TELEFUNKEN Semiconductors

## Phase Control Circuit - Tacho Applications

## Description:

The integrated circuit U209B3, is designed as a phase control circuit in bipolar technology. It has also protection circuit for the supply. Due to integration of many functions, it leads to significant cost and space saving as
well as increased reliability. At the same time, it gives the designer free hand to select varieties of regulators to choose from and switching characteristics according to its choice.

## Features

- Internal frequency to voltage converter
- Externally controlled integrated amplifier
- Automatic soft start with minimised "dead time"
- Voltage and current synchronisation
- Retriggering
- Triggering pulse typ. 155 mA
- Internal supply voltage monitoring
- Temperature compensated reference source
- Current requirement $\leq 3 \mathrm{~mA}$

Package: DIP14, SO16

Figure 1. Block diagram - SO 16 in bracket

Figure 2. Block diagram with typical circuitry for speed regulation

## Description

## Mains Supply

The U209B is designed with voltage limiting and can therefore be supplied directly from the mains. The supply voltage between Pin $2(+\mathrm{pol} / \perp)$ and Pin 3 builds up across $D_{1}$ and $R_{1}$ and is smoothed by $C_{1}$. The value of the series resistance can be approximated using (Figure 2):

$$
\mathrm{R}_{1}=\frac{\mathrm{V}_{\mathrm{M}}-\mathrm{Vs}}{2 \mathrm{I}_{\mathrm{S}}}
$$

Further information regarding the design of the mains supply can be found in the data sheets in the appendix. The reference voltage source on Pin 13 of typ. -8.9 V is derived from the supply voltage and represents the reference level of the control unit.

Operation using an externally stabilised DC voltage is not recommended.

If the supply cannot be taken directly from the mains because the power dissipation in $\mathrm{R}_{1}$ would be too large, then the circuit shown in the following Figure 3 should be employed.

Figure 3. Supply voltage for high current requirements

## Phase Control

The function of the phase control is largely identical to that of the well known integrated circuit U211B. The phase angle of the trigger pulse is derived by comparing the ramp voltage, which is mains synchronised by the voltage detector, with the set value on the control input Pin 4. The slope of the ramp is determined by $\mathrm{C}_{2}$ and its charging current. The charging current can be varied using $\mathrm{R}_{2}$ on Pin 5. The maximum phase angle $\alpha_{\max }$ can also be adjusted using $\mathrm{R}_{2}$.

When the potential on Pin 6 reaches the nominal value predetermined at Pin 11, then a trigger pulse is generated whose width $t_{p}$ is determined by the value of $C_{2}$ (the value of $\mathrm{C}_{2}$ and hence the pulse width can be evaluated by assuming $8 \mu \mathrm{~s} / \mathrm{nF}$.
The current sensor on Pin 1 ensures that, for operation with inductive loads, no pulse will be generated in a new half cycle as long as current from the previous half cycle is still flowing in the opposite direction to the supply voltage at that instant. This makes sure that "Gaps" in the load current are prevented.
The control signal on Pin 11 can be in the range 0 V to -7 V (reference point Pin 2).
If $\mathrm{V}_{11}=-7 \mathrm{~V}$ then the phase angle is at maximum $=\alpha_{\text {max }}$ i. e. the current flow angle is a minimum. The minimum phase angle $\alpha_{\text {min }}$ is when $V_{11}=V_{\text {pin2 }}$.

## Voltage Monitoring

As the voltage is built up, uncontrolled output pulses are avoided by internal voltage surveillance. At the same time, all of the latches in the circuit (phase control, soft start) are reset and the soft-start capacitor is short circuited. Used with a switching hysteresis of 300 mV , this system guarantees defined start-up behaviour each time the supply voltage is switched on or after short interruptions of the mains supply.

