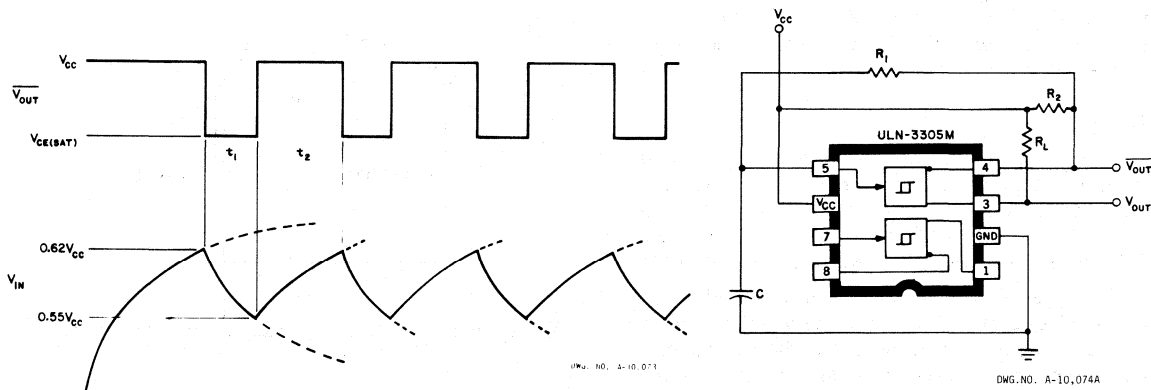

$$t_2 = 0.17 (R_1 + R_2) C$$

$$f = \frac{3.45}{(R_1 + 0.58 R_2) C}$$

From the equations several points are evident:

- A. Within limits, the supply voltage will have no effect on the frequency.
- B. The period t_2 can be adjusted, without affecting t_1 , by varying resistor R_2 .
- C. If R_1 is made very large with respect to R_2 , the effect of R_2 can be minimized or ignored.

With the typical values shown for Figure 7, frequencies of between 4 Hz and 100 kHz are possible.

**Figure 9
ASTABLE MULTIVIBRATORS**

DWG. NO. A-10,075A

Figure 10A

DWG. NO. A-10,076A

Figure 10B

If it is desired to have period t_1 equal to or greater than period t_2 , a slight circuit change is required as shown in Figures 10A and 10B. In either of these configurations the following design equations apply:

$$t_1 = 0.12 (R_1 + R_3) C$$

$$t_2 = 0.17 (R_1 + R_2) C$$

$$f = \frac{3.45}{(R_1 + 0.58 R_2 + 0.41 R_3)}$$

The output will be symmetrical ($t_1 = t_2$) when

$$R_3 = 0.42 R_1 + 1.42 R_2$$

In each of these astable multivibrators certain limitations should be noted.

A. Any d-c load connector to V_{OUT} will change the period t_1 because of the loading effect on R_2 . For this reason, the output should probably be taken from V_{OUT} .

B. The circuit of Figure 10A has a diode voltage drop in the RC timing network and is therefore not recommended for use with very low supply voltages.

C. The capacitor leakage current can be significant for large values of R_1 and, as an extreme, can cause the trigger to "latch up."

Monostable Multivibrators

The basic monostable multivibrator is shown in Figure 11. In the quiescent state, the input and the output are both "low." If a trigger is applied that raises the input to the Schmitt trigger threshold, V_{OUT} will go "high," applying V_{CC} back to the input for a period $t = 0.6 RC$ if resistor R is much greater in value than R_L . The $1 M\Omega$ resistor prevents loading of the network by the trigger.

In this circuit, the output loading of R_L is desirable, provided the device output current rating is not exceeded. The trigger input voltage should be between $0.66 V_{CC} + 0.7 V$ and V_{CC} , and the trigger pulse width must be less than the output pulse width. Output pulse widths of $10\mu s$ to 100 seconds are possible. The input pulse width should be at least 10 ns.

Where output pulse widths are shorter than the trigger pulse width, the circuit shown in Figure 12 is used. In this application, only the leading edge of the trigger pulse is used after being differentiated by one Schmitt trigger. The time constants of the differentiated leading edge then determine the output pulse width as $t_1 = 0.6 RC$.

As before, resistor R is much greater in value than R_L , the trigger input voltage must be between $0.66 V_{CC}$ and V_{CC} , the trigger pulse width must be greater than the output pulse width. In addition, to insure that the timing capacitor completely discharges, period t_2 should be at least five times period t_1 .

CUSTOM CIRCUIT DESIGNS

Sprague is active in the design of standard and custom high-volume integrated circuits and subassemblies for both linear and digital applications. A wide range of semiconductor technologies is available to optimize cost and performance. Often, new processes or innovative circuit designs are required.

The first concern of a designer of a custom device is generally one of cost, though performance, reliability, size, and process are also important considerations.

