IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes to or to discontinue any semiconductor product or service identified in this publication without notice. TI advises its customers to obtain the latest version of the relevant information to verify, before placing orders, that the information being relied upon is current.

TI warrants performance of its semiconductor products to current specifications in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Unless mandated by government requirements, specific testing of all parameters of each device is not necessarily performed.

TI assumes no liability for TI applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.

INTRODUCTION

The 1989 MOS Memory Data Book from Texas Instruments includes complete detailed specifications on the expanding MOS Memory product line including Dynamic Random-Access Memories (DRAMs), Single-In-Line Package DRAM Memory Modules (SIPs), Video Random-Access Memories (VRAMs), First-In First-Out Pseudo Static Memories (FRAMs), Erasable Programmable Read-Only Memories (EPROMs), and MOS one-time Programmable Read-Only Memories (PROMs). Also included are military specifications for DRAMs, VRAMs, EPROMs, and Static Random-Access Memories (SRAMs). This is TI's first MOS Memory data book to include specifications for the VLSI Memory Management products.

The data book is divided into 13 sections. Section 1, *General Information*, includes the table of contents, an alphanumeric index for quickly finding device numbers, a part number guide with ordering information, plus device selection guides, product reference guides, and an IC Line-up chart for a quick overview of the broad TI MOS Memory product line. Page numbers are included on the product selection guides for easy access to the detailed specifications. In Section 2, an *Alternate Source Directory* lists alternate vendor part numbering examples in addition to alternate sources to TI devices (based on published data). Product specifications for over 100 devices can be found in Sections 4 through 8.

Recently published technical articles and product applications information can be found in Section 9. For the first time, a section on *Quality and Reliability* (Section 10) has been included in the TI MOS Memory data book. Because all MOS Memory devices are ESD sensitive, handling guidelines are included in Section 13.

The data sheets within each section are in alphanumeric order; Product Preview information is included at the end of the section. Data sheets listed with a "TMX" prefix and Product Preview disclaimer include target specifications for products that are currently under development at TI. The inclusion of these specifications does not imply that these products are or will be in production, or will meet these parameters.

Additional and/or updated information on these products is available from:

Texas Instruments
Customer Response Center
P.O. Box 809066
Dallas, Texas 75380-9066

For ordering information or further assistance, please contact your nearest Texas Instruments Sales Office or authorized distributor as listed in the back of this book.

DRAM/FRAM/SRAM ORDERING INFORMATION

Factory orders for DRAM/FRAM/SRAMs described in this book should include an eight-part type number as explained in the following example:

TMS 4 4 C 256 -10 DJ -

1) Prefix: _____
 TMS Commercial MOS
 SMJ Military MOS
 TMX Pre-production Commercial MOS

2) Product Family: _____
 4 DRAM/FRAM
 6 SRAM (Military Only)

3) Word Width: _____
 1 x 1
 Blank x 1 (256K and 1 Meg DRAMs Only)
 Blank x 4 (1 Meg FRAM Only)
 4 x 4
 8 x 8 (SRAMs Only)
 9 x 9 (SRAMs Only)

4) Technology: _____
 Blank NMOS
 C CMOS
 CE CMOS with Output Enable Control (SRAMs Only)
 CD CMOS with Separate I/O Pins (SRAMs Only)

5) Density: _____

16 16K SRAM	61 256K VRAM ('4461)
16 64K DRAM ('4416)	288 288K SRAM
64 64K DRAM ('4164)	256 1 Meg DRAM ('44C256)
64 64K SRAM	257 1 Meg DRAM ('44C257)
61 64K VRAM ('4161)	1024 1 Meg DRAM ('4C1024)
72 72K SRAM	1025 1 Meg DRAM ('4C1025)
64 256K DRAM ('4464)	1027 1 Meg DRAM ('4C1027)
256 256K DRAM ('4256)	1050 1 Meg FRAM ('4C1050)
257 256K DRAM ('4257)	251 1 Meg VRAM ('44C251)
256 256K SRAM	

6) Speed Designator: _____

DRAMs	FRAMs	SRAMs
- 8 80 ns	- 3 25 ns	- 25 25 ns
- 10 100 ns	- 4 30 ns	- 35 35 ns
- 12 120 ns	- 6 50 ns	- 45 45 ns
- 15 150 ns		- 55 55 ns
- 20 200 ns		

7) Package: _____

Commercial (Plastic)	Military (Ceramic)
DJ Small Outline J-lead (SOJ)	JD Dual In-line (DIP)
FM Leaded Chip Carrier (PLCC)	FG, FV Leadless Chip Carrier (CLCC)
SD Zig-zag In-line (ZIP)	HJ Small Outline J-lead (SOJ)
N Dual In-line (DIP)	

8) Temperature Range: _____

Commercial	Military
L 0°C to 70°C	M - 55°C to 125°C
Blank 0°C to 70°C (1 Meg DRAM Only)	S - 55°C to 100°C†

† Except SMJ4164 and SMJ4256, which are - 55°C to 110°C.