## Soft-Start

As soon as the supply voltage builds up ( $\mathrm{t}_{1}$ ), the integrated soft-start is initiated. The figure below shows the behaviour of the voltage across the soft-start capacitor and is identical with the voltage on the phase control input on Pin 11. This behaviour guarantees a gentle start-up for the motor and automatically ensures the optimum run-up time.
$\mathrm{C}_{3}$ is first charged up to the starting voltage $\mathrm{V}_{\mathrm{o}}$ with typically $30 \mu \mathrm{~A}$ current ( $\mathrm{t}_{2}$ ). By then reducing the charging current to approx. $4 \mu \mathrm{~A}$, the slope of the charging function is substantially reduced so that the rotational speed of the motor only slowly increases. The charging current then increases as the voltage across $\mathrm{C}_{3}$ increases giving a progressively rising charging function which more and more strongly accelerates the motor with increasing rotational speed. The charging function determines the acceleration up to the set-point. The charging current can have a maximum value of $50 \mu \mathrm{~A}$.

Figure 4. Soft-start

## Frequency to Voltage Converter

The internal frequency to voltage converter (f/V-converter) generates a DC signal on Pin 9 which is proportional to the rotational speed using an AC signal from a tacho-generator or a light beam whose frequency is in turn dependent on the rotational speed. The high impedance input with a switch-on threshold of typ. 100 mV gives very reliable operation even when relatively simple tacho-generators are employed. The tacho-frequency is given by:

$$
\mathrm{f}=\frac{\mathrm{n}}{60} \mathrm{p}[\mathrm{~Hz}]
$$

$\mathrm{n}=$ revolutions per minute
$p=$ number of pulses per revolution
The converter is based on the charge pumping principle. With each negative half wave of the input signal, a quantity of charge determined by $\mathrm{C}_{5}$ is internally amplified and then integrated by $\mathrm{C}_{6}$ at the converter output on Pin 9. The conversion constant is determined by $\mathrm{C}_{5}$, its charging voltage of $\mathrm{V}_{\mathrm{ch}}, \mathrm{R}_{6}$ (Pin 9) and the internally adjusted charge amplification $\mathrm{G}_{\mathrm{i}}$.
$\mathrm{k}=\mathrm{G}_{\mathrm{i}} \cdot \mathrm{C}_{5} \cdot \mathrm{R}_{6} \cdot \mathrm{~V}_{\mathrm{ch}}$
The analog output voltage is given by

$$
\begin{array}{lll} 
& \mathrm{V}_{\mathrm{o}} & =\mathrm{k} \cdot \mathrm{f} . \\
\text { whereas: } & \mathrm{V}_{\mathrm{ch}} & =6.7 \mathrm{~V} \\
& \mathrm{G}_{\mathrm{i}} & =8.3
\end{array}
$$

The values of $\mathrm{C}_{5}$ and $\mathrm{C}_{6}$ must be such that for the highest possible input frequency, the maximum output voltage does $\mathrm{V}_{0}$ does not exceed 6 V . While $\mathrm{C}_{5}$ is charging up the $R_{i}$ on Pin 8 is approx. $6 \mathrm{k} \Omega$. To obtain good linearity of the $f / V$ converter the time constant resulting from $R_{i}$ and $C_{5}$ should be considerably less $(1 / 5)$ than the time span of the negative half cycle for the highest possible input frequency. The amount of remaining ripple on the output voltage on Pin 9 is dependent on $\mathrm{C}_{5}, \mathrm{C}_{6}$ and the internal charge amplification.

$$
\Delta \mathrm{V}_{\mathrm{o}}=\frac{\mathrm{G}_{\mathrm{i}} \cdot \mathrm{~V}_{\mathrm{ch}} \cdot \mathrm{C}_{5}}{\mathrm{C}_{6}}
$$

The ripple $\Delta \mathrm{V}_{\mathrm{o}}$ can be reduced by using larger values of $\mathrm{C}_{6}$, however, the maximum conversion speed will than also be reduced.

The value of this capacitor should be chosen to fit the particular control loop where it is going to be used.

