THE OPTOELECTRONICS DATA BOOK

Few people in the electronics industry realize that optoelectronics technology has a history that precedes the invention of the integrated circuit. It is also a relatively unknown fact that Texas Instruments was a pioneer in the development and manufacture of some of the first optoelectronic components, viz infrared detectors and photovoltaic solar cells, back in 1957.

During the past 26 years TI has continued to develop and build optoelectronic devices and assemblies for end application in the space, military, computer, industrial, and consumer industries. TI opto devices have helped to revolutionize the industry and to make it easier for the design engineer to accomplish his job.

In addition, TI offers the broadest line of opto products in the industry. This ensures that design engineers can obtain more answers to questions involving circuitry and operating conditions by contacting TI.

To complete the service aspect, TI has a worldwide distributor network that stocks almost 225 standard opto devices and assemblies. This means that customers can obtain fast delivery on small quantities required for initial circuit evaluation and purchasing departments can be assured of a local source of supply for production quantities.

It is the purpose of this data book to better acquaint our customers with TI opto products and capabilities. It offers the user a categorized listing of optoelectronic data sheets, application reports, and other information for more than 250 standard devices including 116 new types not included in the fifth edition of this data book. Each product section has a quick reference guide that lists the key electrical parameters and features for products in that section. The table of contents and alphanumeric index identify the new devices in this data book in bold type. A handy replacement guide for obsolete devices is also included.

To further assist the user, there is an interchangeability guide that lists more than 600 optoelectronics devices built by other manufacturers, along with the nearest TI equivalent devices. There is also a glossary of optoelectronic terminology to answer questions on optoelectronic terms and phrases.

This data book's new format will make the designer's job easier to use optoelectronics devices in his new and existing products or applications.

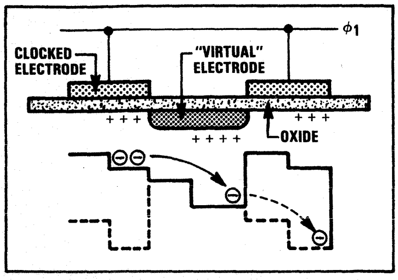

Fig. 1 TI's Patented Virtual Phase Design

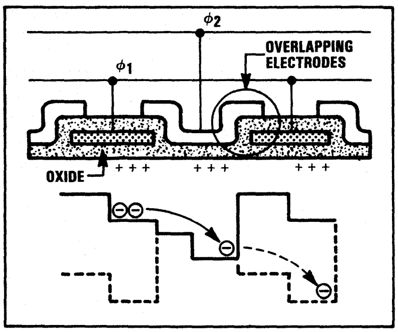

Fig. 2 Standard 2 Phase Design

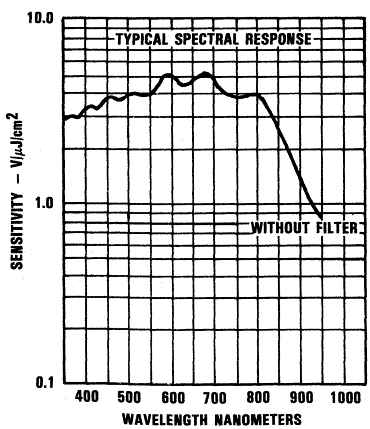

Fig. 3. Typical Sensitivity vs Wavelength

The CCD (Charge Coupled Device) approach to linear image sensing will become the leading edge among industry methods because of process and performance advantages.

Multiple-clock-electrode CCD processing methods have remained complex and difficult to implement in the manufacturing environment with any measure of cost/performance effectiveness ... until now.

The breakthrough: Now, Texas Instruments announces a breakthrough in CCD image sensor processing technology ... Virtual Phase (VP).

This giant technological stride greatly simplifies the processing techniques by **reducing the number of clock electrodes on the device surface to one** (Fig. 1). Other techniques require anywhere from two to three levels (Fig. 2). Additional benefits of this milestone process include simplified device operation and enhanced device quality.

Now, with just one level, the possibility of surface damage and shorts, common to the multilevel approach, is inherently reduced. So, the new Virtual Phase technology can boast the same degree of reliability as standard MOS technology.

The benefits of this TI-patented Virtual Phase technology are:

- Simplified clocking
- Lower noise/Higher dynamic range
- Greater sensitivity to light
- Ease of processing and use
- Greater stability
- Lower dark current
- Improved spectral response in the lower wave length (blue) regions (Fig. 3).

Features:

- Virtual Phase N-Channel silicon MOS technology
- High spectral responsivity ... particularly in the blue region
- Approximately 1-V peak-to-peak output signal
- Dynamic range typically 1000:1
- End-of-scan signal
- Internal dark and white references
- Blemish-free uniformity of image
- Simple, stable operation

description

The TC101, a 1728-element CCD line image sensor, functions in high-resolution image scanning applications such as facsimile and optical character recognition. The 1728 sensor elements provide a 200-points-per-inch resolution across 8.5 inches. The TC101 incorporates virtual-phase MOS technology, which provides simplified operation and high reliability.

This device is supplied in a 24-pin dual-in-line ceramic side-braze package designed for insertion in mounting-hole rows on 15.2-mm (0.600-inch) centers. The glass window may be cleaned by wiping with a cotton swab soaked in alcohol.

Caution. These devices have limited built-in gate protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates. Avoid shorting either OS or EOS to V_{SS} during operation to prevent damage to the output amplifiers.

virtual phase technology

This patented design results in simplified clocking circuits, reduced noise, and greater light sensitivity. The virtual phase utilizes a junction-gate region at the substrate dc potential. This accomplishes the same gating and transport function as a separate gate electrode requiring multiple layers and multiple process steps common in other device designs. The resulting simplicity of process and ease of operation will increase performance and reliability for the user.

functional description

image sensor elements

The line of sensor elements (also called photosites or pixels) consists of 1728 photo-sensitive areas, 12.7 micrometers (0.5 milliinches) square and approximately 12.7 micrometers from center to center. Image photons create electron-hole pairs in the single-crystal silicon. The electrons are collected in the sensor elements and the holes are swept into the substrate. The amount of charge accumulated in each element is a linear function of the incident light and the exposure time. The output signal charge will vary in an analog manner from a thermally generated noise background at zero illumination to a maximum at saturation under bright illumination.

transfer gate

This structure is adjacent to the line of image sensor elements. The charge packets accumulated in the image sensor elements are transferred into the transfer gate storage well when the transfer gate voltage goes high. When the transfer gate voltage goes low, the charge is transferred into the CCD transport shift registers. The transfer gate also controls the exposure time for the sensor elements and permits charges to enter the end-of-scan (EOS) shift registers to create the end-of-scan waveform. In addition, the transfer gate permits entry of charge packets to the transport CCD shift register to create the white reference signals.

shift registers

There are two CCD transport registers, one on each side of the line of image sensor elements and outside of the transfer gate. Alternate charge packets are transferred to the CCD transport shift registers and moved serially to the output amplifier. The phase relationship of the reset clock and the transport clock and the geometric layout of the paths provide for alternate delivery of charge packets to re-establish the original sequence of the linear image data. The two outer buffer CCD shift registers protect the signal charges in the inner transport CCD shift registers from peripherally generated dark current noise.

black and white reference elements

Four additional sensor elements at each end of the sensor element array (labelled "B" in the block diagram) are covered by opaque metallization. They provide a black (no illumination) signal reference that is delivered at each end of the linear image output signal. Also included on the transport CCD shift register, at the opposite end from the amplifier, is an input diode that provides two white reference pulses in the output signal. The reference pulses are useful as inputs to external dc restoration and/or automatic exposure control circuitry. The white reference pulse amplitude is approximately 70% of the maximum output signal amplitude.

output signal amplifier

The charge packets are transported to a precharge diode whose potential changes linearly in response to the amount of the signal charge delivered. This potential is applied to the input gate of an N-channel MOS double-source-follower amplifier to produce an output signal (OS). A reset transistor, driven by the reset clock (RCK), recharges the charge-detector-diode capacitance before the arrival of each new signal charge packet from the CCD shift registers. A reference voltage (V_{REF}) is applied to the drain of the reset transistor and acts to bias the OS and EOS amplifiers. A current sink is used as an on-chip load for the amplifier output. No external current sink is needed. The output signal is a series of negative-going pulses on a dc level.

resolution

The modulation transfer function decreases at longer wavelengths. (See Figures 7 and 8.) If optimum resolution is required with a light source that has a significant infrared component, then the designer must use appropriate filters to restrict the optical pass band to shorter wavelengths.

end-of-scan amplifier

The EOS amplifier is similar to the OS amplifier. XCK transfers charge from the input diode into the EOS register where it is transported at the TCK clock frequency to the EOS amplifier. This EOS pulse is coincident with the first of the two white reference pulses that pass through the odd and even transport CCDs, respectively. The EOS output can be used to alert the external circuitry that the linear image data readout has been completed.

clocks

The transfer clock (XCK) pulse controls the exposure time of the sensor elements. The minimum exposure time is the time required to shift the entire contents of the transport registers to the output signal amplifier and equals 1761 multiplied by the RCK period. The maximum exposure time is determined by the tolerable level of dark signal.

The transport clock (TCK) transports the linear image signal charge from the sensor element region to the output amplifier.

The reset clock (RCK) operates at twice the transport clock frequency so as to recombine the signal charge in the original sequence and present the charge to the output amplifier. The data rate is equal to the reset clock frequency.

The white reference clock (WRCK) runs at the transfer clock frequency and generates the white reference and the end-of-scan pulses. These pulses can be eliminated by connecting WRCK to V_{DD}. Transients on WRCK going below zero volts will cause charge injection resulting in an increase in apparent dark signal.

Figure 3 presents a suggested circuit for generating the clock waveforms. The RCK clock generator runs continuously. A binary divider halves the frequency to create TCK. After all signal charges have been transported to the output amplifier, TCK continues to run to keep thermally generated charges from accumulating in the transport registers.

The XCK and WRCK clock frequencies are submultiples of the TCK frequency. Figure 2 details the timing relationships among the different clock pulses.

functional description

image sensor elements

The line of sensor elements (also called photosites or pixels) consists of 128 photo-sensitive areas, 12.7 micrometers (0.5 milliinches) square and approximately 12.7 micrometers from center to center. Image photons create electron-hole pairs in the single-crystal silicon. The electrons are collected in the sensor elements and the holes are swept into the substrate. The amount of charge accumulated in each element is a linear function of the incident light and the exposure time. The output signal charge will vary in an analog manner from a thermally generated noise background at zero illumination to a maximum at saturation under bright illumination.

transfer gate

This structure is adjacent to the line of image sensor elements. The charge packets accumulated in the image sensor elements are transferred into the transfer gate storage well when the transfer gate voltage goes high. When the transfer gate voltage goes low, the charge is transferred into the CCD transport shift registers. The transfer gate also controls the exposure time for the sensor elements and permits charges to enter the end-of-scan (EOS) shift registers to create the end-of-scan waveform. In addition, the transfer gate permits entry of charge packets to the transport CCD shift register to create the white reference signals.

shift registers

There are two CCD transport registers, one on each side of the line of image sensor elements and outside of the transfer gate. Alternate charge packets are transferred to the CCD transport shift registers and moved serially to the output amplifier. The phase relationship of the reset clock and the transport clock and the geometric layout of the paths provide for alternate delivery of charge packets to re-establish the original sequence of the linear image data. The two outer buffer CCD shift registers protect the signal charges in the inner transport CCD shift registers from peripherally generated dark current noise.

black and white reference elements

Four additional sensor elements at each end of the sensor element array (labelled ''B'' in the block diagram) are covered by opaque metallization. They provide a black (no illumination) signal reference that is delivered at each end of the linear image output signal. Also included on the transport CCD shift register, at the opposite end from the amplifier, is an input diode that provides two white reference pulses in the output signal. The reference pulses are useful as inputs to external dc restoration and/or automatic exposure control circuitry. The white reference pulse amplitude is approximately 70% of the maximum output signal amplitude.

output signal amplifier

The charge packets are transported to a precharge diode whose potential changes linearly in response to the amount of the signal charge delivered. This potential is applied to the input gate of an N-channel MOS double-source-follower amplifier to produce an output signal (OS). A reset transistor, driven by the reset clock (RCK), recharges the charge-detector-diode capacitance before the arrival of each new signal charge packet from the CCD shift registers. A reference voltage (V_{REF}) is applied to the drain of the reset transistor and acts to bias the OS and EOS amplifiers. A current sink is used as an on-chip load for the amplifier output. No external current sink is needed. The output signal is a series of negative-going pulses on a dc level.

resolution

The modulation transfer function decreases at longer wavelengths (see Figures 7 and 8). If optimum resolution is required with a light source that has a significant infrared component, then the designer must use appropriate filters to restrict the optical pass band to shorter wavelengths.

end-of-scan amplifier

The EOS amplifier is similar to the OS amplifier. XCK transfers charge from the input diode into the EOS register where it is transported at the TCK clock frequency to the EOS amplifier. This EOS pulse is coincident with the first of the two white reference pulses that pass through the odd and even transport CCDs, respectively. The EOS output can be used to alert the external circuitry that the linear image data readout has been completed.

clocks

The transfer clock (XCK) pulse controls the exposure time of the sensor elements. The minimum exposure time is the time required to shift the entire contents of the transport registers to the output signal amplifier and equals 161 multiplied by the RCK period. The maximum exposure time is determined by the tolerable level of dark signal.

The transport clock (TCK) transports the linear image signal charge from the sensor element region to the output amplifier.

The reset clock (RCK) operates at twice the transport clock frequency so as to recombine the signal charge in the original sequence and present the charge to the output amplifier. The data rate is equal to the reset clock frequency.

The white reference clock (WRCK) runs at the transfer clock frequency and generates the white reference and the end-of-scan pulses. These pulses can be eliminated by connecting WRCK to V_{DD}. Transients on WRCK going below zero volts will cause charge injection resulting in an increase in apparent dark signal.

Figure 3 presents a suggested circuit for generating the clock waveforms. The RCK clock generator runs continuously. A binary divider halves the frequency to create TCK. After all signal charges have been transported to the output amplifier, TCK continues to run to keep thermally generated charges from accumulating in the transport registers.

The XCK and WRCK clock frequencies are submultiples of the TCK frequency. Figure 2 details the timing relationships among the different clock pulses.

NC — No internal connection

description

The TC103, a 2048-element CCD line image sensor, functions in high-resolution image scanning applications such as facsimile and optical character recognition. The TC103 incorporates virtual-phase MOS technology, which provides simplified operation and high reliability. The 2048 sensor elements provide 8 points-per-millimeter resolution across 256 millimeters.

This device is supplied in a 24-pin dual-in-line ceramic side-braze package designed for insertion in mounting-hole rows on 15,2-mm (0,600-inch) centers. The glass window may be cleaned by wiping with a cotton swab soaked in alcohol.

Caution. These devices have limited built-in gate protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates. Avoid shorting either OS or EOS to V_{SS} during operation to prevent damage to the amplifiers.

virtual phase technology

This patented design results in simplified clocking circuits, reduced noise, and greater light sensitivity. The virtual phase utilizes a junction-gate region at the substrate dc potential. This accomplishes the same gating and transport function as a separate gate electrode requiring multiple layers and multiple process steps common in other device designs. The resulting simplicity of process and ease of operation will increase performance and reliability for the user.

functional description

image sensor elements

The line of sensor elements (also called photosites or pixels) consists of 2048 photo-sensitive areas, 12,7 micrometers (0.5 milliinches) square and approximately 12,7 micrometers from center to center. Image photons create electron/hole pairs in the single-crystal silicon. The electrons are collected in the sensor elements, and the holes are swept into the substrate. The amount of charge accumulated in each element is a linear function of the incident light and the exposure time. The output signal charge will vary in an analog manner from a thermally generated noise background at zero illumination to a maximum at saturation under bright illumination.

transfer gate

This structure is adjacent to the line of image sensor elements. The charge packets accumulated in the image sensor elements are transferred into the transfer gate storage well when the transfer gate voltage goes high. When the transfer gate voltage goes low, the charge is transferred into the CCD transport shift registers. The transfer gate also controls the exposure time for the sensor elements and permits charges to enter the end-of-scan (EOS) shift registers to create the end-of-scan waveform. In addition, the transfer gate permits entry of charge packets to the transport CCD shift register to create the white reference signals.

shift registers

There are two CCD transport registers, one on each side of the line of image sensor elements and outside of the transfer gate. Alternate charge packets are transferred to the CCD transport shift registers and moved serially to the output amplifier. The phase relationship of the reset clock and the transport clock and the geometric layout of the paths provide for alternate delivery of charge packets to re-establish the original sequence of the linear image data. The two outer buffer CCD shift registers protect the signal charges in the inner transport CCD shift registers from peripherally generated dark current noise.

black and white reference elements

Four additional sensor elements at each end of the sensor element array (labelled "B" in the block diagram) are covered by opaque metallization. They provide a black (no illumination) signal reference that is delivered at each end of the linear image output signal. Also included on the transport CCD shift register, at the opposite end from the amplifier, is an input diode that provides two white reference pulses in the output signal. The reference pulses are useful as inputs to external dc restoration and/or automatic exposure control circuitry. The white reference pulse amplitude is approximately 70% of the maximum output signal amplitude.

output signal amplifier

The charge packets are transported to a precharge diode whose potential changes linearly in response to the amount of the signal charge delivered. This potential is applied to the input gate of an N-channel MOS double-source-follower amplifier to produce an output signal (OS). A reset transistor, driven by the reset clock (RCK), recharges the charge-detector-diode capacitance before the arrival of each new signal charge packet from the CCD shift registers. Reference voltage (V_{REF}) is applied to the drain of the reset transistor and acts to bias the OS and EOS amplifiers. A current sink is used as an on-chip load for the amplifier output, so no external current sink is needed. The output signal on pin 2 is a series of negative-going pulses on a dc level.

internal reference voltage

An internal reference voltage (INT REF) is available on the chip to provide the V_{REF} voltage. The required connections appear in Figure 3. If the internal reference voltage is not used, an external voltage is connected directly to pin 1. Pin 5 is then left unconnected.

resolution

The modulation transfer function decreases at longer wavelengths. (See Figures 7 and 8.) If optimum resolution is required with a light source that has a significant infrared component, then the designer must use appropriate filters to restrict the optical pass band to shorter wavelengths.

end-of-scan amplifier

The EOS amplifier is similar to the OS amplifier. XCK transfers charge from the input diode into the EOS register where it is transported at the TCK clock frequency to the EOS amplifier. This EOS pulse is coincident with the first of the two white reference pulses that pass through the odd and even transport CCDs, respectively. The EOS output can be used to alert the external circuitry that the linear image data readout has been completed.

clocks

The transfer clock (XCK) pulse controls the exposure time of the sensor elements. The minimum exposure time is the time required to shift the entire contents of the transport registers to the output signal amplifier and equals 2081 multiplied by the RCK period. The maximum exposure time is determined by the tolerable level of dark signal.

The transport clock (TCK) transports the linear image signal charge from the sensor element region to the output amplifier.

The reset clock (RCK) operates at twice the transport clock frequency so as to recombine the signal charge in the original sequence and present the charge to the output amplifier. The data rate is equal to the reset clock frequency.

The white reference clock (WRCK) runs at the transfer clock frequency and generates the white reference and the end-of-scan pulses. These pulses can be eliminated by connecting WRCK to V_{DD}. Transients on WRCK going below zero volts will cause charge injection resulting in an increase in apparent dark signal.

Figure 3 presents a suggested circuit for generating the clock waveforms. The RCK clock generator runs continuously. A binary divider halves the frequency to create TCK. After all signal charges have been transported to the output amplifier, TCK continues to run to keep thermally generated charges from accumulating in the transport registers.

The XCK and WRCK clock frequencies are submultiples of the TCK frequency. Figure 2 details the timing relationships among the different clock pulses.

functional description

image sensor elements

The line of sensor elements (also called photosites or pixels) consists of 3456 photo-sensitive areas, 10,7 micrometers (0.42 milliinches) square and approximately 10,7 micrometers from center to center. Image photons create electron/hole pairs in the single-crystal silicon. The electrons are collected in the sensor elements, and the holes are swept into the substrate. The amount of charge accumulated in each element is a linear function of the incident light and the exposure time. The output signal charge will vary in an analog manner from a thermally generated noise background at zero illumination to a maximum at saturation under bright illumination.

transfer gate

This structure is adjacent to the line of image sensor elements. The charge packets accumulated in the image sensor elements are transferred into the transfer gate storage well when the transfer gate voltage goes high. When the transfer gate voltage goes low, the charge is transferred into the CCD transport shift registers. The transfer gate also controls the exposure time for the sensor elements and permits charges to enter the end-of-scan (EOS) shift registers to create the end-of-scan waveform. In addition, the transfer gate permits entry of charge packets to the transport CCD shift register to create the white reference signals.

shift registers

There are two CCD transport registers, one on each side of the line of image sensor elements and outside of the transfer gate. Alternate charge packets are transferred to the CCD transport shift registers and moved serially to the output amplifier. The phase relationship of the reset clock and the transport clock and the geometric layout of the paths provide for alternate delivery of charge packets to re-establish the original sequence of the linear image data. The two outer buffer CCD shift registers protect the signal charges in the inner transport CCD shift registers from peripherally generated dark current noise.

black and white reference elements

Four additional sensor elements at each end of the sensor element array (labelled "B" in the block diagram) are covered by opaque metallization. They provide a black (no illumination) signal reference that is delivered at each end of the linear image output signal. Also included on the transport CCD shift register, at the opposite end from the amplifier, is an input diode that provides two white reference pulses in the output signal. The reference pulses are useful as inputs to external dc restoration and/or automatic exposure control circuitry. The white reference pulse amplitude is approximately 100% of the maximum output signal amplitude.

output signal amplifier

The charge packets are transported to a precharge diode whose potential changes linearly in response to the amount of the signal charge delivered. This potential is applied to the input gate of an N-channel MOS double-source-follower amplifier to produce an output signal (OS). A reset transistor, driven by the reset clock (RCK), recharges the charge-detector-diode capacitance before the arrival of each new signal charge packet from the CCD shift registers. Reference voltage (V_{REF}) is applied to the drain of the reset transistor and acts to bias the OS and EOS amplifiers. A current sink is used as an on-chip load for the amplifier output, so no external current sink is needed. The output signal on pin 2 is a series of negative-going pulses on a dc level.

internal reference voltage

An internal reference voltage (INT REF) is available on the chip to provide the V_{REF} voltage. The required connections appear in Figure 3. If the internal reference voltage is not used, an external voltage is connected directly to pin 1. Pin 5 is then left unconnected.

resolution

The modulation transfer function decreases at longer wavelengths. (See Figures 7 and 8.) If optimum resolution is required with a light source that has a significant infrared component, then the designer must use appropriate filters to restrict the optical pass band to shorter wavelengths.

end-of-scan amplifier

The EOS amplifier is similar to the OS amplifier. XCK transfers charge from the input diode into the EOS register where it is transported at the TCK clock frequency to the EOS amplifier. This EOS pulse is coincident with the first of the two white reference pulses that pass through the odd and even transport CCDs, respectively. The EOS output can be used to alert the external circuitry that the linear image data readout has been completed.

clocks

The transfer clock (XCK) pulse controls the exposure time of the sensor elements. The minimum exposure time is the time required to shift the entire contents of the transport registers to the output signal amplifier and equals 3489 multiplied by the RCK period. The maximum exposure time is determined by the tolerable level of dark signal.

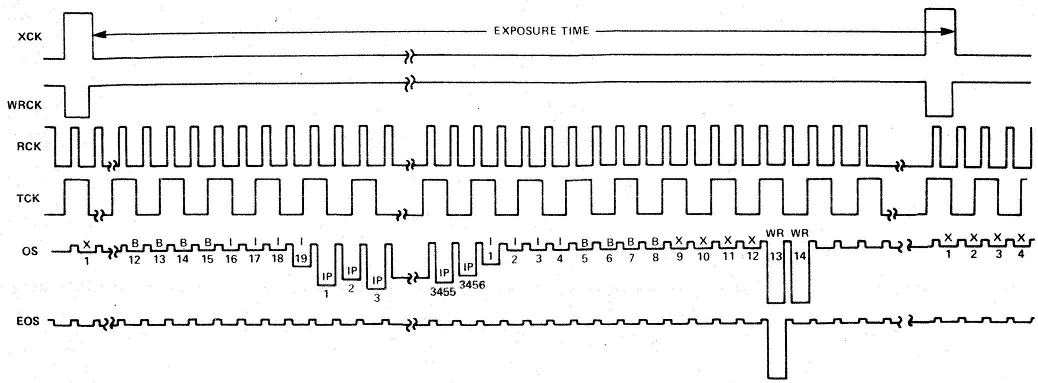
The transport clock (TCK) transports the linear image signal charge from the sensor element region to the output amplifier.

The reset clock (RCK) operates at twice the transport clock frequency so as to recombine the signal charge in the original sequence and present the charge to the output amplifier. The data rate is equal to the reset clock frequency.

The white reference clock (WRCK) runs at the transfer clock frequency and generates the white reference and the end-of-scan pulses. These pulses can be eliminated by connecting WRCK to V_{DD}. Transients on WRCK going below zero volts will cause charge injection resulting in an increase in apparent dark signal.

Figure 3 presents a suggested circuit for generating the clock waveforms. The RCK clock generator runs continuously. A binary divider halves the frequency to create TCK. After all signal charges have been transported to the output amplifier, TCK continues to run to keep thermally generated charges from accumulating in the transport registers.

The XCK and WRCK clock frequencies are submultiples of the TCK frequency. Figure 2 details the timing relationships among the different clock pulses.



Output Signal (OS) pulse identification: I = Isolation pixel, IP = Image pixel, B = Black reference pixel, WR = White reference pixel, X = empty pixel.

description

This 328- X 490-Pixel area sensor is designed to operate in the frame-store mode as a 328H X 245V imager for 525-line US TV applications. The device can also be used in the full-frame mode for long-integration, single-frame applications. Charge packets are transported to a precharged diode whose potential changes in response to the quantity of the signal charge delivered. This potential is applied to an on-chip floating diffusion amplifier to produce a signal voltage at the video output pin. A reset transistor is used to recharge the charge-detector-diode capacitance before the arrival of each new signal charge packet from the serial transport register. The imager is fabricated using virtual phase MOS, technology, which provides greater reliability at lower cost than the conventional 2-phase MOS technologies.

This device is supplied in a 20-pin dual-in-line ceramic side-braze package designed for insertion in mounting-hole rows on 20,3-mm (0.800-inch) centers. The pins in each row are located on 2,54-mm (0.100-inch) centers. Optical quality glass lids cover the image area.

Availability of this device is
scheduled for 3rd quarter 1983

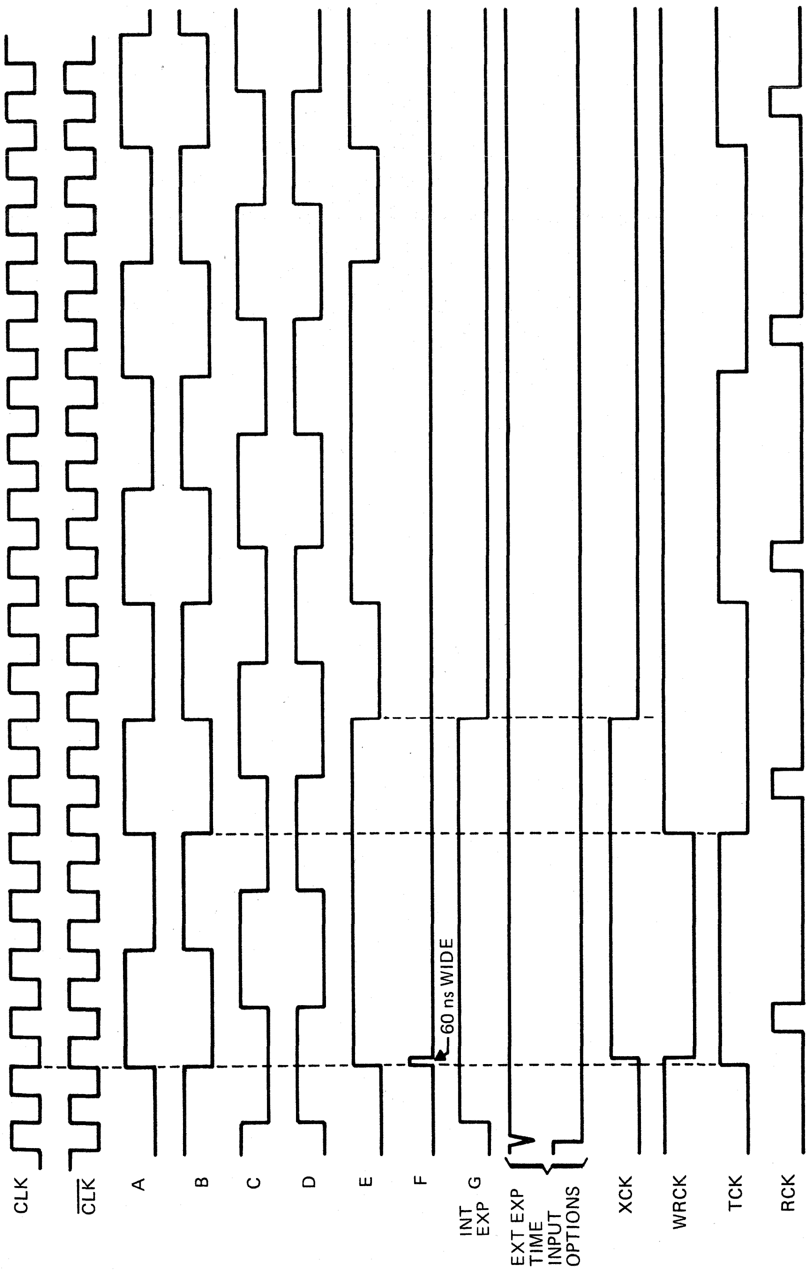
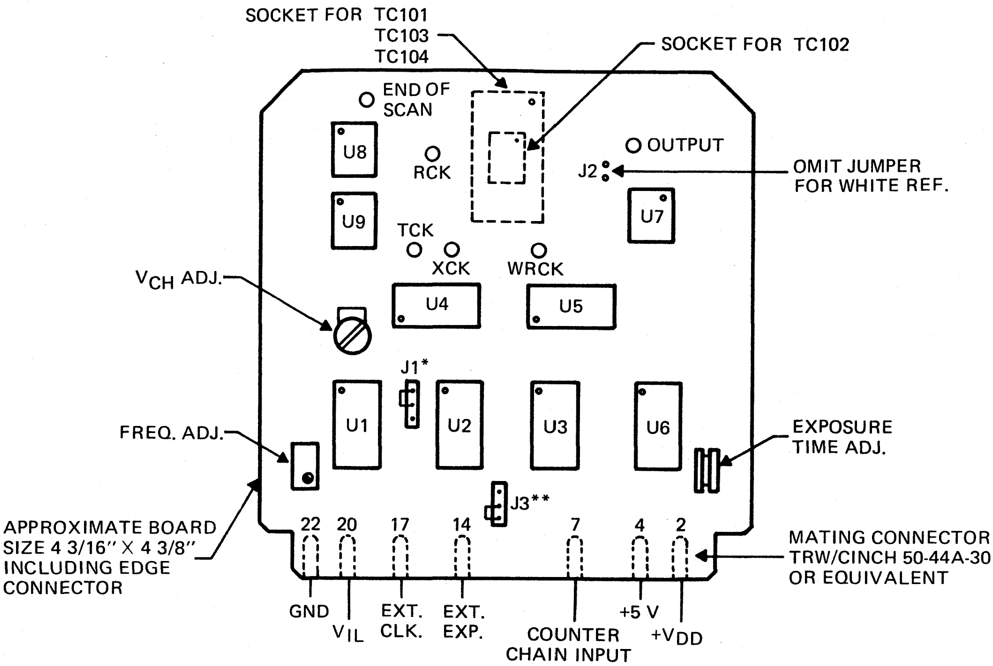
LOGIC TIMING WAVEFORM



LINEAR CCD EVALUATION BOARD



(J1 & J3 SHOWN IN INTERNAL SELECT POSITION)

* J1 = INTERNAL/EXTERNAL CLOCK SELECT

** J3 = INTERNAL/EXTERNAL EXPOSURE TIME SELECT

FEATURES:

- PC401 operates TC101, TC103, and TC104.
- PC402 operates TC102.
- Operates CCD over a 0.2 MHz to 2.0 MHz data rate range.
- HI clock voltage is controlled on the board (V_{CH}) while the LO clock voltage is controlled from the external negative supply (V_{IL}).
- White reference control allows evaluation of this clock's injection stability as well as the signal's elimination in the output.
- Three supply operation:
  +5 V @ 165 mA
  V_{DD} @ 15 mA*
  V_{IL}(R,T,X) nom @ 40 mA*

  *Values from DATA SHEETS
- CCD on opposite side from components and controls to allow clearance for optics.
- Operates CCD over 2- to 16-ms exposure time range with internal adjustment.
- Contains provision to accept both external clock and external exposure time with jitter-free synchronization.
- Output to external exposure control counter chain allows counter to set exposure time in multiples of TCK periods. Output from counter must be returned to external exposure time input.
- Output emitter follower buffered to drive high capacitance load.
- All CCD clock signals have easily accessed test points for scope probes.

DESIGNED TO EMIT NEAR-INFRARED RADIATION WHEN FORWARD BIASED

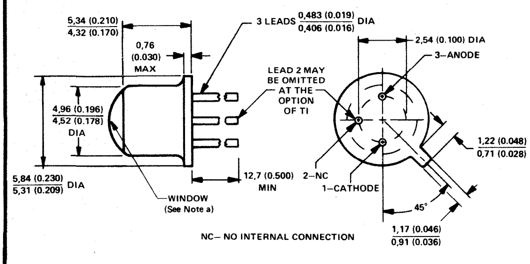
- "B" Versions Especially Designed for Low Degradation and are Direct Replacements for the "A" Versions
- Spectrally and Mechanically Compatible with TIL81 and TIL99 Phototransistors
- Typical Applications Include Card Readers, Encoders, Intrusion Alarms, Sector Sensors, Level Indicators, and Beginning-of-Tape/End-of-Tape Indicators
- TIL31HR2* Includes High-Reliability Processing and Lot Acceptance (See Page 3-11 for Summary of Processing)

mechanical data

Each device is in a hermetically sealed welded case similar to JEDEC TO-18 with window. The TIL31B and TIL34B have convex lenses while that of the TIL33B is essentially flat. A coin header is used to increase dissipation capability. All TO-18 registration notes also apply to this outline. Approximate weight is 0.35 gram.

THE CATHODE IS IN ELECTRICAL CONTACT WITH THE CASE



NOTE:

a. The window is Corning 7052 glass or equivalent.
Window dimensions are:
Minimum diameter . . 3,5 (0.140)
Maximum extension from top of case
TIL31B and TIL34B . . . 1,02 (0.040)
TIL33B 0,26 (0.010)

ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

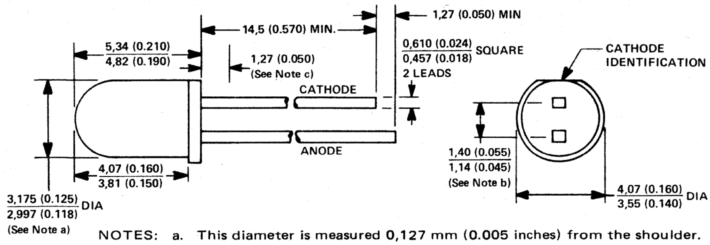
DESIGNED TO EMIT NEAR-INFRARED RADIATION WHEN FORWARD BIASED

- **Output Spectrally Compatible with Silicon Sensors (e.g., TIL78)**
- **High Power Efficiency**
- **High Power Output**
- **High Radiant Intensity**
- **Plastic Package with Two Leads for Ease of Handling**

mechanical data

This device has a tinted molded plastic body similar in size to lamp style T-1.



NOTES: a. This diameter is measured 0,127 mm (0.005 inches) from the shoulder.
b. Lead spacing is measured where the leads emerge from the package.

ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

CL-9

absolute maximum ratings

Reverse Voltage at 25°C Free-Air Temperature	2 V
Continuous Forward Current at (or below) 25°C Free-Air Temperature (See Note 1)	40 mA
Operating Free-Air Temperature Range	−40°C to 100°C
Storage Temperature Range	−40°C to 125°C
Lead Temperature 1,6 mm (1/16 Inch) from Case for 5 Seconds	240°C

operating characteristics at 25°C free-air temperature

	PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
P_O	Radiant Power Output	I_F = 20 mA	0.5	1.2		mW
λ_p	Wavelength at Peak Emission		915	940	975	nm
$\Delta\lambda$	Spectral Bandwidth			50	75	nm
θ_{HI}	Half-Intensity Beam Angle			35°		
V_F	Static Forward Voltage			1.2	1.6	V
t_r	Radiant Pulse Rise Time†	I_{FM} = 40 mA, $t_w \geq 5\ \mu s$		600		ns
t_f	Radiant Pulse Fall Time†			350		

†Radiant pulse rise time is the time required for a change in radiant power output from 10% to 90% of its peak value for a step change in current; radiant pulse fall time is the time required for a change in radiant power output from 90% to 10% of its peak value for a step change in current.

NOTE 1: Derate linearly to 100°C free-air temperature at the rate of 0.53 mA/°C.

mechanical data

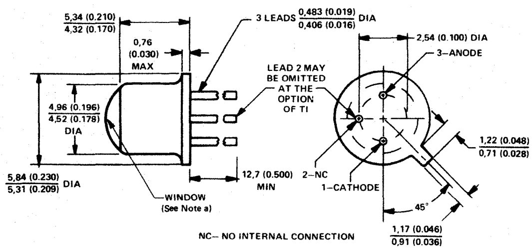
Each device is in a hermetically sealed welded case similar to JEDEC TO-18 with window. The TIL903 has a convex lens while that of the TIL904 is essentially flat.