ORDERING INFORMATION

1

General Information

DRAM MODULE ORDERING INFORMATION

Factory orders for DRAM modules described in this book should include a seven-part type number as explained in the following example:

	TM	024	G	AL	8	-10	L
1) Prefix: _____							
TM TI Module							
2) Memory Device: _____							
4256 256K DRAM, Page Mode							
4257 256K DRAM, Nibble Mode							
4464 256K DRAM							
024 1 Meg DRAM, Enhanced Page Mode							
025 1 Meg DRAM, Nibble Mode							
027 1 Meg DRAM, Static Column Decode Mode							
3) Pinout Configuration: _____							
E G							
F							
4) Board Dimensions: _____							
A K T AD AL							
B L U AF							
C N V AG							
H P AB AH							
5) Word Width Output: _____							
6) Speed Designator: _____							
-10 100 ns							
-12 120 ns							
-15 150 ns							
7) Temperature Range: _____							
L 0°C to 70°C							

EPROM/PROM/EEPROM ORDERING INFORMATION

Factory orders for EPROMs/PROMs described in this book should include a nine-part type number as explained in the following example:

	TMS	27	P	C	512	-10	FM	L	4
1. Prefix: _____									
TMS Commercial MOS SMJ Military MOS TMX Pre-production Commercial MOS									
2) Product Family: _____									
27 EPROM/PROM 28 EEPROM									
3) Erasability: _____									
P Non-erasable Blank Erasable									
4) Technology: _____									
C CMOS Blank NMOS									
5) Density: _____									
291 16K 128 128K 292 16K 256 256K 32 32K 512 512K 49 64K 010 1024K 64 64K 210 1024K									
6) Speed Designator [†] : _____									
35 ns -3, -35 150 ns -1, -15, -150 45 ns Blank, -4, -45 170 ns -1, -17, -170 50 ns -5, -50 200 ns -2, -20, -200 55 ns -5, -55 250 ns Blank, -25, -250 100 ns -10, -100 300 ns -3, -30, -300 120 ns -12, -120 450 ns -45									
7) Package: _____									
PROMs (Plastic) N Dual In-line (DIP) FN Chip Carrier FM Chip Carrier NT 300-mil DIP (TMS27PC49 Only)			EPROMs (Ceramic) J Cerpak/Cerdip JT 300-mil Cerdip (TMS27C49 Only)			EEPROMs J Ceramic DIP N Plastic DIP			
8) Temperature Range: _____									
Commercial E -40°C to 85°C L 0°C to 70°C					Military M -55°C to 125°C S -55°C to 100°C				
9) 168 Hour Burn-in Option: _____									
4 168 Hour Burn-in Blank No Burn-in									

[†]Please check individual data sheets for available speeds.

ORDERING INFORMATION

VLSI MEMORY MANAGEMENT ORDERING INFORMATION

Factory orders for VLSI Memory Management products described in this book should include a four-part type number as explained in the following example:

- SN 74ACT2152 - 25 JD
- 1) Prefix: _____
SN Standard Prefix
THCT Commercial CMOS
TACT Commercial Advanced CMOS
 - 2) Circuit Description: _____
4 to 10 Characters
 - 3) Speed Designator: _____
- xx Speed in ns
 - 4) Package: _____
D, DW "Small Outline" Packages
J, JD Ceramic DIPs
N, NT Plastic DIPs
FK Ceramic Chip Carrier
FN Plastic Chip Carrier

PART I — GENERAL CONCEPTS AND TYPES OF MEMORIES

Address — Any given memory location in which data can be stored or from which it can be retrieved.

Automatic Chip-Select/Power Down — (see Chip Enable Input)

Bit — Contraction of Binary digIT, i.e., a 1 or a 0; in electrical terms the value of a bit may be represented by the presence or absence of charge, voltage, or current.

Byte — A word of 8 bits (see word)

CMOS — A complementary MOS technology which uses transistors with electron (N-channel) and hole (P-channel) conduction.