Production Volume: Unit cost is dependent on quantity. A minimum volume of \$250,000 per year is required after the initial design and development.

Chip Size: Unit cost is directly affected by chip size, which is related to circuit complexity, output-current and output-voltage ratings.

Test Requirements: Logic, d-c, and static measurements are simple, fast, and inexpensive to perform, while linear measurements such as those for distortion, phase and noise affect production rates and increase cost.

Specifications: Well-defined specifications can expedite circuit design. Excessive or arbitrarily tight specifications will reduce yields and increase cost.

Typical Custom Design Schedule

Task	Time in Weeks
Define Specifications	—
Circuit Design	2 to 10
Breadboard Construction	2 to 8
Breadboard Approval	3 to 4
Circuit Layout	2 to 8
Prototype Construction	3 to 8
Production Pilot Run	8 to 12
Production Volume	12 to 16

Total 32 to 66 weeks at an engineering cost of between \$20,000 and \$50,000, not including special test hardware or assembly tooling.

Application Areas of Sprague Expertise

TV — NTSC or PAL, video, chroma, sound, sync, I-F

Toy — sound generators and amplifiers, optolinear, timers, controls

Camera — photodiodes, light integrators, timers, controls

Transistor Arrays — small-signal, control, high-current, SCR

Integrated Component Capability

Transistors: NPN — Beta to 300, BV_{CES} to 120 V, f_T to 500 MHz
 PNP — Beta to 40, BV_{CES} to 100 V, f_T to 4 MHz
 CMOS — V_{TH} 0.8 to 2.5 V, BV_{DS} to 18 V

Resistors: Diffused — $5\Omega/\square$, to 100Ω , 100 V
 $175\Omega/\square$, to $100\text{ k}\Omega$, 100 V
 Ion Implant — $500\Omega/\square$ to $4\text{ k}\Omega/\square$, to 4 M Ω , 20 V
 Thin Film — $2\text{ k}\Omega/\square$, to 2 M Ω , 250 V
 Aluminum — $0.025\Omega/\square$, to 1.0Ω , 150 V

Capacitors: Junction — $0.1\text{ pF}/\text{mil}^2$, to 30 pF, 100 V
 $0.3\text{ pF}/\text{mil}^2$, to 100 pF, 12 V
 $0.9\text{ pF}/\text{mil}^2$, to 300 pF, 6 V
 MOS — $0.1\text{ pF}/\text{mil}^2$, to 30 pF, 50 V
 $0.2\text{ pF}/\text{mil}^2$, to 50 pF, 20 V

Diodes: Zener — 5.7 or 7.0 V, $\pm 0.3\text{ V}$
 Photo — 0.5 A/W or $> 300\text{ nA}/\text{fc}$ at 800 nm
 Schottky — 0.1 to 0.4 V at 1 μA , 0.3 to 0.6 V at 1 mA
 Small Signal — $BV = 7.0\text{ V}$
 Varactor — $C_0/C_5 \approx 2$

Other: SCRs — to 1 A, to 60 V
 PUTs — to 1 A, to 60 V
 I^2L — Propagation delay typically 100 ns
 BiMOS — High-power bipolar plus low-power MOS
 Hall Cells — 35 mV/kG

Control — Schmitt triggers, timers, Hall cells, switching regulators, motor drivers

Radio — A-M, F-M, F-M stereo, A-M stereo

Safety — GFI, smoke detectors, burglar alarms

Audio — 250 mW to 10 W, mono and stereo

Automotive — controls, monitoring, safety, radio

Interface — display drivers, Hall cells, optolinear

Military — communications, fuze, interface

SPRAGUE SEMI-CUSTOM, HIGH-VOLTAGE INTEGRATED CIRCUITS

Sprague semi-custom integrated circuits for transient-prone environments such as automobiles and industrial controls include components that can be used to protect operational circuitry from voltage surges of up to 500 V.

Fabrication of a semi-custom integrated circuit begins with the user's design for interconnecting metal that transforms uncommitted components on a finished wafer into a dedicated and original circuit. Among components available to users of Sprague semi-custom arrays are power transistors with a BV_{CES} of more than 80 V, a minimum of 53 diffused resistors and 140 thin-film polysilicon resistors, capacitors formed by buried-layer and isolation diffusions, vertical PNP transistors as well as NPN and lateral PNP transistors, and emitter-isolation Zener diodes with a nominal breakdown voltage of 5.8 V.

Power transistors in the component arrays can withstand load-disconnect transients of automobile alternators (80 V, 200 ms) without the use of Zener diode clamping circuits.

The greater part of the resistive element of the arrays is made up of dielectrically isolated thin-film resistors that, with their high resistive values and their ability to withstand transients as high as 500 V,

can be used to limit peak transient currents.