All TO-18 registration notes also apply to this outline. Approximate weight is 0.35 gram.

THE ANODE IS IN ELECTRICAL CONTACT WITH THE CASE



NOTE:
a. The window is Corning 7052 glass or equivalent.
Window dimensions are:
Minimum diameter ... 3,5 (0.140)
Maximum extension from top of case
TIL903 .... 1,02 (0.040)
TIL904 .... 0,25 (0.010)

ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

t_f	Radiant Pulse Fall Time†				350		

† Radiant pulse rise time is the time required for a change in radiant power output from 10% to 90% of its peak value for a step change in current; radiant pulse fall time is the time required for a change in radiant power output from 90% to 10% of its peak value for a step change in current.

NOTES: 1. Derate linearly to 80 °C free-air temperature at the rate of 1.82 mA/°C.
2. This value applies for $t_w \leq 10$ μs, f ≤ 1 kHz. See Figure 1.
3. This parameter is measured with an aperture angle of 30°. The symmetry line of the cone is the mechanical axis of the device under test. The apex of the cone coincides with the package shoulder.

MEASURING THE OUTPUT OF INFRARED-EMITTING AND LIGHT-EMITTING DIODES

Ronald D. Grotti and Larry D. Major
Optoelectronics Department

Making accurate radiant-energy measurements involves, if not a little black magic, at least a relatively complicated commercial instrument and a skilled operator. However, the increased use of infrared-emitting diodes (IREDs) and light-emitting diodes (LEDs) as a precision system component has necessitated the development of equipment suitable for measuring radiant energy from IREDs and LEDs in the designer's lab, in the quality control lab, and on the production line. This equipment must be easy to use, provide the necessary accuracy, be calibratable, and be inexpensive.

To develop such equipment requires the selection of a suitable photodetector and the development of the proper calibration and operation procedures. This report describes a method that has been used in the Texas Instruments Optoelectronic Device Department for measuring the output of its radiation-emitting diode products. The apparatus consists simply of a photovoltaic detector connected directly to an ammeter, with a special mechanical fixture to prevent escape of radiant energy.

SELECTION OF DETECTOR

Detectors that might be considered for measuring IRED and LED output include thermopiles, photocells, photodiodes, photomultipliers, and photovoltaic cells. To show why the photovoltaic cell was chosen for this application, a review of pertinent detector characteristics is in order.

Thermopiles can be excellent primary detecting devices but are generally unsuitable for most laboratory and quality control types of service. Not only are they difficult to apply properly, but they are costly, lose their calibration when mishandled, and have an inadequate frequency response.

Photodiodes have good frequency capabilities, are reasonably priced, and are being used in pulse and high-frequency applications. However, most IREDs and LEDs are tested under low-frequency conditions, and therefore frequency response is not a critical sensor parameter. Because the photodiode must be electronically biased, a well-regulated bias supply is required to ensure consistent results.

Good sensitivity and frequency response plus a large detection area are some photomultiplier features. But multielement phototubes are expensive, require high-voltage supplies, and since output is a function of supply voltage, stability problems can arise. Also, if improperly applied, photomultipliers can saturate, causing errors and possibly permanent tube damage.

Photovoltaic cells—particularly the solar-cell variety—have a large active area, good long-term stability, and good spectral matching, are easy to use, and are inexpensive. The frequency response from dc to 100 kHz, although less than that of the photomultiplier and photodiode, is satisfactory for this application. These factors, combined with the fact that power or bias supplies are not required, makes the solar cell appear to have the best combination of qualities for this application.

Using the photovoltaic cell to precisely measure the emitter output and determine its quantum efficiency requires detailed knowledge of the cell, the emitter, and how they are optically coupled. Such knowledge depends not only on the mathematical characterization of the two devices, but on an accurate calibration of the photovoltaic cell. Once these steps have been accomplished, the emitter's power output and its quantum efficiency can be calculated using only two measured values — the emitter's input current and the cell's output current.

THE PHOTOVOLTAIC CELL

Before describing how the photovoltaic cell is calibrated, a few comments on the basic characteristics of this semiconductor device are in order. It is not necessary for our purposes to discuss the theory of operation in detail. Suffice it to say that electron-hole pairs are generated within the device as a function of impinging photons. Only those photons that have a quantum energy larger than the band gap between the valence band and the conduction band generate electron-hole pairs. The lower-energy photons simply transmit through the cell and do not cause an output. The ratio of electrons generated to the total number of incident photons is the cell's quantum efficiency, and is defined as

$$\eta_{SC} = \frac{\text{electrons generated/s}}{\text{incident photons/s}}$$

It is necessary to note that the cell's quantum efficiency is a function of the wavelength (Figure 1). This fact is particularly important because the sensor specifications are often based on the device's sensitivity to a particular wavelength. This quantum efficiency curve can be shaped through various means including the deposition of antireflection coatings on the photovoltaic cell's surface.

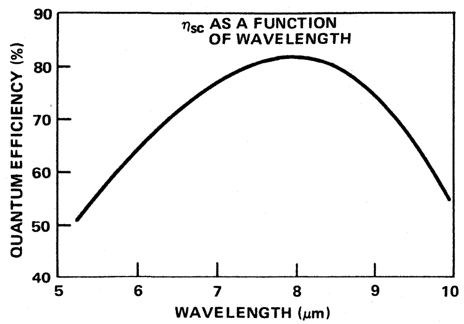

Figure 1. Photodetector Quantum Efficiency Varies as a Function of Wavelength, Thus Making Calibration at a Number of Wavelengths Necessary for General Use

CELL CALIBRATION

Before using the photovoltaic cell to measure the IRED or LED power output, the cell must be calibrated. This calibration is a two-step process, with the first step being the accurate determination of the cell's relative response. This determination is made using a grating monochromator, a tungsten light source, and a thermocouple detector that has a flat response in the spectral region of 500 nm to 1000 nm. Two curves are obtained, one using the thermocouple detector to measure the tungsten source's output and the other using the photovoltaic detector to measure the same output.

By dividing the photovoltaic cell response by the thermocouple response, the relative response of the cell is obtained. The relative response curve allows the measurement of radiation souces with different spectral characteristics to be accurately compared. However, to determine the actual power generated by a particular source using this cell requires another calibration step in which the photovoltaic cell output is determined when illuminated by a radiation source with a known power output. To accomplish this goal, the output of three monochromatic sources (gallium arsenide IRED, helium-neon laser, and argon laser) are measured by the cell being calibrated and by the Eppley thermopile. The quantum efficiency of the cell at the wavelength of each emitter is then found by using the optical power equation:

$$\eta_{SC} = \left(\frac{I_L}{\text{optical power}}\right)\left(\frac{\text{energy}}{\text{photon}}\right)$$

where I_L is the short-circuit current from the photovoltaic cell under test and optical power is the measurement made by the thermopile.

The three quantum efficiencies are then plotted, and a curve is generated that allows the cell to be used to measure accurately any impinging light of known spectral characteristics.

MEASUREMENT PROCEDURE

To employ this calibrated detector in a radiation-emitting diode testing system, it is necessary to develop the relationships that can describe the diode's quantum efficiency.

The diode output is directly proportional to the emitted photon energy and quantity per unit of time. The relation between energy E and wavelength λ is defined as

$$\lambda = \frac{1.24}{E} \text{ or } E = \frac{1.24}{\lambda} \qquad \text{(units are } \mu\text{m and eV)}$$

Energy, and therefore wavelength, of any given photon emitted from an IRED or LED source fall within a distribution curve such as that shown in Figure 2 for a GaAs IRED. To be absolutely accurate in calculating the optical power output of a solid-state source requires a time-consuming graphical integration using Figure 1 and Figure 2. Fortunately, all photons emitted by a monochromatic source have the same energy. Since it is a valid assumption to consider the IRED to be monochromatic, the IRED's optical power can be described to a first approximation without any noticeable error.

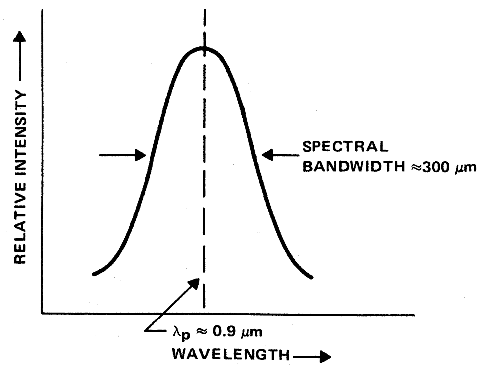

Figure 2. Spectral Characteristics of GaAs Diode Indicate that the Device is Nearly Monochromatic

For simplicity of calculation, let us assume that all photons generated by the IRED are collected by the photovoltaic cell. Therefore, considering the ammeter as a load consisting of a calibrated resistor and microvoltmeter (Figure 3), the current I_L (neglecting the internal resistance R_{shunt} of the photocell) is proportional to the number of photons striking the surface:

$$I_L = \left(\frac{\text{electrons}}{\text{s}}\right)(1.602 \times 10^{-19})$$

and

$$I_L = \eta_{sc}\left(\frac{\text{photons}}{\text{s}}\right)(1.602 \times 10^{-19})$$

therefore,

$$\text{photons/s} = \frac{I_L}{\eta_{sc}\,(1.602 \times 10^{-19})}$$

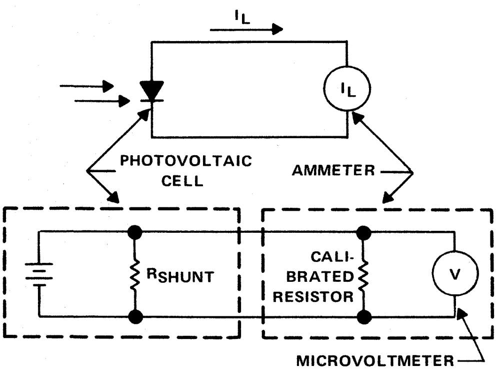

Figure 3. Equivalent Circuit of a Photovoltaic Cell (Silicon Solar Cell) Connected to the Ammeter Used to Measure Short Circuit Current

Knowing I_L, we can now calculate the emitter quantum efficiency η_{em} and optical power P_O:

$$\eta_{em} = \frac{I_L}{\eta_{sc}\, I_D} \quad \text{where } I_D \text{ is IRED current}$$

$$P_O = \left(\frac{I_L}{\eta_{sc}}\right)\left(\frac{\text{energy}}{\text{photon}}\right)$$

Using these equations, we can indeed determine both the quantum efficiency and the optical power generated by the IRED under conditions where all the power emitted is collected by the photovoltaic cells. To ensure the photovoltaic cell receives all emitted photons, it is necessary to build special test fixtures using detectors either singly or in arrays. (See Figures 4 and 5). In either case, the test procedures are the same. However, if such fixtures are not possible, then the percentage of energy emitted that actually reaches the detector must be included in the calculation. This fraction can be determined by dividing the total power emitted by the steradian relationship between the detector and the emitter, the total number of steradians being equal to the aperture area of the detector divided by the square of the distance between the emitter and the detector surface.

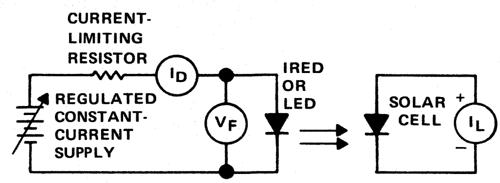

Figure 4. Calibrating the Test Setup

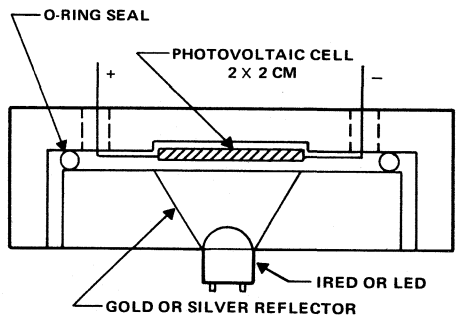

Figure 5. Test Fixture for Capturing the Total Diode Output with a Single Photovoltaic Cell

TESTING PRECAUTIONS

Generally, gallium arsenide and gallium arsenide phosphide (GaAsP) infrared emitters provide an output signal I_L large enough that an ammeter may be used to measure the cell's short-circuit current directly. The measurement of GaAsP visible-light-emitting diodes and tests such as radiant intensity measurements usually produce signal levels that require a calibrated resistor and a microvoltmeter. The important point is that the input impedance of the measuring instrument must be less than 1/10 the value of R_{shunt} to prevent lowering the output of the cell. The exact value of R_{shunt} for photovoltaic cells is difficult to measure, but it is usually in the order of 10 kΩ to 30 kΩ. If the cell has been mistreated, the R_{shunt} may be as low as 1 kΩ or less. Thus, if an electronic ammeter is used in the 3×10^{-6} ampere range, as may be required for testing GaAsP LEDs, the input meter impedance of 300 to 1000 Ω approaches the critical value of the typical solar cell. Thus, these low-level measurements must be made using the resistor-microvoltmeter technique.

The second problem occurs when the photovoltaic cell becomes appreciably self-biased because of the voltage drop developed across the load. Care must be taken to limit this bias to prevent a reduced output signal. As a rule of thumb, this load-voltage drop is kept lower than 50 mV. When measuring high-power emitters, the value of I_L of a 2- by 2-cm photovoltaic cell is capable of reaching the 200-mA level without saturation; therefore at these levels, the input impedance of the ammeter and the value of the calibrated resistor (See Figure 3) must be kept less than 0.25 Ω.

SAMPLE CALCULATION OF DIODE POWER OUTPUT AND QUANTUM EFFICIENCY

Assume the following values:

I_D = emitting diode current = 300 mA

V_F = forward voltage of the emitter = 1.6 volts

I_L = solar cell output signal = 25 mA

λ_p = peak wavelength of the emitter = 0.925 μm

η_{sc} = quantum efficiency of the cell = 0.70 electrons per photon

Then:

η_{em} = emitter quantum efficiency

$$= \left(\frac{I_L}{\eta_{sc}}\right)\left(\frac{I}{I_D}\right) = \left(\frac{25\ \text{mA}}{0.7\ \frac{\text{elect}}{\text{photon}}}\right)\left(\frac{1}{300\ \text{mA}}\right)$$

$$= 0.119\ \text{photons/electron}$$

$$\eta_{em} = 11.9\%$$

$$\text{Optical Power} = P_O = \left(\frac{I_L}{\eta_{sc}}\right)\left(\frac{\text{energy}}{\text{photon}}\right)$$

$$\text{Where energy} = \frac{1.24}{\lambda_p} = \frac{1.24}{0.925} = 1.341\ \text{eV}$$

$$P_O = \left(\frac{25\ \text{mA}}{0.7\ \frac{\text{elect}}{\text{photon}}}\right)\left(1.341\ \frac{\text{eV}}{\text{photon}}\right)$$

$$\text{Power efficiency} = \frac{P_O}{\text{Input Power}}$$

$$= \frac{47.9 \times 10^{-3}\ \text{W}}{I_D V_F} = \frac{47.9 \times 10^{-3}\ \text{W}}{48 \times 10^{-2}\ \text{W}}$$

Power efficiency = 0.0998 = 9.98%

TIES27 GaAs NONCOHERENT INFRARED SOURCE

The TIES27 GaAs noncoherent infrared source is essentially a solution-grown P-N junction. The output of the device is 15 mW minimum with 20 mW being typical at the rated forward current. The device emits in the near-infrared region.

This report presents basic information necessary to utilize this high-power, low-cost industrial IR source. Included in this discussion are the theory of operation, device performance including forward voltage, optical power, spectral distribution, radiance, radiant intensity, thermal impedance, pulse-mode operation and optical design considerations plus typical mechanical specification and application data.

THEORY OF OPERATION

The TIES27 GaAs noncoherent infrared source is a solution grown P-N junction in the shape of an 18-mil-square chip. The chip is mounted on a stud header and encapsulated in an epoxy dome.

When the P-N junction is forward biased, electrons from the N-region are injected into the P-region and radiant quanta (photons) are generated through recombination. The radiant energy emitted is in the near-infrared region.

A flat-geometry GaAs source emitting into air has a critical angle that can be described by:

$$\sin\theta_c = \frac{N_1}{N_2} \qquad (1)$$

where N_1 = index of refraction of air = 1

N_2 = index of refraction of GaAs = 3.6

θ_c = critical angle = 16.1°.

Any radiant energy generated that strikes the surface of the chip at an angle greater than the critical angle will not escape but will be reflected internally. This is shown in Figure 1.

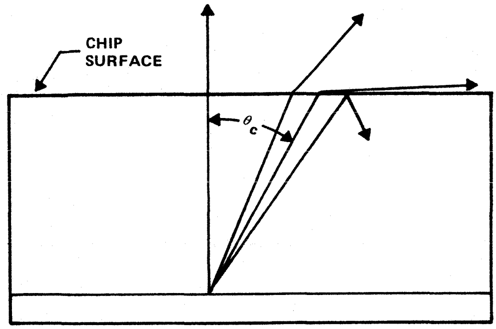

FIGURE 1. Angle of Light Determines if it Escapes or is Reflected Internally

The critical angle of the TIES27 chip has been changed by placing epoxy on the chip. Since the index of refraction of the epoxy is 1.5, the critical angle changes from 16.1° to 24.6°. The improvement factor can be calculated as follows:

$$\alpha = \frac{1 - \cos\theta_2}{1 - \cos\theta_1} = \frac{1 - \cos 24.6^\circ}{1 - \cos 16.1^\circ} = 2.31 \qquad (2)$$

The improvement factor is valid only when the radiant energy that is emitted from the P-N junction can be transmitted through the epoxy and into the air.

The external quantum efficiency of the device can be described as the ratio of optical current output (photons per second) divided by forward input current.

$$\eta_s = \frac{I_\phi}{I_F} \qquad (3)$$

4

SPECIAL FUNCTION IR EMITTERS

DEVICE PERFORMANCE

Forward Voltage

At a constant temperature, the voltage change as a function of current can be predicted from equation (4):

$$\Delta V_F = \frac{nKT}{q} \log e \frac{I_{F1}}{I_{F2}} \quad (4)$$

where V_F = forward voltage

I_F = forward current

$\frac{KT}{q} \approx 26$ mV

n = constant

The value of n ranges from 1 to 3 for the TIES27 with n being larger at small forward bias currents. Exact values for n may be obtained by characterizing the diode under the operating conditions to which it will be exposed.

The typical distribution of the forward voltage at the rated current of 300 mA will range from 1.3 volts to a maximum of 2.2 volts.

Optical Power

The TIES27 generates an optical output power of 15 mW minimum. The optical output power approximates a linear function of the forward bias current when operated above a few milliamperes and at or below the maximum specified forward current. Figure 2 shows relative optical power versus forward drive current.

The optical output power can be described by Equation (5):

$$P_o = I_\phi E$$

where I_ϕ = optical output current = $\eta_s I_F$ (5)

$$E = \frac{1.24}{\lambda_p}$$

λ_p = peak wavelength in micrometers

The optical power of the TIES27 varies inversely with temperature. A typical curve of optical output power versus temperature is shown in Figure 3.

Spectral Distribution

The distribution of emission wavelengths of the TIES27 is narrow; half-power wavelengths are typically separated by 450 angstroms. The peak wavelength ranges from 9300 to 9450 angstroms when operated at rated forward current (300 mA) at 25°C stud temperature. The peak wavelength (λ_p) is a function of forward bias current and temperature. The change in wavelength of peak intensity versus case (stud) temperature is shown in Figure 4.

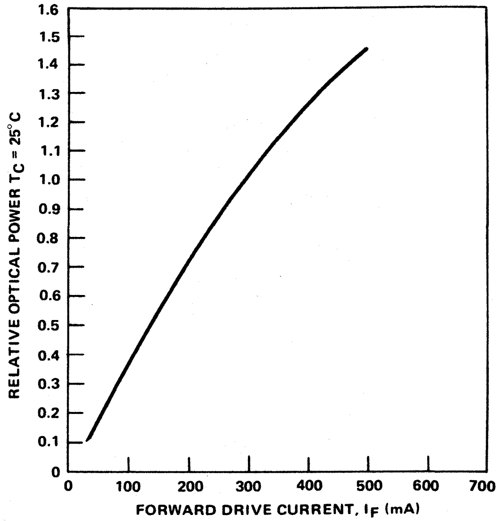

FIGURE 2. Relative Optical Power versus Forward Drive Current for TIES27. T = 25°C.

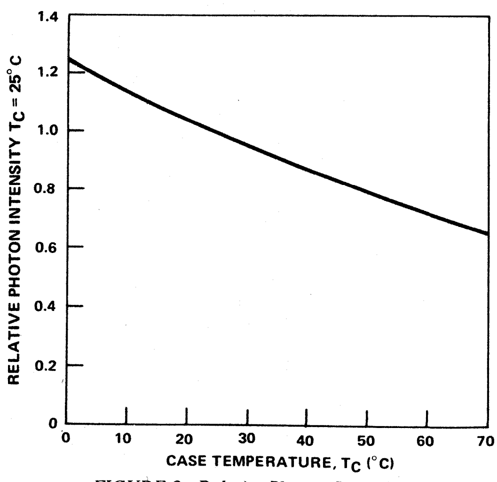

FIGURE 3. Relative Photon Intensity versus Case Temperature

4 SPECIAL FUNCTION IR EMITTERS

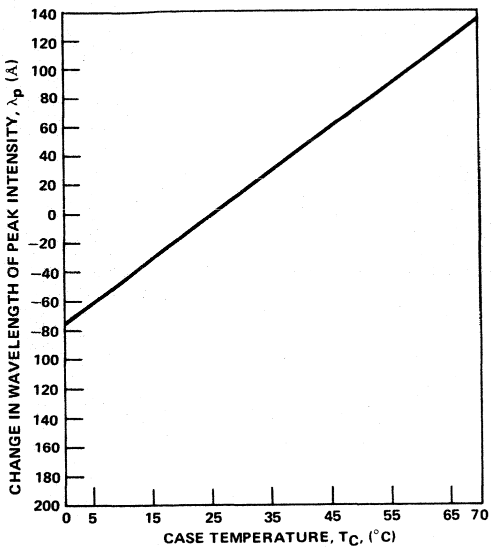

FIGURE 4. Change in Wavelength of Peak Intensity versus Case (Stud) Temperature. $I_F = 300$ mA.

Radiance

Radiance (L_e) is defined as radiant intensity emitted per unit area. In the case of the TIES27, the radiance can be calculated by using Equations (5) – (8):

$$P_o = I_\phi E \qquad (5)$$

where I_ϕ = optical output current = $\eta_s I_F$

$$E = \frac{1.24}{\lambda_p}$$

λ_p = peak wavelength in micrometers.

$$L_e = \frac{P_o/\Omega}{A} \qquad (6)$$

where P_o = total optical power

Ω = solid angle of emission in steradians

A = Area of active region in cm^2.

For the TIES27 (active area is 18 X 18 mils),

$$A = (0.018 \times 2.54)^2\ \text{cm}^2 = 2.09 \times 10^{-3}\ \text{cm}^2 \qquad (7)$$

$$L_e = \frac{(15 \times 10^{-3}\ \text{W})/(2\pi\ \text{sr})}{2.09 \times 10^{-3}\ \text{cm}^2} \qquad (8)$$

$$= 1.14\ \text{W} \cdot \text{sr}^{-1}/\text{cm}^2$$

It should be pointed out that this is the worst case because the TIES27 does not emit uniformly into 2π steradians but into a solid angle less than 2π.

Radiant Intensity

The radiant intensity of an isotropic radiator is equal in all directions, therefore, the radiant intensity is equal to

$$I_e = \frac{P}{2\pi}. \qquad (9)$$

where I_e = radiant intensity (W/sr)

P = total optical power (W)

However, most GaAs infrared emitters are not perfect isotropic radiators and the radiant intensity is higher on the optical axis or within a few degrees of the optical axis. Figure 5 shows a typical intensity pattern for the TIES27.

Thermal Resistance

The thermal resistance of the TIES27 is typically in the range of 12°C/W. The chip is mounted directly to the stud which when heatsinked properly can be approximated to the first order as an infinite heatsink. It is important to note that the thermal resistance is a very difficult parameter to determine and measured values from different groups of processed material may have a wide distribution.

Pulse Mode Operation

The TIES27 is capable of being pulsed at relatively high peak currents. The limiting factor, as it is in most pulsed mode applications, is the interfaces and not the P-N junction–the power density gets so large in the bonding wire or the contact pad that catastrophic failures occur. For example, a 1-mil gold wire that is 0.5 inches long has a power density of approximately 4200 W/cm^3 with 300 mA flowing through it. However, by increasing the current to 1 amp, the power density increases to approximately 47,000 W/cm^3.

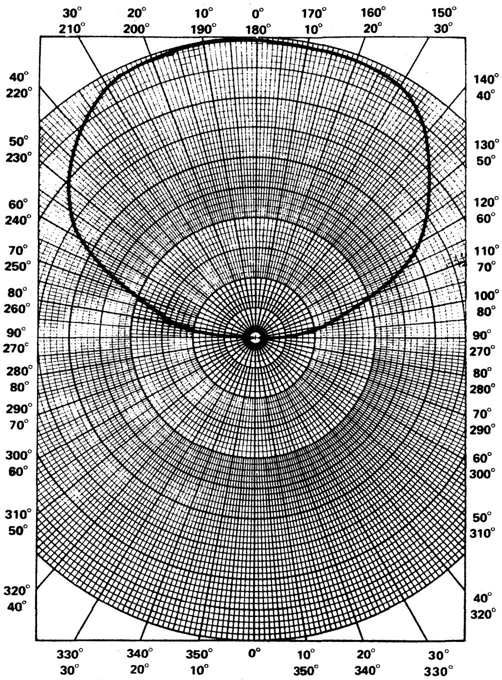

FIGURE 5. A Typical Intensity Pattern for the TIES 27

There are tradeoffs that must be considered when operating in the pulse mode such as duty cycle, repetition rate, and peak current. The peak current can be approximated with reasonable accuracy by using

$$I_{FM} = (I_F \max)/D = I_F \max \left(\frac{T}{t}\right) \qquad (10)$$

where I_{FM} = maximum peak current

I_F max = maximum-rated continuous forward current

D = duty cycle

T = period of frequency

t = diode "on" time

However, careful judgement should be used to ensure that the peak current does not exceed a level that will cause the bonding wires to open. The TIES27 should not be exposed to peak pulses of current greater than 4 amperes with an appropriate duty cycle. Figure 6 shows typical peak power

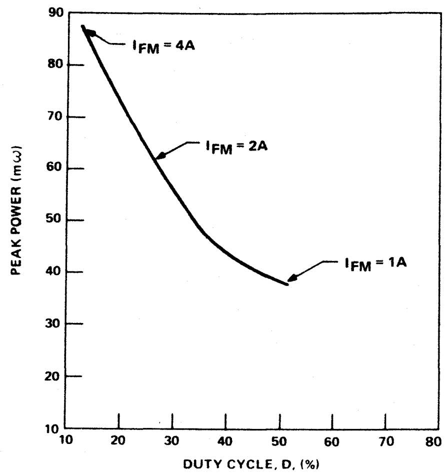

FIGURE 6. Typical Peak Power of TIES 27 at 10 kHz with Various Peak Current Levels at Various Duty Cycles

obtained when the device was operated at a frequency of 10 kHz with current levels of 1 ampere, 2 amperes and 4 amperes at respective duty cycles of 50%, 25%, and 12.5% – higher current pulses than equation (10) defines.

Optical Design Considerations

Since the TIES27 emits into such a large pattern (approximately 2π steradians), it is necessary to use some form of optics to collect and direct that portion of the optical power that will be used.

The amount of optical power collected can be determined quickly once the optics have been defined. The following is an example that illustrates the effect of the f-number of the lens on the power transmitted.

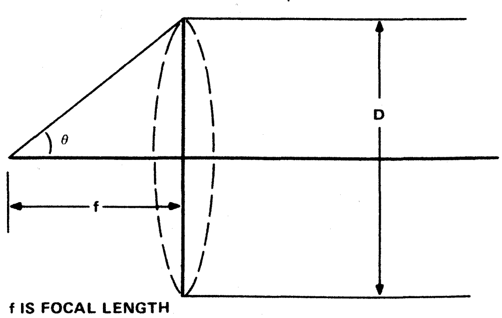

FIGURE 7. Typical Optical Collection Configuration

$$P_t = P_o \left(\frac{\Omega_c}{\Omega_e}\right) \eta_t = \qquad (11)$$

$$P_o \left(\frac{2\pi\,(1 - \text{Cos}\,\theta)}{2\pi}\right) \eta_t$$

where P_t = optical power transmitted in the beam of the collection optics.

P_o = the total radiated optical power.

Ω_c = the solid angle of collection in steradians.

Ω_e = the solid angle of emission in steradians.

η_t = the transmission efficiency of the lens.

θ = the half angle of the collection cone.

Table 1

f-number	θ (°)	1 − Cos θ	P_t (mW)
1.0	26.6	0.1	1.5
1.4	19.6	0.06	0.8
2.0	14.0	0.03	0.45
2.8	10.2	0.02	0.3
4.0	7.0	0.01	0.15

TYPICAL APPLICATION DATA

Figure 8 shows an economical approach for modulating a TIES27. This circuit features excellent bandwidth as well as high peak currents. Figures 9, 10, and 11 show the performance data for the circuit shown in Figure 8.

MECHANICAL DATA

The device is encapsulated and mounted on a stud header. The cathode is in electrical contact with the solder lug. The anode is in electrical contact with the stud, which is insulated from the case by a glass-to-metal seal. Soldered connections should not be made directly to the stud because of the low-thermal-resistance path between stud and emitting element.

TEXAS INSTRUMENTS CUSTOMIZED OPTOELECTRONIC ARRAYS

The 1N5722 through 1N5725 series is available mounted in printed circuit boards for custom-designed array or matrix applications. The array is a complete unit, without the problems associated with small, difficult-to-handle components. These arrays can be designed for punched-card or tape readers, position indicators, pattern and character recognition, shaft encoders, and many other special applications.

Texas Instruments custom-array techniques offer many advantages:

- The arrays are pre-assembled and tested, ready for installation.
- Custom arrays can be manufactured in almost any configuration to allow maximum design flexibility.
- Sensitivity across an entire array will be matched to within 50%.
- GaAs sources can be furnished to give complete solid-state matched sets for specific applications.
- Arrays with components firmly soldered into place on both sides of a printed circuit board are more rugged than individually wired sensing devices.

Specifying optoelectronic arrays is easy; all that is required is a print of the array and the desired specifications.

TI sales engineers will assist in developing specifications for special applications.

D1960, NOVEMBER 1974—REVISED MARCH 1976

TYPE TIL99 N-P-N PLANAR SILICON PHOTOTRANSISTOR

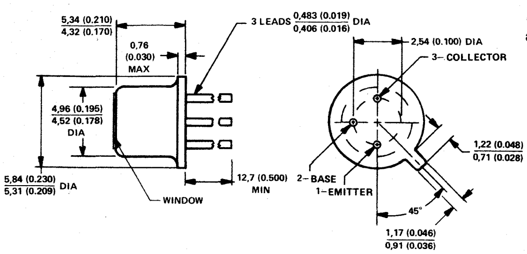
FOR WIDE-ANGLE VIEWING APPLICATIONS

- Recommended for Application in Character Recognition, Tape and Card Readers, Velocity Indicators, and Encoders
- Spectrally and Mechanically Compatible with TIL31B, TIL903, and TIL904 IR Emitter
- Glass-to-Metal-Seal Header
- Base Connection Externally Available
- Saturation Level Directly Compatible with Most TTL/DTL

mechanical data

The device is in a hermetically sealed package with glass window. The outline of the TIL99 is similar to TO-18 except for the window. All TO-18 registration notes also apply to this outline.

THE COLLECTOR IS IN ELECTRICAL CONTACT WITH THE CASE



NOTE:
a. The window is Corning 7052 glass or equivalent.
Window dimensions are:
Minimum diameter. . 3,5 (0.140)
Maximum extension from top of case. 0,26 (0.010)

ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES.

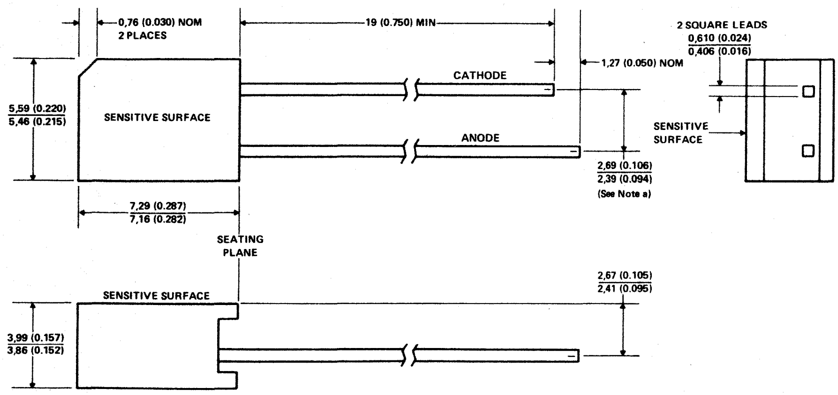
- High Photosensitivity
- Fast Response
- Low-Cost Plastic Package
- Designed for Infrared Remote-Control Systems
- Compatible with TIL38, TIL39, TIL905, and TIL906 IR Emitters

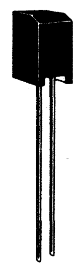
description

The TIL100 is a high-speed PIN photodiode designed to operate in the reverse-bias mode. It provides low capacitance with high speed and high photosensitivity suitable for near-infrared applications.

mechanical data

The photodiode chip is mounted on a lead frame and molded in a black infrared-transmissive plastic. The active chip area is typically 8,83 millimeters (0.0137 square inches). Its centerline is nominally 4 millimeters (0.157 inch) above the seating plane.





NOTE a: Lead spacing is measured at the seating plane.

ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

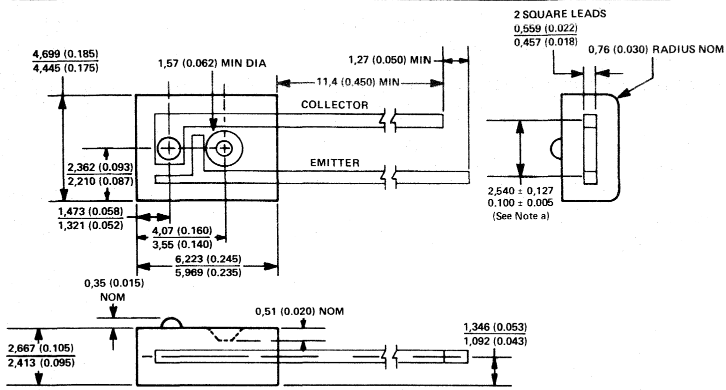
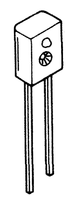
D2691, FEBRUARY 1983

- **Recommended for Applications Requiring Low-Cost Discrete Phototransistors**
- **Spectrally and Mechanically Matched with TIL40 Infrared Emitter**
- **Designed for use in Housings or Printed Circuit Boards**

mechanical data

This device has a blue-tinted molded plastic body and is similar to TIL412 except the pinout is reversed.





NOTE a: Lead spacing is measured where the leads emerge from the package.

ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES.

absolute maximum ratings at 25 °C free-air temperature (unless otherwise noted)

Collector-Emitter Voltage	30 V
Emitter-Collector Voltage	7 V
Continuous Collector Current	50 mA
Continuous Device Dissipation at (or below) 25 °C Free-Air Temperature (See Note 1)	50 mW
Operating Free-Air Temperature Range	−40 °C to 80 °C
Storage Temperature Range	−40 °C to 100 °C
Lead Temperature 1,6 mm (1/16 inch) from Case for 5 Seconds	260 °C

electrical characteristics at 25 °C free-air temperature

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
$V_{(BR)CEO}$	Collector-Emitter Breakdown Voltage	I_C = 100 μA, E_e = 0	30			V
$V_{(BR)ECO}$	Emitter-Collector Breakdown Voltage	I_E = 100 μA, E_e = 0	7			V

TEXAS INSTRUMENTS CUSTOMIZED OPTOELECTRONIC ASSEMBLIES

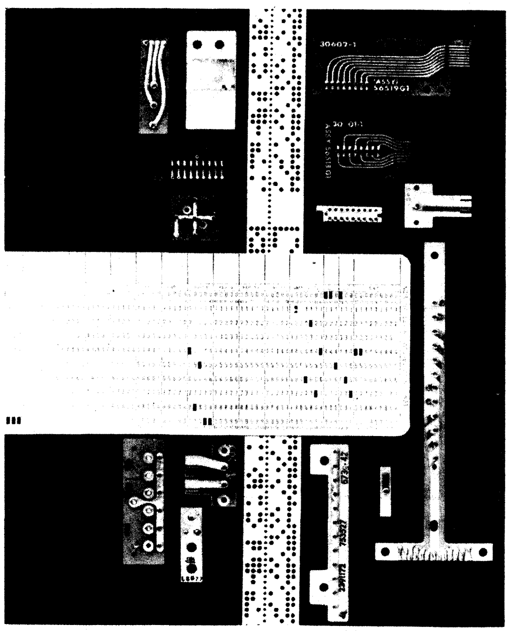
The TIL601 through TIL604, LS600 series is available mounted in printed circuit boards for custom-designed array or matrix applications. The array is a complete unit, without the problems associated with small, difficult-to-handle components. These arrays can be designed for punched-card or tape readers, position indicators, pattern and character recognition, shaft encoders, and many other special applications.