Chip Enable Input — A control input to an integrated circuit that when active permits operation of the integrated circuit for input, internal transfer, manipulation, refreshing, and/or output of data and when inactive causes the integrated circuit to be in a reduced power standby mode.

Chip Select Input — Chip select inputs are gating inputs that control the input to and output from the memory. They may be of two kinds:

1. Synchronous—Clocked/latched with the memory clock. Affects the inputs and outputs for the duration of that memory cycle.
2. Asynchronous—Has direct asynchronous control of inputs and outputs. In the read mode, an asynchronous chip select functions like an output enable.

Column Address Strobe (CAS) — A clock used in dynamic RAMs to control the input of column addresses. It can be active high (CAS) or active low ($\overline{\text{CAS}}$).

Data — Any information stored or retrieved from a memory device.

DIP — Dual In-line Package.

Dynamic (Read/Write) Memory (DRAM) — A read/write memory in which the cells require the repetitive application of control signals in order to retain the stored data.

- NOTES:
1. The words "read/write" may be omitted from the term when no misunderstanding will result.
 2. Such repetitive application of the control signals is normally called a refresh operation.
 3. A dynamic memory may use static addressing or sensing circuits.
 4. This definition applies whether the control signals are generated inside or outside the integrated circuit.

Electrically Erasable Programmable Read-Only Memory (EEPROM) — A nonvolatile memory that can be field-programmed like a PROM or EPROM, but that can be electrically erased by a combination of electrical signals at its inputs.

Erasable and Programmable Read-Only Memory (EPROM) — A field-programmable read-only memory that can have the data content of each memory cell altered more than once.

Erase — Typically associated with EPROMs and EEPROMs. The procedure whereby programmed data is removed and the device returns to its unprogrammed state.

FRAM — First-in First-out pseudo static RAM or Field RAM.

Field-Programmable Read-Only Memory — (see One-time Programmable Read-Only Memory)

Fixed Memory — A common term for ROMs, EPROMs, EEPROMs, etc., containing data that is not normally changed. A more precise term for EPROMs and EEPROMs is nonvolatile since their data may be easily changed.

Fully Static RAM — In a fully static RAM, the periphery as well as the memory array is fully static. The periphery is thus always active and ready to respond to input changes without the need for clocks. There is no precharge required for static periphery.

GLOSSARY/TIMING CONVENTIONS/DATA SHEET STRUCTURE

K — When used in the context of specifying a given number of bits of information, $1K = 2^{10} = 1024$ bits. Thus, $64K = 64 \times 1024 = 65,536$ bits.

Large-Scale Integration (LSI) — The description of any IC technology that enables condensing more than 100 gates onto a single chip.

Mask-Programmed Read-Only Memory — A read-only memory in which the data content of each cell is determined during manufacture by the use of a mask, the data content thereafter being unalterable.

Memory — A medium capable of storing information that can be retrieved.

Memory Cell — The smallest subdivision of a memory into which a unit of data has been or can be entered, in which it is or can be stored, and from which it can be retrieved.

Metal-Oxide Semiconductor (MOS) — The technology involving photolithographic layering of metal and oxide to produce a semiconductor device.

NMOS — A type of MOS technology in which the basic conduction mechanism is governed by electrons. (Short for N-channel MOS)

Nonvolatile Memory — A memory in which the data content is maintained whether the power supply is connected or not.

One-time Programmable Read-Only Memory (PROM) — A read-only memory that after being manufactured, can have the data content of each memory cell altered once.

Output Enable — A control input that, when true, permits data to appear at the memory output, and when false, causes the output to assume a high-impedance state. (See also chip select)

PLCC — Plastic Leaded Chip Carrier package.

PMOS — A type of MOS technology in which the basic conduction mechanism is governed by holes. (Short for P-channel MOS)

Parallel Access — A feature of a memory by which all the bits of a byte or word are entered simultaneously at several inputs or retrieved simultaneously from several outputs.

Power Down — A mode of a memory during which the device is operating in a low-power or standby mode. Normally read or write operations of the memory are not possible under this condition.

Program — Typically associated with EPROM and PROM memories, the procedure whereby logical 0s (or 1s) are stored into various desired locations in a previously erased device.

Program Enable — An input signal that when true, puts a programmable memory device into the program mode.

Programmable Read-Only Memory (PROM) — (see One-time Programmable Read-Only Memory)

Printed Wiring Board (PWB) — A substrate of epoxy glass, clad material, or other material upon which a pattern of conductive traces is formed to interconnect the components which will be mounted upon it.

Read — A memory operation whereby data is output from a desired address location.