Because these polysilicon resistors are not polarity sensitive (no PN junction is formed by the thin-film manufacturing process), they are inherently protected from damage by voltage-supply reversal. The high values of resistance available with these components are particularly useful in applications requiring low levels of power dissipation and standby current.

The arrays also have capacitive elements with typical values of 80 pF for use in applications requiring supply stabilization or noise suppression.

Vertical PNP transistors, with current-gain typically two or three times greater than the h_{FE} of lateral PNPs, complement the arrays' standard set of NPN and PNP transistors. Vertical PNPs can be used in a current-mirror (Figures 1 and 2) to reduce error introduced by base currents from 20% to less than 1%. The devices can also be used in a differential amplifier configuration (Figure 3) to decrease base-current requirements.

More complete information on development of these semi-custom, high-voltage integrated circuits is presented in Sprague Technical Paper TP 81-3.

PRELIMINARY INFORMATION

(Specifications Subject to Change Without Notice)

FEATURES

- $BV_{CES} = 80 \text{ V Min.}$
- 250 mA Outputs
- 500 Volt Resistors
- High-Gain PNP Transistors
- 80 pF Capacitors
- Time and Cost Savings

TUFF CHIP SEMI-CUSTOM integrated circuits offer substantial time and cost savings for custom circuit applications requiring from 5,000 to 200,000 pieces. This is an area that previously was met by hybrid circuits and, in some cases, by printed wiring boards.

The **TUFF CHIP** semi-custom approach utilizes a standard array of components fabricated on a single silicon chip: the ULN-2350C contains 480 separate elements; the ULN-2351C provides 276. Besides the traditional complement of NPN and lateral PNP transistors, high-gain vertical PNP transistors are included.

The user lays out the interconnecting circuit, similar to a printed wiring board layout, on sheets provided by Sprague Electric. The artwork is checked by Sprague engineers, and used to generate the customer's proprietary metal mask. Finished circuits are electrically probed and visually inspected. Chips are tray-packed for hybrid circuit manufacturers or are mounted in plastic, ceramic, or hermetic dual in-line packages with from 8 to 28 pins.

TUFF CHIP components are optimized for a minimum BV_{CES} of 80 volts. Two or four 250 mA power transistors are provided, and these may be paralleled for high current requirements. On-chip transient protection of sensitive circuit

89 × 104 mils

Optional Package Capabilities

Standard integrated circuits from Sprague Electric Company are most often furnished in packages meeting industry or military standards (JEDEC TO-87, TO-91, TO-99, TO-100, or TO-116, or MIL-M-38510). However, on special order, other packages or assemblies of packaged devices can also be supplied. A few special order devices are illustrated above, including special heat sink tabs, subminiature plastic packages, printed wiring boards, flexible circuits, and complex assemblies. Devices with photodiodes are furnished in clear plastic cases.

THERMAL DESIGN FOR PLASTIC INTEGRATED CIRCUITS

PROPER THERMAL DESIGN is essential for reliable operation of many electronic circuits. Under severe thermal stress, leakage currents increase, materials decompose, and components drift in value or fail. Present-day linear integrated circuits are capable of delivering 5 to 10 watts of continuous power. Previously, such power levels came only with discrete metal can power transistors. It was relatively easy to determine the thermal resistance of these devices and attach a massive heat sink. However, in many markets, economic factors now dictate the use of molded dual in-line plastic packaged monolithic circuits. The guidelines to be discussed will provide the circuit design engineer with information on maintaining junction temperature below a safe limit under worst case conditions.

Design Considerations

Four factors must be considered before the required heat-sinking can be determined. These are:

1. Maximum ambient temperature
2. Maximum allowable chip temperature
3. Junction-to-ambient thermal resistance
4. Continuous chip power dissipation

Maximum ambient temperature for the integrated circuit is normally between $+70^{\circ}\text{C}$ and $+85^{\circ}\text{C}$ and is usually dependent on the case material. In most applications, however, the limiting factor is the associated discrete components and a limit of about

$+50^{\circ}\text{C}$ is specified. The maximum allowable chip temperature is usually $+150^{\circ}\text{C}$ for silicon.

Thermal resistance is the all-important design factor. It is composed of several individual elements, some of which are determined by the integrated circuits manufacturer, and some by the user.

Chip Power Dissipation

The chip power dissipation should be obtainable from the manufacturer's specifications. In most applications it is a variable and determined by the user when he specifies the circuit variables.

A typical example is the Sprague Type ULN-2277 dual 2-watt audio power amplifier. Power dissipation is determined by the load impedance, the required peak output power, the acceptable amount of total harmonic distortion (THD), and the supply voltage (V_{CC}). This is illustrated in Figures 1-3. Note that for a given supply voltage, the chip dissipation may be greatest at some point below the peak output power rating and must be considered.