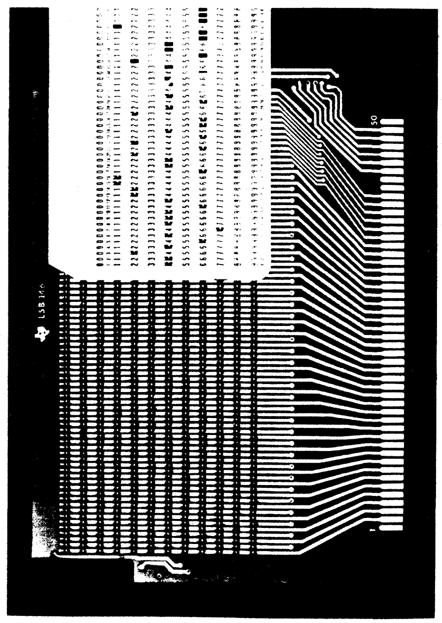
Texas Instruments custom-array techniques offer many advantages:

- The arrays are preassembled and tested, ready for installation.
- Custom arrays can be manufactured in almost any configuration to allow maximum design flexibility.
- Sensitivity across an entire array will be matched to within 50%.
- Associated components such as ICs and switches can be mounted directly on the printed circuit board.
- Arrays with components firmly soldered into place on both sides of a printed circuit board are more rugged than individually wired sensing devices.

Specifying optoelectronic arrays is easy; all that is required is a print of the array and the desired specifications.

TI sales engineers will assist in developing specifications for special applications.





- **This processing applies only to devices ordered under the part number TIL604HR2**
- **For electrical and mechanical specifications, refer to page 5-31**

This processing and lot acceptance follow the sequence of tests in MIL-S-19500 for JANTX types. This is not to be construed to be a JANTX-qualified part. A detail specification is available upon request through your TI Field Sales Office or Optoelectronics Marketing at the following address:

SILICON AVALANCHE PHOTODIODE

D518, JUNE 1968—REVISED SEPTEMBER 1982

OPTIMIZED FOR HIGH-SPEED DETECTION OF NEAR-INFRARED RADIANT ENERGY

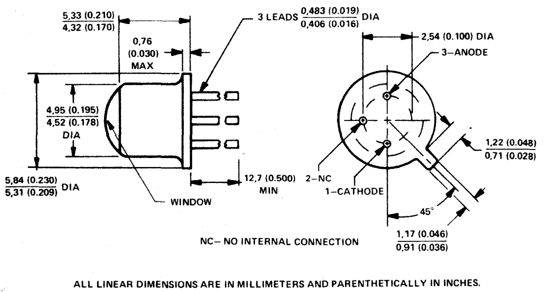
- **Useful from Audio to Microwave Frequencies**
- **Typical Photocurrent Gain of > 600**
- **Active Area of 5 X 10^{-4} cm^2 (Diameter = 10 Mils)**
- **Typical System Noise Equivalent Power of 10^{-12} W/$\sqrt{Hz}$ at 1 GHz**

description

The TIED56 is a high-speed, high-resistivity photodiode. It is designed to operate in the reverse-voltage avalanche region just below the breakdown voltage. This results in a photocurrent signal gain of a magnitude dependent on the reverse voltage. The signal gain ahead of the input noise of typical amplifiers provides for enhancement of the signal-to-noise ratio in most optical receiver systems.

mechanical data

The device is in a hermetically sealed package with a glass lens or window. The outline is similar to TO-18.



ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES.

THE ANODE IS IN ELECTRICAL CONTACT WITH THE CASE.

MAXIMUM WINDOW EXTENSION FROM TOP OF CASE IS 1,02 (0.040) MINIMUM DIAMETER IS 3,81 (0.150).

THE WINDOW IS BORO-SILICATE GLASS.

absolute maximum ratings

Continuous Power Dissipation at (or below) 25°C Case Temperature (See Note 1) . . . . 100 mW

TYPE TIED59 SILICON AVALANCHE PHOTODIODE

OPTIMIZED FOR HIGH-SPEED DETECTION OF NEAR-INFRARED RADIANT ENERGY

- **Isolated Case for Shielding**
- **Useful from Audio to Microwave Frequencies**
- **Typical Photocurrent Gain of >600**
- **Active Area of 4.5 X 10^{-3} cm^2 (Diameter = 30 Mils)**
- **Typical System Noise Equivalent Power of 2 X 10^{-13} W/$\sqrt{}$Hz at 30 MHz Bandwidth**

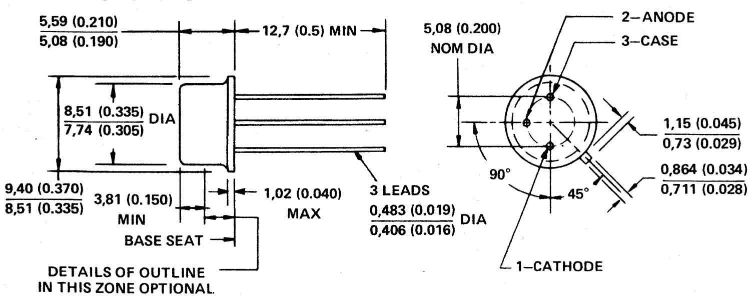
description

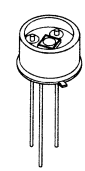
The TIED59 is a high-speed, high-resistivity photodiode. It is designed to operate in the reverse-voltage avalanche region just below the breakdown voltage. This results in photocurrent signal gain of a magnitude dependent on the reverse voltage. The signal gain ahead of the input noise of typical amplifiers provides for enhancement of the signal-to-noise ratio in most optical receiver systems. The TIED59 is similar to TIED56 except that it has a larger active area making it more useful in lens systems with small f-numbers or where focusing is a problem.

mechanical data

The device is in a hermetically sealed welded case similar to, but slightly shorter then, JEDEC TO-39. The window is borosilicate glass. Its nominal dimensions are: diameter, 6,6 mm (0.260 inch); thickness, 1,5 mm (0.060 inch); and distance from front surface of the window to the active area, 1,9 mm (0.075 inch).

THE ACTIVE ELEMENTS ARE ELECTRICALLY INSULATED FROM THE CASE





ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES.

D1951, NOVEMBER 1974—REVISED SEPTEMBER 1982

TYPES TIED87, TIED88, TIED89 SILICON AVALANCHE PHOTODIODE/REFERENCE DIODE PAIRS

OPTIMIZED FOR HIGH-SPEED DETECTION OF NEAR-INFRARED RADIANT ENERGY

- **Photodiode and Reference Diode with Matched Breakdown Characteristics**
- **Both Diodes Mounted on Common Ceramic but Isolated Electrically**
- **Choice of Active Areas of Photodiode:**

  5×10^{-4} cm^2 (Diameter = 10 Mils) for TIED87
  4.5×10^{-3} cm^2 (Diameter = 30 Mils) for TIED88
  1.8×10^{-2} cm^2 (Diameter = 60 Mils) for TIED89

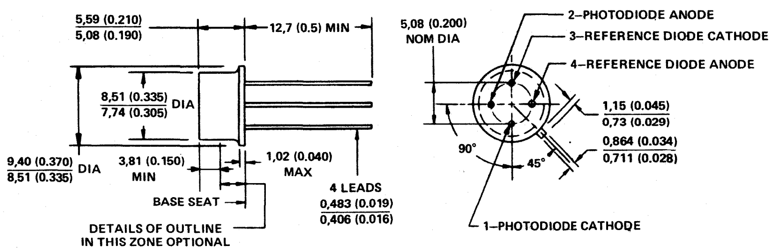
description

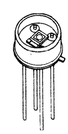
These diode pairs consist of an avalanche photodiode (APD) and a small reference diode that have been manufactured together to ensure close matching of both the breakdown voltages and the temperature coefficients of the two diodes. This makes it possible to build a temperature-compensating bias circuit that will hold the avalanche gain constant over wide temperature variations.

mechanical data

Each diode pair is in a hermetically sealed welded case similar to, but slightly shorter than, JEDEC TO-12. The window is borosilicate glass. Its dimensions are: diameter, 6,6 mm (0.260 inch); thickness, 1,5 mm (0.060 inch); and distance from front surface of the window to the active area, 1,9 mm (0.075 inch).

THE REFERENCE DIODE CATHODE IS IN ELECTRICAL CONTACT WITH THE CASE





ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES.

NOTES: 2. Temperature coefficient, $\alpha_{V(BR)}$, is determined by the formula:

$$\alpha_{V(BR)} = \frac{V_{(BR)} @ 125°C - V_{(BR)} @ -65°C}{125°C - (-65°C)}$$

3. Gain M_T is measured at the reverse voltage at which the noise deviates from the theoretical linear characteristic. See Figure 1. Radiant flux is as required to give a photocurrent of 0.1 nA rms at V_R = 40 V.

†Dark Current is the sum of surface current and gain M times the bulk current.

‡E_e is the incident radiant-power per unit area.

APDs

TYPICAL APPLICATION DATA

The bias voltage applied to the APD should closely match the breakdown voltage of the reference diode (within ±10 V). In Figure 7, the bias voltage can be *increased* by *lowering* the value of the gain-control resistor. More importantly, the *change* with temperature in applied bias to the APD should closely match the *change* in breakdown voltage of the reference diode. Typically the temperature coefficient of constant avalanche gain is 2 mV/°C higher than the temperature coefficient of breakdown under conditions of constant current. The temperature coefficient of the bias circuit may be adjusted by insertion of a temperature-sensitive device in the pass element or the error amplifier.

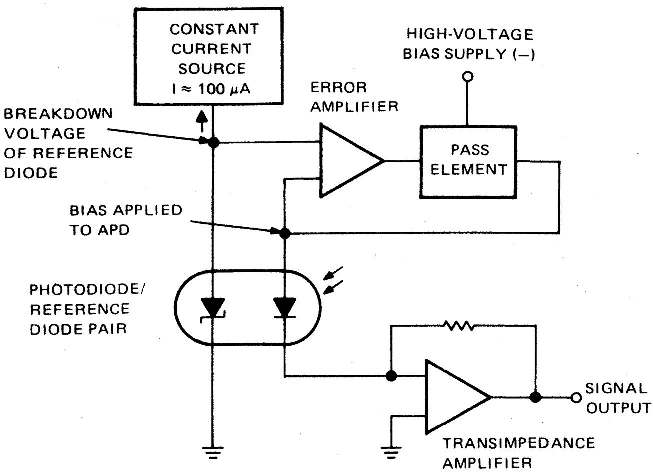

FIGURE 6–BLOCK DIAGRAM OF TEMPERATURE COMPENSATING BIAS CIRCUIT

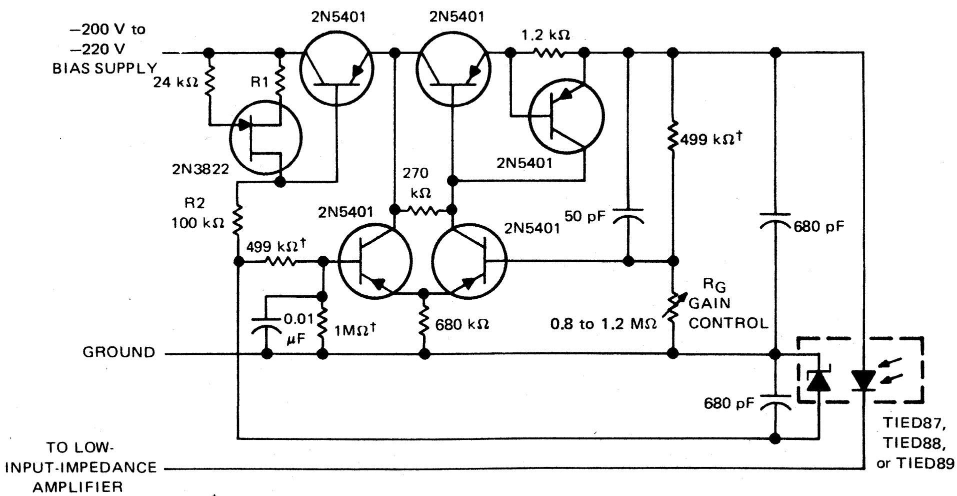

†These resistors are T2 metal film ¼ W 1%. Other resistors are ¼ W carbon.
R1 is selected to give approximately 220 μA current through R2.
Capacitors are ceramic disc, 500 V.

GALLIUM ARSENIDE DIODE INFRARED SOURCE OPTICALLY COUPLED TO A HIGH-GAIN N-P-N SILICON PHOTOTRANSISTOR

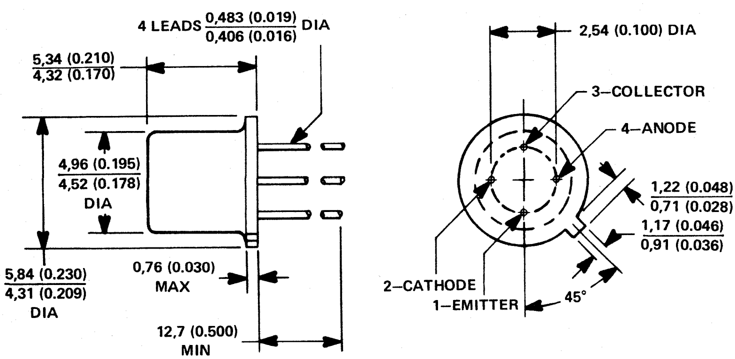
- **Photon Coupling for Isolator Applications**
- **Very High Current Transfer Ratio . . . 500%**
- **High-Voltage Electrical Isolation . . . 1-kV Rating**
- **Stable Over Wide Temperature Range**
- **Hermetically Sealed TO-72 Package**

description

This optocoupler features an improved current transfer ratio (CTR) at an input of one milliampere making it ideal for coupling with isolation from low-output MOS and CMOS devices to power devices or other systems. Typical applications include motor-speed controls, numeric control systems, meters, and instrumentation.

mechanical data

THE COLLECTOR IS IN ELECTRICAL CONTACT WITH THE CASE



ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES.
ALL JEDEC TO-72 DIMENSIONS AND NOTES ARE APPLICABLE

*absolute maximum ratings at 25°C free-air temperature (unless otherwise noted)

Input to-Output Voltage	±1 kV
Collector-Emitter Voltage	40 V
Emitter-Collector Voltage	7 V
Input Diode Reverse Voltage	2 V
Input Diode Continuous Forward Current at (or below) 65°C Free-Air Temperature (See Note 1)	40 mA
Continuous Collector Current	50 mA
Peak Diode Current ($t_w < 1\ \mu s$, PRR < 300 pps)	1 A
Continuous Transistor Power Dissipation at (or below) 25°C Free-Air Temperature (See Note 2)	190 mW
Operating Free-Air Temperature Range	−55°C to 125°C
Storage Temperature Range	−55°C to 125°C
Lead Temperature 1/16 Inch from Case for 10 Seconds	240°C

NOTES: 1. Derate linearly to 125°C free-air temperature at the rate of 0.67 mA/°C.
2. Derate linearly to 125°C free-air temperature at the rate of 1.9 mW/°C.

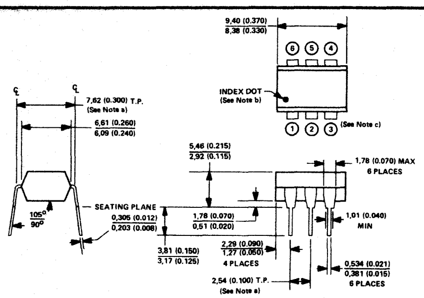
COMPATIBLE WITH STANDARD TTL INTEGRATED CIRCUITS

- **Gallium Arsenide Diode Infrared Source Optically Coupled to a Silicon N-P-N Phototransistor**
- **High Direct-Current Transfer Ratio**
- **High-Voltage Electrical Isolation . . . 2.5-kV, 1.5-kV, or 0.5-kV Rating**
- **Plastic Dual-In-Line Package**
- **High-Speed Switching . . . t_r = 2 μs, t_f = 2 μs Typical**

mechanical data

The package consists of a gallium arsenide infrared-emitting diode and an n-p-n silicon phototransistor mounted on a 6-lead frame encapsulated within an electrically nonconductive plastic compound. The case will withstand soldering temperature with no deformation and device performance characteristics remain stable when operated in high-humidity conditions. Unit weight is approximately 0.52 grams.



NOTES:
a. Leads are within 0,127 (0.005) radius of true position (T.P.) with maximum material condition and unit installed.
b. Pin 1 identified by index dot.
c. Terminal connections:
   1. Anode } Infrared-emitting diode
   2. Cathode
   3. No internal connection
   4. Emitter } Phototransistor
   5. Collector

GALLIUM ARSENIDE DIODE INFRARED SOURCE OPTICALLY COUPLED TO A HIGH-GAIN N-P-N SILICON PHOTOTRANSISTOR

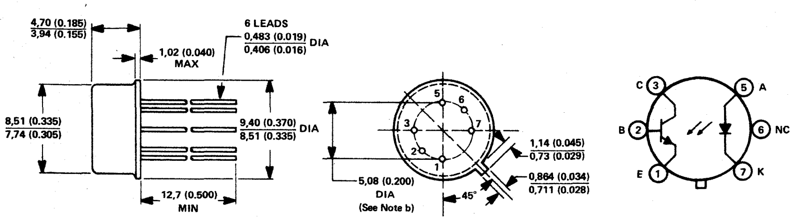
- JAN, JANTX, JANTXV Versions Available
- Very High Current Transfer Ratio . . . 500% Typical (4N49)
- Photon Coupling for Isolator Applications
- Base Lead Provided for Conventional Transistor Biasing
- High-Speed Photodiode-Mode Operation
- High-Voltage Electrical Isolation . . . 1-kV Rating
- Stable over Wide Temperature Range
- Hermetically Sealed Package

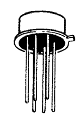
description

This opto coupler features an improved current transfer ratio (CTR) at an input of one milliampere making it ideal for coupling with isolation from low-output MOS and CMOS devices to power devices or other systems. Typical applications include motor-speed controls, numeric control systems, meters, and instrumentation.

*mechanical data

THE COLLECTOR IS IN ELECTRICAL CONTACT WITH THE CASE





NOTES: a. All linear dimensions are in millimeters and parenthetically in inches.
b. Leads having maximum diameter shall be within 0,18 mm (0.007 inches) of true position relative to a maximum-width tab when measured in the gaging plane between 1,371 mm (0.054 inches) and 1,397 mm (0.055 inches) below the seating plane.

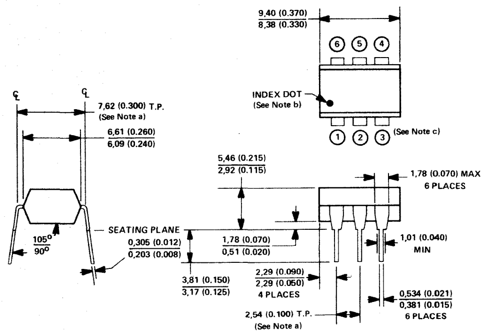
COMPATIBLE WITH STANDARD TTL INTEGRATED CIRCUITS

- **Gallium Arsenide Diode Infrared Source Optically Coupled to a Silicon N-P-N Phototransistor**
- **High Direct-Current Transfer Ratio**
- **Base Lead Provided for Conventional Transistor Biasing**
- **High-Voltage Electrical Isolation . . . 1.5-kV or 3.55-kV Rating**
- **Plastic Dual-In-Line Package**
- **High-Speed Switching: t_r = 5 μs, t_f = 5 μs Typical**
- **Designed to be Interchangeable with General Instruments MCT2 and MCT2E**

mechanical data

The package consists of a gallium arsenide infrared-emitting diode and an n-p-n silicon phototransistor mounted on a 6-lead frame encapsulated within an electrically nonconductive plastic compound. The case will withstand soldering temperature with no deformation and device performance characteristics remain stable when operated in high-humidity conditions. Unit weight is approximately 0.52 grams.



NOTES:

a. Leads are within 0,13 mm (0.005 inch) radius of true position (T.P.) with maximum material condition and unit installed.

b. Pin 1 identified by index dot.

c. Terminal connections:

1. Anode } Infrared-emitting diode
2. Cathode
3. No internal connection
4. Emitter } Phototransistor
5. Collector
6. Base

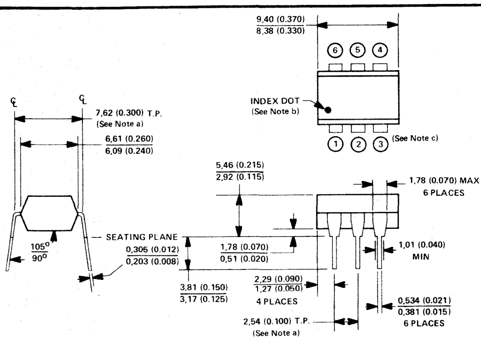
- Typical Applications Include Remote Terminal Isolation, SCR and Triac Triggers, Mechanical Relays, and Pulse Transformers

mechanical data

The package consists of a gallium arsenide infrared-emitting diode and an n-p-n silicon darlington-connected phototransistor mounted on a 6-lead frame encapsulated within an electrically nonconductive plastic compound. The case will withstand soldering temperature with no deformation and device performance characteristics remain stable when operated in high-humidity conditions. Unit weight is approximately 0.52 grams.



NOTES:

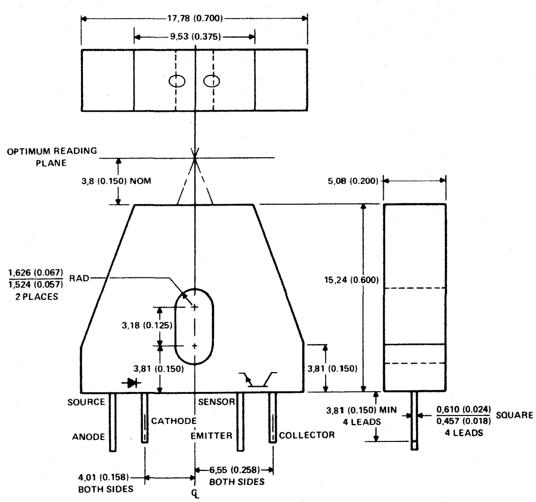
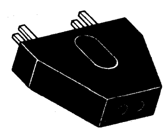
- Designed for Sensing Applications such as Line Finders, Batch Counters, Level Indicators, and Beginning-of-Tape/End-of-Tape Indicators

mechanical data

The assembly consists of an infrared emitting diode and an n-p-n silicon phototransistor mounted in a plastic housing. The assembly will withstand soldering temperature with no deformation and device performance characteristics remain stable when operated in high-humidity conditions. Total assembly weight is approximately 1.2 grams.





NOTE: Tolerance is ± 0,25 mm (0.010 inch) unless otherwise noted.

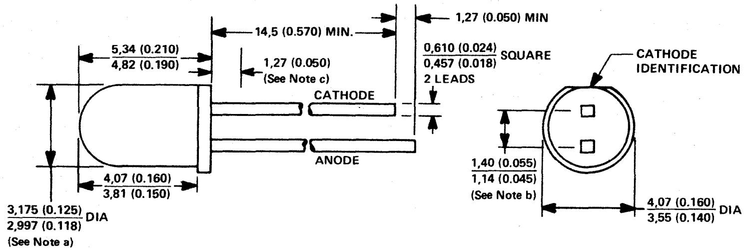
YELLOW, RED, OR GREEN HIGH-INTENSITY LIGHT SOURCES

- Good Viewing Angles
- Rugged Construction
- Solid-State Reliability
- Compatible with TTL Circuitry
- Versatile Mounting in PCB, Panel, or Socket

DEVICE	DESCRIPTION
TIL212	Yellow source Diffused yellow plastic body
TIL216	Red source Diffused red plastic body
TIL232	Green source Diffused green plastic body

mechanical data

These devices are similar in size to lamp style T-1 and may be panel-mounted using mounting clip TILM1 (formerely TIL209MC).



NOTES: a. This diameter is measured 0,127 mm (0.005 inches) from the shoulder.
b. Lead spacing is measured where the leads emerge from the package.
c. Within this zone the package contour is not controlled.

ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

GALLIUM ARSENIDE PHOSPHIDE LIGHT-EMITTING DIODES

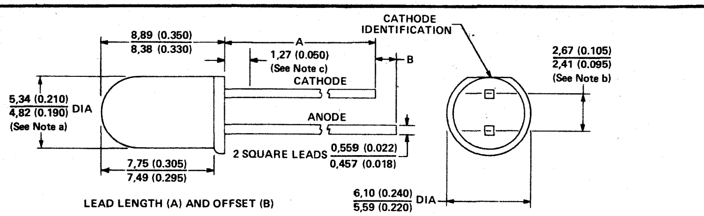
D1638, JULY 1973—REVISED FEBRUARY 1983

DESIGNED TO EMIT VISIBLE RED LIGHT WHEN FORWARD BIASED

- Recommended for Panel Mounted Visual Indicators
- High Brightness with Solid-State Reliability
- Compatible with Most TTL Circuits
- Leads of TIL220 and TIL221 are Designed to be Wire-Wrapped
- Leads of TIL220S are Designed for PCB Insertion
- Filled-Epoxy Lens of TIL220 and TIL220S Provides Diffused Source
- Clear-Epoxy Lens of TIL221 Provides Pin-Point Source

mechanical data

TIL220 and TIL220S both have red molded filled-epoxy bodies. TIL221 has a colorless clear molded epoxy body. The devices are similar in size to lamp style T1¾ and may be panel mounted using mounting clip TILM4.



LEAD LENGTH (A) AND OFFSET (B)

DEVICE	A	B
TIL220, TIL221	19 (0.750) MIN	1,27 (0.050) MIN
TIL220S	3,3 (0.130) MIN	0,25 (0.010) MIN

NOTES:
a. This diameter is measured 0,13 (0.005) above the shoulder.
b. Lead spacing is measured where the leads emerge from the package.
c. Within this zone the package contour is not controlled.

ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

absolute maximum ratings

Reverse Voltage at 25°C Free-Air Temperature	3 V
Continuous Forward Current at (or below) 25°C Free-Air Temperature (See Note 1)	50 mA
Power Dissipation	See Note 2
Operating Free-Air Temperature Range	−40°C to 80°C
Storage Temperature Range	−40°C to 100°C
Lead Temperature 1,6 mm (1/16 Inch) from Case for 3 Seconds	260°C

operating characteristics at 25°C free-air temperature

PARAMETER		TEST CONDITIONS	TIL220, TIL220S			TIL221			UNIT

TYPE TILM1 LED PANEL MOUNTING BUSHING

FORMERLY TIL209MC
FOR LIGHT-EMITTING DIODES SIMILAR IN SIZE TO LAMP STYLE T1

installation instructions

The bushing can be mounted in any panel having a thickness up to 2 mm (5/64 inch). To mount the bushing, drill a hole of diameter 5,2 mm (13/64 or 0.205 inch) and remove the extruded burr. Insert the bushing through the front of the panel. While holding the bushing in place, insert the LED from the rear of the panel until the LED snaps into place.

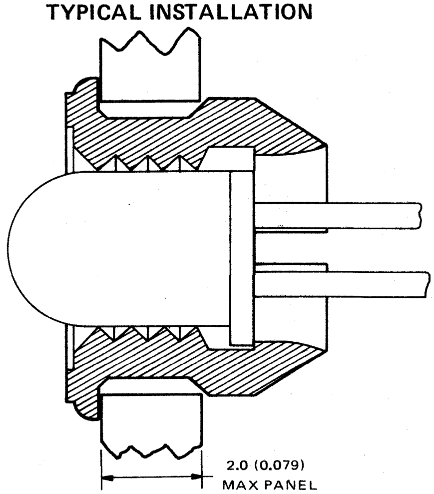
ALL DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES AND ARE NOMINAL

TYPICAL INSTALLATION



LED PANEL MOUNTING BUSHING WITH LOCK COLLAR

D2689, DECEMBER 1982

CAN BE USED AS A REPLACEMENT FOR TIL220MC AND TILM2 FOR LIGHT-EMITTING DIODES SIMILAR IN SIZE TO LAMP STYLE T1 3/4

installation instructions

This mounting bushing can be mounted in any panel having a thickness up to 3.2 mm (0.125 inch). To mount the bushing, drill a hole of diameter 6,35 mm (0.250 inch) and remove the extruded burr. Insert the bushing through the front of the panel. While holding the bushing in place, insert the LED from the rear of the panel until the LED snaps into place. The orientation of the flat side of the LED, which denotes the cathode lead, must be noted prior to insertion. After the LED is seated with its mounting flange snapped in the slot, push the lock collar over the rear side of the bushing until seated flush with the panel.

description

These displays are intended for use under pulsed conditions by enabling each character cathode sequentially and enabling the desired anodes in phase with the character-enabling pulse. The pulse rate is kept high enough so that the light from each character appears to the eye to be constant.

absolute maximum ratings

Reverse Voltage at 25°C Free-Air Temperature, Each Segment . . . . 5 V
Peak Forward Current at (or below) 25°C Free-Air Temperature, Each Segment . . . . 200 mA
Average Forward Current at (or below) 25°C Free-Air Temperature, Each Segment (See Note 1) . . . . 7 mA
Average Power Dissipation at (or below) 25°C Free-Air Temperature, Each Character (See Note 2) . . . . . . 138 mW
Operating Free-Air Temperature Range . . . . −40°C to 85°C
Storage Temperature Range . . . . −40°C to 100°C
Lead Temperature 1,6 mm (1/16 inch) below Seating Plane for 5 Seconds . . . . 260°C

operating characteristics of each segment at 25°C free-air temperature

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_v	Average Luminous Intensity per Character with All Segments Conducting Except DP and CO (See Note 3)	I_F = 30 mA per segment, See Note 4	0.45	1.65		mcd
λ_p	Wavelength at Peak Emission		640	655	680	nm
λ_d	Dominant Wavelength (See Note 5)			640		nm
$\Delta\lambda$	Spectral Bandwidth			20		nm
V_F	Static Forward Voltage	I_F = 30 mA		1.7	1.9	V
I_R	Static Reverse Current	V_R = 5 V		10	100	μA

NOTES: 1. This average applies for any 10-ms period.
2. Derate linearly to 62 mW at 85°C at the rate of 2.17 mW/°C.
3. Luminous intensity is measured with a light sensor and filter combination that approximates the CIE (International Comission on Illumination) eye-response curve. The luminous intensity ratio between segments within a digit is designed so that each segment will have the same luminance. Thus all the segments will appear to the eye to have equal brightness.
4. These parameters must be measured at t_w = 312 μs, duty cycle = 6.25%.
5. The dominant wavelength λ_d is derived from the CIE chromaticity diagram and is the single wavelength that defines the color of the emitted light.

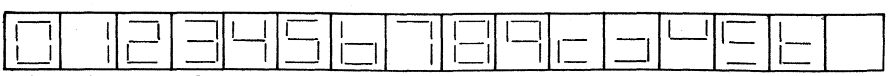
H = high level (logic 1 in positive logic), L = low level (logic 0 in positive logic), X = irrelevant.

†BI/RBO is wire-AND logic serving as blanking input (BI) and/or ripple-blanking output (RBO).

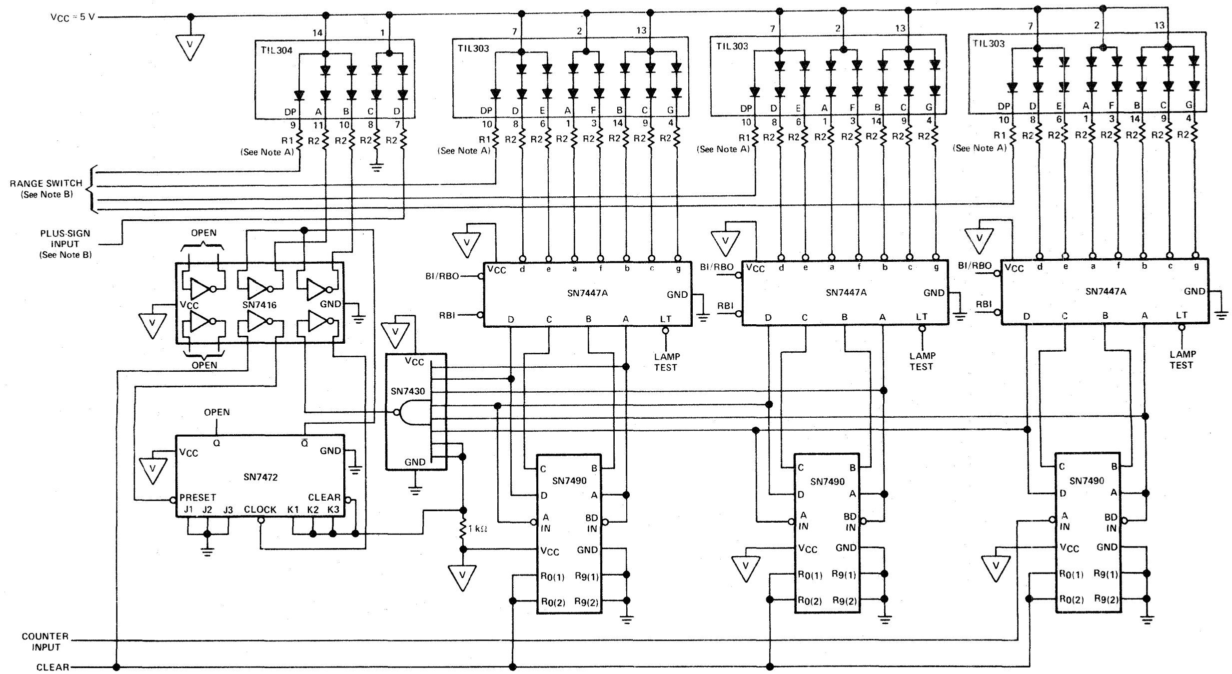
NOTES:
1. The blanking input (BI) must be open or held at a high logic level when output functions 0 through 15 are desired. The ripple-blanking input (RBI) must be open or high if blanking of a decimal zero is not desired.
2. When a low logic level is applied directly to the blanking input (BI), all segment outputs are off regardless of any other input.
3. When the ripple-blanking input (RBI) and inputs A, B, C, and D are at a low logic level with the lamp test input high, all segment outputs are off and the ripple-blanking output (RBO) of the decoder goes to a low level (response condition).
4. When the blanking input/ripple blanking output (BI/RBO) is open or held high and a low is applied to the lamp-test input, all segments are illuminated.



NUMERICAL DESIGNATIONS—RESULTANT DISPLAYS

TYPICAL APPLICATION DATA

The TIL303, TIL303A, TIL304, and TIL304A are used in this application to make a three-digit display with sign, which is capable of 100% overrance ("1" plus three digits). The decimal point is located via an external range switch. The clear function will blank the overflow digit and reset the three digits to zero. Following resetting, input pulses will be counted, decoded, and displayed.



NOTES: A. R1 and R2 are selected for desired brightness.
B. Grounding of any of these lines will illuminate the associated function.

SYNCHRONOUS BCD COUNTER, 4-BIT LATCH, DECODER/DRIVER, SEVEN-SEGMENT LED DISPLAY WITH DECIMAL POINT

TEXAS INSTRUMENTS
INCORPORATED
POST OFFICE BOX 225012 • DALLAS, TEXAS 75265

description

These internally-driven seven-segment light-emitting-diode (LED) displays contain a BCD counter, a four-bit latch, and a decoder/LED driver in a single 16-pin package. A description of the functions of the inputs and outputs of these devices follows:

FUNCTION	PIN NO.	DESCRIPTION
CLEAR INPUT	12	When low, resets and holds counter at 0. Must be high for normal counting.
CLOCK INPUT	15	Each positive-going transition will increment the counter provided that the circuit is in the normal counting mode (serial and parallel count enable inputs low, clear input high).
PARALLEL COUNT ENABLE INPUT (PCEI)	9	Must be low for normal counting mode. When high, counter will be inhibited. Logic level must not be changed when the clock is low.
SERIAL COUNT ENABLE INPUT (SCEI)	10	Must be low for normal counting mode, also must be low to enable maximum count output to go low. When high, counter will be inhibited and maximum count output will be driven high. Logic level must not be changed when the clock is low.
MAXIMUM COUNT OUTPUT	7	Will go low when the counter is at 9 and serial count enable input is low. Will return high when the counter changes to 0 and will remain high during counts 1 through 8. Will remain high (inhibited) as long as serial count enable input is high.
LATCH STROBE INPUT	5	When low, data in latches follow the data in the counter. When high, the data in the latches are held constant, and the counter may be operated independently.
LATCH OUTPUTS (Q_A, Q_B, Q_C, Q_D)	4, 1, 2, 3	The BCD data that drives the decoder can be stored in the 4-bit latch and is available at these outputs for driving other logic and/or processors. The binary weights of the outputs are: $Q_A = 1$, $Q_B = 2$, $Q_C = 4$, $Q_D = 8$.
DECIMAL POINT INPUT	13	Must be high to display decimal point. The decimal point is not displayed when this input is low or when the display is blanked.
BLANKING INPUT (BI)	14	When high, will blank (turn off) the entire display and force RBO low. Must be low for normal display. May be pulsed to implement intensity control of the display.
RIPPLE-BLANKING INPUT (RBI)	6	When the data in the latches is BCD 0, a low input will blank the entire display and force the RBO low. This input has no effect if the data in the latches is other than 0.
RIPPLE-BLANKING OUTPUT (RBO)	11	Supplies ripple-blanking information for the ripple-blanking input of the next decade. Provides a low if BI is high, or if RBI is low and the data in the latches is BCD 0; otherwise, this output is high. This pin has a resistive pull-up circuit suitable for performing a wire-AND function with any open-collector output. Whenever this pin is low the entire display will be blanked; therefore, this pin may be used as an active-low blanking input.

The TTL MSI circuits contain the equivalent of 86 gates on a single chip. Logic inputs and outputs are completely TTL/DTL compatible. The buffered inputs are implemented with relatively large resistors in series with the bases of the input transistors to lower drive-current requirements to one-half of that required for a standard Series 54/74 TTL input. The serial-carry input, actually two internal loads, is rated as one standard series 54/74 load.

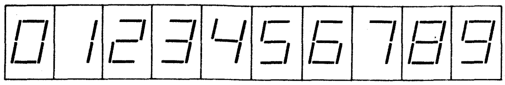
TEXAS INSTRUMENTS
INCORPORATED
POST OFFICE BOX 225012 • DALLAS, TEXAS 75265

description (continued)

The logic outputs, except RBO, are active pull-up, and the latch outputs Q_A, Q_B, Q_C, and Q_D are each capable of driving three standard Series 54/74 loads at a low logic level or six loads at a high logic level while the maximum-count output is capable of driving five Series 54/74 loads at a low logic level or ten loads at a high logic level. The RBO node with passive pull-up serves as a ripple-blanking output with the capability to drive three Series 54/74 loads.