## Control Amplifier

The integrated control amplifier with differential input compares the set value (Pin 10) with the instantaneous value on Pin 9 and generates a regulating voltage on the output Pin 11 (together with external circuitry on Pin 12) which always tries to hold the real voltage at the value of the set voltages. The amplifier has a transmittance of typically $110 \mu \mathrm{~A} / \mathrm{V}$ and a bipolar current source output on Pin 11 which operates with typically $\pm 100 \mu \mathrm{~A}$. The amplification and frequency response are determined by $\mathrm{R}_{7}, \mathrm{C}_{7}, \mathrm{C}_{8}$ and $\mathrm{R}_{8}$ (can be left out). For operation as a power divider, $\mathrm{C}_{4}, \mathrm{C}_{5}, \mathrm{R}_{6}, \mathrm{C}_{6}, \mathrm{R}_{7}, \mathrm{C}_{7}, \mathrm{C}_{8}$ and $\mathrm{R}_{8}$ can be left out. Pin 9 should be connected with Pin 11 and Pin 7 with Pin 2. The phase angle of the triggering pulse can be adjusted using the voltage on Pin 10. An internal limiting circuit prevents the voltage on Pin 11 from becoming more negative than $\mathrm{V}_{\mathbf{1 3}}+1 \mathrm{~V}$.

## Pulse Output Stage

The pulse output stage is short circuit protected and can typically deliver currents of 125 mA . For the design of smaller triggering currents, the function $I_{G T}=f\left(R_{G T}\right)$ has been given in the data sheets in the appendix.

## Automatic Retriggering

The automatic retriggering prevents half cycles without current flow, even if the triacs is turned off earlier e.g. due to not exactly centred collector (brush lifter) or in the event of unsuccessful triggering. If it is necessary, another triggering pulse is generated after a time lapse of $t_{P P}=4.5 t_{\mathrm{P}}$ and this is repeated until either the triac fires or the half cycle finishes.

## General Hints and Explanation of Terms

To ensure safe and trouble-free operation, the following points should be taken into consideration when circuits are being constructed or in the design of printed circuit boards.

- The connecting lines from $\mathrm{C}_{2}$ to Pin 6 and Pin 2 should be as short as possible, and the connection to Pin 2 should not carry any additional high current such as the load current. When selecting $\mathrm{C}_{2}$, a low temperature coefficient is desirable.
- The common (earth) connections of the set-point generator, the tacho-generator and the final interference suppression capacitor $C_{4}$ of the $f / V$ converter should not carry load current.
- The tacho generator should be mounted without influence by strong stray fields from the motor.

## Ozone Depleting Substances Policy Statement

It is the policy of TEMIC TELEFUNKEN microelectronic GmbH to

1. Meet all present and future national and international statutory requirements.
2. Regularly and continuously improve the performance of our products, processes, distribution and operating systems with respect to their impact on the health and safety of our employees and the public, as well as their impact on the environment.

It is particular concern to control or eliminate releases of those substances into the atmosphere which are known as ozone depleting substances (ODSs).

The Montreal Protocol (1987) and its London Amendments (1990) intend to severely restrict the use of ODSs and forbid their use within the next ten years. Various national and international initiatives are pressing for an earlier ban on these substances.

TEMIC TELEFUNKEN microelectronic GmbH semiconductor division has been able to use its policy of continuous improvements to eliminate the use of ODSs listed in the following documents.

1. Annex A, B and list of transitional substances of the Montreal Protocol and the London Amendments respectively
2. Class I and II ozone depleting substances in the Clean Air Act Amendments of 1990 by the Environmental Protection Agency (EPA) in the USA
3. Council Decision 88/540/EEC and 91/690/EEC Annex A, B and C (transitional substances) respectively.

TEMIC can certify that our semiconductors are not manufactured with ozone depleting substances and do not contain such substances.

We reserve the right to make changes to improve technical design and may do so without further notice. Parameters can vary in different applications. All operating parameters must be validated for each customer application by the customer. Should the buyer use TEMIC products for any unintended or unauthorized application, the buyer shall indemnify TEMIC against all claims, costs, damages, and expenses, arising out of, directly or indirectly, any claim of personal damage, injury or death associated with such unintended or unauthorized use.