As shown in the figures, a peak output power of 2 watts per channel with 3% maximum THD would mean a chip power dissipation of about 2.7 W and a V_{CC} of 15 V with a load impedance of 4Ω , or 1.8 W and 15 V at 8Ω , or 1.4 W and 19 V at 16Ω . In general, the highest load impedance for a given output power is the most desirable (within the output voltage capability of the device).

Heat Dissipation

In any circuit involving power, a major design objective is to reduce the temperature of the components in order to improve reliability, reduce cost, or improve operation. The logical place to start is with the heat-producing component itself. First, keep the amount of heat generated to a minimum. Second, get rid of the heat that must be generated.

Heat generation can be minimized through proper circuit design. Heat dissipation is a function of thermal resistance.

With the typical discrete component, heat dissipation can be accomplished by fastening it directly to the chassis. Dual in-line plastic packaged integrated circuits, however, are quite a bit different. Their shape is not conducive to fastening directly to the chassis, they are normally installed in a plastic socket or on a printed wiring board, and the heat producing chip is not readily accessible.

Some users specify unusual packages so as to get the heat sink as close as possible to the chip and/or provide an attachment point for an external heat sink. A common factor in many of these special designs is that the lead frame is an integral part of the heat sink.

Since the plastic package may have a thermal resistance of between 50 and 100°C/W and the lead frame a thermal resistance of only 10 to 20°C/W, this would seem like the best route to go.

Standard Packages

The most common lead frame material has been Kovar (an iron-nickel-cobalt alloy). Its coefficient of expansion is close to that of silicon thereby minimizing mechanical stresses. However, Kovar has a relatively high thermal resistance and consequently is not suitable for standard lead frames in high power dissipation circuits. For these applications, copper or copper-alloy lead frames should be used. Additionally, some type of added heat sinking may be necessary. Thus lead frame configurations are

being altered from the standard 14-pin or 16-pin designs.

Rapidly becoming an industry standard is the "bat-wing" package. This package is the same size as a 14-pin dual in-line package, but the center portion of the frame is left as tabs, measuring about 1/4" square. These tabs can be soldered, welded, or bolted to a heat sink, or inserted directly into some sockets. The worst case thermal resistance of various lead frames (Θ_{JC}) is given below.

Lead Frame	Thermal Resistance
14-pin Kovar	47°C/W
14-pin copper	19°C/W
"Bat-wing"	11°C/W

Which Heat Sink?

If the integrated circuit manufacturer has done his job well, the chip-to-ambient thermal resistance will be minimized for maximum chip power dissipation. It would appear that even the Kovar lead frame would be adequate for most applications. However, the total thermal resistance (Θ_{JA}) is also dependent on a stagnant layer of air at the lead frame-ambient interface which will support a temperature gradient. The total thermal resistance of a non-heat sinked dual in-line plastic package is therefore much higher. Since air is a natural thermal insulator, maximum heat transfer is through convection and the total thermal resistance will decrease some at high power levels.

Lead Frame	Total Thermal Resistance	Max. Power Diss. (W) at 50°C T _A , 150°C T _J
14-Pin Kovar	120°C/W	0.83
14-Pin Copper	72°C/W	1.39
"Bat-Wing"	50°C/W	2.0

Ignoring any safety margin and device performance, even the "bat-wing" is now only barely adequate for most applications. The obvious solution is the use of an external heat sink.

PACKAGE INFORMATION (Continued)

Referring to Figures 4 and 5, the thermal resistance requirement of the heat sink is found at the junction of the specified chip power dissipation and maximum ambient temperature. These curves are typical of those furnished in many monolithic integrated circuit data sheets. Actual performance in a specific situation depends on factors such as the proximity of objects interfering with air flow, heat radiated or convected from other components, atmospheric pressure, and humidity. A good safety factor is therefore in order.

Figure 4

Dwg No. A-11.432

Figure 5

Dwg No. A-11.433

Heat sinks for plastic dual in-line packages can be of almost unlimited variety in design, material, and finish. Economics will normally play a very important role in the selection of any heat sink.

The least expensive and easiest to fabricate heat sink is the plain copper sheet. It is also very effective in reducing the total thermal resistance. The necessary dimensions can be obtained from Figure 6. These heat sinks are square in geometry, 0.015 inches thick, mounted vertically on each side of the lead frame, and with a dull or painted surface (Figure 7). The heat sinks should be soldered directly to the lead frame (approximately 0.3°C/W interface thermal resistance).

The plain copper sheet heat sink is also available commercially and may be less expensive than in-house manufacture. Two standard types are the Staver V7 and V8.

Dwg No. A-11.434

Figure 6

Dwg No. A-11.435

Figure 7

Heat Sink Finishes

Although plain copper is an effective heat sink, it is sometimes desirable to have something that is more appealing to the eye. For this reason, and others, many heat sinks are either painted or anodized.