The LED driver outputs are designed specifically to maintain a relatively constant on-level current of approximately seven milliamperes through each LED segment and decimal point. All inputs are diode-clamped to minimize transmission-line effects, thereby simplifying system design. Maximum clock frequency is typically 18 megahertz and power dissipation is typically 600 milliwatts with all segments on.

The display format is as follows:



The displays may be interconnected to produce an n-digit display with the following features:

- Ripple-blanking input and output for blanking leading or trailing zeroes
- Floating-decimal-point logic capability
- Overriding blanking for suppressing entire display or pulse-modulation of LED brightness
- Dual count-enable inputs for parallel look-ahead and serial ripple logic to build high-speed fully synchronous, multidigit counter systems with no external logic, minimizing total propagation delay from the clock to the last latch output
- Provision for ripple-count cascading between packages
- Positive-edge-triggered synchronous BCD counter
- Parallel BCD data outputs available to drive logic processors or remote slaved displays simultaneously with data being displayed
- Latch strobe input allows counter to operate while a previous data point is displayed
- Reset-to-zero capability with clear input.

absolute maximum ratings over operating case temperature range (unless otherwise noted)

Supply Voltage, V_{CC} (See Note 1): Continuous . . . . 5.5 V
Nonrepetitive Peak, $t_w \leq 100$ ms . . . . 7 V
Input Voltage (See Note 1) . . . . 5.5 V
Operating Case Temperature Range (See Note 2) . . . . 0°C to 85°C

description

These internally-driven seven-segment light-emitting-diode (LED) displays contain a five-bit latch and a decoder/LED driver in a single 16-pin package. A description of the functions of the inputs and outputs of these devices follows:

FUNCTION	PIN NO.	DESCRIPTION
LATCH STROBE INPUT	5	When low, the data in the latches follow the data on the latch inputs. When high, the data in the latches are held constant and are unaffected by new data on the latch inputs.
LATCH DATA INPUTS A, B, C, D, DP	15, 10, 6, 7, 12	Data on these inputs are entered into the latches under the control of the latch strobe input. The binary weights of the inputs are: A = 1, B = 2, C = 4, D = 8. DP is decimal point latch data input.
LATCH OUTPUTS Q_A, Q_B, Q_C, Q_D, Q_{DP}	4, 1, 2, 3, 14	The BCD data that drives the decoder is stored in the five latches and is available at these outputs. The binary weights of the outputs are: $Q_A = 1$, $Q_B = 2$, $Q_C = 4$, $Q_D = 8$. Q_{DP} is decimal point latch output.
BLANKING INPUT	11	When low, will blank (turn off) the entire display. Must be high for normal operation of the display.
LED TEST INPUT	13	When low, will turn on the entire display, overriding the data in the latches and the blanking input. Must be high for normal operation of the display.

FUNCTION TABLE

FUNCTION	LATCH INPUTS						BLANKING	LED	LATCH OUTPUTS					DISPLAY	
	D	C	B	A	DP	STROBE	INPUT	TEST	Q_D	Q_C	Q_B	Q_A	Q_{DP}	TIL308	TIL309

description (continued)

The TTL MSI circuits contain the equivalent of 78 gates on a single chip. Logic inputs and outputs are completely TTL/DTL compatible. The buffered inputs are implemented with relatively large resistors in series with the bases of the input transistors to lower drive-current requirements to one-half of that required for a standard Series 54/74 TTL input.

Some of the additional features of these displays are as follows:

- Latched BCD and decimal point logic outputs provided to drive logic processors simultaneously with the displayed data
- Minimum number of inputs required . . . 4-line BCD plus decimal point
- Overriding blanking for suppressing entire display or for pulse-modulation of LED brightness
- LED test input to simultaneously turn on all display segments and decimal point
- Can be operated in a real-time mode or latched-update-only mode by use of the latch strobe input
- Displays numbers 0 thru 9 as well as A, C, E, F, or minus sign
- Can be blanked by entry of BCD 13 or by use of the blanking input
- Decimal point controlled independently with decimal-point latch
- Constant-current-source TTL-LED interface for optimum performance.

The latch outputs except Q_{DP} are active pull-up, and each one, except Q_{DP}, is capable of driving three standard Series 54/74 loads. The LED driver outputs are designed specifically to maintain a relatively constant on-level current of approximately seven milliamperes through each LED segment and decimal point. All inputs are diode-clamped to minimize transmission-line effects, thereby simplifying system design. Power dissipation is typically 575 milliwatts with all segments on.

absolute maximum ratings over operating case temperature range (unless otherwise noted)

Supply Voltage, V_{CC} (See Note 1): Continuous . . . . 5.5 V
Nonrepetitive Peak, $t_w \leq 100$ ms . . . . 7 V
Input Voltage (See Note 1) . . . . 5.5 V
Operating Case Temperature Range (See Note 2) . . . . 0°C to 85°C
Storage Temperature Range . . . . −25°C to 85°C

NOTES: 1. Voltage values are with respect to network ground terminal.
2. Case temperature is the surface temperature of the plastic measured directly over the integrated circuit. Forced-air cooling may be required to maintain this temperature.

NOTES:
a. All linear dimensions are in millimeters and parenthetically in inches.
b. Lead dimensions are not controlled above the seating plane.
c. Centerlines of character segments and decimal points are shown as dashed lines. Associated dimensions are nominal.
d. The true-position pin spacing is 2,54 mm (0.100 inch) between centerlines. Each centerline is located within 0,26 mm (0.010 inch) of its true longitudinal position relative to pins 1 and 14.
e. On TIL311A devices, the 3 mold indentations are not present.

description

This hexadecimal display contains a four-bit latch, decoder, driver, and 4 X 7 light-emitting-diode (LED) character with two externally-driven decimal points in a 14-pin package. A description of the functions of the inputs of this device follows.

FUNCTION	PIN NO.	DESCRIPTION
LATCH STROBE INPUT	5	When low, the data in the latches follow the data on the latch data inputs. When high, the data in the latches will not change. If the display is blanked and then restored while the enable input is high, the previous character will again be displayed.
BLANKING INPUT	8	When high, the display is blanked regardless of the levels of the other inputs. When low, a character is displayed as determined by the data in the latches. The blanking input may be pulsed for intensity modulation.
LATCH DATA INPUTS (A, B, C, D)	3, 2, 13, 12	Data on these inputs are entered into the latches when the enable input is low. The binary weights of these inputs are A = 1, B = 2, C = 4, D = 8.
DECIMAL POINT CATHODES	4, 10	These LEDs are not connected to the logic chip. If a decimal point is used, an external resistor or other current-limiting mechanism must be connected in series with it.
LED SUPPLY	1	This connection permits the user to save on regulated V_{CC} current by using a separate LED supply, or it may be externally connected to the logic supply (V_{CC}).
LOGIC SUPPLY (V_{CC})	14	Separate V_{CC} connection for the logic chip.
COMMON GROUND	7	This is the negative terminal for all logic and LED currents except for the decimal points.

The LED driver outputs are designed to maintain a relatively constant on-level current of approximately five milliamperes through each of the LED's forming the hexadecimal character. This current is virtually independent of the LED supply voltage within the recommended operating conditions. Drive current varies slightly with changes in logic supply voltage resulting in a change in luminous intensity as shown in Figure 2. This change will not be noticeable to the eye. The decimal point anodes are connected to the LED supply; the cathodes are connected to external pins. Since there is no current limiting built into the decimal point circuits, this must be provided externally if the decimal points are used.

The resultant displays for the values of the binary data in the latches are as shown below.

mechanical data

The GaAsP monolithic chips (one for each digit) are mounted on a printed-circuit board. A clear plastic lens is attached to the p-c board providing protection for the chips and resulting in a magnified digit image of 2,6 mm (0.102 inch). The same lens is used for all three types.

The display may be mounted by use of a lead-frame assembly on 2,54-mm (0.100-inch) centers with the pins soldered into the p-c board holes, or by insertion into a p-c board edge connector. A rosin-core 60/40 tin/lead wire solder or a low-temperature deactivating flux with solid-core 60/40 solder can be used for hand-soldering operations.

Chlorinated hydrocarbon solvents must not be used for cleaning as the plastic lens may be damaged. Methanol, isopropanol, ethanol, Freon TP-35†, or Freon TE-35† solvents may be used with caution. Time must be allowed for the solvent to evaporate from beneath the display lens.

mechanical data (continued)

The display chips are mounted on a lead frame, and this assembly is then molded within an electrically nonconductive plastic case. To optimize device performance, materials are used that are limited to certain solvents for cleaning operations. It is recommended that only Freon TF†, isopropanol, or water be used. For high contrast, the displays have a gray top surface.

SOLID-STATE COMMON-CATHODE RED DISPLAY WITH RIGHT-HAND DECIMAL POINTS

- 6,9-mm (0.270-Inch) Character Height
- Multiplex Operation — Minimum Pin Connections
- High Luminous Intensity
- Wide Viewing Angle
- Viewing Distance up to 4.5 Meters (15 Feet)

applications

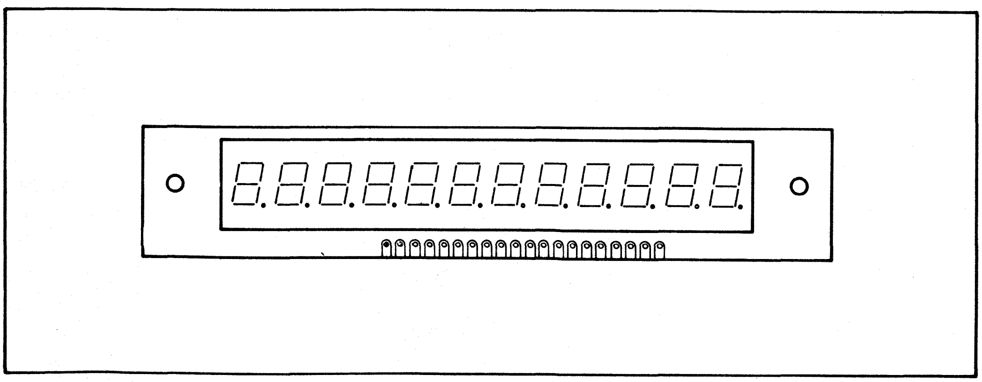
- Digital Frequency Read-Out
- Calculators
- Instrumentation Displays
- Data Terminals

description

This multidigit display is formed by mounting and bonding LED chips on a printed circuit board. Individual reflectors are used over the LED chips on each digit to form the segments. A diffuser placed over the reflectors results in a uniformly bright segment with a high contrast ratio.

The anodes of all like-positioned segments are connected together on the printed circuit board and brought out to a common pad connection. This type of configuration requires a minimum number of pad connections, but it requires that the display be used in a multiplexed mode. Each character is enabled sequentially by its cathode line and the desired segment and decimal anodes are enabled in phase with the cathode enabling pulse.

A peak current of 96 milliamperes is recommended for normal operating conditions at a duty cycle of 8.3% to obtain adequate display brightness. The pulse rate should be high enough so that the light from each character appears constant. A minimum pulse rate of 60 hertz can be used; however, rates of one kilohertz to ten kilohertz are recommended.



Copyright © 1982 Texas Instruments Incorporated

mechanical data

The display may be mounted by soldering the pads directly to another printed-circuit board, by use of a lead-frame assembly on 0.100-inch centers with the pins soldered into the p-c board holes, or by insertion into a p-c board edge connector. A rosin-core 60/40 tin/lead solder, or a solid-core 60/40 solder with a low-temperature deactivating flux can be used for hand-soldering operations. Soldering temperature of each pad should not exceed 230°C for five seconds. Care should be exercised to keep the temperature of the plastic cover below 100°C as higher temperatures or direct contact of a hot soldering iron with the plastic could cause distortion or deformation of the character appearance.

Flux clean up using chlorinated hydrocarbon solvents should be avoided as they may damage the plastic parts. Methanol, isopropanol, ethanol, or Freon† TP-35 may be used with caution. Solvents can leave residues that may blur or obstruct the image.

product options

Texas Instruments Incorporated can supply multidigit displays that are variations of the basic 12-digit TIL804. Options include fewer digits or decimal points than 12 each and a choice of location of the omitted digits or decimal points. Fewer than eight digits are not recommended in order to be effective from the standpoints of cost and physical size. For custom arrangements contact your TI field office or Optoelectronics Marketing at the following address:

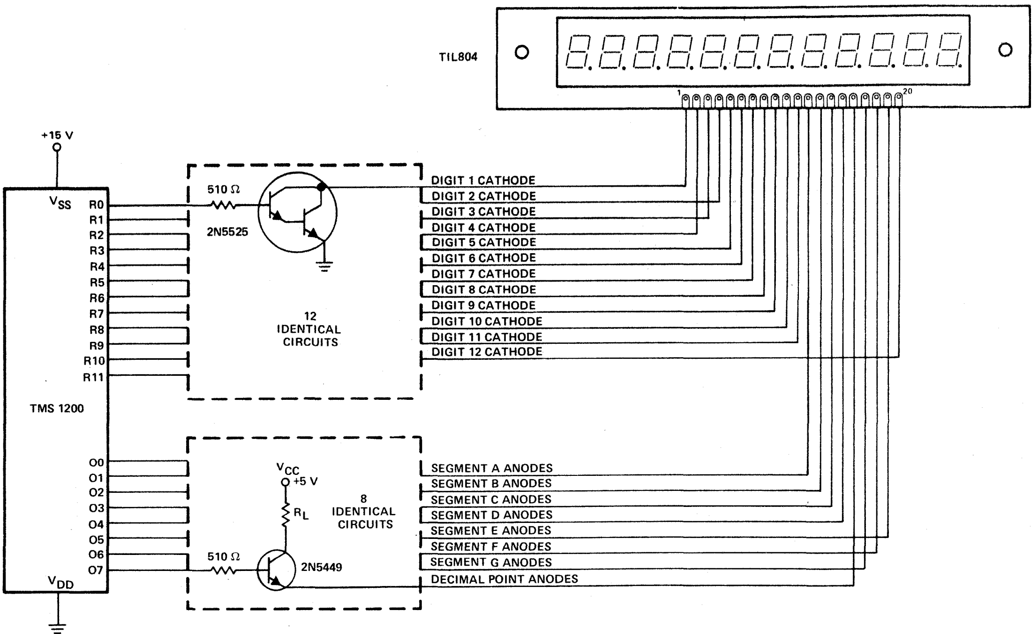
TYPICAL APPLICATION DATA

Each digit of the display is connected in a common-cathode configuration and the anodes of like-positioned segments of all digits are connected together for multiplex operation. Normal operation of each digit is 8.3% (1/12) duty cycle or less, except on custom devices with fewer digits. For example, a device with eight digits might be operated at 12.5% (1/8) duty cycle.

Figure 3, below, shows a typical interface circuit between the TIL804 and a TMS 1200 microcomputer. The typical conditions shown are intended as a guide only. These conditions will give a bright display easily read under high ambient light conditions as would be found in an office or laboratory; that is, 25 to 50 foot candles. If a brighter display is required, the average and peak currents through the segments could be increased.

Note that the display is to be operated under multiplexed conditions only.



$$R_L = \frac{V_{DD} - V_{CE(sat)}\ (2N5449) - V_{CE(sat)}\ (2N5525) - V_{F(LED)}}{I_{FM}}$$

TYPICAL CONDITIONS

$V_{CC} = 5$ V
$V_{CE(sat)}$ (2N5449) = 0.2 V
$V_{CE(sat)}$ (2N5525) = 1.0 V
$V_{F(LED)} = 1.8$ V
$I_{FM} = 96$ mA
Duty Cycle = 8.3%
$R_L = 21\ \Omega$

H = high level (logic 1 in positive logic), L = low level (logic 0 in positive logic), X = irrelevant.

†BI/RBO is wire-AND logic serving as blanking input (BI) and/or ripple-blanking output (RBO).
‡These segments would be on if the SN74247 or SN74LS247 were used.

NOTES: 1. The blanking input (BI) must be open or held at a high logic level when output functions 0 through 15 are desired. The ripple-blanking input (RBI) must be open or high if blanking of a decimal zero is not desired.
2. When a low logic level is applied directly to the blanking input (BI), all segment outputs are off regardless of any other input.
3. When the ripple-blanking input (RBI) and inputs A, B, C, and D are at a low logic level with the lamp test input high, all segment outputs are off and the ripple-blanking output (RBO) of the decoder goes to a low level (response condition).
4. When the blanking input/ripple blanking output (BI/RBO) is open or held high and a low is applied to the lamp-test input, all segments are illuminated.

*description

This hexadecimal display contains a four-bit latch, decoder, driver, and 4 X 7 light-emitting-diode (LED) character with two externally driven decimal points in a 14-pin package. A description of the functions of the inputs of this device follows.

FUNCTION	PIN NO.	DESCRIPTION
LATCH STROBE INPUT	6	When low, the data in the latches follow the data on the latch data inputs. When high, the data in the latches will not change. If the display is blanked and then restored while the enable input is high, the previous character will again be displayed.
BLANKING INPUT	8	When high, the display is blanked regardless of the levels of the other inputs. When low, a character is displayed as determined by the data in the latches. The blanking input may be pulsed for intensity modulation.
LATCH DATA INPUTS (A, B, C, D)	3, 2, 13, 12	Data on these inputs are entered into the latches when the enable input is low. The binary weights of these inputs are A = 1, B = 2, C = 4, D = 8.
DECIMAL POINT CATHODES	4, 10	These LEDs are not connected to the logic chip. If a decimal point is used, an external resistor or other current-limiting mechanism must be connected in series with it.
LED SUPPLY	1	This connection permits the user to save on regulated V_{CC} current by using a separate LED supply, or it may be externally connected to the logic supply (V_{CC}).
LOGIC SUPPLY (V_{CC})	14	Separate V_{CC} connection for the logic chip.
COMMON GROUND	7	This is the negative terminal for all logic and LED currents except for the decimal points.

The LED driver outputs are designed to maintain a relatively constant on-level current of approximately five milliamperes through each of the LED's forming the hexadecimal character. This current is virtually independent of the LED supply voltage within the recommended operating conditions. Drive current varies with changes in logic supply voltage resulting in a change in luminous intensity as shown in Figure 2. The decimal point anodes are connected to the LED supply; the cathodes are connected to external pins. Since there is no current limiting built into the decimal point circuits, this must be provided externally if the decimal points are used.

The TTL MSI chip is specially designed with a wider supply voltage range than standard Series 54/74 circuits so that it will operate from either a five-volt or a six-volt power supply.

The resultant displays for the values of the binary data in the latches are as shown below.

c. Centerlines of character segments and decimal points are shown as dashed lines. Associated dimensions are nominal.

*description

The 4N57 contains a seven-segment numeric display with left-hand decimal and a TTL MSI BCD-to-seven-segment decoder and driver. It accepts four-line binary-coded-decimal (BCD) input in negative logic and displays the decimal number in a seven-segment format. Invalid inputs are automatically blanked (see function table). A low-logic-level voltage (≤0.8 V) at the decimal point input turns on the decimal independently of the BCD inputs. The decimal point, as well as each segment, is driven by a constant current from the logic chip. Varying the LED supply voltage will not significantly affect the brightness of the display. The brightness may be controlled by pulse-width modulation of the BCD inputs alternating between a valid code and an invalid code (e.g., all inputs low).

*description

The 4N58 is a 5 X 7 matrix of light-emitting diodes plus a decimal point. The device includes an IC logic chip similar to SN54174 containing six D-type flip-flops that can transfer data from a character generator to the five columns of the matrix and the decimal point. The chip also includes six cathode column drivers with series limiting resistors.

The rows are strobed by sequentially applying a positive voltage to each row input. As each row is strobed the data set up at column inputs are transferred to the column drivers on the rising edge of each clock pulse. A high column input causes the LED to turn on. After the minimum hold time requirement has been satisfied, the column data inputs may change whether the clock is high or low.

YELLOW HEXADECIMAL DISPLAY WITH LOGIC

description

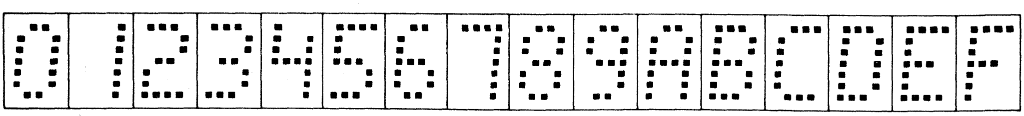
The TIL509 is a hexadecimal display containing a four-bit latch, decoder, driver, and 4 X 7 yellow light-emitting diode (LED) character with two externally driven decimal points in a 14-pin package. Electrically this device is identical to the TIL311 and 4N56.

FUNCTION	PIN NO.	DESCRIPTION
LATCH STROBE INPUT	6	When low, the data in the latches follow the data on the latch data inputs. When high, the data in the latches will not change. If the display is blanked and then restored while the enable input is high, the previous character will again be displayed.
BLANKING INPUT	8	When high, the display is blanked regardless of the levels of the other inputs. When low, a character is displayed as determined by the data in the latches. The blanking input may be pulsed for intensity modulation.
LATCH DATA INPUTS (A, B, C, D)	3, 2, 13, 12	Data on these inputs are entered into the latches when the enable input is low. The binary weights of these inputs are A = 1, B = 2, C = 4, D = 8.
DECIMAL POINT CATHODES	4, 10	These LEDs are not connected to the logic chip. If a decimal point is used, an external resistor or other current-limiting mechanism must be connected in series with it.
LED SUPPLY	1	This connection permits the user to save on regulated V_{CC} current by using a separate LED supply, or it may be externally connected to the logic supply (V_{CC}).
LOGIC SUPPLY (V_{CC})	14	Separate V_{CC} connection for the logic chip.
COMMON GROUND	7	This is the negative terminal for all logic and LED currents except for the decimal points.

The LED driver outputs are designed to maintain a relatively constant on-level current of approximately five milliamperes through each of the LED's forming the hexadecimal character. This current is virtually independent of the LED supply voltage within the recommended operating conditions. Drive current varies with changes in logic supply voltage resulting in a change in luminous intensity as shown in Figure 2. The decimal point anodes are connected to the LED supply; the cathodes are connected to external pins. Since there is no current limiting built into the decimal point circuits, this must be provided externally if the decimal points are used.

The TTL MSI chip is specially designed with a wider supply voltage range than standard Series 54/74 circuits so that it will operate from either a five-volt or a six-volt power supply.

The resultant displays for the values of the binary data in the latches are as shown below.



0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15

operating characteristics at 25°C free-air temperature

PARAMETER		TEST CONDITIONS		MIN	TYP	MAX	UNIT
$V_{(BR)CEO}$	Collector-Emitter Breakdown Voltage	I_C = 100 μA, See Note 2	P_I = 0,	30			V
$V_{(BR)ECO}$	Emitter-Collector Breakdown Voltage	I_E = 100 μA,	P_I = 0	7			V
I_D	Dark Current	V_{CE} = 10 V,	P_I = 0		5	40	nA
R_e	Radiant Responsivity (see Note 3)	V_{CC} = 5 V, See Figure 1	P_I = 1 μW,	60	120		A/W
t_r	Rise Time (see Note 4)	V_{CC} = 5 V, See Figure 2	R_L = 100 Ω		10		ns
			R_L = 1 kΩ		25		
			R_L = 10 kΩ		150		

NOTES: 2. The radiant power input P_I is the radiant power measured with a large-area detector from the output end of a 10-m fiber-optic cable assembly incorporating a graded-index optical fiber with a 100-μm core diameter, a 140-μm cladding diameter, and a numerical aperture of ≤0.30. A TIES495 GaAlAs infrared-emitting diode with λ_p = 820 nm is used at the input end of the fiber-optic cable assembly. The TIES495 has a typical half-intensity beam angle of 20°.

3. Radiant responsivity is defined as the change of detector current output divided by the change of radiant power input P_I.

4. Rise time is the time required for a change in detector current output from 10% to 90% of its peak value for a step change of incident radiant power. The fall time is approximately equal to the rise time.

		t_w = 250 ns,	See Figure 3					35	50	
I_{CC}	Supply Current	P_I = 0,	See Figure 1	3	4.0	5	3.3	4.4	5.5	mA

*Radiant responsivity is defined as the absolute change of output voltage divided by the change of radiant power input P_I. The steady-state radiant responsivity $R_{e(s)}$ applies for incident radiant power pulse durations of greater than 2 μs. The pulse radiant responsivity for short radiant power pulse durations is discussed below. The maximum output voltage change should be less than 0.7 V to maintain linear operation and to minimize pulse duration distortion. Bypass capacitors between V_{CC} (Pin 4) and GND (Pin 3) are required; a 1-μF tantalum capacitor in parallel with a 0.01-μF ceramic disc capacitor is recommended to be placed as close as possible to the device pins.

†The output voltage response to a step change of incident radiant power consists of two components: a fast component due to radiation absorbed in the photodiode high-field junction depletion region, and a slow component due to radiation absorbed in the photodiode nondepleted regions. The amplitude of the fast component is characterized by the pulse radiant responsivity $R_{e(p)}$ for short incident radiant power pulse durations.

‡Equivalent input noise radiant power P_n equals the RMS output noise voltage V_n divided by the steady-state radiant responsivity $R_{e(s)}$.

§The radiant power input P_I is the radiant power measured with a large-area detector from the output end of a 10-m fiber-optic cable assembly that incorporates a graded-index optical fiber with a 100-μm core diameter, a 140-μm cladding diameter, and a numerical aperture of ≤ 0.30. A TIES495 820-nm GaAlAs infrared-emitting diode is used at the input end of the fiber optic cable assembly. The TIES495 has a typical half-intensity beam angle of 20 degrees.

¶Capacitive coupling is required for load resistances smaller than 10,000 ohms to minimize disturbance of the quiescent dc output voltages.

#The pulsed transition time $t_{t(p)}$ is the time required for the output voltage to change from 20% to 80% of its peak value for short incident radiant power pulse durations. The transition time of the trailing edge is approximately equal to that of the leading edge. The output voltage pulse duration is typically 6 ns less than the incident radiant power pulse duration due to differences of propagation delay times for the leading and trailing transitions. The overall 10% to 90% rise time is typically 250 ns for pulse durations greater than 2 μs.

		TIES495		50	75	160	
		TIES496		80	110	240	
P_O	Pulsed Radiant Power Output (see Note 4)	TIES494	I_{FM} = 100 mA, See Note 5		90		μW
		TIES495			150		
		TIES496			220		
λ_p	Wavelength at Peak Emission		I_F = 50 mA	790	820	860	nm
$\Delta\lambda$	Spectral Bandwidth		I_F = 50 mA		40		nm
θ_{HI}	Half-Intensity Beam Angle		I_F = 50 mA		20°		
V_F	Static Forward Voltage		I_F = 50 mA		1.6	2	V
V_F	Forward Voltage		I_F = 100 mA, See Note 5		1.8		V
C	Capacitance		V_F = 0		200		pF
t_r	Radiant Pulse Rise Time (see Note 6)		I_{FM} = 50 mA, $t_w \geq$ 100 ns, See Figure 2		12	20	ns

NOTES: 4. The radiant power output, P_O, is the radiant power transmitted through a 0,2-mm (0.008-inch) diameter mechanical aperture into a numerical aperture of 0.25. The radiant power coupled into a graded-index optical fiber with a 100-μm core diameter, a 140-μm cladding diameter, and a numerical aperture of 0.3 is typically 24% of P_O. The radiant power coupled into a graded-index optical fiber with a 50-μm core diameter, a 125-μm cladding diameter, and a numerical aperture of 0.2, is typically 4.5% of P_O.
5. These parameters must be measured using pulse techniques. $t_w \leq 100\ \mu s$, duty cycle ≤50%.
6. Radiant pulse rise time is the time required for a change in radiant intensity from 10% to 90% of its peak value for a step change in forward diode current. The typical electrical bandwidth (in MHz) at which the radiant power output is reduced to $1/\sqrt{2}$ of the maximum low-frequency value is approximately $350/t_r$ (t_r in ns) or 29 MHz. The typical optical bandwidth at which the radiant power output is reduced to 1/2 of the maximum low-frequency value is approximately $610/t_r$ or 50 MHz. The radiant pulse fall time is typically equal to or less than the radiant pulse rise time.

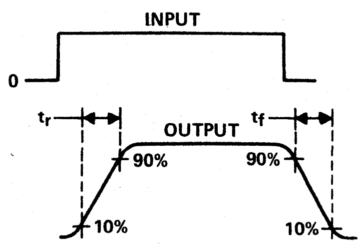
Adjust amplitude of input pulse for I_{FM} = 50 mA



WAVEFORMS

NOTES: a. The input current waveform is supplied by a pulse generator with the following characteristics: Z_o = 50 Ω, $t_w \geq$ 100 ns, $t_r \leq$ 2ns.

b. The output waveform is monitored on an oscilloscope with the following characteristics: Z_{in} = 50 Ω, $t_r \leq$ 2 ns. The measured rise time is corrected for the combined rise times (≤6 ns) of the receiver circuit and the oscilloscope.

High-Reliability Optoelectronic Products

Texas Instruments offers a large selection of high-reliability optoelectronic devices consisting of displays, optocouplers, infrared emitters, and infrared detectors/sensors. See referenced data sheets listed below for complete specifications on each device.

HI-REL LED DISPLAYS

- **In moisture-resistant ceramic packages**
- **TTL compatibility and reliability**

Available in

- **High-intensity red or yellow**
- **7-segment red**
- **Hexadecimal red or yellow**
- **Alphanumeric red or yellow**

For applications involving military or adverse environmental conditions, TI offers a variety of high-reliability moisture-resistant displays. These red and yellow LED displays offer high luminous intensity coupled with a wide viewing angle and low power requirements.

JEDEC PART NO.	TI PART NO.	TYPE OF CHARACTER	CHARACTER HEIGHT mm (INCHES)	COLOR OF DISPLAY	PACKAGE	REMARKS	PAGE
4N41	TIL501*	7-segment	6,9 (0.270)	Red	14-lead hermetically sealed dual-in-line	Electrically and mechanically interchangeable with TIL302	11-3

*These part numbers have been replaced by the JEDEC part numbers shown.

HI-REL OPTOCOUPLERS (OPTOISOLATORS)

- Hermetically sealed TO-72 and TO-78 metal-can packages
- JAN, JANTX, and JANTXV versions available (4N22 and 4N47 series)
- Stable over wide temperature ranges
- High current transfer ratios (CTR)
- High-voltage electrical isolation . . . 1-kV rating

*"Super-couplers" are optocouplers having high CTR (current transfer ratio) at low I_F.

HI-REL EMITTERS AND DETECTORS

- **Hermetically sealed packages**
- **Wide temperature storage and operating range**
- **Spectrally and mechanically matched IR pairs**
- **Pill packages and TO-18 packages**

The devices listed below are subjected to the processing and lot acceptance in accordance to the sequence of tests in MIL-S-19500 for JANTX types. These are not to be construed to be JANTX-qualified parts. A detail specification is available upon request through your Field Sales Office or Optoelectronics Marketing at the following address:

Quality and Reliability

- Quality/Reliability Program
- Device Reliability Data

TEXAS INSTRUMENTS QUALITY/RELIABILITY PROGRAM FOR OPTOELECTRONICS

Texas Instruments has an extensive commitment to produce optoelectronic products with the highest quality and reliability performance possible. TI monitors the entire semiconductor process, from the earliest stages of crystal formation through completion of the final device. These monitored processes which follow rigid Quality Standards are illustrated in Table I. As an added emphasis on our quality trust, TI incorporates Quality Reviews with some of our major customers to monitor their incoming inspection reports with our reporting system. These customers' inputs are reviewed on a monthly basis by the top management of Texas Instruments and are used to constantly update our standard within the industry. Our continuing goal is to be the Number 1 supplier in the industry, and we have set up our QA Program to meet this challenge.

The broad spectrum of industrial and/or military applications demand our products to be operative under adverse conditions and prolonged usage. Refer to Table II for our overall testing capability. Table III defines the military standard test capabilities available at TI.

Extensive facilities are used in our failure analysis laboratory to analyze in-house and field failures of our products. Table IV illustrates our Failure Analysis Procedures and our test facilities.

In summary, this chapter includes the following tables:

Table I	General Standard Device Flow
Table II	Overall Test Capability
Table III	Military Standard Test Capability
Table IV	Failure Analysis Capability

Reliability data on our products is consolidated every 3 months and is available upon request by contacting your local TI Field Sales Office or by contacting TI direct.

Table I. General Standard Device Flow

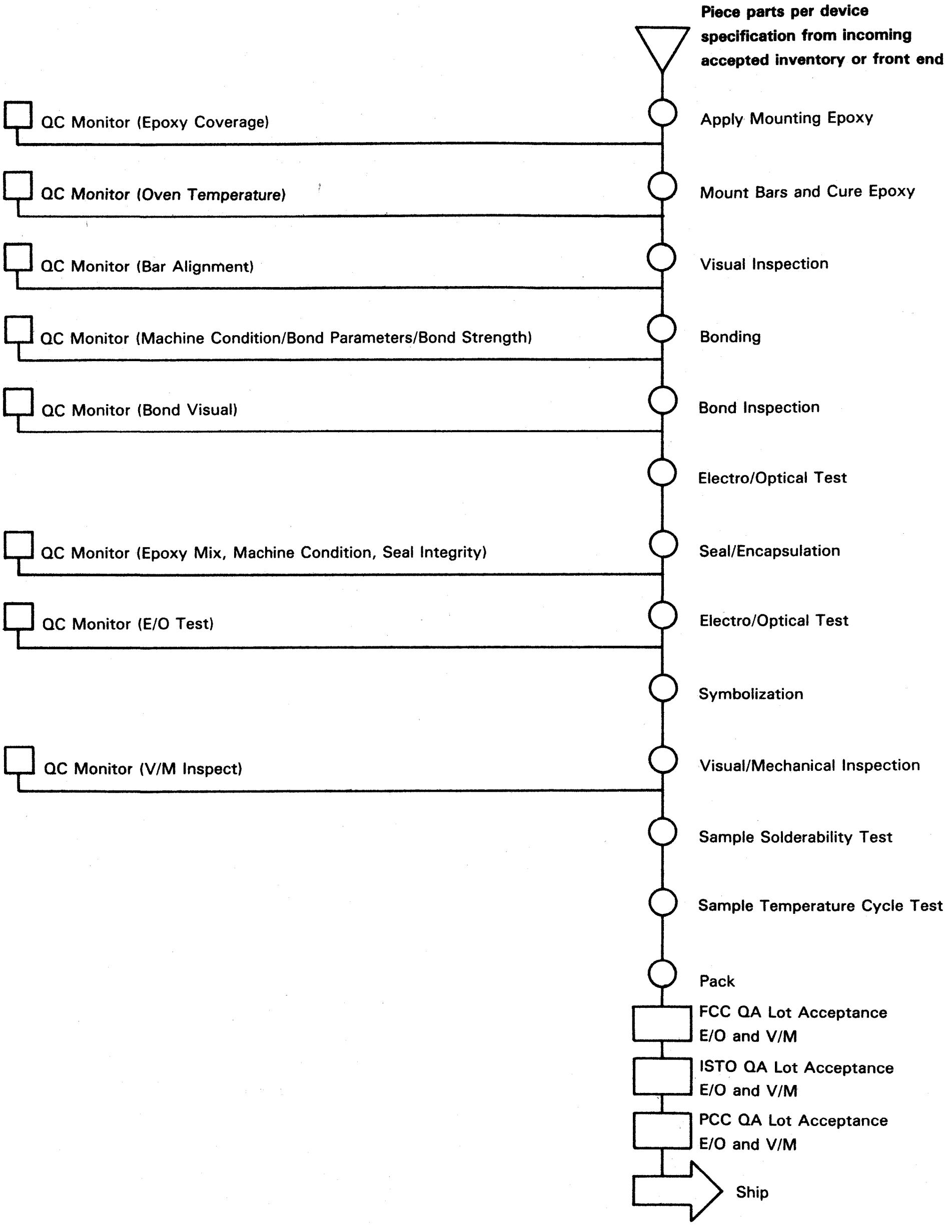

Table II. Overall Test Capability

Test	Capability
Acceleration, Sustained (Centrifuge)	50 to 50,000 G (standard) 50,000 to 125,000 G (nonstandard)*
Bond Strength	0 to 25 grams
Altitude (Barometric Pressure, Reduced)	150,000 ft simulated altitude
Dew Point	−65 °C to 150 °C
Electrostatic Susceptibility, MIL-STD-883, Method 3015	
Flammability	800 °C to 1100 °C
Moisture Resistance	+2 °C to +96 °C, 40% to 100% RH
Particle Detection	
Acoustical (PIND)	$\geq$0.1 microgram
Electrical	Intermittency $\geq$ 1 μs with 100-mV amplitude
Pressure Cooker	0 to 15 psig of steam pressure
Radiographic Inspection (X-Ray)	
Film	Resolution to 0.001 inch, 150 kV, 5 mA
Real Time	360° rotation — Resolution to 0.001 inch
Salt Atmosphere/Spray	25 °C to 45 °C, up to 20% salt solution
Seal	
Gross Leak	
Bubble	$\geq 1 \times 10^{-5}$ atm cm^3/s
Dye Penetrant	$\geq 5 \times 10^{-6}$ atm cm^3/s
Weight Gain	$> 2 \times 10^{-6}$ atm cm^3/s
Radioactive Tracer Gas	$\geq 1 \times 10^{-10}$ atm cm^3/s
Symbolization (Resistance to Solvents)	
Shock (Mechanical)	To limits of: MIL-STD-202, Method 213 MIL-STD-750 MIL-STD-810, Method 516 MIL-STD-883
Solderability, Meniscograph	MIL-STD-883, Method 2022
Solderability/Soldering	Up to 280 °C
Temperature Cycling	−185 °C to 300 °C
Terminal Strength (Lead Integrity)	Lead Fatigue, Tension, Torque
Thermal Shock	−196 °C to 200 °C
Ultrasonics	0 to 100 psi at 40 kHz or 25 kHz
Ultraviolet Exposure	To 12.5 mW/cm^2
Vibration, Fatigue	10 to 100 Hz, 5 to 70 G
Vibration, Random	20 to 2000 Hz, Power Spectral Density 1.3 G^2/Hz
Vibration, Variable	5 to 2000 Hz as limited by 1 inch double amplitude and 60 inches/second velocity. 0 to 70 G (standard), 70 to 100 G (nonstandard)*

*Limited fixture availability.