Read-Only Memory (ROM) — A memory in which the contents are not intended to be altered during normal operation.

NOTE: Unless otherwise qualified, the term "read-only memory" implies that the contents is determined by its structure and is unalterable.

Read/Write Memory — A memory in which each cell may be selected by applying appropriate electrical input signals and the stored data may be either (a) sensed at appropriate output terminals, or (b) changed in response to other similar electrical input signals.

Row Address Strobe (RAS) — A clock used in dynamic RAMs to control the input of the row addressed. It can be active high (RAS) or active low ($\overline{\text{RAS}}$).

- SOJ** — Small Outline J-lead package.
- Scaled-MOS (SMOS)** — MOS technology under which the device is scaled down in size in three dimensions and in operating voltages allowing improved performance.
- Semi-Static (Quasi-Static, Pseudo-Static) RAM** — In a semi-static RAM, the periphery is clock-activated (i.e., dynamic). Thus the periphery is inactive until clocked, and only one memory cycle is permitted per clock. The peripheral circuitry must be allowed to reset after each active memory cycle for a minimum precharge time. No refresh is required.
- Serial Access** — A feature of a memory by which all the bits are entered sequentially at a single input or retrieved sequentially from a single output.
- SIP** — Single In-line package.
- Small Outline Integrated Circuit (SOIC)** — A package in which an integrated circuit chip can be mounted to form a surface-mounted component. It is made of a plastic material which can withstand high temperatures and has leads formed in a gull-wing shape along its two longer sides for connection to a PWB footprint.
- Static RAM (SRAM)** — A read/write random-access device within which information is stored as latched voltage levels. The memory cell is a static latch that retains data as long as power is applied to the memory array. No refresh is required. The type of periphery circuitry sub-categorizes static RAMs.
- Very-Large-Scale Integration (VLSI)** — The description of any IC technology that is much more complex than large-scale integration (LSI), and involves a much higher equivalent gate count. At this time an exact definition including a minimum gate count has not been standardized by JEDEC or the IEEE.
- Volatile Memory** — A memory in which the data content is lost when power supplied is disconnected.
- Word** — A series of one or more bits that occupy a given address location and that can be stored and retrieved in parallel.
- Write** — A memory operation whereby data is written into a desired address location.
- Write Enable** — A control signal that when true causes the memory to assume the write mode, and when false causes it to assume the read mode.
- ZIP** — Zig-zag In-line package.

**PART II — OPERATING CONDITIONS AND CHARACTERISTICS
(INCLUDING LETTER SYMBOLS)**

Capacitance

The inherent capacitance on every pin, which can vary with various inputs and outputs.

Example symbology:

C_i	Input capacitance
C_o	Output capacitance
$C_i(D)$	Input capacitance, data input

Current

High-level input current, I_{IH}

The current into an input when a high-level voltage is applied to that input.

High-level output current, I_{OH}

The current into* an output with input conditions applied that according to the product specification will establish a high level at the output.

Low-level input current, I_{IL}

The current into an input when a low-level voltage is applied to that input.

Low-level output current, I_{OL}

The current into* an output with input conditions applied that according to the product specification will establish a low level at the output.

Off-state (high-impedance-state) output current (of a three-state output), I_{OZ}

The current into* an output having three-state capability with input conditions applied that according to the product specification will establish the high-impedance state at the output.

Short-circuit output current, I_{OS}

The current into* an output when the output is short-circuited to ground (or other specified potential) with input conditions applied to establish the output logic level farthest from ground potential (or other specified potential).

Supply current, I_{BB} , I_{CC} , I_{DD} , I_{PP}

The current into, respectively, the V_{BB} , V_{CC} , V_{DD} , V_{PP} supply terminals.

*Current out of a terminal is given as a negative value.

Operating Free-Air Temperature

The temperature (T_A) range over which the device will operate and meet the specified electrical characteristics.

Operating Case Temperature

The case temperature (T_C) range over which the device will operate and meet the specified electrical characteristics.

Voltage

High-level input voltage, V_{IH}

An input voltage within the more positive (less negative) of the two ranges of values used to represent the binary variables.

NOTE: A minimum is specified that is the least positive value of high-level input voltage for which operation of the logic element within specification limits is guaranteed.

High-level output voltage, V_{OH}

The voltage at an output terminal with input conditions applied that according to the product specification will establish a high level at the output.

Low-level input voltage, V_{IL}

An input voltage level within the less positive (more negative) of the two ranges of values used to represent the binary variables.