The most common finish is probably black anodizing. It is economical and offers a good appearance. The black finish will also increase the performance of the heat sink, due to radiation, by as much as 25%. However, since anodizing is an electrical and thermal insulator, the heat sink should have an area free of anodize where the heat-generating device is attached.

Other popular finishes for heat sinks are irridite and chromic acid dips. They are economical and have negligible thermal and electrical resistances. These finishes, however, do not enjoy the 25% increase in performance that a dull black finish has.

Forced Air Cooling

The performance of many heat sinks can be increased by as much as 100% by forcing air over the fins. Where space is a problem, the cost of a small fan can often be justified. If a fan is required for other purposes, it is advantageous to place the semiconductor heat source in the air flow. A rule-of-thumb is that semiconductor failure rate is halved for each 10°C reduction in junction operating temperature.

Chip Design

Proper thermal design by the integrated circuit user can reduce the operating temperature of the semiconductor junction. However, the minimum chip temperature at any power level is determined solely by the device manufacturer. For this reason, care must be taken in choosing the manufacturer. "Exact equivalent" integrated circuits are not necessarily identical. Electrically and mechanically they may be the same, but thermal differences can mean that "identical" audio power amplifiers will not put out the same power without exceeding the rated junction temperature.

The circuit manufacturer must optimize his chip design so that component drift is minimized and/or equalized so that rated performance can actually be obtained under maximum thermal stress.

Note in Figures 8 and 9 that the Darlington input differential pairs are cross-connected so as to minimize differences in gain as a function of output transistor power dissipation. Transistor Q₄, being closest to the output power transistors is naturally the hottest; Q₃ is a degree or two cooler; Q₁ and Q₂ are about equal and midway between Q₃ and Q₄. The gain of the Q₁-Q₂ Darlington pair is about equal to the gain of Q₃-Q₄ at all output power levels because of careful thermal design.

Figure 8

Figure 9

In certain specialized applications, thermal coupling can be used to a distinct advantage. Experimentally, thermal coupling has been used to provide a low-pass feedback network which otherwise could be obtained only with very large values of capacitance.

APPENDIX

The following is intended to review terminology and compare thermal circuits with the more familiar electrical quantities.

The first law of thermodynamics states that energy cannot be created or destroyed but can be converted from one form to another. The second law of thermodynamics states that energy transfer will occur only in the direction of lower energy. In the semiconductor junction, the electrical energy is converted to thermal energy. Since no heat will be stored at the junction, the heat will flow to a lower temperature medium, air. The rate of heat flow is dependent on the resistance to that flow and the temperature difference between the source and the sink.

Figure 10

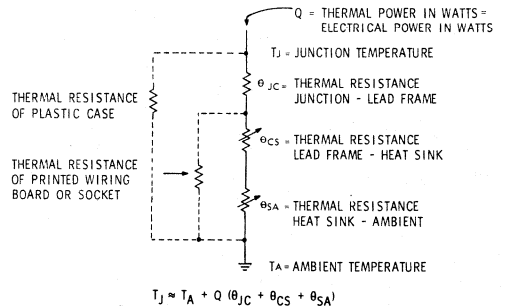

Dwg No. A-11.437

This thermal electrical analogy is convenient only for conduction problems where heat flow and temperature obey linear equations. The analogy becomes much more complex for situations involving heat flow by convection and radiation. Where these two modes are not negligible, they can be approximated by an equivalent thermal resistance. If ignored, the error introduced will only improve the device reliability.

A simplified thermal flow diagram of a molded dual in-line package and heat sink is shown. The

The foregoing discussion has covered the average thermal characteristics of today's dual in-line plastic integrated circuits. The specific devices will vary with the different packages and bonding techniques employed, but the concepts will remain the same.

thermal resistance of the lead frame-heat sink-ambient is shown as a variable resistor, because this is under the control of the user and may be varied over a considerable range.

Computing IC Temperature Rise

Heat is the enemy of integrated circuits—particularly power devices. Here's how to use thermal ratings to determine safe IC operation.

Reprinted by permission from the June 9, 1977 issue of MACHINE DESIGN, Copyright © 1977 by Penton/IPC Inc., Cleveland, Ohio.

EXCESSIVE heat shortens the life of an IC and reduces its operating capability. Until recently, ICs were capable of operating only in low-power applications requiring perhaps a few milliwatts of power. But now, new ICs handle several hundred milliamperes and drive devices such as relays, solenoids, stepping motors, and incandescent lamps. These high power levels may increase IC temperatures substantially and are capable of destroying devices unless appropriate precautions are taken.