†Call Physical Test supervisor for available fixtures
*Also perform mechanical shock per MIL-STD-810B, Method 516.

Table III. Military Standard Test Capability (Continued)

TEST CATEGORY	MIL-STD-202	MIL-STD-750	MIL-STD-883
Vibration, Random‡	All Conditions		
Vibration, Variable Frequency‡	All Conditions	All Conditions	All Conditions
X-Ray, Film§	All Conditions	All Conditions	All Conditions
X-Ray, Real Time (TV X-Ray)§	All Conditions	All Conditions	All Conditions

‡ Also perform random vibration and vibration, variable frequency per MIL-STD-810B, Method 514.1, procedures I, II, III, IV, V, VI, and VII. Omit paragraph 4.5.1.1, Resonant Search, and paragraph 4.5.1.2, Resonant Dwell.

§ Radiographic inspection is performed in accordance with many government and customer specifications. Before any new radiographic specification is acceptable for use as a test standard within the Semiconductor Group, it must be approved by Environmental Test Services. For questions pertaining to a particular specification, contact the Radiographic Group supervisor or cost center manager—phone (214) 995-3397 or 995-3931.

Table IV. Failure Analysis Capabilities

I. Nondestructive Techniques
- A. Hermeticity evaluation
- B. X-ray interpretation of bonding and die mount.
- C. Electrical characterization
  1. Breakdown, leakage, and functional tests run at temperature extremes.
  2. Polaroid documentation of curve traces and/or oscilloscope traces

II. Destructive Techniques
- A. Decapsulation/Delid of devices
- B. Probe and isolation of electrical defects
- C. Layer-by-layer removal of device levels by selective etching
- D. Microsection analysis
  1. Sections taken at shallow to 90° angles — sample sizes to 1.5 inches
  2. Selective staining to delineate diffusions, dielectrics, etc.
  3. Thickness measurements by SEM or optical microscopy
- E. Optical microphotography — magnifications to 5000X
- F. Infrared microscopy — transmission and reflection
- G. Nanometrics
- H. Planar plasma etching
- I. Scanning electron microscopy — SEM
  1. Routine magnification to 50,000X
  2. 50-Å resolution
  3. Back-scattered electron detector
  4. Military product lot acceptance of metallization
  5. Voltage contrast
  6. Specimen current amplifier
- J. Electron microprobe
  1. Chemical detection of elements with atomic number greater than 11.
  2. Typical 4- to 5-μm beam penetration
  3. Spot size typically 1000 to 2000 Å
- K. Auger spectroscope
- L. Ion microprobe mass analysis
- M. Gas and/or plastic composition analysis

LS600 RELIABILITY DATA

INTRODUCTION

Texas Instruments designs and builds quality and reliability into all the products that it offers in the electronic marketplace. The quality control organization is uniquely responsible for coordinating the total effort and for providing direct action necessary to assure that quality and reliability objectives are met. Accordingly, quality control reaches from raw material inputs to evaluation of finished goods as evidenced by the many inspections and tests shown on the typical light sensor flow diagram in Figure 1.

The reliability data shown in this report is based on extensive tests performed by Texas Instruments to assure continued leadership in optical sensor quality and reliability. More than 42,200 units have been subjected to life test with an accumulation of over 39,000,000 device hours. The data is complete, representing all devices produced during the years 1966 through 1982. The tests were performed on ungraded, unburned-in devices and are typical of TI sensor products.

OPERATING LIFE TESTS

The 25°C life tests were performed with incident light intensity adjusted for power dissipation of each device of 50 milliwatts at 10 volts V_{CE}. Readings of dark current (I_D) and light current (I_L) were made at 0, 250, 500, and 1000 hours. Failure criteria were 0.2 μA maximum for I_D and 20% degradation of limits for I_L. A total of 3210 sensors were tested to these criteria with 6 failures. These samples were taken from lots whose total count exceeded 1,050,000 sensors. Data from these tests are shown in Figure 2.

The 55°C life tests were performed with incident light intensity adjusted for power dissipation on each device of 50 milliwatts at V_{CE} = 10 V. Readings of dark current (I_D) and light current (I_L) were made at 0, 168, and 1000 hours. failure criteria were 0.2 μA maximum for I_D and ±40% change in I_L within original specification limits. A total of 16,810 units were tested to these criteria with 55 failures. These samples were taken from lots whose total count exceeded 9,000,000 sensors. Data from these tests are shown in Figure 3.

The long-term reliability of the LS600 sensor is demonstrated by the plots shown in Figure 6 and Figure 7. The data is completely representative of all tests conducted during the reporting period. The projected degradation limits are based upon the exponential distribution of failure. Extended tests performed on small samples confirm that the degradation is within the limits as shown.

ENVIRONMENTAL TESTS

The tests listed in Figure 8 were performed on samples of the product with the catastrophic or degradation failures as shown. It must be pointed out that test conditions shown are not the ultimate strength of the product but represent the test requirements imposed by our customers. The ultimate strength of these devices is much higher in most cases. Inquiries concerning response to particular requirements should be addressed to your TI sales representative.

HIGH-TEMPERATURE REVERSE BIAS

Devices are stored in dark ovens at 150°C with 45 volts applied for 1000 hours. Readings of dark current (I_D), breakdown voltage ($V_{(BR)CEO}$), and light current (I_L) were made at 0, 168, and 1000 hours. Failure criteria were 0.2 μA maximum for I_D and 60% degradation within original limits for I_L. A total of 17,723 units were tested to these criteria with 75 failures. These samples were taken from lots whose total count exceeded 9,000,000 sensors. Data from these tests are shown in Figure 4.

STORAGE LIFE TESTS

Devices were stored in ovens at 150°C for 500 and 1000 hours (depending upon requirements). Readings of dark current (I_D) and light current (I_L) were made at 0, 168, and 1000 hours. Failure criteria were 0.2 μA maximum for I_D and 20% degradation of limits for I_L. A total of 5200 units were tested to these criteria with 6 failures. These samples were taken from lots whose total count exceeded 1,000,000 sensors. Data from these tests are shown in Figure 5.

TIL604HR HIGH-RELIABILITY PHOTOTRANSISTOR

Texas Instruments has always been known as a producer of high-quality products, and the LS600 series phototransistor is no exception as evidenced by the testing of more than 31,000 units with an accumulation of over 30,000,000 hours without a catastrophic failure. This small pill package, developed by Texas Instruments, has an excellent record for reliability over more than 10 years in military and aero-space applications. Utilizing the expertise, techniques, and processes developed during these years of building the LS600 phototransistors to high-reliability customer specifications, Texas Instruments now offers the TIL604HR2 as a standard high-reliability device to customers requiring extra reliability in their applications.

The phototransistors and the complementary TIL24HR2 infrared emitters are now available as standard product items. For more information, contact your nearest TI sales representative, or Optoelectronics Department Product Marketing.

TIL23, TIL24 RELIABILITY DATA

INTRODUCTION

Texas Instruments has long been noted as a quality producer of semiconductor components. The TIL23 and TIL24 solid-state infrared-emitting diodes (IRED's) are high-quality, reliable additions to its line of optoelectronic products. They have been designed as highly reliable, long-life products capable of meeting demanding military and commercial needs. Quality control of these products begins with incoming inspection of raw materials and is continued throughout the manufacturing process as shown in assembly-test flow diagram (Figure 1). Conscientious quality control practiced by the manufacturing organization and monitored at critical steps by the quality control organization ensures that the designed reliability will be achieved in the finished product.

Since this product was announced in 1970, some five million device hours of reliability testing have been accumulated on ungraded, unburned-in samples, and additional data is continuously being accumulated. This report summarizes, in graphical form, data on the operating life of TIL23 and TIL24 at 10, 30, and 50 mA at 25°C and 50 mA at 55°C. Results of various mechanical and temperature stress tests are also presented.

OPERATING LIFE TESTS

Room temperature (25°C) life tests were performed at three different current levels: 10 mA, 30 mA and 50 mA. Readings of power output were made with a solar cell in a short-circuit current mode at 0, 168, 500 and 1,000 hours. Forward voltage was read at these intervals and no significant changes were observed. Extended operating life tests at 25°C (4,000 hours) on 300 units have substantiated the extrapolated degradation rates shown in Figures 2, 3, 4 and 5.

Since 1976 3,792,000 device hours have been accumulated on samples (see Figures 6 and 7) operated for 1000 hours. Failure criteria were degradation of output power of more than 50% or a change in V_F of more than 5%. Readings were taken at 0, 168, and 1000 hours. The samples were taken from lots whose total count exceeded three million LED's.

STORAGE LIFE TESTS

High-temperature (85°C) storage tests were performed for 1000 hours on 3312 devices (see Figure 8). Only one unit (ΔV_F = 19%) exceeded the failure criteria of 50% degradation of output power or 5% change in V_F.

ENVIRONMENTAL TESTS

The tests listed in Figure 10 were performed on samples of the product with the catastrophic failures as shown. It should be noted that the test conditions shown are not the ultimate strength of the product but represent the test requirements imposed by our customers. The ultimate strength of these devices is much higher in most cases. Inquiries concerning response to particular requirements should be addressed to your TI sales representative.

TIL24HR2, TIL31BHR2. . .HIGH-RELIABILITY INFRARED EMITTERS

Texas Instruments now offers the TIL24HR2 and TIL31BHR2 as standard product items to customers requiring extra reliability in their applications. The TIL24HR2 and TIL31BHR2 are used to provide dependable and reliable infrared sources in military and aerospace applications. The TIL24HR2 and TIL31BHR2 infrared emitters and the complementary TIL81HR2 and TIL604HR2 phototransistors are now available as standard product items. For more information, contact your nearest TI sales representative or Optoelectronic Department Product Marketing.

- Interfacing Using Optocouplers
- Bar-Code Scanner

APPLICATIONS SUMMARY

OPTOELECTRONICS IN ROBOTIC APPLICATIONS

A robot system is a good example of a system that can apply many optoelectronic devices. The block diagram of Figure 1 illustrates functions that must be considered when designing a robot system. These functions include displays to provide information to the operator for the operation of the system as well as indicators to alert the operator of any system problems. Optical sensors provide information to the computer about the position, velocity, and acceleration of the moving parts of the robot. Vision can be included to provide information to the computer about the location of parts and/or the condition of the parts that the robot must handle. Tactile feedback of some form may be necessary so that the robot does not apply excessive force to the parts it must move. The data from the sensors is transmitted to the computer to provide the necessary control.

LEDs (green or red) are good choices to alert operators to problems, to use as on/off indicators, and to display binary system status. Seven-segment displays (single or multidigit), hexadecimal displays, and alphanumeric displays are available to provide communication from the computer to the operator about more detailed status of the robot. Sensor/detector arrays of various types can be used with encoder discs and reflective surfaces as shown in Figure 1 to provide position information, velocity information, and to serve as limit switches to prevent excessive range of motion. Optoisolators (optocouplers) can be used with fiber-optic links to transmit data both to the robot and to the control system. Such couplers provide electrical isolation between the high-power circuits necessary to drive the robot and the low-power circuits used in the computer or microprocessor.

An interfacing scheme for a simple pick and place robot is shown in Figure 2. This system uses a TMS9900-101M microcomputer coupled to a terminal, memory expansion, and I/O interface. Robot inputs are from sensors represented in Figure 2 by switches SWO-SW11. The output from the CPU to the robot is to solenoids SOLO-SOL11, which represent relays or stepping motors.

Figure 3 shows the output coupling from the 9901 (Programmable Systems Interface) IC to the solenoids. The TIL119 optocoupler provides isolation from the higher voltage required to operate the solenoids as well as isolation from the noise generated by the magnetic field when the solenoid is turned on and off. The values of resistors and choice of transistors will depend on the size of the solenoid and can be calculated using standard design procedures.

Figure 4 is the input coupling needed from the robot to the interface IC. The optocoupler again provides isolation between the robot's high-power circuits and the low-power 9901 interface IC. R1 and R2 are chosen for the logic level and forward current desired. The switch SWO can be the output from a sensor detector array such as TIL143. The phototransistor of the TIL143 can be connected directly in place of the TIL119.

APPLICATIONS 5

LOW-VOLTAGE MONITOR

description

Figure 1a gives a circuit that can be used to monitor the voltage of a battery and warns the operator when the battery voltage is below a preset level by turning on an LED. In the circuit shown, the values are set for a 12-volt automobile battery. The preset level is 10 volts. The important devices in this application are the comparator, LM239, and the LED, TIL209A. The comparator is a device that senses two different voltages and provides an output that is either low voltage or high voltage, depending on the relative size of the two input voltages. One of the inputs is called the noninverting input and is designated by a plus sign, while the other is the inverting input and is designated by a minus sign. If V+ is more positive than V−, the output is high. If V− is more positive than V+, the output is low. Figure 1b shows how the output switches with V− set at +5 volts. If V+ is less than +5 volts, the output voltage is low. If V+ is greater than +5 volts, the output voltage is high.

In the circuit shown in Figure 1a, the reference voltage at the inverting (−) input of the LM239 comparator is set by a 5-volt zener diode. R1 and R2 are used as a voltage divider to provide one-half the battery voltage to the noninverting (+) input. When the battery voltage decreases to less than 10 volts, the voltage at the noninverting input goes below 5 volts, which is less than the reference voltage. This causes the output of the amplifier to switch from a high level to a low level, which turns on the LED. Current through the LED is limited by R4. By using eight such circuits and selecting appropriate values of R1 and R2 for each, a battery status display could be made to indicate the battery voltage in one-volt steps from 7 volts to 15 volts. If the number of levels to be detected is more than two, it probably is less expensive and possibly more reliable to use complete packaged analog level detectors because of the single integrated circuit and the reduced number of components.

Figure 1. Low-Voltage Monitor

Application

Any battery operated circuit that is critical can use such a monitor circuit to signal the fact that preventive maintenance must be performed.

INDICATOR OF ANALOG QUANTITIES

The circuit shown in Figure 1 uses TI's TL500C and TL502C analog-to-digital (A/D) converter integrated circuits to provide an accurate display of an analog input voltage. With the input circuit shown, the display provides a readout proportional to the intensity of the light incident on the phototransistor. Since the TIL81 responds to radiation in the range of 500 to 1100 nanometers, while the human eye responds to radiation in the range of 400 to 700 nanometers, it is responding more to infrared than to the visible spectrum.

If input circuit number 1 is used as an alternate input circuit, the display is an accurate thermometer that can be calibrated to display either degrees Celsius or degrees Fahrenheit.

The alternative input circuit number 2 can be used to provide an output that is proportional to milliamperes of input current. At the same time, or it might be an independent requirement, electrical isolation is obtained between the input transducer and the display unit.

Two parts are required for the complete integrated circuit A/D converter, an analog processor and a digital signal controller. The analog processor is controlled by digital signals from the controller to provide the basic function for a dual-slope integrating A/D converter.

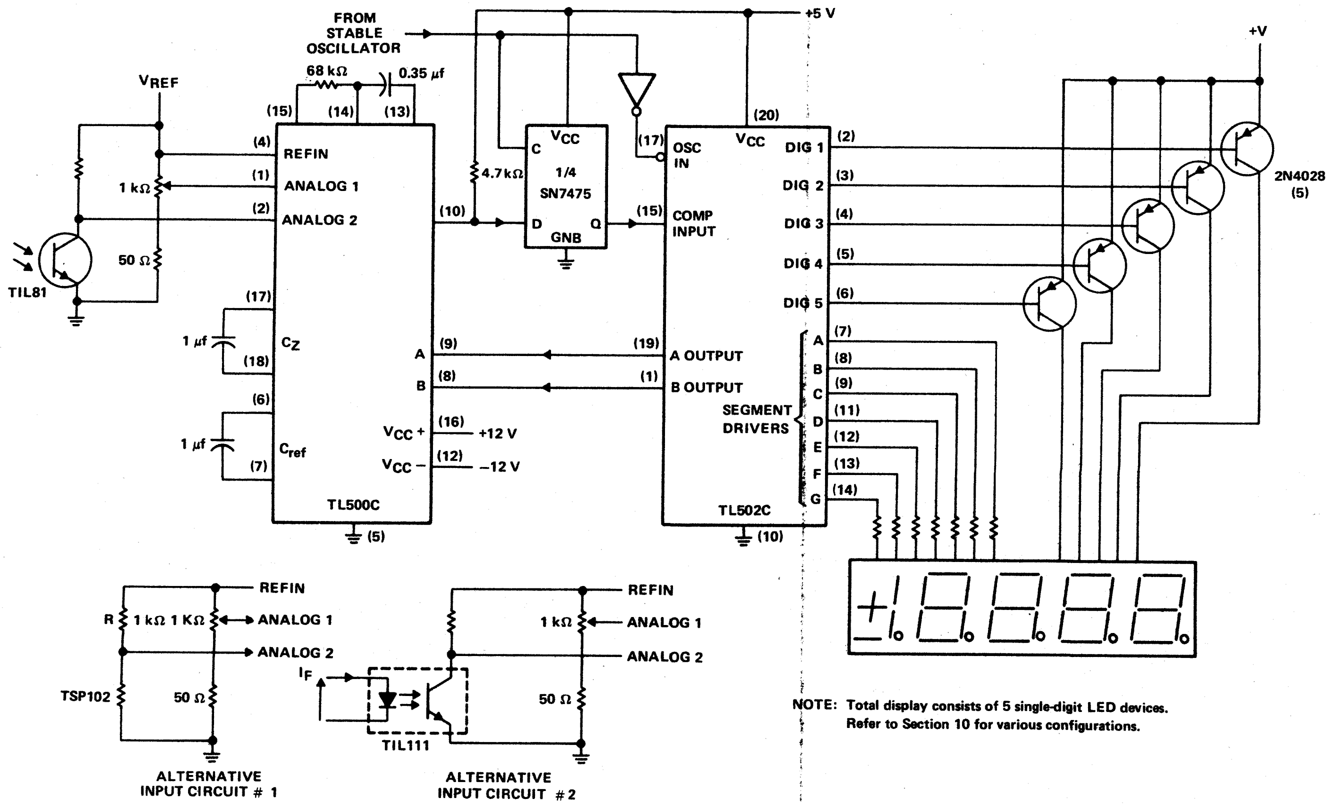
The analog processor (TL500C and TL501C) contains the necessary analog switches and decoding circuits, a reference voltage generator, a buffer, an integrator, and a comparator. The easiest way to complete the A/D converter is to use the matching digital processors (TL502C, TL503C) but the analog processor can also be controlled by discrete logic circuits or a microprocessor that has been programmed with the proper routine.

Each TL502C and TL503C includes oscillator, counter, control logic, and digit enable circuits. The TL502C provides multiplexed outputs for seven-segment displays, while the TL503C has multiplexed BCD outputs to couple directly to other computer circuits, or to displays requiring BCD code.

The TL500C and TL501C analog processors are designed to automatically compensate for internal zero offsets, to integrate a differential voltage at the analog inputs, to integrate a voltage at the reference input in the opposite direction, and to provide an indication of zero-voltage crossing.

The TL500C provides 4 1/2-digit readout accurately when used with a precision external reference voltage. The TL501C provides 100-ppm linearity error and 3 1/2-digit accuracy capability. These devices are manufactured using TI's advanced technology to produce JFET, MOSFET, and bipolar devices on the same chip. The TL500C and TL501C are intended for operation over the temperature range of 0 °C to 70 °C.

When the analog processor and digital processor are used together they provide an A/D converter that has automatic zero-offset compensation, true differential inputs, high-impedance inputs, and outputs that can drive up to 4 1/2 digits of display. As a result, the A/D converter is a very versatile circuit combination for converting analog inputs from high-impedance sensors of light intensity, pressure, temperature, moisture, and position and can be used to provide display and control signals for weight scales, industrial controllers, thermometers, light-level indicators, etc.



NOTE: Total display consists of 5 single-digit LED devices. Refer to Section 10 for various configurations.

Figure 1.

FLUID LEVEL CONTROLLER

description

Figure 1 shows a typical circuit that can be used to maintain fluid between two levels. The timing diagram is shown in Figure 2. When the fluid drops below level B, detector Q2 provides a current that produces a positive-going voltage pulse to the noninverting input of comparator 2. Comparator 2 produces a high-logic-level voltage at the set input of the RS flip-flop consisting of two cross-coupled NOR gates. This sets the output of the flip-flop to a high-logic-level voltage. When the flip-flop output goes to the high-logic-level voltage, the buffer amplifier passes a control signal to turn on the pump and the fluid level begins to rise. As soon as the level goes above B, detector Q2 is turned off, the comparator switches back, and the set input to the flip-flop goes low. However, the flip-flop output remains at a high-logic-level voltage because the reset input is also at a low-logic-level voltage. When the fluid level reaches level A, detector Q1, which has been producing photocurrent, turns off and provides a negative-going voltage pulse at the inverting input of comparator 1. As a result, the output voltage level of comparator 1 goes to a high-logic-level voltage. This resets the RS flip-flop and the flip-flop output goes to a low-logic-level voltage and the resulting control signal turns off the pump. When the fluid level drops below level A, detector Q1 again produces photocurrent to raise the voltage at the inverting input of comparator 1 above the reference. The output of comparator 1 and the reset input of the flip-flop go to a low-logic-level voltage. However, because the set input is low also, the flip-flop output remains at the low-logic-level voltage. Therefore, the pump remains off until the fluid level drops below level B again.

The parallel RC circuit connecting the emitters of Q1 and Q2 to the comparators acts as a differentiating circuit that couples sharp changes to the comparators, but filters out slow changes due to varying ambient light conditions.

applications

Variations on this control circuit can be made to keep something that moves within certain boundary conditions. An elevator is a good example.

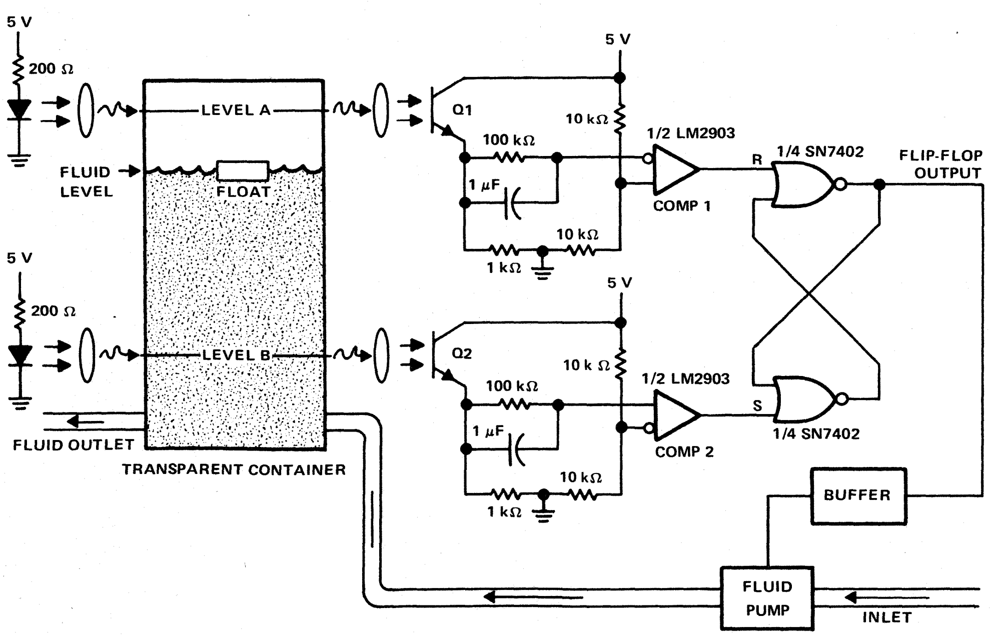


Figure 1. Fluid Level Controller

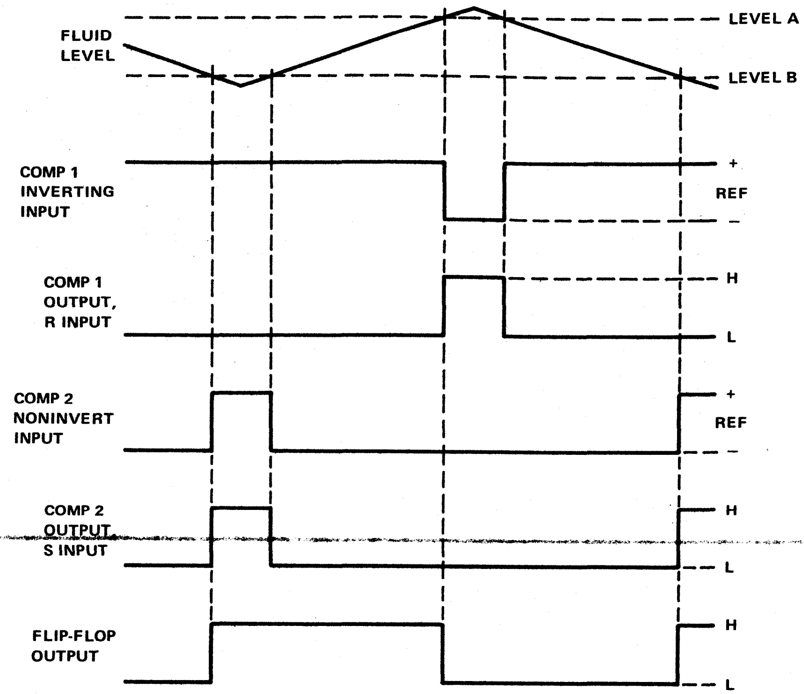

Figure 2. Timing Diagram

APPLICATIONS 5

VOLTAGE-LEVEL INDICATOR

description

The circuit in Figure 1 provides a visual indication of the input analog voltage level. The circuit uses a type TL489C 5-step analog level detector, which has a high input impedance at pin 8 and open-collector outputs capable of sinking up to 40 milliamperes. This makes it suitable for driving a linear array of 5 LEDs to indicate the level is 5 steps. The voltage at the analog input should be scaled by the input potentiometer R2 and the series resistor R1 to ensure that the voltage at pin 8 is in the range of zero to approximately one volt and should never exceed eight volts. The TL489C operates from a standard 5-volt V_{CC} and the LEDs are supplied from V+. If a logarithmic display is desired the TL487C 5-step logarithm analog level detector can be substituted for the TL489C. LEDs 1, 2, 3, 4, and 5 will turn on sequentially as the input voltage at pin 8 of the TL489C increases by 200-millivolt steps. LED 1 will also flash periodically when the input voltage at pin 8 is less than 200 millivolts. The resistor value for R3 is selected by:

$$R3 = \frac{V+ - V_{LED} - V_{OL}}{I_{LED}}$$

$$R3 = \frac{V+ - V_{LED} - 0.5\ V}{I_{LED}}$$

where $V_{OL} = 0.5$ V.

calculations

For an I_{LED} current of 10 mA, $V_{LED} = 1.6$ V and with V+ = 12 V, the resistor value would be:

$$R3 = \frac{(12 - 1.6 - 0.5)\ V}{10\ mA} = \frac{9.9\ V}{10\ mA}$$

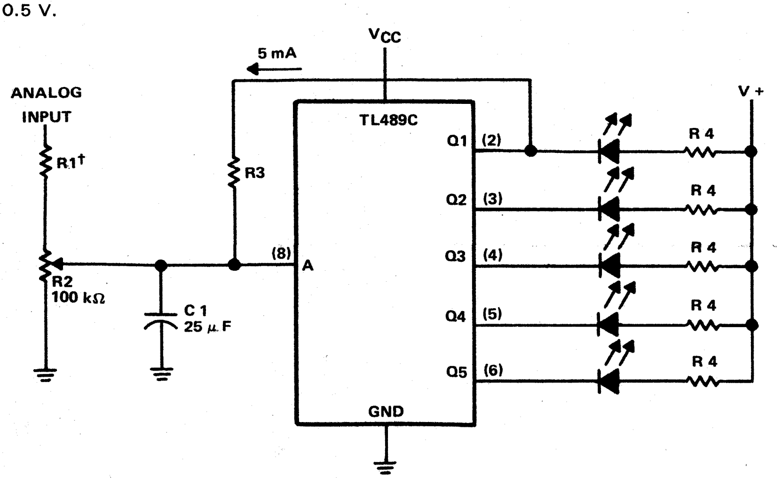
9.9 V is essentially 10 V, therefore,

$$R3 = \frac{10}{10 \times 10^{-3}}$$

$$R3 = 1\ k\Omega$$

further discussion

When the analog input is less than 200 millivolts, output 2 of TL489C is off. Under these conditions, C1 charges to V+ through R4, the LED, and R3. R4 is chosen to make



† R1 is chosen to ensure that the voltage across R2 is less than 8 volts. Normally it will be set to 1 volt.

Figure 1. 5-Step Voltage-Level Indicator

the charging current equal to 5 milliamperes when the voltage across C1 is zero. Therefore,

$$5\ \text{mA} = \frac{V+ - V_{LED}}{R3 + R4}$$

$$R3 + R4 = \frac{12 - 1.6}{5\ \text{mA}}$$

$$R4 = \frac{12 - 1.6}{5\ \text{mA}} - R3$$

$$R4 = \frac{10.4}{5\ \text{mA}} - 1\ \text{k}\Omega$$

$$R4 = 2.08\ \text{k}\Omega - 1\ \text{k}\Omega$$

Subtracting and using a standard value,

$$R4 = 1\ \text{k}\Omega$$

When C1 charges above 200 millivolts, the TL489C output 2 is pulled down to $V_{CE(sat)}$ and discharges C1 below the input threshold and the TL489C output 2 is turned off. As a result, C1 starts to charge again and the cycle repeats causing the LED in output 2 to flash. When the input is well above 200 millivolts, output 2 is always on at $V_{CE(sat)}$ and C1 remains discharged.

a 10-step indicator

A TL490C can be used to provide a 10-step display of the voltage level as shown in Figure 2. The TL490C is a 10-step adjustable analog level detector that is also capable of sinking up to 40 milliamperes at each output. The voltage range at the input pin should range from 0 to 2 volts.

Circuits of this type are useful as liquid-level indicators, pressure indicators, and temperature indicators. They may also be used with a set of active filters to provide a visual indication of harmonic content of audio signals.

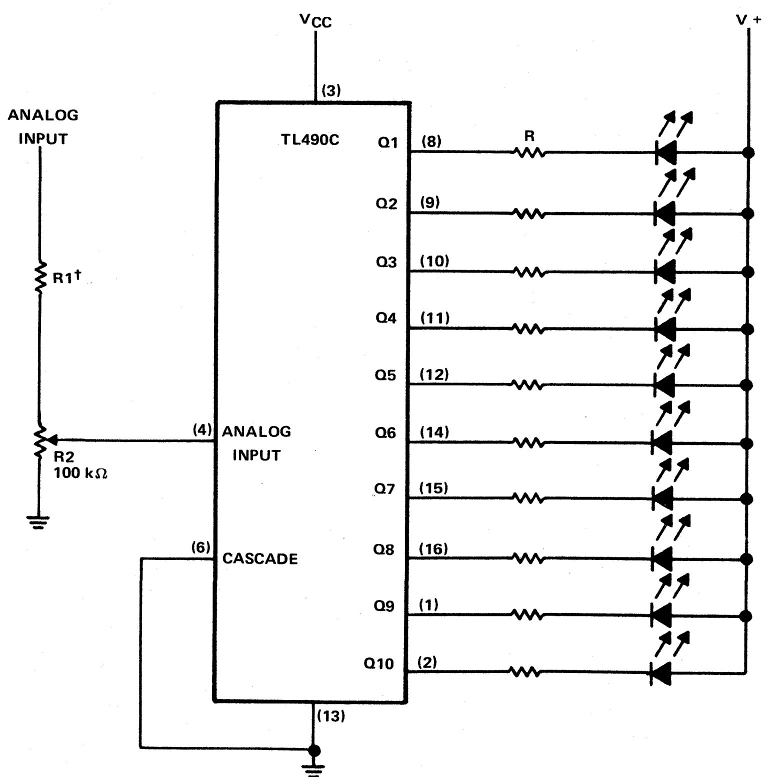


Figure 2. 10-Step Voltage-Level Indicator

†R1 is chosen to ensure that the voltage across R2 is less than 8 volts. Normally it will be set to 1 V.

PULSE GENERATED BY INTERRUPTING A LIGHT BEAM

description

The circuit of Figure 1 is designed to put out a pulse when an object on the conveyor belt blocks the light source. The light source is a tungsten lamp (at 2870 K), which will keep the TIL81 phototransistor turned on. This produces a high-logic-level voltage at pin 1 of the SN7414 Schmitt-trigger inverter and a TTL-compatible low logic level at pin 5 of the monostable multivibrator SN74121. When an object blocks the light, the TIL81 turns off causing the Schmitt-trigger inverter to trigger the one-shot SN74121. The R_{ext} and C_{ext} shown in Figure 1 are selected to give an output pulse of 100-microsecond duration when B (pin 5) is triggered by a positive-going pulse. Other values of R and C for pulse durations from 50 nanosconds to 10 milliseconds are shown in Figures 3 and 4. The SN7414 Schmitt-trigger provides pulses with steep transistions from slowly varying waveforms that are input from the TIL81.

application

As shown in Figure 1, the circuit can be used in many manufacturing operations where the primary function can be triggered by interrupting a light beam counting objects as they move down a conveyor, triggering a drilling or insertion action after a part has moved into place, or opening sorting bins or closing sorting bins after a part has moved in place.

Opening doors when people walk onto a surface pad, detecting when an object moves into a light beam, and sensing opaque surfaces over transparent surfaces are a few more typical types of applications.

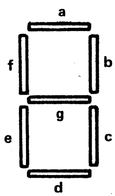
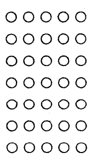
MULTIPLEXING DISPLAYS

seven-segment displays

To display numbers and symbols an array of display elements is required. Two common configurations are shown in Figure 1. Figure 1a shows the seven-segment display that can be used to display the decimal numerals and some alphabetical characters by turning on appropriate segment patterns. Figure 1b shows a 5 × 7 dot matrix that can be used to display any alphanumeric symbol by turning on the appropriate dot pattern. The pattern required for each



a. SEVEN-SEGMENT LED DISPLAY



b. 5 X 7 DOT MATRIX DISPLAY

Figure 1. Display Matrices

number, character, or symbol to be displayed must be stored in a read-only memory or a display decoder in order to properly display a desired character. The interface to a seven-segment display is the BCD-to-seven-segment decoder driver like the SN7446 shown in Figure 2a. The input to the decoder is the BCD code for the number to be displayed. The RBI and BI signals can be taken low to turn off all segments, regardless of the input code. When BI is high, the LT (amp test) input can be brought low to turn on all segments to perform a lamp test operation. The BI/RBO can serve as an output for ripple blanking to other decoders. When RBI is brought low, RBO as an output will go low for rippling a blanking signal to other display decoders. The segment drivers A through H are connected to the LED's of the display to control which LED's are turned on.

The entire circuit and display is available as a single device, the TIL321A, shown in Figure 2b. This device has the 4-bit BCD code input, a decimal point input, and depends on a non-BCD code to provide blanking. Devices also exist that include a register as well as a decoder/driver and display in the same unit. The TIL308 shown in Figure 2c is one of those. It stores the four BCD inputs in a quadruple S-R flip-flop whose outputs are available from the device. There is a latch strobe input that, when low, stores the BCD code in the 4-bit register. There is a blanking input, BI, that, when low turns off all segments, and an LED test input that, when low, turns on all segments. If the LED test and the BI inputs are both high, the display shows the number whose code is latched in the device data register. Such a register simplifies the I/O requirements of the microcomputer since it can be treated as a complete stsorage location. It may be connected to either the data bus or any special system I/O bus.

The interface to a 5 × 7 or other dot matrix is handled in much the same way as the seven-segment device. The simplest device of this type is the TIL311, which displays hexadecimal characters using LEDs arranged on a 4 × 7 dot matrix pattern as shown in Figure 3a. It includes a 4-bit data register with a latch strobe input that causes the 4-bit input data to be entered while the strobe is low. As long as the strobe stays high, the information displayed and stored will not change. Thus, one could treat the strobe as a rising-edge latch signal. The overall structure of the TIL311 is shown in Figure 3. There is a blanking input that, when high, causes the display to be blanked. There is a left and right decimal point input available.