NOTE: A maximum is specified that is the most positive value of low-level input voltage for which operation of the logic element within specification limits is guaranteed.

Low-level output voltage, V_{OL}

The voltage at an output terminal with input conditions applied that according to the product specification will establish a low level at the output.

Supply voltages, V_{BB} , V_{CC} , V_{DD} , V_{PP}

The voltages supplied to the corresponding voltage pins that are required for the device to function. From one to four of these supplies may be necessary, along with ground, V_{SS} .

Time Intervals

New or revised data sheets in this book use letter symbols in accordance with standards recently adopted by JEDEC, the IEEE, and the IEC. Two basic forms are used. The first form is usually used in this book when intervals can easily be classified as access, cycle, disable, enable, hold, refresh, setup, transition, or valid times and for pulse durations. The second form can be used generally but in this book is used primarily for time intervals not easily classifiable. The second (unclassified) form will be described first. Since some manufacturers use this form for all time intervals, symbols in the unclassified form are given with the examples for most of the classified time intervals.

Unclassified time intervals

Generalized letter symbols can be used to identify almost any time interval without classifying it using traditional or contrived definitions. Symbols for unclassified time intervals identify two signal events listed in from-to sequence using the format:

$${}^tAB-CD$$

Subscripts A and C indicate the names of the signals for which changes of state or level or establishment of state or level constitute signal events assumed to occur first and last, respectively, that is, at the beginning and end of the time interval. Every effort is made to keep the A and C subscript length down to one letter, if possible (e.g., R for \overline{RAS} and C for \overline{CAS}).

Subscripts B and D indicate the direction of the transitions and/or the final states or levels of the signals represented by A and C, respectively. One or two of the following is used:

- H = high or transition to high
- L = low or transition to low
- V = a valid steady-state level
- X = unknown, changing, or "don't care" level
- Z = high-impedance (off) state

The hyphen between the B and C subscripts is omitted when no confusion is likely to occur.

For examples of symbols of this type, see TMS4256 (e.g., t_{RLCL}).

Classified time intervals (general comments, specific times follow)

Because of the information contained in the definitions, frequently the identification of one or both of the two signal events that begin and end the intervals can be significantly shortened compared to the unclassified forms. For example, it is not necessary to indicate in the symbol that an access time ends with valid data at the output. However, if both signals are named (e.g., in a hold time), the from-to sequence is maintained.

GLOSSARY/TIMING CONVENTIONS/DATA SHEET STRUCTURE

Access time

The time interval between the application of a specific input pulse and the availability of valid signals at an output.

Example symbology:

Classified	Unclassified	Description
$t_a(A)$	t_{AVQV}	Access time from address
$t_a(S), t_a(CS)$	t_{SLQV}	Access time from chip select (low)

Cycle time

The time interval between the start and end of a cycle.

NOTE: The cycle time is the actual time interval between two signal events and is determined by the system in which the digital circuit operates. A minimum value is specified that is the shortest interval that must be allowed for the digital circuit to perform a specified function (e.g., read, write, etc.) correctly.

Example symbology:

Classified	Unclassified	Description
$t_c(R), t_c(rd)$	$t_{AVAV(R)}$	Read cycle time
$t_c(W)$	$t_{AVAV(W)}$	Write cycle time

NOTE: R is usually used as the abbreviation for "read"; however, in the case of dynamic memories, "rd" is used to permit R to stand for RAS.

Disable time (of a three-state output)

The time interval between the specified reference points on the input and output voltage waveforms, with the three-state output changing from either of the defined active levels (high or low) to a high-impedance (off) state.

Example symbology:

Classified	Unclassified	Description
$t_{dis(S)}$	t_{SHQZ}	Output disable time after chip select (high)
$t_{dis(W)}$	t_{WLQZ}	Output disable time after write enable (low)

These symbols supersede the older forms tp_{VZ} or tp_{XZ} .

Enable time (of a three-state output)

The time interval between the specified reference points on the input and output voltage waveforms, with the three-state output changing from a high-impedance (off) state to either of the defined active levels (high or low).

NOTE: For memories these intervals are often classified as access times.

Example symbology:

Classified	Unclassified	Description
$t_{en(SL)}$	t_{SLQV}	Output enable time after chip select low

These symbols supersede the older form tp_{ZV} .

Hold time

The time interval during which a signal is retained at a specified input terminal after an active transition occurs at another specified input terminal.