Thermal Characteristics

The thermal characteristics of any IC are determined by four parameters. Maximum allowable IC chip junction temperature T_J and thermal resistance R_θ are specified by the IC manufacturer. Ambient temperature T_A and the power dissipation P_D are determined by the user. Equation 1 expresses the rela-

Why IC Temperatures Rise

IC temperature T_J is determined by ambient temperature T_A , heat dissipated P_D , and total thermal resistance R_θ . This total thermal resistance is comprised of three individual component resistances: chip R_c , lead frame R_l , and heat sink R_s .

tion of these parameters.

$$T_J = T_A + P_D R_\theta \quad (1)$$

Junction temperature T_J usually is limited to 150°C for silicon ICs. Devices may operate momentarily at slightly higher temperatures, but device life expectancy decreases exponentially for extended high-temperature operation. Usually, the lower the junction operating temperature, the greater the anticipated life of the IC.

Ambient temperature T_A is

traditionally limited either to 70°C or 85°C for plastic dual in-line packages (DIPs) or 125°C for hermetic devices. Again, the objective is to operate at as low a junction temperature as practical.

Thermal resistance R_θ is the basic thermal characteristic for ICs. It is usually expressed in terms of °C/W and represents the rise in junction temperature with a unit of power applied in still air. (The reciprocal of thermal resistance is thermal conductance, or derating factor,

What the Curves Show

The junction temperature of an IC depends on several factors, including the thermal resistance of the IC and the operating duty cycle. Graphs showing the relationship of these factors are often useful in specifying an IC.

Typical thermal-resistance ratings for ICs in still air range from 60°C/W to 140°C/W . The slope of each curve on this graph is equal to the derating factor $G\theta$, which is the reciprocal of thermal resistance $R\theta$. For an ambient temperature of 50°C , a typical 14-lead flatpack with an $R\theta$ of 140°C/W can dissipate about 0.7 W. A typical DIP, however, with 14 copper-alloy leads can dissipate almost 1.7 W at 50°C .

The highest allowable package power dissipation shown here is 2.5 W. Other special-purpose DIP packages are available with power dissipation ratings as high as 3.3 W at 0°C ($R\theta = 45^{\circ}\text{C/W}$). If not for package limitations, IC chip dissipation might be greater than 9 W at an ambient temperature of up to 70°C .

Although the curve for plastic DIPs goes all the way to 150°C , they ordinarily are not used in ambients above 85°C because of traditional package limitations. Hermetic DIPs are specified to temperatures of 125°C , and at 150°C the device should be derated to 0 W. The higher specification limits for hermetic devices is the result of their design for use in rigorous, high-reliability military applications.

Duty cycle is important in calculating IC junction temperature because average power—not instantaneous power—is responsible for heating the IC. To convert from peak power to average power, multiply the peak power dissipation by the duty cycle. The average-power rating is then used with the thermal-resistance rating to calculate the IC junction temperature. Thus, short duty cycles allow peak power to be high without exceeding the 150°C junction-temperature limit. However, this consideration applies only to ON times of less than 0.5 sec.

$G\theta$ expressed as $\text{W}/^{\circ}\text{C}$.) Thermal resistance of an IC consists of several distinct components, the sum of which is the specified thermal resistance. For a typical IC, these components of thermal resistance are 0.5°C/W per unit thickness of the silicon chip, 0.1 to 3°C/W per unit length of the lead frame, and up to $2,000^{\circ}\text{C/W}$ per unit thickness of still air surrounding the IC. DIPs are used more than any

other type of packaging for ICs and newer copper-alloy lead frames provide a superior thermal rating over the standard iron-nickel-cobalt alloy (Kovar) lead frames. However, power ICs are also available in other packages such as flatpacks and TO-type cans.

The power P_p that an IC can safely dissipate usually depends on the size of the IC chip and the type of packaging. Most

common copper-frame DIPs can dissipate about 1.5 W, although some special-purpose types have ratings as high as 5 W.

Power Dissipation

Total IC power to be dissipated depends on input current, output current, voltage drop, and duty cycle. Thus, for many industrial digital-control ICs, logic-gate power P_l (typically less than 0.1 W) and output

power P_o must be determined to find the total power to be dissipated. Total power dissipation for these logic devices is the sum of P_I and P_o .

$$P_I = n(V_{CC}I_{CC}) \quad (2)$$

$$P_o = n(V_{CE(SAT)}I_C) \quad (3)$$

where V_{CC} = logic-gate supply voltage, I_{CC} = logic-gate ON current, $V_{CE(SAT)}$ = output saturation voltage, I_C = output load current, and n = number of logic gates. Manufacturers usually list typical and maximum values for these voltages and currents. For thermal considerations it is best to use the maximum values so that worst-case power dissipation is determined.

If the duty cycle of the device is longer than 0.5 sec, the peak power dissipation is the sum of the logic-gate power P_I and output power P_o for the logic ON state alone. If the ON time is less than 0.5 sec, however, average power dissipation must be calculated from instantaneous ON and OFF power P_{ON} and

Finding Safe Operating Limits

Here's how to calculate the safe operating limits for an IC. The first two examples are simple calculations involving maximum allowable power and are straightforward. The third and fourth examples are more complex and involve logic power, output power, and duty cycle.