The control of a 5 × 7 dot matrix display device like the TIL305 requires a ROM or EPROM in which the display pattern for each character to be displayed is stored. The basic circuit structure is shown in Figure 4 for an individual interface to a TIL305. The TTL signals from the seven input lines (ASCII code inputs) are connected to the inputs I1 through I7. The current-drive capability is provided by SN75491 drivers acting as sink drivers from the output lines 01 through 07 and as source drivers for the column lines on the TIL305. At the time a column line is driven with current, the column select code CA through CE must simultaneously be applied to the column select lines of the EPROM. The EPROM outputs the seven row signals for a

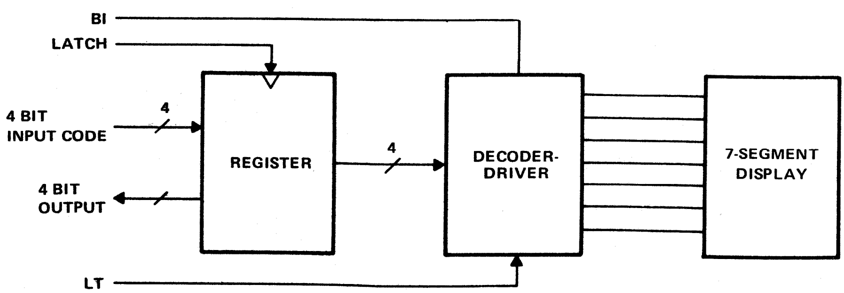
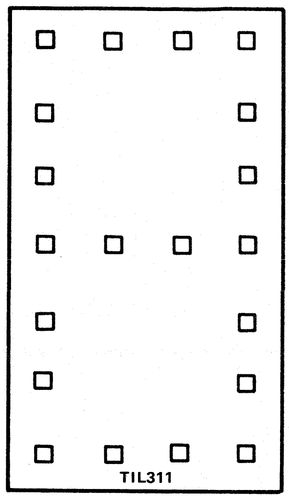
b. TIL321A

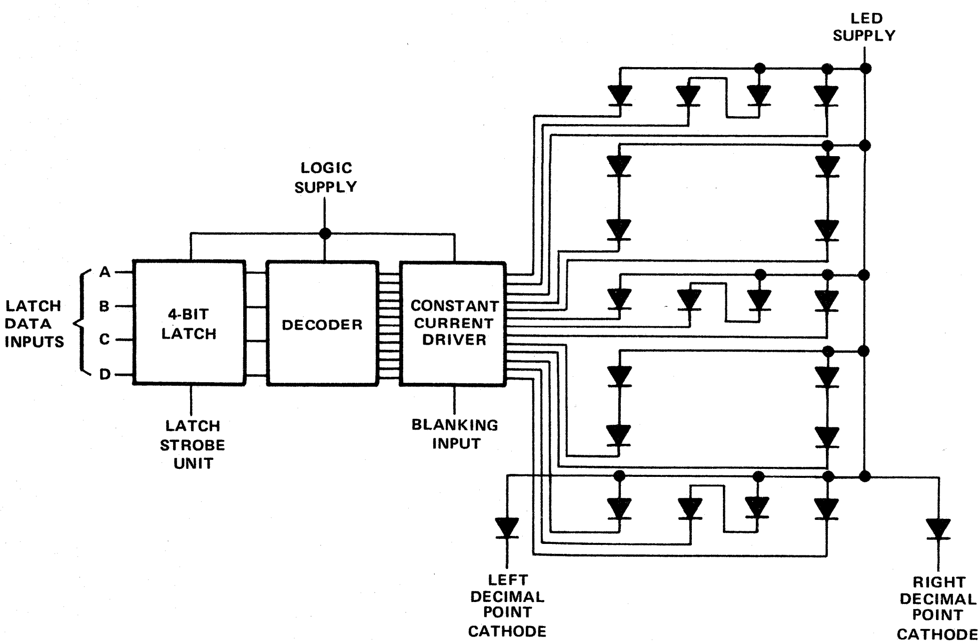


c. TIL308

Figure 2. Seven-Segment Displays



a. MATRIX 4 X 7 PATTERN.



b. SCHEMATIC

Figure 3. 4 X 7 Matrix

selected character for a selected column. Thus, the circuitry must scan through the columns at an appropriate rate by using either a ring counter or a counter-decoder combination.

In the example of Figure 4, an SN75496 5-bit ring counter is set up so that only one bit position will have a 1 at any given time. This is achieved with the wired-NAND control (SN7416) on the serial input. For example, if all outputs A through E (all bits) in the register are 0, the serial input line will be at the 1 level, and a 1 will be shifted into the first bit position. This 1 (in the A position) causes the serial input line to go low (to a 0), which will be shifted in to fill the lower bits with zeroes. The original 1 will propagate through to E with each rising edge of the clock. When the 1 is at E, a 1 will again be generated at the serial input to insert a new 1 into A when the 1 is shifted out of E. Thus, there is only one 1 in the shift register at any time. Only one column of the EPROM is addressed at any time, and only one column of LED drivers is turned on at any time. Also in the example of Figure 4, the unijunction oscillator is set to provide a clock pulse sequence at a frequency of about 1,000 pulses per second. A new column is selected and turned on for about a millisecond, and a column is on 20 percent of the time.

The circuit of Figure 4 provides only a single-character display position. If a multiple-position character display is required, it is not reasonable to provide a separate EPROM for each display unit. In other words, it is not feasible to repeat the circuit of Figure 4 for each character in the multiple position display. A circuit that shares the EPROM resource must be used. This means that the display must provide a RAM for storage of the character codes to be displayed and a sequence controller that will sequence through the codes stored in RAM while the different TIL305s are activated. The basic structure is shown in Figure 5 for a 16-character display.

There must be 16-location RAM, and each location must store a 6-bit ASCII code. There must be a modulo-16 counter that determines which RAM code and character position is to be used at any given time. The TIL305 that is activated is selected by the output of a 4-to-16 decoder. The decoder turns on one group of the SN75493 sink drivers for the selected character position. The sink drivers for all other character positions are turned off, and the associated TIL305s for those positions remain off. The modulo-16 counter is incremented by the trailing edge of output E from the central 5-bit ring counter, since that marks the beginning of the new column 1 display. There must be a provision for writing into the RAM from the processor and a write control signal, W′, that will switch the RAM address from the modulo-16 counter to the processor address lines. The SN74LS245 for each bit provides the switching required. This connection allows the information being displayed to be controlled by processor memory write or output operations. The overall structure of Figure 5 is somewhat complicated, but it can be cost effective in both power dissipation and parts costs. A similar approach can be used for time multiplexing of 7-segment displays to save power consumption.

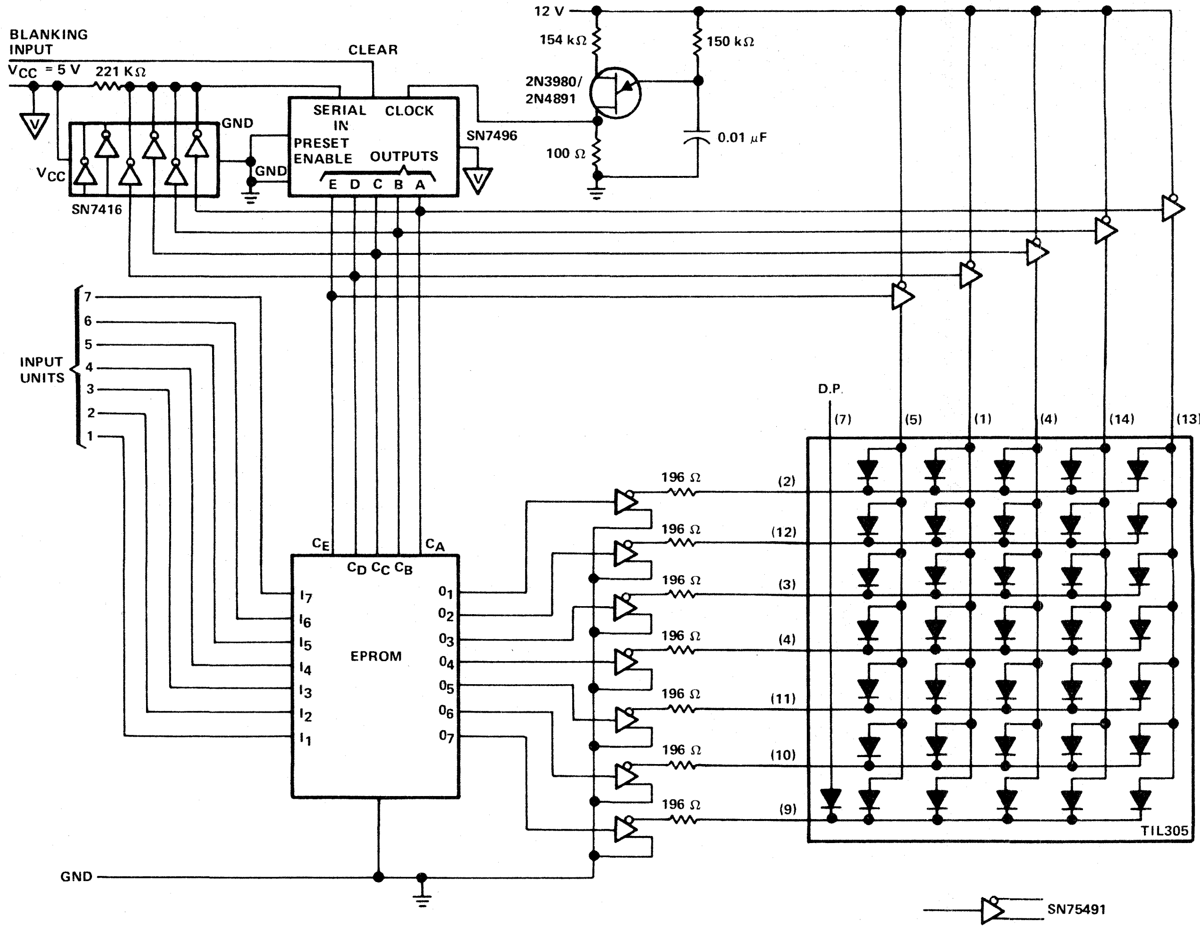


Figure 4. 5 X 7 Matrix

15 APPLICATIONS

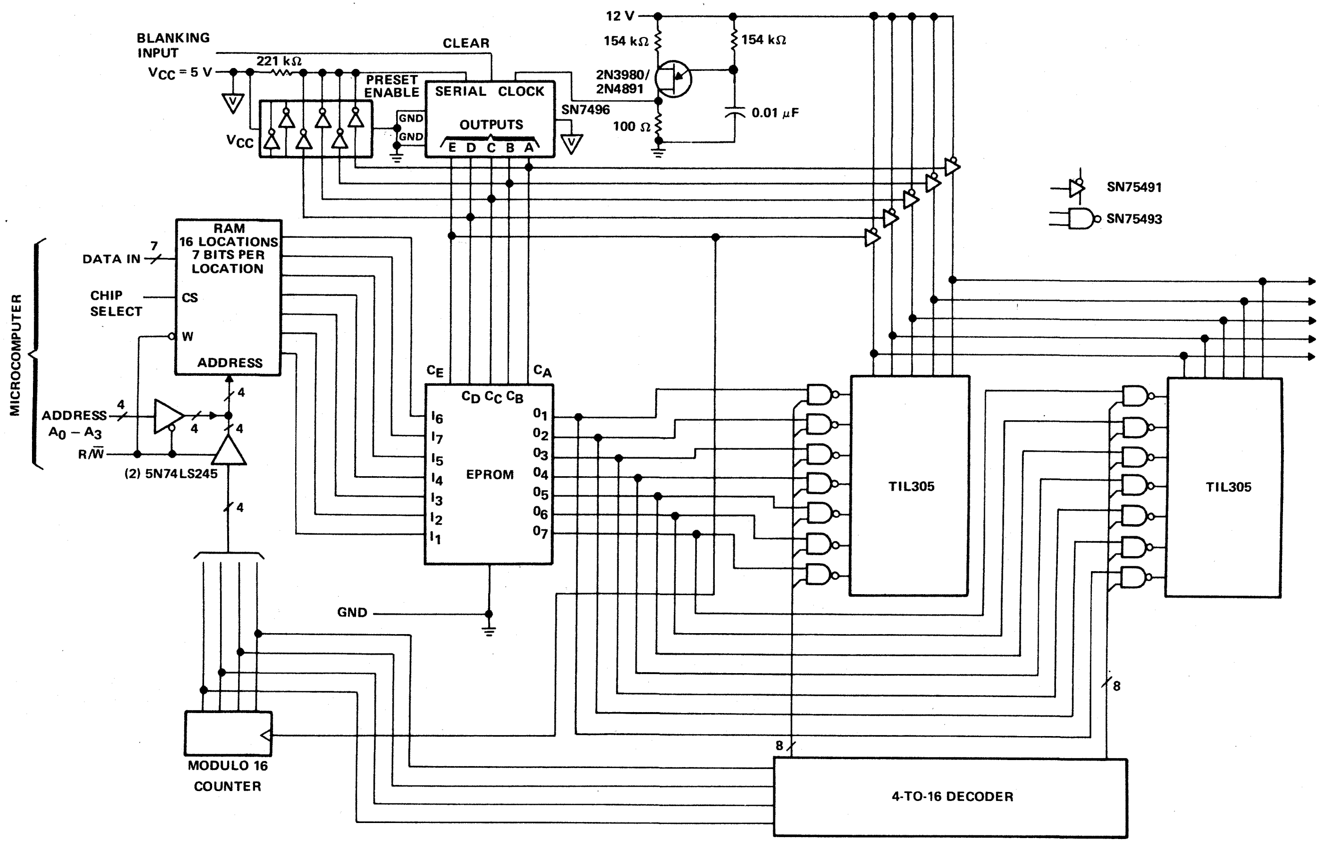

Figure 5. 16-Character Display

TIL311 HEXADECIMAL LED DISPLAY

The TIL311 is designed to store and display decimal and hexadecimal data. The device consists of an MSI logic chip to perform logic and storage functions plus a light emitting diode (LED) display in a single 14-pin dual in-line package.

It accepts parallel 8-4-2-1 data on four input lines and displays the corresponding decimal or hexadecimal character on a 4-by-7 dot matrix. Figure 1 illustrates the hexadecimal character representation for the decimal numbers 0 through 15. The logic levels are designed to be TTL compatible: a high level is 2 V to 5 V, a low level is 0 V to 0.8 V.

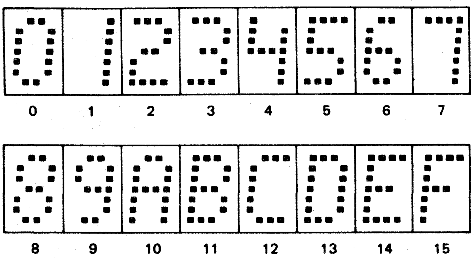

FIGURE 1. TIL311 Hexadecimal Character Configuration

The block diagram in Figure 2 shows the major sections of the TIL311: latches, decoder, current driver, and LED display. The inputs are DATA, LATCH STROBE, BLANKING, and DP. DATA is parallel 8-4-2-1 coded data. When LATCH STROBE is low, the data in the latches follow the data inputs. When LATCH STROBE goes high, the data on the input lines at strobe time is stored in the latches.

The 4-bit code is decoded and the required diodes are turned on via the constant-current drivers to display the proper character.

The LED display contains two decimal points: one to the left and one to the right of the character. A low input to one of the DP inputs will turn that decimal point on.

BLANKING must be low to display the character. When BLANKING goes high, the character is turned off regardless of the inputs. The BLANKING input does not change the data stored in the latches. BLANKING may be pulsed to intensity-modulate the display. The apparent brightness of the display is proportional to the duty cycle of the modulating signal, assuming a frequency high enough to avoid visible flicker. For example, at 1 kHz, a 50% duty

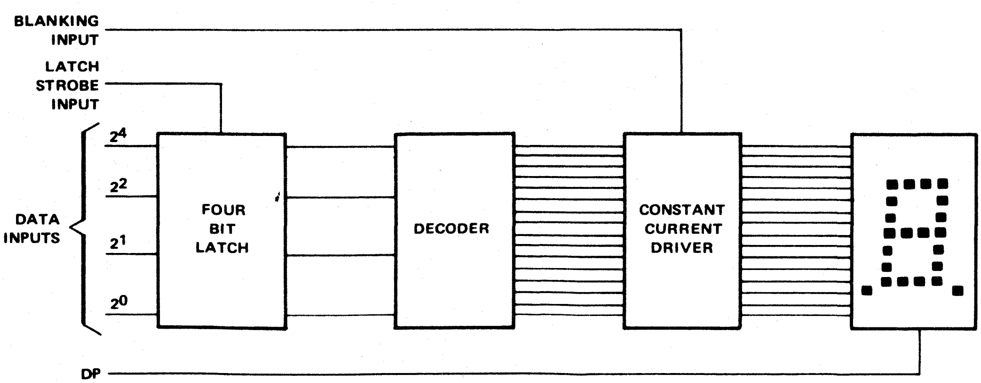

FIGURE 2. TIL311 Hexadecimal Display Block Diagram

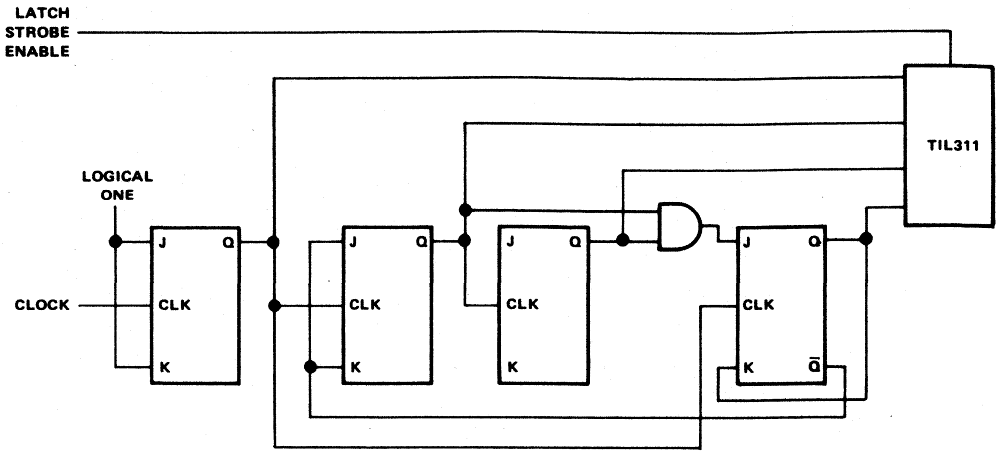

FIGURE 3. TIL311 Used As Counter Display

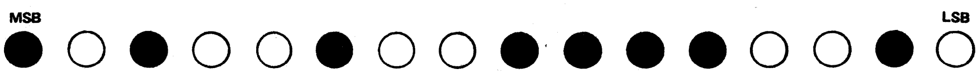

FIGURE 4. Discrete Light Display for a 16-Bit Register

cycle would cause an apparent brightness of 50% of the steady-state brightness.

Figure 3 illustrates the use of the TIL311 as a decimal display. The JK flip-flops are connected as a count-by-ten counter and represent one decade position in a multi-decade counter. The four Q outputs of the four flip-flops furnish the data inputs to the TIL311. Normally LATCH STROBE will be held high so that the display does not follow the counting. When counting is complete for a given time base, LATCH STROBE is pulsed with a negative-going pulse. The new data is then transferred from the decade counter into the latches and displayed.

Another application for the TIL311 is to display register information on computer control panels and service panels. Figure 4 illustrates the use of discrete lights to display the contents of a 16-bit register. The length of the display can easily lead to errors in interpretation of the data. Figure 5 illustrates the use of the TIL311 to display the same data in the same 16-bit register. The 16 register positions are divided into four 4-bit groups. The four bits in each group provide the inputs to each of four TIL311 displays. The resulting four hexadecimal character display provides a more concise interpretation of the register data.

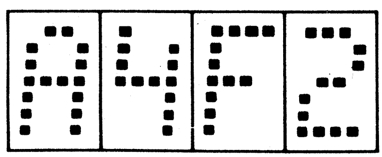

FIGURE 5. Hexadecimal Display for a 16-Bit Register

COUNTING CIRCUITS USING TIL306 AND TIL308 LEDs

Digital instruments have experienced a constant evolution since 1960. Counters that once occupied several inches of rack space in a 19-inch rack have been replaced by units the size of a text book with performance characteristics surpassing the older models. A major contribution to these changes is the continued advances in solid-state devices: integrated circuits have replaced the tubes and transistors and light-emitting diodes (LEDs) have replaced the incandescent displays.

Texas Instruments has introduced a new product that simplifies further the design of systems utilizing counters or digital read-outs. By combining an IC chip to perform the logic function and an LED display in a single 16-pin dual in-line package, Texas Instruments has provided the designer a device that reduces the complexity of his system without reducing flexibility of design. Two of these devices are the TIL306 and TIL308. The TIL306 and TIL308 have decimal points to the left side of the character. The TIL307 and TIL309 have decimal points to the right side of the character, but are otherwise identical to the TIL306 and TIL308, respectively. They can be combined to count, store, and display data in multiple decade positions.

CIRCUIT DESCRIPTION

The TIL306, as shown in Figure 1, consists of four major sections: counter, latches, decoder/driver, and LED display.

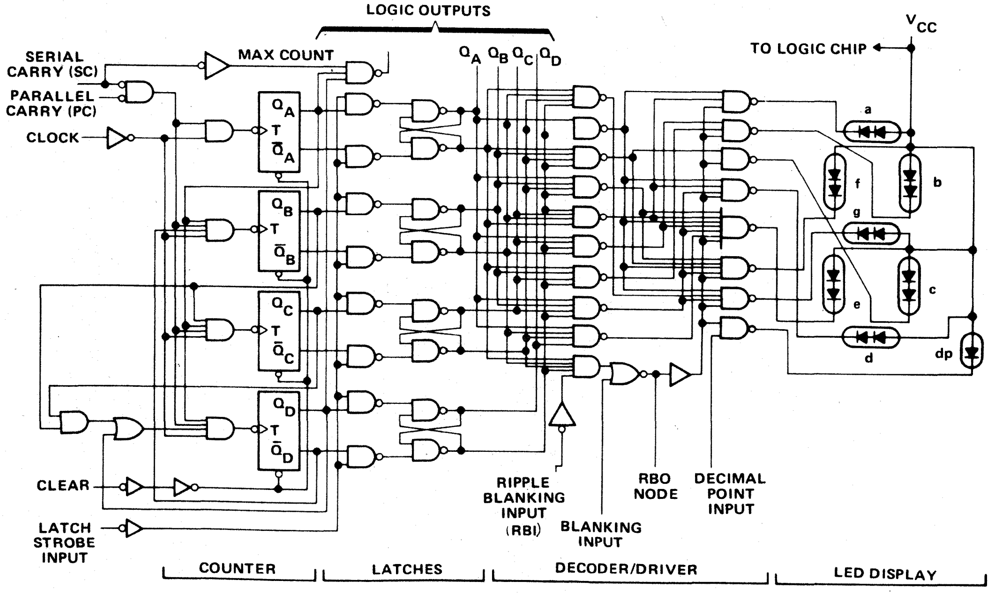

FIGURE 1. Functional Block Diagram of TIL306

The counter is connected as a synchronous counter. This configuration takes advantage of the minimal propogation delay to give maximum speed capability. Inputs to the counter are CLEAR, CLOCK, SERIAL CARRY, and PARALLEL CARRY. The counter and its inputs generate an output, MAX COUNT. Additional connections are LATCH STROBE, BLANKING, RIPPLE BLANKING, RBO, DECIMAL POINT and LOGIC OUTPUTS. All inputs and outputs are designed to be TTL compatible. A high level is a minimum of 2 V and a low level is a maximum of 0.8 V. A low input to CLEAR will reset the counter to zero independently of any other input. As long as the input remains low the counter remains at zero. A high is required to allow the counter to count.

The CLOCK input is the signal to be counted. With an input the counter will advance from 0 to 9. At a count of 9 the counter automatically resets to 0 with the next pulse. The counter changes state on the positive-going edge of the clock pulse. The clock pulse to the counter is controlled by SERIAL CARRY and PARALLEL CARRY.

The MAX COUNT output goes low when the counter reaches a count of 9, and then goes high when the counter progresses to 0 on the next clock input. This output can be connected to the CLOCK input of the next decade position for asynchronous operation or to the SERIAL CARRY input of the next decade position for synchronous operation.

A high on SERIAL CARRY inhibits the counter and forces MAX COUNT to go high regardless of the state of the counter stages. When SERIAL CARRY and PARALLEL CARRY go low, the CLOCK is enabled to the counter stages and the MAX COUNT gate is allowed to sense the status of the counter. The logic level of SERIAL CARRY must not be allowed to change while CLOCK is low or erroneous counts may result.

PARALLEL CARRY permits look ahead carry inputs from lower order decade positions. A high input inhibits the clock to the counter stages. When PARALLEL CARRY and SERIAL CARRY go low the clock to the counter stages is enabled. The logic level of PARALLEL CARRY must not be allowed to change while CLOCK is low or erroneous counts may result.

LATCH STROBE transfers the data in the counter stages to the latch storage to be displayed. With LATCH STROBE low, the latch flip-flops follow the states of the counter flip-flops. When LATCH STROBE goes high, the counter data is stored in the latch flip-flops. The counter can continue to count while the previous information is stored in the latches.

The DECIMAL POINT input controls the display of the decimal point. A high is required to turn on the LED decimal point display.

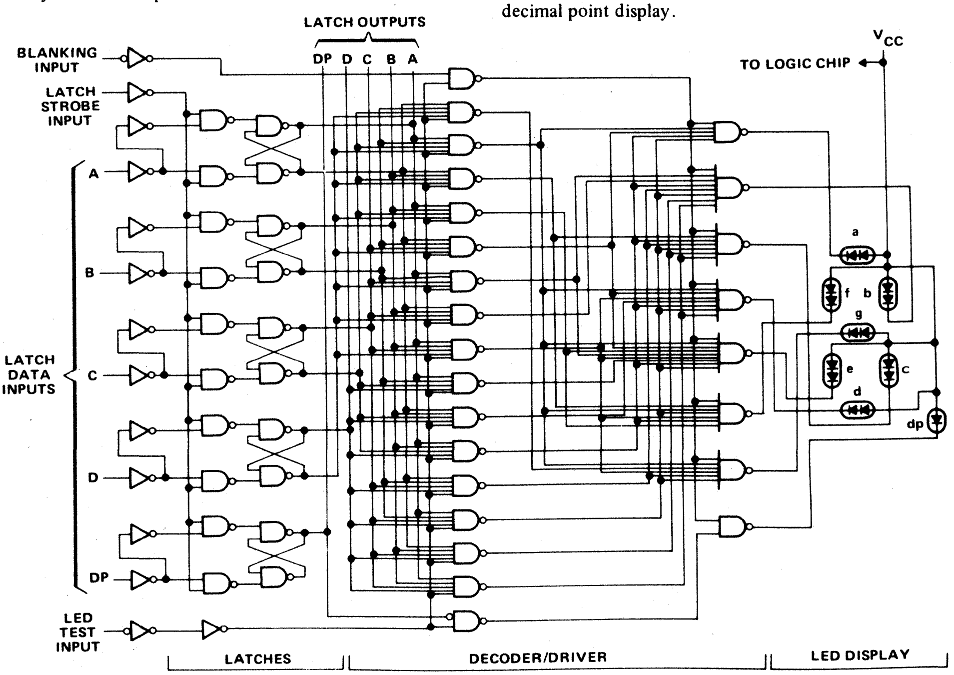

FIGURE 2. Functional Block Diagram of TIL308

A high on BLANKING inhibits the driver and gates and blanks the LED display. For normal operation, the BLANKING input must be low.

A low on RIPPLE BLANKING blanks the display if the latch flip-flops contain a count of zero. This combination also forces the RBO NODE to go low. By connecting the RBO NODE of one decade position to the RIPPLE BLANKING input of the next decade position, zero suppression can be achieved. This is discussed in detail in a later portion of this report, Counter Circuit Description. The RBO NODE has a resistor pullup, which allows this output to be used as an input. A low level applied to RBO will blank the LED display independently of other input.

The TIL308 looks physically identical to the TIL306. However, the TIL306 contains a counter section: the TIL308 does not. The TIL308 accepts 8-4-2-1 BCD code from external sources, stores it in latches, and displays the stored character by means of an LED display. As shown in Figure 2, the TIL308 consists of the three major sections: latch, decoder/driver, and LED display.

The inputs and outputs, designed to be TTL compatible, consist of DATA INPUTS, DATA OUTPUTS, LATCH STROBE, BLANKING, and LED TEST.

The BCD data and decimal point on the DATA INPUT lines are transferred into the latch flip-flops when LATCH STROBE is low. The BCD data and decimal point data stored in the latches are available at DATA OUTPUT. With LATCH STROBE high the DATA INPUT lines can change without effecting the data stored in the latches.

BLANKING must be high to display the data stored in the latches. When BLANKING goes low, the decoder drivers are inhibited and LED display is turned off. The data stored in the latches are not effected by BLANKING.

LED TEST can be used to test the LED display. A low to LED TEST will override all other signals and turn all of the LEDs on. LED TEST does not change the status of the latches.

With the basic operation of the circuits outlined, two typical interconnection methods are shown in Figure 3 and 4. Figure 3 shows the TIL306 connected in the synchronous mode. Figure 4 shows the TIL306 in the asynchronous mode. The asynchronous mode will be used in the following example of a counter.

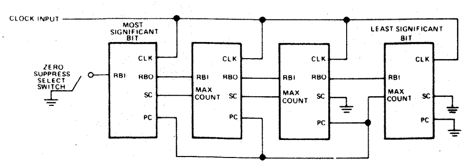

FIGURE 3. TIL306 Interconnections for Synchronous-Count Mode and High-Order-Zero Suppression.

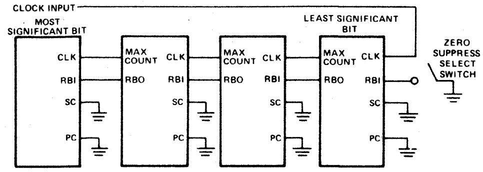

FIGURE 4. TIL306 Interconnections for Asynchronous-Counting Mode and Low-Order-Zero Suppression.

COUNTER CIRCUIT DESCRIPTION

The counter is a major constituent in digital instruments. Digital voltmeters, frequency counters, event counters, and period counters all have a circuit in common, very much like the one shown in Figure 4.

The circuit to be discussed in detail in this report incorporates both the TIL306 and the TIL308. One of the limiting factors of the TIL306 is that the counter typically does not count faster than 18 MHz. Combining the TIL306 with a TIL308 and feeding the TIL308 from a high-speed counter expands the system to a much higher frequency. Figure 5 shows a BCD counter capable of working at 100 MHz. The circuit consists of two SN74S112 Schottky

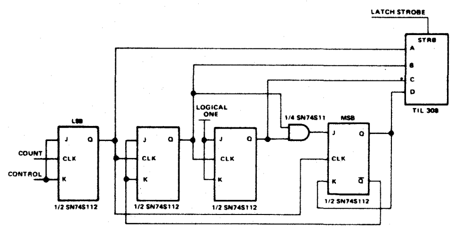

FIGURE 5. 100 MHz Decade Counter Using Texas Intruments Schottky TTL Logic and A TIL308 Display.

TTL circuits and one SN74S11 Schottky TTL circuit. This configuration results in an asynchronous BCD counter capable of dividing a 100-MHz signal down to 10 MHz. The speed is a result of Texas Instruments Schottky TTL devices that allow flip-flops to toggle in excess of 100 MHz. The Q outputs of the four flip-flops are fed into one TIL308, resulting in a decade with readout. The following decade position consists of a TIL306, which is capable of handling the 10 MHz rate. This circuit can be expanded even further by preceeding the Schottky counter stage with an ECL counter stage. ECL IC flip-flops with a 400-*MHz* toggle rate and discrete built ECL flip-flops with a toggle rate of 800 MHz are possible. Figure 6 shows a block diagram of a stage which is capable of counting up to 800 MHz. Since ECL levels do not coincide with TTL levels, an ECL-TTL converter is necessary. The output of the converter will drive the TIL308 without any interference caused by switching speed problems.

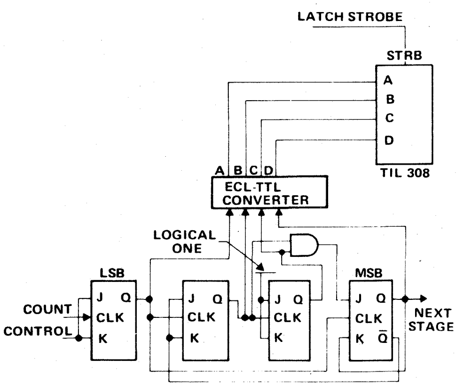

FIGURE 6. 800-MHz Decade Counter Using ECL Logic and A TIL308 Display.

TIL306 devices shows a big empty surface in the middle of the board and considerably fewer interconnects to the display. The cost savings resulting from using such a counter are quite obvious.

Figure 9 is a photo of a 100-MHz counter using seven TIL306 devices and two TIL308 devices. A compact assembly technique reduced the total size.

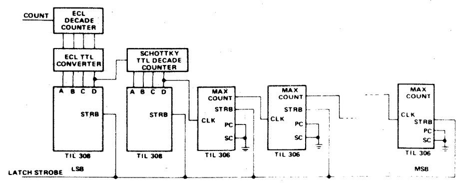

FIGURE 7. Nine-Digit Counter

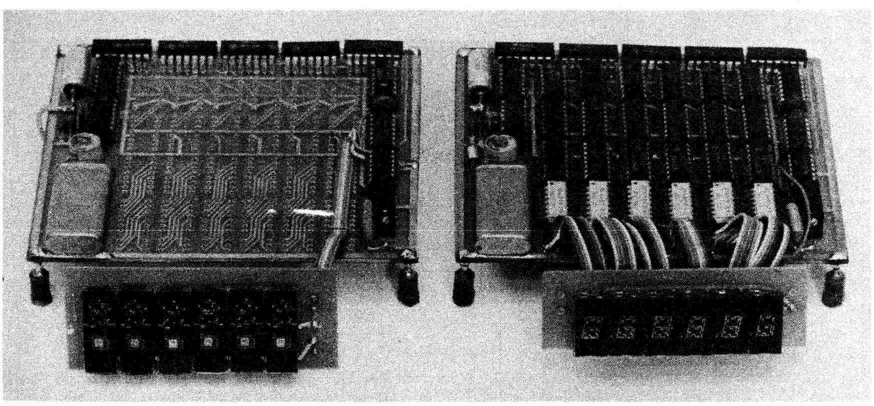

A *B*

FIGURE 8. Two Counters with Identical Performance. Counter (A) Uses TIL306 Devices; Counter (B) Does not. Note how many less Components are Needed in the Counter Using TIL306 Devices.

Figure 7 is a block diagram representation of a nine-digit readout, consisting of an ECL decade counter with a TIL308 display and a Schottky TTL decade counter with a TIL308 display, as just described, and seven TIL306 devices. Part count is minimal, and the complexity of the PC Board is minimized.

Figure 8 is a photo of two counters with identical performance illustrating the difference in component count between a conventional counter consisting of SN7490, SN7475, and SN7447 TTL integrated circuits, resistors, with a display using TIL302 devices, and a counter using TIL306 devices. Both counters are specified to operate up to 15 MHz using a six-digit readout. The counter using

in Figure 5 and seven TIL306 devices. This counter is capable of measuring frequencies up to 100 MHz and time with 10-nanosecond resolution. Again minimum part count and simplicity have been the major objectives. The unit is universal and the counter can be expanded into other functions by adding circuits to the basic building block.

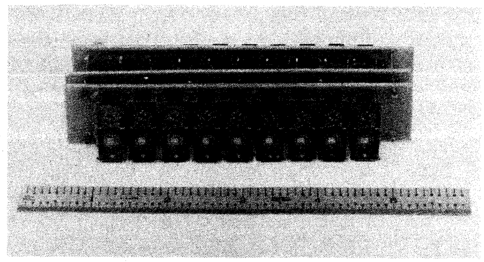

FIGURE 11. The Three Basic Circuit Boards Fastened Together into A Compact, High-Density Unit

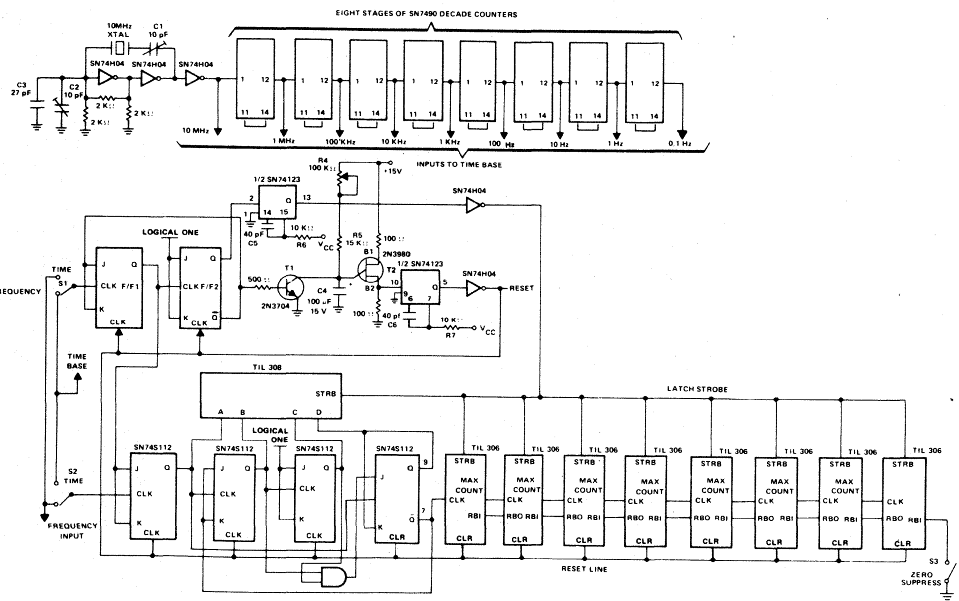

FIGURE 12. Schematic of A Frequency and Time Counter

Figure 11 shows the assembly technique for high density component packing. The total size is 1.2 inches high, 1.2 inches deep and 4.25 inches wide. This counter can be incorporated in a lightweight and portable instrument. Total power dissipation is 9 watts.

Figure 12 shows a complete schematic of a frequency and time counter incorporating the 100-MHz stage shown

The counter has three main functional sections: timebase, control, and counter.

The top part of Figure 12 is the time base. A 10-MHz oscillator is formed using two SN74H04 TTL high-speed inverters. The output is coupled through a third inverter to isolate the oscillator from the rest of the circuit. Capacitor C1 is a coarse adjust and capacitor C2 is a fine adjust. C2 should be a piston capacitor to allow finer resolution during adjustment. For more accurate requirements, a separate oscillator in a temperature-controlled oven with AGC circuitry can replace this circuit. The output of the oscillator is fed into a divider chain consisting of eight SN7490 decade dividers. Timing signals from 10 MHz to 0.1 Hz are generated and switch selectable as the time base. In the middle of the schematic in Figure 10 is the control circuit. The purpose of the control circuit is to gate the counter, and to generate latch strobe, and reset signals.