- NOTES:
1. The hold time is the actual time interval between two signal events and is determined by the system in which the digital circuit operates. A minimum value is specified that is the shortest interval for which correct operation of the digital circuit is guaranteed.
 2. The hold time may have a negative value in which case the minimum limit defines the longest interval (between the release of the signal and the active transition) for which correct operation of the digital circuit is guaranteed.

Example symbology:

Classified	Unclassified	Description
$t_h(D)$	tWHDX	Data hold time (after write high)
$t_h(RHrd)$	trHWH	Read (write enable high) hold time after \overline{RAS} high
$t_h(CHrd)$	tCHWH	Read (write enable high) hold time after \overline{CAS} high
$t_h(CLCA)$	tCL-CAX	Column address hold time after \overline{CAS} low
$t_h(RLCA)$	trL-CAX	Column address hold time after \overline{RAS} low
$t_h(RA)$	trL-RAX	Row address hold time (after \overline{RAS} low)

These last three symbols supersede the older forms:

NEW FORM	OLD FORM
$t_h(CLCA)$	$t_h(ACL)$
$t_h(RLCA)$	$t_h(ARL)$
$t_h(RA)$	$t_h(AR)$

NOTE: The from-to sequence in the order of subscripts in the unclassified form is maintained in the classified form. In the case of hold times, this causes the order to seem reversed from what would be suggested by the terms.

Pulse duration (width)

The time interval between the specified reference points on the leading and trailing edges of the pulse waveform.

Example symbology:

Classified	Unclassified	Description
$t_w(W)$	tWLWH	Write pulse duration
$t_w(RL)$	trLRH	Pulse duration, \overline{RAS} low

Refresh time interval

The time interval between the beginnings of successive signals that are intended to restore the level in a dynamic memory cell to its original level.

NOTE: The refresh time interval is the actual time interval between two refresh operations and is determined by the system in which the digital circuit operates. A maximum value is specified that is the longest interval for which correct operation of the digital circuit is guaranteed.

Example symbology:

Classified	Unclassified	Description
t_{rf}		Refresh time interval

Setup time

The time interval between the application of a signal at a specified input terminal and a subsequent active transition at another specified input terminal.

- NOTES:
1. The setup time is the actual time interval between two signal events and is determined by the system in which the digital circuit operates. A minimum value is specified that is the shortest interval for which correct operation of the digital circuit is guaranteed.
 2. The setup time may have a negative value in which case the minimum limit defines the longest interval (between the active transition and the application of the other signal) for which correct operation of the digital circuit is guaranteed.

Example symbology:

Classified	Unclassified	Description
$t_{su(D)}$	tDVWH	Data setup time (before write high)
$t_{su(CA)}$	tCAV-CL	Column address setup time (before \overline{CAS} low)
$t_{su(RA)}$	tRAV-RL	Row address setup time (before RAS low)

Transition times (also called rise and fall times)

The time interval between two reference points (10% and 90% unless otherwise specified) on the same waveform that is changing from the defined low level to the defined high level (rise time) or from the defined high level to the defined low level (fall time).

Example symbology:

Classified	Unclassified	Description
t_t		Transition time (general)
$t_t(CH)$	tCHCH	Low-to-high transition time of \overline{CAS}
$t_r(C)$	tCHC	\overline{CAS} rise time
$t_f(C)$	tCLCL	\overline{CAS} fall time

Valid time

- (a) General

The time interval during which a signal is (or should be) valid.

- (b) Output data-valid time

The time interval in which output data continues to be valid following a change of input conditions that could cause the output data to change at the end of the interval.

Example symbology:

Classified	Unclassified	Description
$t_v(A)$	tAXQX	Output data valid time after change of address.

This supersedes the older form $tpvX$.

PART III — TIMING DIAGRAMS CONVENTIONS

TIMING DIAGRAM SYMBOL	MEANING	
	INPUT FORCING FUNCTIONS	OUTPUT RESPONSE FUNCTIONS
	Must be steady high or low	Will be steady high or low
	High-to-low changes permitted	Will be changing from high to low some time during designated interval
	Low-to-high changes permitted	Will be changing from low to high sometime during designated interval
	Don't Care	State unknown or changing
	(Does not apply)	Centerline represents high-impedance (off) state.

PART IV — BASIC DATA SHEET STRUCTURE

The front page of the data sheet begins with a list of key *features* such as organization, interface, compatibility, operation (static or dynamic), access and cycle times, technology (N or P channel, silicon or metal oxide gate), and power. In addition, the top view of the device is shown with the *pinout* provided. Next a general *description* of the device, system interface considerations, and elaboration on other device characteristics are presented. The next section is an explanation of the device's *operation* which includes the function of each pin (i.e., the relationship between each input (output) and a given type of memory). The functions basically involve starting, achieving, and ending a given type of memory cycle (e.g., programming or erasing EPROMs, or reading a memory location).