Problem: Determine the maximum allowable power dissipation that can be handled safely by a 16-lead Kovar DIP with an R_{θ} of 125°C/W in an ambient temperature of 70°C.

Solution: From Equation 1, the maximum allowable power dissipation P_D for this IC is

$$P_D = \frac{150^\circ\text{C} - 70^\circ\text{C}}{125^\circ\text{C/W}} = 0.64 \text{ W}$$

Problem: Determine the maximum allowable power dissipation that can be handled by a 14-lead copper DIP

with a derating factor G_{θ} of 16.67 mW/°C in an ambient of 70°C.

Solution: Since the derating factor G_{θ} is the reciprocal of thermal resistance R_{θ} , the maximum allowable power dissipation P_D from Equation 1 is

$$P_D = (150^\circ\text{C} - 70^\circ\text{C}) \times (16.67 \text{ mW/}^\circ\text{C}) = 1.33 \text{ W}$$

Problem: Calculate the maximum junction temperature for a quad power driver with a thermal resistance of 60°C/W in an ambient of 70°C and which is controlling a 250 mA load on each of the four outputs.

Solution: To determine the maximum (worst case) junction temperature for this IC, the maximum total power dissipation must be determined from the data listed on the IC data sheet. The specifications are usually listed as typical and minimum or maximum values. It is important to use maximum voltage and current limits to insure an adequate design. Common maximum values for an

P_{OFF} from

$$P_D = DP_{ON} + (1 - D)P_{OFF} \quad (4)$$

Corrective Actions

If the junction temperature or the required power dissipation

of the IC is calculated to be greater than the maximum values specified by the manufacturer, device reliability and operating characteristics possi-

Measuring IC Temperature

Sometimes IC junction temperature cannot be calculated readily and instead must be measured. Measurement should be made when there is insufficient data with which to calculate, when the effects of external variables such as forced-air cooling or enclosure size must be determined, or as a check on the manufacturer's specifications regarding package thermal resistance.

The most popular technique for measuring IC temperature uses the characteristic of a diode to reduce its forward voltage with temperature. Many IC chips have some sort of accessible diode—parasitic, input protection, base-emitter junction, or output clamp. With this technique, a "sense" diode is calibrated so that forward voltage is a direct indicator of diode junction temperature. Then, current is applied to some other component on the chip to simulate operating conditions and to produce a temperature rise. Since the thermal resistance of the silicon chip is low, the temperature of the sense diode is assumed to be the same as the rest of the monolithic chip.

The sense diode should be calibrated over at least the expected junction operating temperature chamber. Apply an accurately measured, low current of about 1 mA through the

sense diode and measure the forward voltage in 25°C increments after stabilization at each temperature. This calibration provides enough data for at least six points to construct a diode-forward-voltage versus junction-temperature graph at the specified forward current. A typical 25°C forward voltage is between 600 and 750 mV and decreases 1.6 to 2.0 mV/°C.

For power levels above 2 W, it may be necessary to use more than a single transistor if only the device saturation voltage and sink current are used. When higher power is desired, keep the output out of saturation.

Measuring the sense-diode forward voltage may require a considerable waiting period (10 to 15 minutes) for thermal equilibrium. In any event, at the instant of measurement, the heating power may have to be disconnected since erroneous readings may result from IR drop in circuit common leads. Various circuit connections (such as four-point Kelvin) may be arranged to reduce or eliminate this source of error.

The IC junction temperature can be determined by comparing the voltage measurement with the internal power source against the voltage measurement with the temperature chamber.

Industrial power driver are $V_{CC} = 5.25$ V, $I_{CC} = 25$ mA, and $V_{CE(SAT)} = 0.7$ V, and $I_o = 250$ mA. From Equations 2 and 3, worst case logic and output power dissipation are

$$P_l = 4(5.25 \text{ V} \times 25 \text{ mA}) = 525 \text{ mW}$$

$$P_o = 4(0.7 \text{ V} \times 250 \text{ mA}) = 700 \text{ mW}$$

Thus, the total worst case power dissipation P_D is 525 mW plus 700 mW, or 1.225 W. From Equation 1, maximum junction temperature T_j is

$$T_j = 70^\circ\text{C} + (1.225 \text{ W}) \left(\frac{16.67 \text{ mW}/^\circ\text{C}}{1} \right) = 143.5^\circ\text{C}$$

Problem: Determine the acceptable duty cycle for a hermetic power driver with a thermal resistance of 100°C/W in an ambient of 85°C and which is controlling load currents of 250 mA on each of four outputs.