The input of F/F1 is the time base signal in the frequency measuring mode or the unknown time period in the time measuring mode.

With all circuits reset, the $\overline{Q}$ output of F/F2 holds a high level at the JK inputs of F/F1. With a pulse coming into the F/F1, Q of F/F1 changes from 0 to 1 on the negative-going edge. This 1 is applied to the first stage of the counter, allowing it to count. F/F2 does not change state since it changes only on a negative-going edge. With the next pulse to the clock input of F/F1, F/F1 changes state on the negative-going edge, changing the Q output from logical 1 to logical zero. This negative-going transition sets F/F2 and at the same time stops the counter from counting. With F/F2 set, $\overline{Q}$ of F/F2 is a 0. A 0 at the JK inputs of F/F1 inhibits change with any additional pulses coming into its clock input. The Q output of F/F2 is connected to the input of a monostable multivibrator, 1/2 SN74123. This multivibrator generates a short positive-going pulse at the Q output. The pulse width is determined by the RC combination R6C5 and is set in this application to 150 nanoseconds. The output signal is inverted and applied to the Latch Strobe inputs of the TIL306 and TIL308 devices. This pulse transfers the data from the counters into the latches to be displayed.

The $\overline{Q}$ of F/F2 is connected to the JK inputs of F/F1 and also through a resistor to transistor T1. During counting operation $\overline{Q}2$ is high, turning T1 on and preventing C4 from charging. At the end of the count cycle, the $\overline{Q}2$ is low, turning T1 off. The capacitor C4 begins charging through resistors R4 and R5. R4 is adjustable and allows a variation in the display time. R5 prevents the charging current and the current through T1 from exceeding 1 mA when R4 is turned to zero. Once the charge across C4 reaches the firing potential of the unijunction, T2, the unijunction generates a positive pulse at Base 2, which is coupled into the monostable multivibrator, SN74123. The positive pulse determined by R7C6, 150 nanoseconds wide, is inverted by an inverter, 1/6 of SN74H04, and applied to the reset input of the TIL306 devices, the four F/Fs of the first counter stage, and the two F/Fs in the control section. With F/F1 and F/F2 reset the JK inputs are reset to a high level by F/F2 and the circuit is again ready to handle the incoming signal.

The bottom part of the schematic in Figure 10 shows the counter section. The first stage is made up of two SN74S112, one SN74S11, and one TIL308. The two SN74S112 circuits and one SN74S11 circuit form a decade counter consisting of four flip-flops and one gate. Schottky TTL devices are used because of the speed requirement. If only a 70-MHz counting rate is required, this circuit could be a single SN74196 circuit. The $\overline{Q}$ output of the fourth F/F is connected to the clock input of the first TIL306. The maximum count of the TIL306 is connected to the clock input of the next TIL306. This operation is the asynchronous mode, which is acceptable for counter purposes.

The counter is controlled by the two inputs to the first F/F of the first decade. The clock input is the unknown frequency in the frequency mode, or the known time pulses from the time base in the time-measuring mode. The JK inputs are connected to the Q output of the control F/F. This signal gates the counter. As already explained, a high level to the JK inputs allows the F/F to change state on a negative edge of a pulse applied to the clock input. With the JK inputs low, the clock input does not affect the F/F.

To complete the operation of the counter, the Latch Strobe and the Reset are applied to the circuit as shown. S3 allows choosing between suppression or displaying of zeroes to the left of the most significant digit. With the switch closed, a ground is applied to the ripple blanking input of the most significant digit. If this digit is a zero, the display is blanked and the ripple blanking output goes zero. This output is connected to the next digit and the process repeated until all leading zeroes are suppressed. If switch S3 is opened the high-order zeroes are displayed. All that is necessary for operation of the counter now is to provide a power supply and a signal to be counted.

OPTOCOUPLERS IN CIRCUITS

optocouplers in circuits

There are many situations in which information must be transmitted between switching circuits electrically isolated from each other. This isolation has been commonly provided by relays, isolation transformers, and line drivers and receivers. There is, however, another device that can be used quite effectively to solve these problems. This device is the optocoupler. The need for the optocoupler is most prominent in areas where high voltage and noise isolation, as well as small size, are considered important. By coupling two systems together with the transmission of radiant energy (photons), the necessity for a common ground is eliminated — the main purpose of the optocoupler — and the systems can be effectively isolated.

Four Texas Instruments optocoupler devices, the TIL102, TIL103, TIL120, and TIL121, are discussed in this report. How these devices can be used in various circuits to provide proper isolation in many systems will be a key part of this discussion. There are many circuit applications for optocouplers; however, the ones offered in this report are just several which can be of special use. Complete specifications for these devices are not included here but are available elsewhere in this book.

description of an optocoupler

Basically, a Texas Instruments optocoupler consists of a GaAs (gallium arsenide) infrared-emitting diode (IRED) as the input stage and a silicon n-p-n phototransistor as the output stage. The coupling medium between diode and sensor is an infrared-transmitting ("IR") glass, as used in the TIL102/TIL103, TIL120/TIL121. Photons emitted from the diode (emitter) have wavelengths of about 900 nanometers. The sensor transistor responds most efficiently to photons having this same wavelength. Consequently, the input and output devices are spectrally matched for optimum transfer characteristics.

Equivalent circuits for the TIL102/TIL103 and TIL120/TIL121 are shown in Figures 1 and 2. For both families of devices, a current source between the collector and base of the sensor is used to represent the virtual base current generated by incident photons striking the base. This base current is proportional to the amount of radiation emitted from the diode. The collector-base and base-emitter junction capacitances are shown for both devices since they are used to determine the rise and fall times of the output current waveform. Because a relatively large transistor base area is necessary for increased sensor efficiency, the collector-base junction capacitance is fairly large.

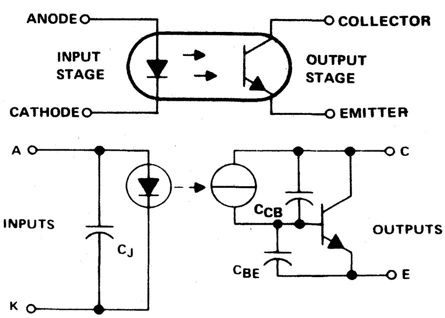

FIGURE 2. Terminal Connections and Equivalent Circuit for the TIL120/TIL121

APPLICATIONS 15

characteristics of an optocoupler

To fully utilize the advantages offered by an optocoupler, it is necessary that the circuit designer become aware of some of its characteristics. The difference in characteristics between the families is attributed mainly to the difference in construction.

The characteristics most useful to the designer are as follows:

1. High-voltage isolation. High-voltage isolation between the inputs and outputs is obtained by the physical separation between emitter and sensor. This isolation is possibly the most important advantage of the optocoupler. These devices can withstand large potential differences, depending on the type of coupling medium and construction of the package. The IR glass separating the emitter and sensor in the TIL102/TIL103 and TIL120/TIL121 has an isolation capability of 1000 V. The isolation resistance is greater than $10^{12}\ \Omega$.
2. Noise isolation. Electrical noise in digital signals received at the input of the optocoupler is isolated from the output by the coupling medium. Since the input is a diode, common-mode noise is rejected.
3. Current gain. The current gain (output current/input current) of an optocoupler is largely determined by the efficiency of the n-p-n sensor and by the type of transmission medium used. For the TIL103, the current gain is greater than unity, which in many cases eliminates the need for current amplifiers in the output. However, both the TIL102/TIL103 and TIL120/TIL121 have output current levels that are compatible with inputs of digital integrated circuits such as 54/74 TTL. Figures 3 and 4 show typical input-to-output current relationships.
4. Small size. The dimensions of these devices enable them to be used on standard printed-wiring boards. The TIL102/TIL103 and TIL120/TIL121 are built in a metal can similar to a transistor package. The physical dimensions of these packages are shown in Figures 5 and 6.

These are some of the prime characteristics of an optocoupler that can be used effectively to isolate two systems.

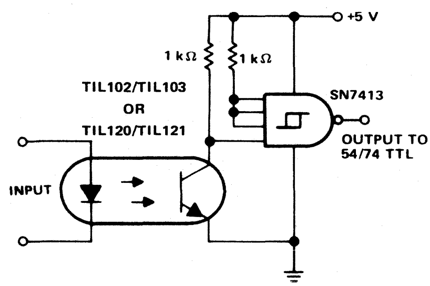
typical circuit applications

The characteristics and advantages of an optocoupler enable the designer to use it in a wide range of circuit applications. Important among the applications of an optocoupler are those involving 54/74 TTL and similar digital integrated-circuit families. As was mentioned previously, an optocoupler has output currents compatible with TTL inputs. This compatibility enables it to be especially attractive as an interface element between digital systems. The device is particularly beneficial in applications where high voltage differences may exist between systems. However, it is not limited only to digital applications, as shown by the following examples.

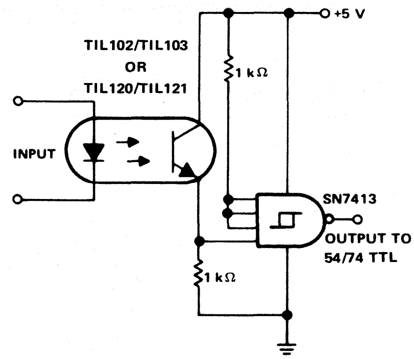
driving 54/74 TTL

An effective method of coupling an optocoupler to TTL circuitry is by using a Schmitt trigger that has an output level compatible with standard TTL devices. By coupling any of the Texas Instruments optocouplers to the SN7413, as shown in Figure 7, the isolated signal at the input can be converted to TTL logic levels. Noise immunity is provided by the coupler as well as by the threshold level of the SN7413.

The optocoupler can also be employed as part of a Schmitt trigger circuit that utilizes discrete components. Because the output of the optocoupler is a transistor, it can be used as the input stage to the



(a) NON-INVERTING FUNCTION



(b) INVERTING FUNCTION

FIGURE 7. Schmitt Trigger Coupling Optocoupler to 54/74 TTL Inputs

trigger as shown in Figure 8. For this circuit, regeneration or positive feedback is provided by the coupled emitters of Q1 and Q2. The output of this circuit is noninverting and is compatible with TTL logic.

Another Schmitt trigger utilizing discrete components that makes use of the base connection of the TIL102/TIL103 is shown in Figure 9. In this circuit, positive feedback is provided from the collector of Q2 to the base of Q1. Resistor R1 limits the base current to Q1 and keeps the device off when there is no signal at the emitter. As with the circuit in Figure 8, the output of this circuit is noninverting and compatible with TTL levels.

transmission-line isolator

By using an optocoupler between two systems coupled by a transmission line, effective line isolation can be achieved. Figure 10 shows a typical interface

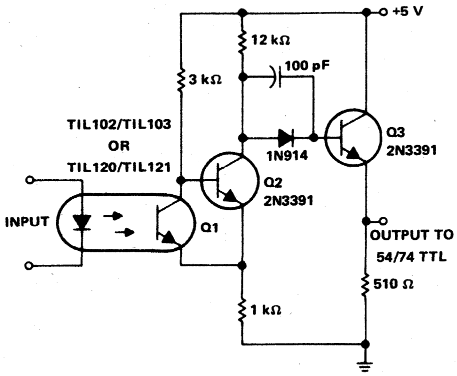


FIGURE 8. Optocoupler with Discrete-Component Schmitt Trigger for Driving 54/74 TTL

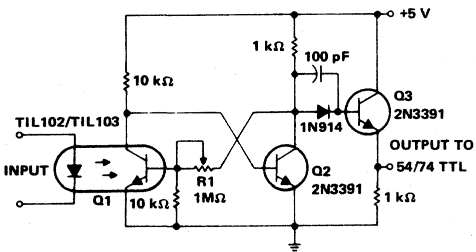

FIGURE 9. TIL102/TIL103 in a Schmitt Trigger for Driving 54/74 TTL

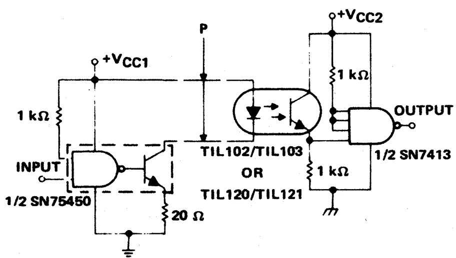

FIGURE 10. Typical Transmission Line Isolator

system using TTL integrated circuitry coupled by a twisted-pair line. The SN75450B is the input stage driving the transmission line and emitter of the opto-coupler. The IRED requires about 20 mA during "turn-on," which is well below the maximum current rating of the transistor. At the receiving end of the line, the phototransistor is coupled to an SN7413 for fast pulse generation. The output of this system is a noninverted pulse. However, by rearranging the optocoupler and the SN7413 as shown in Figure 7(a), the output may be inverted.

As simple as it seems, employing an optocoupler this way provides isolation for both noise and high voltage. An isolation transformer or relay could accomplish the task, but it would not be as fast as the optocoupler. Also, a line driver and receiver combination could be used to eliminate the noise and increase the speed, but it would be very ineffective if there were high potential differences between the input and output.

solid-state relay

Through the use of transistor circuits, mechanical relays are slowly being replaced by solid-state relays. In some cases, the solid-state relay (SSR) offers distinct advantages over its mechanical counterpart. For example, an SSR has the advantage that it has neither moving parts nor fragile wires, and it has faster switching speeds and longer operating life. However, one disadvantage of an SSR is that it generally has a lower degree of input/output isolation than a mechanical relay. To overcome this disadvantage in the SSR, an optocoupler can be used as the isolating input stage as shown in the block diagram in Figure 11. The control stage may consist of discrete transistors or integrated circuits, while the output stage consists of high-power switching devices.

A simple isolated latch circuit, which is somewhat of an SSR, is shown in Figure 12. The output of the optocoupler is used to fire the SCR that provides power to the load. To turn off the load current, the supply voltage V_{CC2} must be removed.

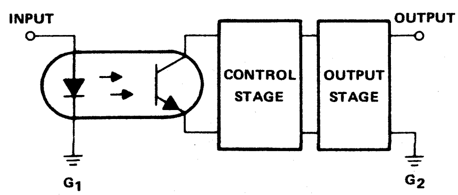

FIGURE 11. Typical Solid-State Relay Using an Optocoupler

isolated chopper circuit

Chopper circuits that use mechanical relays suffer from a speed problem as well as switching transients

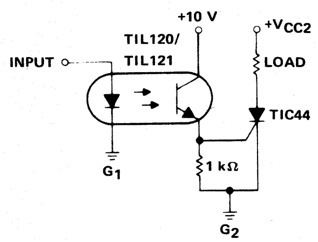

FIGURE 12. Solid-State Latch Using a TIL120/TIL121

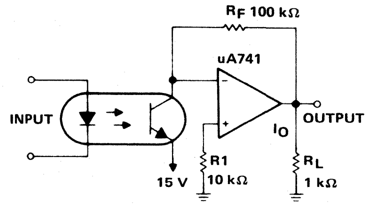

FIGURE 14. Isolated Pulse Amplifier Using Optocoupler uA741 Operational Amplifier

at the load. By using bipolar transistors or FETs as series and shunt switching elements, the speed may be improved; but capacitive coupling to the switching circuitry may still produce transient ''spikes'' on the output signal. By using an optocoupler to switch the input signal as shown in Figure 13, the switching circuitry can be isolated from the output, thereby

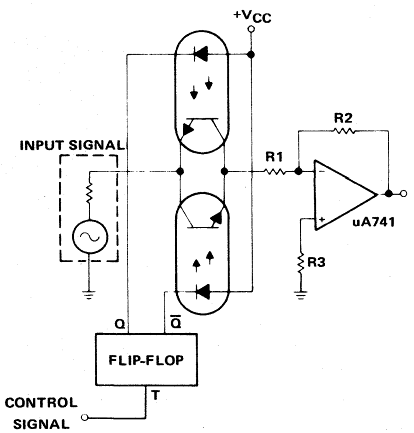

FIGURE 13. Chopper Circuit Using Optocouplers

reducing output ''spikes''. The use of two couplers in the configuration shown allows chopping of either positive or negative input signals with a frequency of one-half that of the input to the flip-flop. The uA741 operational amplifier is used to increase the output signal with a gain of R2/R1.

pulse amplifiers

Pulse amplification, as well as isolation, can be achieved by using an optocoupler with a pulse amplifier. The circuit shown in Figure 14 uses an isolator with a uA741 operational amplifier to amplify the pulse appearing at the anode of the IRED. The gain of this circuit is controlled by the feedback resistor R_F. An amplifier employing discrete components and that uses the TIL102/TIL103 as part of the current feedback pair is shown in Figure 15. The feedback resistor R1 controls the current gain as well as the output d-c level.

Figure 16 shows an optocoupler with a voltage-feedback amplifier that has a gain of 1 + R2/R1. This type of amplifier offers high input impedance, which will not load the emitter of the sensor transistor.

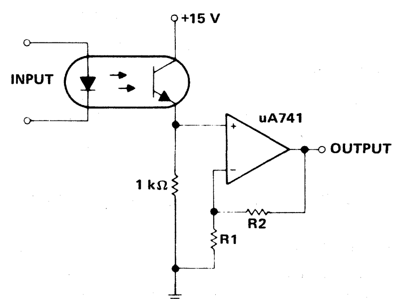

FIGURE 16. Voltage-Feedback Pulse Amplifier with Optocoupler

INTERFACING USING OPTOCOUPLERS

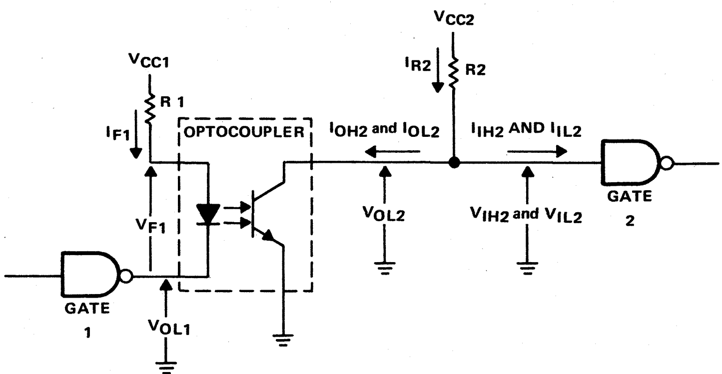
description

A very useful application of optocouplers is in the interface between different families of digital logic circuits. The worst-case design process should include consideration of data rates, power supply variations, component tolerances, and temperature ranges as well as the characteristics of the digital logic families. Consider the general circuit of Figure 1.

$$I_{OL2} \geqslant I_{R2} - I_{L2} \qquad (2)$$

The first step in the design procedure is to select I_{F1}, the forward current through the emitter of the optocoupler. Then using equation 3, R1 is computed:

$$R1 = \frac{V_{CC1} - V_{F1(typ)} - V_{OL1(typ)}}{I_{F1(typ)}} \qquad (3)$$



NOTE: V_{OL2} = LOW-LEVEL OUTPUT VOLTAGE OF COUPLER WHEN COUPLER IS ON
V_{IL2} = LOW-LEVEL INPUT VOLTAGE SPECIFIED FOR GATE 2.

Figure 1. Optocoupler Interface Circuit

When the output of logic circuit 1 is low (V_{OL1}), the output of the optocoupler is also low (V_{OL2}). Since V_{OL2} is the input to logic circuit 2, it must be less than the maximum required logic low input voltage (V_{IL2}), in order to hold logic circuit 2 in a stable state. The criteria that must be met at this point is given in equation 1.

$$V_{OL2}\text{ (coupler)} \leqslant V_{IL2}\text{ (max) (logic circuit)} \qquad (1)$$

When the coupler output is in the low state it must not only sink the current through R2, I_{R2}, but it must also sink any current required out of the logic circuit 2 input in order to hold logic circuit 2 input to V_{IL2} or less.

Using the current directions specified in Figure 1 and with the conditions of equation 1 satisfied, the conditions required for the coupler current, I_{OL2}, can be expressed as in equation 2.

A standard value resistor for R1 is selected as close to the value computed using equation 3. A tolerance for this resistor is specified from which the maximum and minumum values for R1 are computed using equations 4a and 4b as follows:

$$R1(max) = R1\left(1 + \frac{tol}{100}\right) \qquad (4a)$$

$$R1(min) = R1\left(1 - \frac{tol}{100}\right) \qquad (4b)$$

"tol" is the percent tolerance of the resistor. With the results of operations 4a and 4b, the maximum and minimum values of I_{F1} can be determined using equation 5a and 5b.

$$I_{F1(max)} = \frac{V_{CC1(max)} - V_{F1(min)} - V_{OL1(min)}}{R1(min)} \qquad (5a)$$

$$I_{F1(min)} = \frac{V_{CC1(min)} - V_{F1(max)} - V_{OL1(max)}}{R1(max)} \quad (5b)$$

The output current of the coupler depends on the current transfer ratio (CTR) of the device. CTR is defined by equation 6a as the coupler output current, I_{OL2}, divided by the forward current, I_{F1}, of the coupler diode emitter.

$$CTR = \frac{I_{OL2}}{I_{F1}} \quad (6a)$$

If CTR is not given as a data sheet parameter, it can be calculated from other data sheet specifications (e.g., $I_{C(on)}$ at a certain I_F) or from curves of I_{OL} (sometimes called I_C) vs I_F given in the data sheet. In many cases CTR will be a number less than one, in other cases it will be greater than 1.

Using equation 6a with CTR converted to a percent, the coupler collector current can be computed using equation 6b.

$$I_{OL2(min)} = \frac{(\%\ CTR) \times I_{F1(min)}}{100} \quad (6b)$$

The minimum value for R2 can be calculated using equation 7.

$$R2(min) = \frac{V_{CC2(max)} - V_{OL2(max)}}{I_{OH2(max)} + I_{IH2(max)}} \quad (7)$$

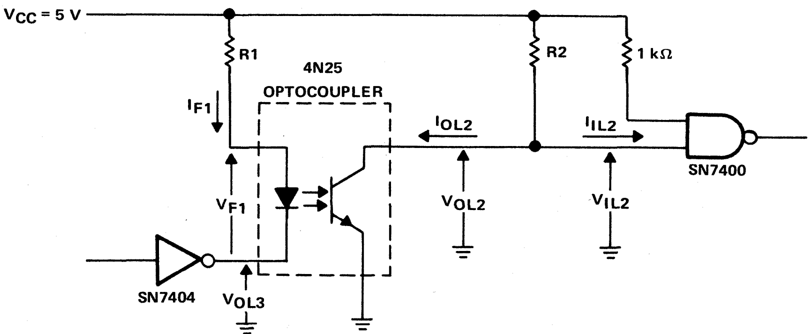
The maximum value of R2 is determined from the condition that exists when the optocoupler output transistor is in the off state. Under these conditions any offstate current, I_{OH}, and any current into the input of gate 2 must not drop the voltage across R2 to the point where the input to gate 2 goes below its required high-level limit value, V_{IH}. These limit conditions are expressed in equation 8, again using Figure 1. I_{OH2} is the current into the output collector and I_{IH2} is the input current to gate 2 when the gate input is at a voltage equal to or greater than the $V_{IH(min)}$ voltage required. $I_{OH2(max)}$, $V_{IH(min)}$, and $I_{IH2(max)}$ are taken from data sheet specifications.

$$R2\ (max) = \frac{V_{CC2(min)} - V_{IH2(min)}}{I_{OH2(max)} - I_{IH2(max)}} \quad (8)$$

R2 is selected between the limits of R2(min) and R2(max). Capacitive effects on response time are less when R2 is closer to R2(min), while maintaining the low-logic-level voltage, V_{IL2}. As the CTR of the optocoupler degrades, correct circuit operation will be maintained longer with R2 closer to R2(max). Final selection depends on which parameter is more important in the application.

example number 1

In Figure 2, a 4N25 optocoupler is to be driven by an SN7404 gate output and will drive the input of an SN7400 gate. The specifications for the logic levels and input and output currents for the Series 74 logic family are given in Table 1.



NOTE: V_{OL2} = LOW-LEVEL OUTPUT VOLTAGE OF COUPLER WHEN COUPLER IS ON.
V_{IL2} = LOW-LEVEL INPUT VOLTAGE SPECIFIED FOR SN7400.

Figure 2. Optocoupler Interface Circuit

Table 1. Series 74 Family Data

TTL Family	V_{IL} V	I_{IL} mA	V_{IH} V	I_{IH} μA	V_{OL} V	I_{OL} mA	V_{OH} V	I_{OH} μA
74	0.8	−1.6	2	40	0.4	16	2.4	−400
74H	0.8	−2	2	50	0.4	20	0.24	−500
74LS	0.8	−0.3	2	20	0.5	8	2.7	−400
74L	0.7	−0.18	2	10	0.4	3.6	2.4	−200
74S	0.8	−2	2	50	0.5	20	2.7	−1000

For the particular calculations the values in Table 2 will be used.

Table 2 Calculation Values

TTL	4N25	Power Supply
$V_{IH(min)} = 2\ V$	$CTR(min) = 20\%$	$V_{CC} = 5\ V \pm 5\%$
$V_{IL(max)} = 0.8\ V$	$V_{F(min)} = 1.2\ V$ @ 10 mA	
$I_{IH(max)} = 40\ \mu A$	$V_{F(typ)} = 1.25\ V$ @ 10 mA	
$I_{IL(max)} = -1.6\ mA$	$V_{F(max)} = 1.5\ V$ @ 10 mA	
$I_{OH(max)} = 400\ \mu A$	$I_{OL(max)} = 50\ V$	
$V_{OL(typ)} = 0.2\ V$	$V_{OL(max)} = 0.5\ V$	
$V_{OL(max)} = 0.4\ V$		

calculations

1) Select $I_F = 20\ mA$

2) Check equation 1

$V_{OL}(coupler) \leq V_{IL2}$ (logic circuit)

$0.5\ V \leq 0.8\ V$ It checks.

From equation 3, assuming the V_F at 20 milliamperes is not 0.05 volt greater than the value at 10 milliamperes.

$$3)\ R1 = \frac{5 - 1.25 - 0.2}{20\ mA}$$

$R1 = 178\ \Omega$

Select standard value $R1 = 180\ \Omega \pm 10\%$.

Therefore,

4) $R1(max)\ 180 + 18 = 198\ \Omega$

$R1(min)\ 180 - 18 = 172\ \Omega$

5) From equation 5a and 5b,

using $V_{OL(typ)} = 0.2\ V$ for $V_{OL(min)}$

$$I_{F1(max)} = \frac{(5.25 - 1.2\ V - 0.2)\ V}{171\ \Omega} = 21.38\ mA$$

$$I_{F1(min)} = \frac{(4.75 - 1.5\ V - 0.4)\ V}{198\ \Omega} = 14.39\ mA$$

6) From equations 6 and 7

$$I_{OL2(min)} = \frac{14.39\ mA \times 20}{100} = 2.878\ mA$$

$$R2(min) = \frac{(5.25 - 0.5)\ V}{2.878\ mA + (-1.6\ mA)} = 3.72\ k\Omega$$

$$7)\ R2(max) = \frac{4.75 - 2}{400\ \mu A + 40\ \mu A} = 6.25\ k\Omega$$

A choice of 4.7 Ω ±10% for R2 is suitable for this design.

example number 2

A similar approach can be used when interfacing discrete phototransistors to digital logic circuits. Consider a TIL81 connected in the phototransistor mode to an SN7400 as shown in Figure 3. The data for this situation is shown in Table 3.

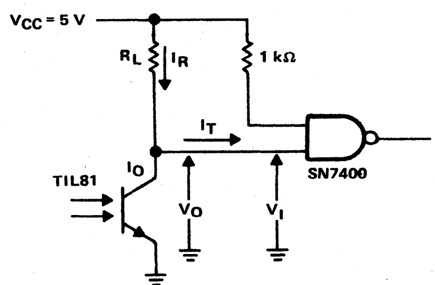


Figure 3. Phototransistor Interface Circuit

Table 3. Calculation Values

SN7400	TIL81	Power Supply
$V_{IH(min)} = 2\ V$	$I_D = 20\ \mu A$ (dark current)	$V_{CC} = 5\ V \pm 5\%$

$V_{OL(max)} = 0.4\ V$		

calculations

In this application the equations before equation 7 are ignored. From equation 7 and 8, the values for R2(min) and R2(max) can be calculated. This application is very sensitive to ambient light. Therefore, care must be taken to shield out ambient light.

Assuming 95% of the ambient light is shielded out,

$$R_{L(min)} = \frac{5.25 - 0.8}{2\text{ mA} + (-1.6\text{ mA})} = \frac{4.45\text{ V}}{0.4\text{ mA}} = 11.1\text{ k}\Omega$$

$$R_{L(max)} = \frac{(4.75 - 2.0)\text{ V}}{I_{OH} + 40\,\mu\text{A}}$$

Substituting $I_{OH} = I_D + [1 - (n/100)]\, I_{OL}$, where n = 95%

$$R_{L(max)} = \frac{4.75 - 2.0}{20\,\mu\text{A} + (1 - \frac{95}{100})\,2\text{ mA} + 40\,\mu\text{A}}$$

$$= \frac{2.75\text{ V}}{20\,\mu\text{A} + 100\,\mu\text{A} + 40\,\mu\text{A}}$$

$$= \frac{2.75\text{ V}}{160\,\mu\text{A}}$$

$$= 17.2\text{ k}\Omega$$

R_L is chosen as a standard value, 14.7 kΩ.

example number 3

If the 74LS series is used with 80% light blocked, from Table 1 $I_{IL(max)}$ = 0.36 mA instead of 1.6 mA and $I_{IH(max)}$ = 20 μA instead of 40 μA.

$$R_{L(max)} = \frac{4.75 - 2}{20\,\mu\text{A} + (1 - 80/100)\,2\text{ mA} + 20\,\mu\text{A}} = 6.25\text{ k}\Omega$$

and

$$R_{L(min)} = \frac{5.25 - 0.8}{2\text{ mA} + (-0.36\text{ mA})} = 2.71\text{ k}\Omega$$

Therefore, R_L can be selected between 6.25 kΩ and 2.71 kΩ.

examples number 4 and 5

Substituting appropriate values when the 74L series is used with 80% light blocked, then the values of $R_{L(max)}$ and $R_{L(min)}$ are 6.4 kΩ and 2.5 kΩ.

For the 74H series, $R_{L(max)}$ is 5.85 kΩ and $R_{L(min)}$ is unbounded.

bar codes and bar code scanners

Many point-of-purchase cash registers (terminals) identify the product that is sold by scanning a code of lines printed on the label or packaging for the product. The printed code is called a bar code. A typical bar code is shown in Figure 1.

Bar codes are usually horizontal with alternating vertical dark bars and light spaces. Data is encoded by varying the width of these bars and spaces. To retrieve data a scanner is moved across the bar code by the operator. The bar-code-pattern must be large enough to allow the operator to easily move the tip of the scanner across the bar code and remain within the space allocated to the code (see Figure 1).

There are a variety of bar codes in use. Some of these are:

MSI
UPC (Universal Product Code)
EAN (European Article Number)
CODABAR
2-of-5
2-of-5-Interleaved
Code 39

Detail specifications and tolerances relating to many of the bar codes do not exist. Lack of detailed specification

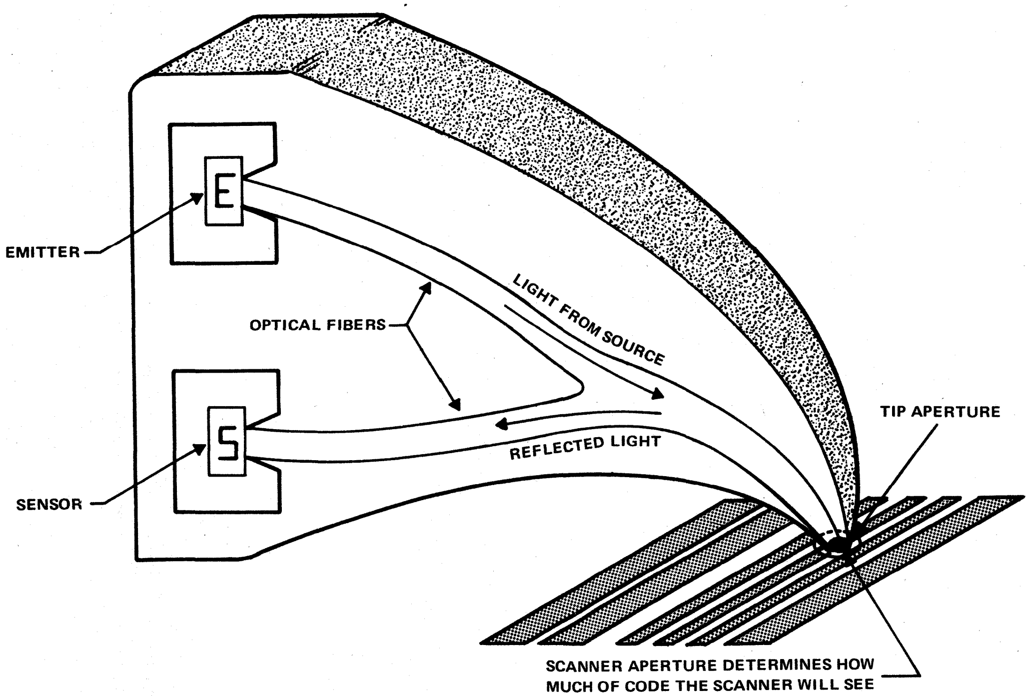

Figure 1. Bar Code Wand

allows wide variations in a single bar code by different users. As a result, any bar-code scanner must be designed to handle wide variations.

The TI bar-code reader is a self-contained wand scanner. This scanner has both a light source and a light detector in the same package as shown in Figure 1. In this case, the light emitted from the source is projected through an opening in the tip of the wand. The beam of light strikes the bar code and is reflected back into the wand tip to the light detector. The light source is connected to the tip through an optical fiber, which guides the light to the tip. The reflected light uses the same optical path from the tip back to a "Y" junction, and then a portion of the reflected light is directed to the detector

wand scanner aperture

The aperture of a scanner refers to the diameter of the opening through which the reflected light passes. The aperture determines how much of the code the scanner will see. These are shown in Figure 1. Do not mistake the aperture of the scanner with the aperture of the scanner tip. The tip aperture is selected such that all of the wand apertures will work with a single tip. Thus, a scanner with a 6-mil aperture sees an area with a diameter of 0.006 inch.

The amount of light reaching the detector depends on the scanner aperture size. Large scanner apertures allow greater amounts of reflected light to reach the detector, while smaller apertures allow lesser amounts of light. Because the detector has a nominal range of light to which it will respond, scanners with smaller apertures may require more light from the source than larger ones to meet the reflected light requirements of the detector. In general, scanners with small apertures will consume more power than scanners with large apertures.

Some bar codes can be read better by scanners with large apertures while with other bar codes, a small aperture is best. To understand why this is true, a closer look at how the scanner works is in order. Refer to Figure 2. Figure 2a shows a large aperture; Figure 2b shows a small aperture.

If the aperture of the scanner is too large and the bar width too small, the scanner will not recognize the bar. For example, if the bar is 4 mils wide and the aperture is 10 mils, 60% of the aperture will reflect light from the spaces on each side of the bar. The detected light may not decrease to a level that will allow the bar to be recognized.

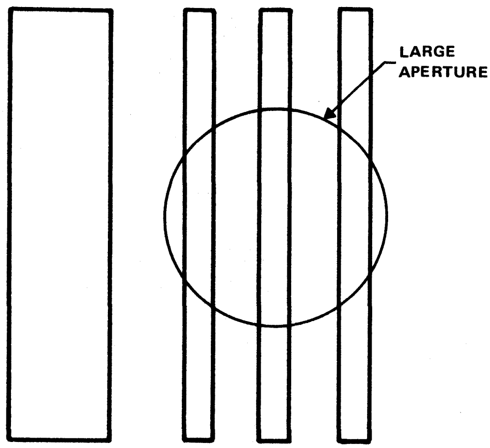
If the aperture selected is too small, a print flaw such as an ink speck may be incorrectly decoded as a narrow bar, or an ink void recognized as a space.

Contrast or recognition tolerance and power consumption form the selection criteria for scanner aperture selection with respect to a given bar code. The aperture must be small enough to recognize the bars and large enough to tolerate the print flaws. Its power consumption must be acceptable for the desired application.

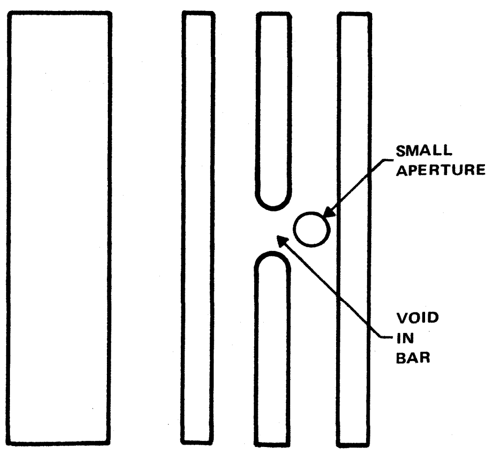
sample rate and velocity

In order to decode information contained in the bar-code pattern, the relative widths of the light and dark bars have to be determined. If the velocity of the wand moving past the bar code were constant, the distance the wand traveled could be measured linearly and the widths of the bars could be expressed in thousands of inches. Unfortunately the velocity of the wand is not constant. Each person using a wand will scan bar codes differently than another person. Typically scanning velocities are in the range of 76 to 760 millimeters (3 to 30 inches) per second.