Augmenting the descriptive text there appears a *logic symbol* prepared in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12 and explained in Section 11 of this book. Following the symbol is usually a *functional block diagram*, a flowchart of the basic internal structure of the device showing the signal paths for data, addresses, and control signals, as well as the internal architecture. Usually the next few pages contain the absolute maximum ratings (e.g., voltage supplies, input voltage, and temperature) applicable over the *operating free-air temperature range*. If the device is used outside of these values, it may be permanently destroyed or at least it would not function as intended. Next, typically, are the *recommended operating conditions*, (e.g., supply voltages, input voltages, and operating temperature). The memory device is guaranteed to work reliably and to meet all data sheet parameters when operated in accord with the recommended operating conditions and within the specified timing. If the device is operated outside of these limits (minimum/maximum) it is no longer guaranteed to meet the data sheet parameters. Operation beyond the absolute maximum ratings can result in catastrophic failures.

The next section provides a table of *electrical characteristics over full ranges of recommended operating conditions* (e.g., input and output currents, output voltages, etc.). These are presented as minimum, typical, and maximum values. Typical values are representative of operation at an ambient temperature of $T_A = 25^\circ\text{C}$ with all power supply voltages at nominal value. Next, input and output capacitances are presented. Each pin has a capacitance (whether an input, an output, or control pin). Minimum capacitances are not given, as the typical and maximum values are the most crucial.

GLOSSARY/TIMING CONVENTIONS/DATA SHEET STRUCTURE

3

Glossary/Timing Conventions/Data Sheet Structure

The next few tables involve the device timing characteristics. The parameters are presented as minimum, typical (or nominal), and maximum. The *timing requirements over recommended supply voltage range and operating free-air temperature* indicate the device control requirements such as hold times, setup times, and transition times. These values are referenced to the relative positioning of signals on the timing diagrams, which follow. The *switching characteristics over recommended supply voltage range* are device performance characteristics inherent to device operation once the inputs are applied. These parameters are guaranteed for the test conditions given. The interrelationship of the timing requirements to the switching characteristics is illustrated in *timing diagrams* for each type of memory cycle (e.g., read, write, program.)

At the end of a data sheet additional *applications information* may be provided such as how to use the device, graphs of electrical characteristics, or other data on electrical characteristics.

TMS4256, TMS4257 262,144-BIT DYNAMIC RANDOM-ACCESS MEMORIES

MAY 1983—REVISED JANUARY 1988

- 262,144 × 1 Organization
- Single 5-V Power Supply
 - 5% Tolerance Required for TMS4256-8
 - 10% Tolerance Required for TMS4256-10, -12, -15, and TMS4257-10, -12, -15
- JEDEC Standardized Pinouts
- Performance Ranges:

DEVICE	ACCESS TIME ROW ADDRESS (MAX)	ACCESS TIME COLUMN ADDRESS (MAX)	READ OR WRITE CYCLE (MIN)	VDD TOLERANCE
'4256-8	80 ns	40 ns	160 ns	± 5%
'4256-10				
'4257-10	100 ns	50 ns	200 ns	± 10%
'4256-12				
'4257-12	120 ns	60 ns	220 ns	± 10%
'4256-15				
'4257-15	150 ns	75 ns	260 ns	± 10%

- Long Refresh Period . . . 4 ms (Max)
- Operations of the TMS4256/TMS4257 Can Be Controlled by TI's SN74ALS2967, SN74ALS2968, and THCT4502 Dynamic RAM Controllers
- All Inputs, Outputs, and Clocks Fully TTL Compatible
- 3-State Unlatched Outputs
- Common I/O Capability with "Early Write" Feature
- Page Mode ('4256) or Nibble-Mode ('4257)
- Low Power Dissipation
- $\overline{\text{RAS}}$ -Only Refresh Mode
- Hidden Refresh Mode
- $\overline{\text{CAS}}$ -Before- $\overline{\text{RAS}}$ Refresh Mode
- Available with MIL-STD-883B Processing and L(0°C to 70°C), E(-40°C to 85°C), or S(-55°C to 100°C) Temperature Ranges (SMJ4256, with 10% Power Supply)

PIN NOMENCLATURE	
A0-A8	Address Inputs
CAS	Column-Address Strobe
D	Data In
NC	No Connection
Q	Data Out
RAS	Row-Address Strobe
VDD	5-V Power Supply
VSS	Ground
W	Write Enable

262,144-BIT DYNAMIC RANDOM-ACCESS MEMORIES

description

The TMS4256 and TMS4257 are high-speed, 262,144-bit dynamic random-access memories, organized as 262,144 words of one bit each. They employ state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

The '4256-8 with a 5% voltage tolerance has a maximum $\overline{\text{RAS}}$ access time of 80 ns. The '4256/'4257-10, -12, and -15 with 10% voltage tolerances have maximum $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns, respectively.