Solution: From Equation 1, the allowable average power dissipation

P_D for this IC is

$$P_D = \frac{150^\circ\text{C} - 85^\circ\text{C}}{100^\circ\text{C}/\text{W}} = 0.65 \text{ W}$$

This means that there is 0.65 W limit on average power, but, not instantaneous power. If the duty cycle is low enough, and the ON time is not more than about 0.5 sec, the average power dissipation can be considerably lower than the peak power. The ON, or peak power, is determined from the data sheet maximum values of V_{CC} , I_{CC} , and $V_{CE(SAT)}$ at the specified load current of 250 mA. From Equations 2 and 3, logic-gate power P_l and output power P_o for the ON state are

$$P_l = 4(5.5 \text{ V} \times 26.5 \text{ mA}) = 583 \text{ mW}$$

$$P_o = 4(0.7 \text{ V} \times 250 \text{ mA}) = 700 \text{ mW}$$

Instantaneous ON power P_{ON} is the sum of P_l and P_o for the ON state, or 1.283 W. The OFF power is primarily the

power dissipated by the logic in the OFF state, and is found by using the I_{CC} maximum rated current listed on the specification sheet. The power dissipated in the output stage can be calculated from the leakage current I_C and supply voltage V_{CC} . From Equations 2 and 3, logic-gate power P_l and output power P_o for the OFF state are

$$P_l = 4(5.5 \text{ V} \times 7.5 \text{ mA}) = 165 \text{ mW}$$

$$P_o = 4(100 \text{ V} \times 0.1 \text{ mA}) = 40 \text{ mW}$$

Instantaneous OFF power P_{OFF} is the sum of P_l and P_o for the OFF state, or 205 mW. From Equation 4, acceptable duty cycle D is

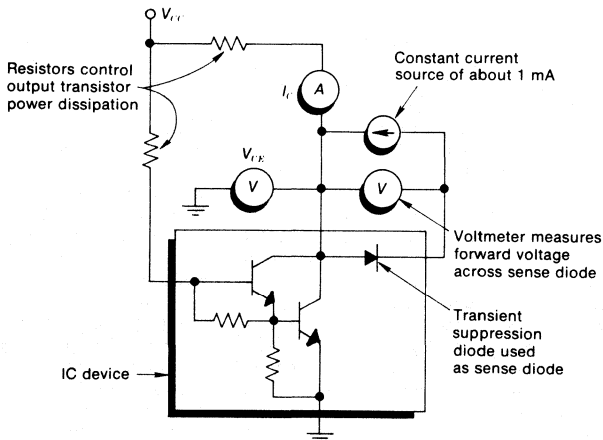

$$D = \frac{P_D - P_{OFF}}{P_{ON} - P_{OFF}} = \frac{0.65 \text{ W} - 0.205 \text{ W}}{1.283 \text{ W} - 0.205 \text{ W}} = 41.9\%$$

ably will be reduced. Possible solutions are: 1. Modify or partition the circuit design so the IC is not required to dissipate as much power. 2. Reduce the

thermal resistance of the IC by using a heat sink or forced-air cooling. 3. Reduce the ambient temperature by moving heat-producing components such as

transformers and resistor away from the IC. 4. Specify different IC with improved thermal or electrical characteristics (if available).

Setting Up the Circuit

Input power is negligible compared to output power and is therefore not measured.

Calibrating the Sense Diode

Operating and Handling Practices for MOS Integrated Circuits

Handling Practices - Packaged Devices

Sprague Electric incorporates input protection diodes in all of its MOS/CMOS devices. Because of the very high input resistance in MOS devices, the following practices should be observed for protection against high static electrical charges:

1. Device leads should be in contact with a conductive material except when being tested or in actual operation.
2. Conductive parts of tools, fixtures, soldering irons and handling equipment should be grounded.
3. Devices should not be inserted into or removed from test stations unless the power is off.
4. Neither should signals be applied to the inputs while the device power supply is in an off condition.
5. Unused input leads should be committed to either V_{SS} or V_{DD} .

Handling Practices - Die

A conductive carrier should be used in order to avoid differences in voltage potential.

Automatic Handling Equipment

Grounding alone may not be sufficient and feed mechanisms should be insulated from the devices under test at the point where the devices are connected to the test equipment. Ionized air blowers can be of aide here and are available commercially. This method is very effective in eliminating static electricity problems.

Ambient Conditions

Dry weather with accompanying low humidity tends to intensify the accumulation of static charges on any surface. In this atmosphere, proper handling procedures take on added importance. If necessary, steam injectors can be procured commercially.

Alert Failure Modes

The common failure modes that appear when static energy exists and when proper handling practices are not used are:

1. Shorted input protection diodes.
2. Shorted or 'blown' open gates.
3. Open metal runs.

Simple diagnostic checks with curve tracers or similar equipment readily identifies the above failure modes.