Since the movement of the wand is variable, the widths of the bars are determined by measuring the relative time the wand sees them. This is done by sampling the wand output at a constant rate and comparing the rate of change between the light and dark bars to the constant rate. This is controlled by software within the processor that controls the display terminal.



a. LARGE APERTURE

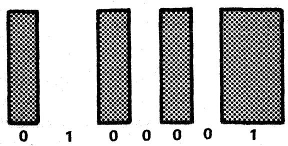


b. SMALL APERTURE

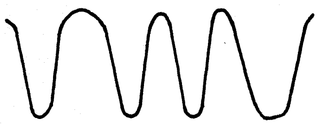
Figure 2. Example of Scanner Apertures

bar-code decoding

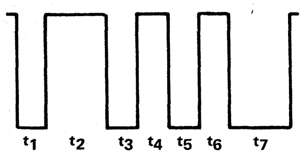
When a wand scanner is moved across a bar code as shown in Figure 3a, an electrical signal is produced by the scanner as shown in Figure 3b. It is this signal that is converted to a digital output signal as shown in Figure 3c, and interpreted to determine the proper character represented by the bar code. Each light and dark space in the bar code is equal to or greater than a unit size called a module.



a. BAR CODE AND BINARY CODE



b. WAND OUTPUT SIGNAL



c. DIGITAL OUTPUT SIGNAL

Figure 3. Digital Output Signal From Bar Code

Electrical signal periods are not measured in terms of inches or millimeters, but instead are measured in terms of time. In order to produce the signal, the scanner is moved across the bar code with a certain velocity. If the velocity of the scanner was known and constant, the signal could be accurately translated to inches. The width of the bars and spaces could then be determined and compared. Since the velocity is not known, width is expressed as a function of time. Not only is velocity unknown, it is also not constant across the bar code. This is the result of the human operator. Because the operator cannot maintain precise velocity, some degree of tolerance must be built into the decoding scheme. Even if velocity were constant, dimensional widths between different sizes of bar codes would produce varying signal widths in terms of time.

A velocity of 76 to 760 millimeters (3 to 30 inches) per second is tolerable for most operators and code types. This represents a variable relationship of 1 to 10. Since the module variation in Figure 3 is only 2 to 1, individual module measurement is meaningless. Thus, module width comparison is the only approach.

In the illustrated code, the characters may be represented with seven binary bits. Seven binary bits provide 128 variations. However, in this case, other restraints are imposed on the code to provide such things as self-checking. This limits the variations to 20 possibilities and decoding short cuts may be used.

Instead of arriving at the conclusion that timing widths represented by t_1, t_3, t_4, t_5, and t_6, are approximately the same and are approximately one-half the widths represented by t_2 and t_7, which could yield a binary number of 0100001, a different approach is used.

The odd times representing the bars are compared to each other on a pair-by-pair basis. The possibility for each comparison is that the second time is equal to, less than, or greater than, the first time.

Example: 1. $t_1 : t_3$ equal
2. $t_3 : t_5$ equal
3. $t_5 : t_7$ greater than

Similarly, the even times representing spaces can be compared.

Example: 1. $t_2 : t_4$ less than
2. $t_4 : t_6$ equal

To understand this approach, digits can be assigned to these comparative relationships.

equal is 1
greater is 2
less is 0

The result from the above comparisons would be a number 11201. This number is smaller in size than the number 0100001. The number could then be used as a table pointer to reach the resultant character. The advantage of this short-cut approach is that the table can be divided into five parts. As each comparison is made, the number of possibilities is reduced so that the part of the table to be considered can be reduced until finally the fifth comparison locates the exact number to reach the digit. If the binary approach to interpretation is used, it cannot be achieved until all the times are presented (the complete character is scanned).

MSI bar code characteristics

The MSI Bar Code has these characteristics. The bars and spaces are binary in width. The narrow ones are one module wide and wide ones are two modules wide as shown in Figure 4. Each character is composed of four data bits; each bit is three modules wide and made up of a bar and a space. Thus, each character contains four bars and four spaces. The primary algorithm is binary and applied only to the dark bars. The narrow bars are assigned a binary zero; the wide ones are assigned a binary one. The bar code character set is limited to the digits 0 through 9 by definition. The characters are encoded in the bar code by the secondary algorithm, which is binary coded decimal (BCD). Table 1 lists the character set for MSI Bar Code.

Table 1.MSI Character Set

Decimal	BCD
0	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000
9	1001
Start Symbol	1
Stop Symbol	00

The code is not self-checking,i.e., the algorithm does not allow each character to be checked independently of the other characters.

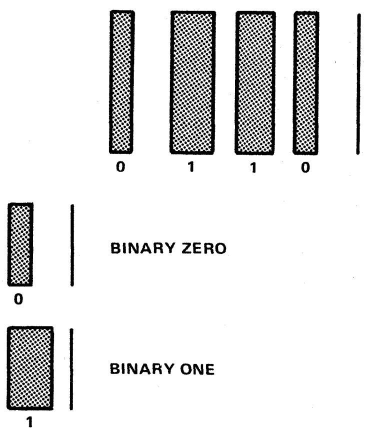


Figure 4. MSI Bar Code

The MSI code can be considered self-clocking, however, with the timing track being an integral part of the code. The complete symbol consists of the following elements: a forward start code, the data characters, one or two check digits, and a reverse start code as shown in Figure 5. The forward start code is a single 'one' bit (wide bar/narrow space) and the reverse start code, sometimes referred to as the stop code, is a single 'zero' bit followed by a narrow bar (narrow bar/wide space/narrow bar). The start symbol and the stop symbol are dissimilar and allow bidirectional scanning. The data field is between the start/stop codes and can extend to 15 characters (including two check digits). The two check digits associated with the MSI bar code are the last two digits (left to right) in the code. Each check digit is the checking digit for all preceding digits. Thus, the second check digit checks the first check digit.

The second check digit is always IBM modulus 10. It is used exclusively by the scanner circuitry and is not transferred to the terminal with the other scanned digits. The check bit is a calculated number based on dividing by the modulus number. The first check digit may be retained with the other digits of the bar code, or it may be discarded. It is, however, used by the checking circuitry and thus, must be valid. The decision to retain it, or drop it, is controlled by a terminal parameter. If the terminal parameter is set to retain this check digit, the check digit may be either IBM modulus 10 or IBM modulus 11. However, if the terminal parameter is set to discard this check digit, it must be IBM modulus 10.

code 39 bar code characteristics

The bars and spaces in Code 39 are binary in width: the narrow bars and spaces represent a binary zero and the wide bars and spaces represent a binary one. Each character is made up of 9 elements, five bars and four spaces. Three of these elements are wide and six are narrow, hence, the name Code 39 (3 or 9). Figure 6 illustrates the character structure. The primary algorithm is binary and is applied to both the bars and the spaces in the code. Narrow bars or spaces represent binary zero and wide bars or spaces represent binary one.

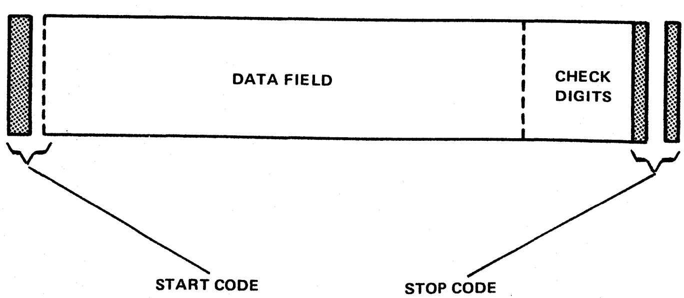

Figure 5. MSI Bar Code

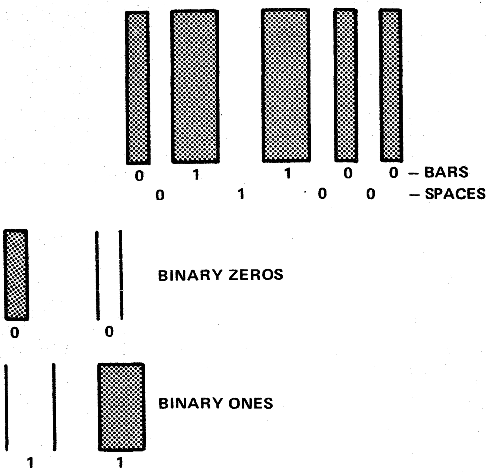

Figure 6. Code 39 Bar Code

D	00101	0010	Z	01100	1000
E	10100	0010	–	00011	1000
F	01100	0010	.	10010	1000
G	00011	0010	Space	01010	1000
H	10010	0010	$	00000	1110
I	01010	0010	/	00000	1101
J	00110	0010	+	00000	1011
K	10001	0001	%	00000	0111
L	01001	0001			
START:	00110	1000			
STOP:	00110	1000			

The character set of Code 39 is alphanumeric being made up of the following 43 characters: 0 through 9 and A through Z, 6 special characters, and a space character. The characters are encoded though the secondary algorithm, which is modified Binary Coded Decimal (BCD). Table 2 lists the complete character set. Code 39 is a variable-length code. The maximum length is typically 32 characters. The code is self-checking and utilizes inner character gaps, however, it is not a self-clocking code. The complete symbol comprises a start code, the data field, and a stop code as shown in Figure 7. The asterisk symbol is used for both the start and stop codes, and allows bidirectional scanning.

Numeric values are assigned to each Code 39 character as shown in Table 3.

Table 3 – Code 39 Numeric Values

0	0	F	15	U	30
1	1	G	16	V	31
2	2	H	17	W	32
3	3	I	18	X	33
4	4	J	19	Y	34
5	5	K	20	Z	35
6	6	L	21	–	36
7	7	M	22	.	37
8	8	N	23	Space	38
9	9	O	24	$	39
A	10	P	25	/	40
B	11	Q	26	+	41
C	12	R	27	%	42
D	13	S	28		
E	14	T	29		

Since Code 39 is discrete, i.e., self-checking; it does not require a check digit. An optional check digit may be employed when necessary. The check digit is the modulus 43 sum of all the character values in a given message, and is printed as the last data character. For example, the sum of the values of the following data would be:

Data 12345ABCDE/
Sum of Values = 1 + 2 + 3 + 4 + 5 + 10 + 11 + 12 + 13 + 14 + 40 = 115
115/43 = 2 Remainder 29

The check digit is the character corresponding to the value of the remainder, which in this example is 29 or "T". The data above with its check digit reads:

12345ABCDE/T

2-of-5-interleaved characteristics

The 2-of-5 and 2-of-5-Interleaved bar codes are quite similar and will be discussed together in this section. The differences will be pointed out as they arise. The bars and spaces of both codes are binary in width. The narrow bars and spaces are one module wide and the wide bars and spaces are three modules wide (Refer to Figure 8). A character is made up of 5 bars, 4 spaces that separate them, plus the space following the last bar. In 2-of-5-Interleaved (Figure 9), one character is made up of 5 bars and the second character is made up of the 5 spaces. Thus, the two characters are interleaved. The different spaces of the bar codes can be noted by comparing Figure 8 and Figure 9.

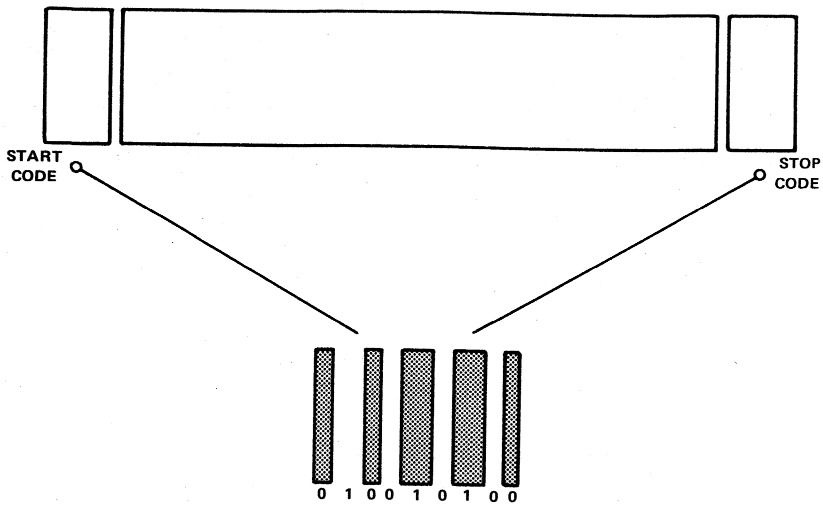

Figure 7. Code 39 Bar Code

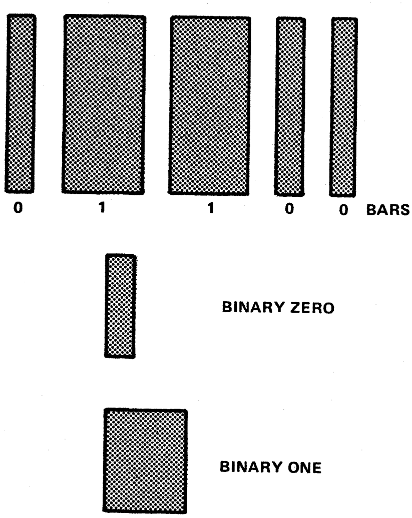

Figure 8. 2-of-5 Bar Code

The primary algorithm is binary for both codes. It is applied only to the dark bars in the 2-of-5 code with all the spaces being one module wide, but in the 2-of-5-Interleaved the algorithm applies to both bars and spaces. A narrow bar or space is assigned a binary zero and a wide bar or space is assigned a binary one.

The character set for both 2-of-5 and 2-of-5-Interleaved is 0 through 9, a start code, and a stop code. The secondary algorithm is modified BCD as shown in Table 4. In the 2-of-5 code, a character is encoded in the dark bars while the spaces have no value. In the 2-of-5-Interleaved code, the first character is encoded in the dark bars and a second character is encoded in the spaces. These codes are both self-checking, however, they are not self-clocking codes.

Figure 10 illustrates the complete symbols for the two codes. The symbol consists of a start code, the data field, and a stop code. The data field is variable in length and may contain any number of characters.

The start and stop codes are unique and provide bidirectional scanning. The start code for 2-of-5 is a "1 1 0" and the stop code is a "1 0 1." The start code for 2-of-5-Interleaved is "0 0" and the stop code is "1 0".

Table 4. 2-of-5, 2-of-5-Interleaved Character Set

Decimal	Modified BCD	
0	00110*	
1	10001	
2	01001	
3	11000	
4	00101	
5	10100	
6	01100	
7	00011	
8	10010	
9	01010	
	START CODE	STOP CODE
2-of-5	110	101
2-of-5-Interleaved	00	10

*The decimal "0" is an exception to this modified BCD. Its BCD value of eleven must be ignored.

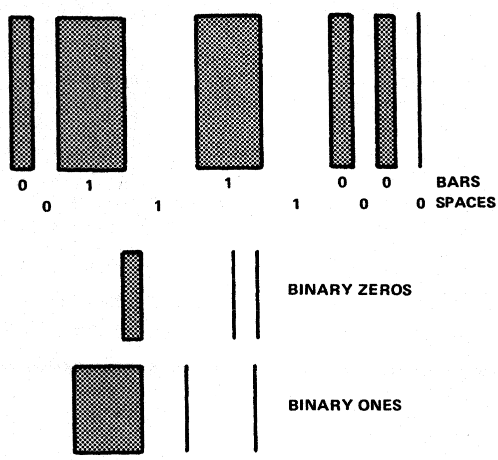

Figure 9. 2-of-5-Interleaved Bar Code

print quality

The process of printing the bar code symbols must be carefully controlled to assure that the printed labels are close to the specifications. Lithography, Gravure, letter press, Offset, and dot-matrix printing techniques are currently being used to print bar-code labels, however, the quality of the print is more important than the type of printer used. If details that effect the quality of the bar code-label are understood, an analysis of any label can be made with little regard for the type of printer used. Dot matrix printers do have special problems because of their nonuniform structure, but the same basic requirements must be met in order to reproduce readable labels.

The items that effect print quality of the labels are: the background substrate, ink reflectance, contrast, voids and specks, edge roughness, and ink spread (or shrink). Background substrate refers to the material that the labels will be printed on. It should be white and have a matte finish rather than a high gloss. A background diffuse reflectance of 70 to 80% in the near infrared spectrum is desirable. This reflectance directly effects the contrast of the label. The ink film color should be black and not exceed 24% reflectance in the near-infrared spectrum. The reflectance value should not vary more than 5% within the same character. A carbon-based ink should be used, not an alcohol-based ink. The contrast refers to the difference of the ink reflectance and the background reflectance and should be 50 to 65%. Voids are a result of missing ink coverage. They usually appear in the form of small light spots within the individual bars. seldom can voids be prevented entirely. However, it is essential to good first-pass read rates that they remain within acceptable tolerances. A speck is the opposite of a void. It is extraneous ink in the space or light bar area. Like voids, specks should be held within acceptable tolerances.

In general, the width of these anomalies is more critical then the height. An anomaly with a large height dimension increases its probbility of detection by the scanner. However, if its width is quite small, the bar code interpretation logic can accommodate the flow. If the width of the anomaly is large, and it is detected by the scanner, the results will be a "no read" of the bar code. Most bar

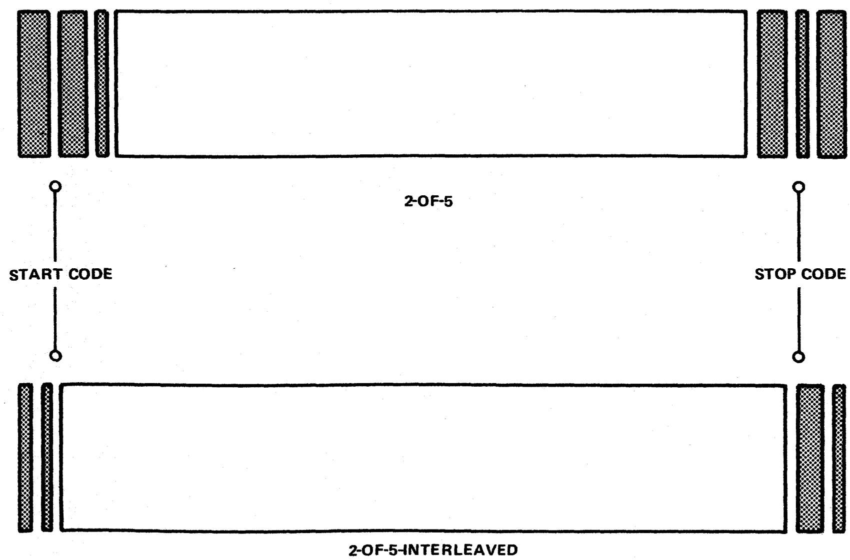

Figure 10. 2-of-5-Interleaved Bar Code

codes have sufficient checks to prevent a misread assuming the vendor makes all of the checks.

Edge roughness pertains to the left and right terminal borders of the dark bars. Edge roughness affects the width of the bars. If the bars are not printed with crisp terminal borders, it is difficult to maintain the bar width tolerances specified by the specific bar code.

Over and under printing is the result of too much or too little ink in printing the bar code. Over printing will make the dark bars wider and the light bars or spaces narrower. Under printing has the opposite effect. Either of these conditions will affect wand scanning if the tolerances of the bars and spaces are exceeded. Figure 11 illustrates the effects of over or under printing.

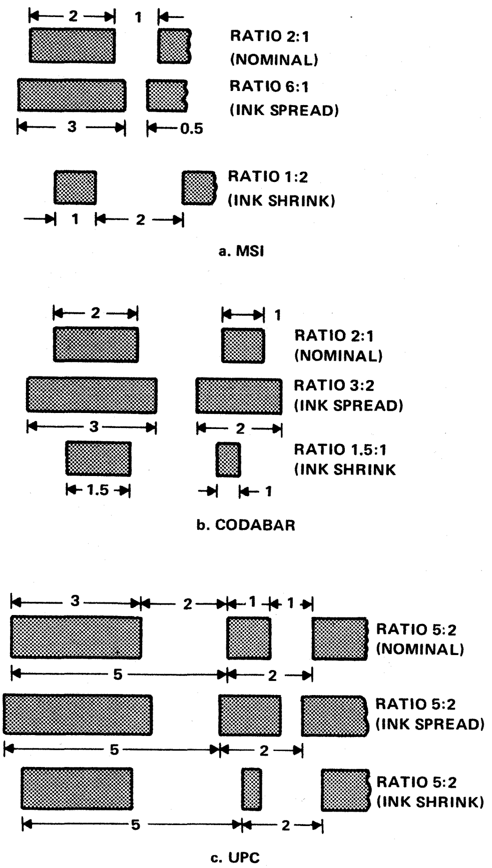

Figure 11. Effects of Uniform Ink Shrinks or Spreads

why codes won't read

There are many reasons some bar codes won't read while others are readable. The first is that the electronics fails. The wand or wand electronics can malfunction as well as the terminal itself. The second is the label itself and any number of problems can degrade an otherwise effective scanning system.

The wand has been designed so that when the tip of the wand is in contact with the symbol, the reflected image will be accurately focused on the detector. If the wand is not touching the symbol, i.e., scanning symbols through thick glass, a very poor read rate will occur. The reason is that the focal length of the wand has been changed and the detector cannot focus on the symbol.

Labels must be printed to the specifications established by the coding authority. A label that is out of specification may or may not read well depending upon how out of tolerance the symbol is after being printed. All labels cannot be read optimally with all wands as shown in Figure 12. You can have a high-resolution wand designed to read complex codes such as a CODABAR and Code 39, and a low-resolution wand for less critical codes. The low-resolution wand is less sensitive to printing anomalis making it more suitable for applications using dot matrix printers. Labels printed using alcohol-based ink may read very poorly or not at all. Alcohol-based ink has a very poor light absorption factor resulting in low contrast. To ensure adequate contrast between the background substrate and the printed bar code, a carbon-based ink should be used.

In summary, even though many bar codes exist, the technology of the scanners and optoelectronic emitters and sensors is such that most variations can be accommodated.

OPTOELECTRONICS INTERCHANGEABILITY GUIDE

The following interchangeability guide for known optoelectronic devices is intended to serve as a substitution guide for competitive devices to Texas Instruments Optoelectronic Product Line.

Texas Instruments direct replacement devices are believed to be pin-for-pin, mechanically, and electrically interchangeable devices. However, TI does not guarantee that interchangeability in particular application is exact in all respects. Therefore the applicable product sheet should be used to determine product interchangeability. Contact your local TI Sales Office, Authorized Distributor, or Optoelectronic Marketing (Dallas, Texas) for assistance in selecting the appropriate devices for your application.

GLOSSARY
OPTOELECTRONIC TERMS AND DEFINITIONS

Introduction

This glossary contains letter symbols, abbreviations, terms, and definitions commonly used with optoelectronic devices. Most of the information was obtained from JEDEC Standard No. 77.

Index to Glossary by Symbols and Abbreviations

APD	Avalanche photodiode
B	Demodulation bandwidth
E_e	Irradiance
E_v	Illuminance
f_{mod}	Modulation frequency
H	Irradiance
$I_{C(off)}$	Off-state collector current
$I_{C(on)}$	On-state collector current
I_D	Dark current
I_e	Radiant intensity
I_F	Forward current
I_L	Light current
I_R	Reverse current
IRED	Infrared-emitting diode
I_v	Luminous intensity
L_e	Radiance
L_v	Luminance
LED	Light-emitting diode
M	Photocurrent gain†
NEP	Noise equivalent power (spectral density)
P_n	Noise equivalent power (spectral density)
P_O	Radiant flux or power output
Q_e	Radiant energy
Q_v	Luminous energy
R_e	Radiant responsivity
R_v	Luminous responsivity
sr	Steradian
t_d	Delay time
t_f	Fall time
t_f	Radiant pulse fall time
t_r	Radiant pulse rise time
t_r	Rise time
t_s	Storage time
V_F	Forward voltage
VLED	Visible-light-emitting diode
Δf	Noise equivalent bandwidth
$\Delta\lambda$	Spectral bandwidth
θ_{HI}	Half-intensity beam angle
λp	Wavelength at peak emission
Φ_e	Radiant flux
Φ_v	Luminous flux

†M is also the symbol for luminous or radiant exitance; however, these terms are not used in this publication.

Units of Measurement

Unit	Symbol	Note
ampere†	A	
angstrom	Å	1 Å = 10^{-10} m = 10^{-4} µm = 0.1 nm
candela†	cd	1 cd = 1 lm/sr
candela/foot²	cd/ft²	1 cd/ft² = 10.76391 cd/m²
candela/meter²†	cd/m²	
degree Celsius†	°C	
	°K	See K
farad†	F	
foot	ft	1 ft = 0.3048 m (exactly)
footcandle	fc	1 fc = 1 lm/ft² = 10.76391 lx
footlambert	fL	1 fL = (1/π) cd/ft² = 3.426259 cd/m²
hertz†	Hz	
inch	in	1 in = 2.54 cm (exactly)
kelvin†	K	Formerly °K, degree Kelvin
lambert	L	1 L = 3183.099 cd/m²
lumen†	lm	
lux†	lx	1 lx = 1 lm/m²
meter†	m	
mho	mho	1 mho = 1 S
micron	µ	The equivalent unit µm is preferred
mil	mil	1 mil = 10^{-3} in = 0.0254 mm (exactly)
nit	nt	1 nt = 1 cd/m²
ohm†	Ω	
phot	ph	1 ph = 1 lm/cm²
second†	s	
siemens†	S	
steradian†	sr	
stilb	sb	1 sb = 1 cd/cm²
volt†	V	
watt†	W	

†International System (SI) units.

Metric Multipliers

Many of the preceding unit symbols can be combined with the metric multipliers that follow.

Symbol	Prefix	Multiple
G	giga	10^9
M	mega	10^6
k	kilo	10^3
h	hecto	10^2
da	deka	10
d	deci	10^{-1}
c	centi	10^{-2}
m	milli	10^{-3}
µ	micro	10^{-6}
n	nano	10^{-9}
p	pico	10^{-12}
f	femto	10^{-15}

Terms and Definitions

Avalanche Photodiode (APD)

A photodiode that is intended to take advantage of avalanche multiplication of photocurrent. As the reverse-bias voltage approaches the breakdown voltage, hole-electron pairs created by absorbed photons acquire sufficient energy to create additional hole-electron pairs when they collide with substrate atoms; thus a multiplication of signal current is achieved.
NOTE: APD's are especially suited for low-noise and/or high-speed applications.

Axis of Measurement

The direction from the source of radiant energy, relative to the mechanical axis, in which the measurement of radiometric and or spectroradiometric characteristics is performed.

Beam-Lead Phototransistor

A phototransistor chip with thick-film leads formed on the chip that project cantilever-style beyond the chip periphery for attachment to a separate substrate.
NOTE: When assembled into arrays and mounted on a ceramic substrate, beam-lead phototransistor arrays offer accurate spacing on centers too close for conventional discrete packages and too far apart for monolithic arrays; see TI Bulletin CB-128 for further information.

Brightness

See Luminance

Color Temperature

The temperature of a blackbody having the same visible color as that of a given non-blackbody radiator.
TYPICAL UNIT: K (formerly $^{\circ}$K).

Conversion Efficiency (of a Photon-Emitting Device)

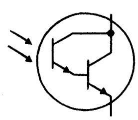
The ratio of maximum available luminous or radiant flux output to total input power.

Dark Current (I_D)

The current that flows through a photosensitive device in the dark condition.
NOTE: The dark condition is attained when the electrical parameter under consideration approaches a value that cannot be altered by further irradiation shielding.

Darlington-Connected Phototransistor

A phototransistor the collector and emitter of which are connected to the collector and base, respectively, of a second transistor. The emitter current of the input transistor is amplified by the second transistor and the device has very high sensitivity to illumination or irradiation.
GRAPHIC SYMBOL:



NOTE: The base region(s) may or may not be brought out as (an)electrical terminal(s).

TEXAS INSTRUMENTS
INCORPORATED
POST OFFICE BOX 225012 • DALLAS, TEXAS 75265

D-C Transfer Ratio (of an Opto-coupler)

The ratio of the dc output current to the dc input current.

Delay Time (t_d)

The time interval from the point at which the leading edge of the input pulse has reached 10% of its maximum amplitude to the point at which the leading edge of the output pulse has reached 10% of its maximum amplitude.

Demodulation Bandwidth (B)

The frequency interval in which the demodulated output of a photodetector, or a system including a photodetector, is not more than 3 dB below the midband output. Midband output is the output in the region of flat response or the average output over a specific frequency range.

Electroluminescence

The direct conversion of electrical energy into visible radiation.

Fall Time (t_f)

The time duration during which the trailing edge of a pulse is decreasing from 90% to 10% of its maximum amplitude.

Forward Current (I_F)

The current through a semiconductor diode when the p region (anode) is at a positive potential with respect to the n region (cathode).

Forward Voltage (V_F)

The voltage across a semiconductor diode associated with the flow of forward current. The p-region is at a positive potential with respect to the n-region.

Gain-Bandwidth Product (of an Avalanche Photodiode)

The gain times the frequency of measurement when the device is biased for maximum obtainable gain.

Half-Intensity Beam Angle (θ_{HI})

The angle within which the radiant intensity is not less than half of the maximum intensity.

Hexadecimal Display

A solid-state display capable of exhibiting numbers 0 through 9 and alpha characters A through F.
NOTE: The TIL311 and TIL505 are hexadecimal displays each with an integral TTL circuit that will accept, store, and display 4-bit binary data.

Illuminance (Illumination) (E_v)

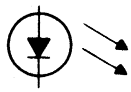
The luminous flux density incident on a surface; the quotient of the flux divided by the area of illuminated surface.
TYPICAL UNITS: lm/ft^2, $lx = lm/m^2$. $1\ lm/ft^2 = 10.76391\ lx$.

Infrared Emission

Radiant energy that is characterized by wavelengths longer than visible red, i.e., about 0.78 μm to 100 μm.

Infrared-Emitting Diode (IRED)

A diode capable of emitting radiant energy, in the infrared region of the spectrum, resulting from the recombination of electrons and holes.
NOTE: TI manufactures GaAs and GaAlAs radiant-energy sources that emit in the 0.82-μm to 0.94-μm portion of the near-infrared region. These emitters are spectrally matched with TI silicon photodetectors.
GRAPHIC SYMBOL:



Irradiance (E_e, formerly H)

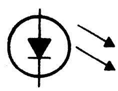
The radiant flux density incident on a surface; the quotient of the flux divided by the area of irradiated surface.
TYPICAL UNITS: W/ft^2, W/m^2. 1 W/ft^2 = 10.76391 W/m^2.

Light Current (I_L)

The current that flows through a photosensitive device, such as a phototransistor or a photodiode, when it is exposed to radiant energy.

Light-Emitting Diode (LED)

A diode capable of emitting luminous energy resulting from the recombination of electrons and holes.
NOTE: In popular usage, this term is sometimes used for infrared-emitting diodes.
GRAPHIC SYMBOL:



Luminance (L_V) (Photometric Brightness)

The luminous intensity of a surface in a given direction per unit of projected area of the surface as viewed from that direction.
TYPICAL UNITS: fL, cd/ft^2, cd/m^2. 1 fL = (1/π) cd/ft^2 = 3.426259 cd/m^2.

Luminous Energy (Q_V)

Energy traveling in the form of visible radiation.
TYPICAL UNITS: lm · s

Luminous Flux (Φ_V)

The time rate of flow of luminous energy.
TYPICAL UNIT: lm
NOTE: Luminous flux is related to radiant flux by the eye-response curve of the International Commission on Illumination (CIE). At the peak response (λ = 555 nm), 1 W = 680 lm.

Luminous Intensity (I_V)

Luminous flux per unit solid angle in a given direction.
TYPICAL UNIT: cd. 1 cd = 1 lm/sr.

Luminous Responsivity (R_V)

The quotient of the rms value of the fundamental component of the electrical output divided by the rms value of the fundamental component of the luminous flux of a specified distribution.
TYPICAL UNITS: V/lm, A/lm

Modulation Frequency (f_{mod})

The frequency of modulation of the luminous or radiant flux.

Noise Equivalent Bandwidth (Δf)

The equivalent bandwidth of a flat (or white) sharp-cutoff noise spectrum, having the same maximum value and containing the same noise power as the actual broadband output noise power of the device or circuit.
TYPICAL UNIT: Hz

Noise Equivalent Power (P_n or NEP)

The rms value of the fundamental component of a modulated radiant flux incident on the detector area that will produce a signal (voltage or current) at the detector output that is equal to the broadband rms noise (voltage or current).
TYPICAL UNIT: W
NOTE: The noise equivalent power equals the broadband output noise (voltage or current) divided by the responsivity (in volts/watt or amperes/watt).

Noise Equivalent Power (P_n or NEP) (Spectral Density)

The noise equivalent power in a one-Hertz bandwidth at the detector output.
TYPICAL UNIT: $W/Hz^{1/2}$
NOTE: The noise equivalent power spectral density equals the noise equivalent power divided by the square root of the noise bandwidth.

Off-State Collector Current ($I_{C(off)}$) (of an Opto-coupler)

The output current when the input current is zero.

On-State Collector Current ($I_{C(on)}$) (of an Opto-coupler)

The output current when the input current is above the threshold level.
NOTE: An increase in the input current will usually result in a corresponding increase in the on-state collector current.

Optical Axis

A line about which the radiant-energy pattern is centered.
NOTES: 1. The radiant-energy pattern may be nonsymmetrical.
2. The optical axis may deviate from the mechanical axis.

Opto-coupler (Optically Coupled Isolator, Photo-coupler)

A device designed for the transformation of electrical signals by utilizing optical radiant energy so as to provide coupling with electrical isolation between the input and the output.
NOTE: As manufactured by Texas Instruments, these devices consist of a gallium arsenide infrared-emitting diode and a silicon phototransistor and provide high-voltage isolation between separate pairs of input and output terminals.

Optoelectronic Device

A device that is responsive to or that emits or modifies coherent or noncoherent electromagnetic radiation in the visible, infrared, and/or ultraviolet spectral regions; or a device that utilizes such electromagnetic radiation for its internal operation.

Photocurrent

The difference between light current (I_L) and dark current (I_D) in a photodetector.

Photocurrent Gain (M) (of an Avalanche Photodiode)

The ratio of photocurrent at high bias voltage to that at low bias voltage. (See also avalanche photodiode definition).

Photodetector, Photosensitive Device

A device that is responsive to electromagnetic radiation in the visible, infrared, and/or ultraviolet spectral regions.

Photodiode

A diode that is intended to be responsive to radiant energy.
GRAPHIC SYMBOLS:

NOTE: The photodiode is characterized by linearity between the input radiation and the output current. It has faster switching speeds than a phototransistor.

Photometric Axis

See Axis of Measurement.

Photometric Brightness

See Luminance.

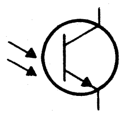
Photon

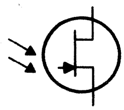
A quantum (the smallest possible unit) of radiant energy; a photon carries a quantity of energy equal to Planck's constant (6.6262×10^{-34} joule/hertz) times the frequency.

TEXAS INSTRUMENTS
INCORPORATED
POST OFFICE BOX 225012 • DALLAS, TEXAS 75265

Phototransistor

A transistor (bipolar or field-effect) that is intended to be responsive to radiant energy.
NOTE: The base region or gate may or may not be brought out as an external terminal.
GRAPHIC SYMBOLS:





Quantum Efficiency (of a Photosensitive Device)

The fractional number of effective electron-hole pairs produced within the device for each incident photon. For devices that internally amplify or multiply the electron-hole pairs (such as phototransistors or avalanche photodiodes), the effect of the gain is to be excluded from quantum efficiency.

Quantum Efficiency, External (of a Photoemitter)

The number of photons radiated for each electron flowing into the radiant source.

Radiance (L_e)

The radiant intensity of a surface in a given direction per unit of projected area of the surface as viewed from that direction.
TYPICAL UNIT: $W \cdot sr^{-1} m^{-2}$.

Radiant Energy (Q_e)

Energy traveling in the form of electromagnetic waves.
TYPICAL UNITS: $W \cdot s$, J

Radiant Flux or Power Output (Φ_e or P_O)

The time rate of flow of radiant energy.
TYPICAL UNITS: W

Radiant Intensity (I_e)

Radiant flux per unit solid angle in a given direction.
TYPICAL UNIT: W/sr

Radiant Pulse Fall Time (t_f)

The time required for a radiometric quantity to change from 90% to 10% of its peak value for a step change in electrical input.

Radiant Pulse Rise Time (t_r)

The time required for a radiometric quantity to change from 10% to 90% of its peak value for a step change in electrical input.

Radiant Responsivity (R_e)

The quotient of the rms value of the fundamental component of the electrical output divided by the rms value of the fundamental component of the radiant flux of a specified distribution.
TYPICAL UNITS: V/W, A/W

Reverse Current (I_R)

The current through a semiconductor diode when the n region (cathode) is at a positive potential with respect to the p region (anode).

Reverse Voltage (V_R)

The voltage across a semiconductor diode associated with the flow of reverse current. The n region is at a positive potential with respect to the p region.

Rise Time (t_r)

The time duration during which the leading edge of a pulse is increasing from 10% to 90% of its maximum amplitude.

Series Resistance

The undepleted bulk resistance of the photodiode substrate.
NOTE: This characteristic becomes significant at higher frequencies where the capacitive reactance of the junction is of the same or lower magnitude compared to the series resistance.

Spectral Bandwidth ($\Delta\lambda$)

The wavelength interval in which the spectral concentration of a photometric or radiometric quantity is not less than half of its maximum value.
TYPICAL UNITS: Å, μm, nm

Steradian (sr)

A unit of solid angular measurement equal to the solid angle at the center of a sphere subtended by a portion of the surface area equal to the square of the radius; there are 4π steradians in a complete sphere. The number of steradians in a cone of full angle θ is $2\pi\ (1 - \cos 0.5\theta)$.

Storage Time (t_s)

The time interval from a point at which the trailing edge of the input pulse has dropped to 90% of its maximum amplitude to a point at which the trailing edge of the output pulse has dropped to 90% of its maximum amplitude.

Visible Emission

Radiant energy that is characterized by wavelengths of about 0.38 μm to 0.78 μm.

Visible-Light-Emitting Diode (VLED)

Synonym for Light-Emitting Diode (LED)
NOTE: Strictly speaking, the adjective "visible" is redundant; however, this term is frequently used when there is a likelihood of confusion with infrared-emitting diodes.

Wavelength at Peak Emission (λ_p)

The wavelength at which the spectral radiant intensity is maximum.
TYPICAL UNITS: Å, μm, nm. $1\ \text{Å} = 10^{-4}\ \mu\text{m} = 0.1\ \text{nm}$.