New SMOS technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{DD} peaks are 125 mA typical, and a -1 V input voltage undershoot can be tolerated, minimizing system noise considerations.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The '4256 and '4257 are offered in 16-pin plastic dual-in-line, 16-pin plastic zig-zag in-line (ZIP), and 18-lead plastic chip carrier packages. They are guaranteed for operation from 0°C to 70°C. The dual-in-line package is designed for insertion in mounting-hole rows on 7,62-mm (300-mil) centers.

operation

address (A0 through A8)

Eighteen address bits are required to decode 1 of 262,144 storage cell locations. Nine row-address bits are set up on pins A0 through A8 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the nine column-address bits are set up on pins A0 through A8 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select, activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state for the entire cycle, permitting common I/O operation.

data in (D)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. This latch can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal.

data out (Q)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output goes active after the access time interval $t_{\text{a}}(\text{C})$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{\text{a}}(\text{R})$ is satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ is low; $\overline{\text{CAS}}$ going high returns it to a high-impedance state. In a read-modify-write cycle, the output will follow the sequence for the read cycle.

refresh

A refresh operation must be performed at least once every four milliseconds to retain data. This can be achieved by strobing each of the 256 rows (A0-A7). A normal read or write cycle will refresh all bits in each row that is selected. A $\overline{\text{RAS}}$ -only operation can be used by holding $\overline{\text{CAS}}$ at the high (inactive) level, thus conserving power as the output buffer remains in the high-impedance state.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

The $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is utilized by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ (see parameter t_{CLRL}) and holding it low after $\overline{\text{RAS}}$ falls (see parameter t_{RLCHR}). For successive $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh cycles, $\overline{\text{CAS}}$ can remain low while cycling $\overline{\text{RAS}}$. The external address is ignored and the refresh address is generated internally.

hidden refresh

Hidden refresh may be performed while maintaining valid data at the output pin. This is accomplished by holding $\overline{\text{CAS}}$ at V_{IL} after a read operation and cycling $\overline{\text{RAS}}$ after a specified precharge period, similar to a $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh cycle. The external address is also ignored during the hidden refresh cycles. The data at the output pin remains valid up to the maximum $\overline{\text{CAS}}$ low pulse duration, $t_{\text{w}}(\text{CL})$.

page mode (TMS4256)

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing random column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. The maximum number of columns that can be addressed is determined by $t_{\text{w}}(\text{RL})$, the maximum $\overline{\text{RAS}}$ low pulse duration.

nibble mode (TMS4257)

Nibble-mode operation allows high-speed serial read, write, or read-modify-write access of 1 to 4 bits of data. The first bit is accessed in the normal manner with read data coming out at $t_{\text{a}}(\text{C})$ time. The next sequential nibble bits can be read or written by cycling $\overline{\text{CAS}}$ while $\overline{\text{RAS}}$ remains low. The first bit is determined by the row and column addresses, which need to be supplied only for the first access. Column A8 and row A8 (CA8, RA8) provide the two binary bits for initial selection of the nibble addresses. Thereafter, the falling edge of $\overline{\text{CAS}}$ will access the next bit of the circular 4-bit nibble in the following sequence:

In nibble-mode, all normal memory operations (read, write, or read-modify-write) may be performed in any desired combination.

power-up

To achieve proper device operation, an initial pause of 200 μs is required after power up, followed by a minimum of eight initialization cycles.

Continued next page.

NOTE 3: Timing measurements are referenced to V_{IL} max and V_{IH} min.

[†]All cycle times assume $t_t = 5$ ns.

[‡]In a read-modify-write cycle, t_{CLWL} and $t_{su(WCH)}$ must be observed. Depending on the user's transition times, this may require additional \overline{CAS} low time ($t_w(CL)$). This applies to page-mode read-modify-write also.

[§]In a read-modify-write cycle, t_{RLWL} and $t_{su(WRH)}$ must be observed. Depending on the user's transition times, this may require additional \overline{RAS} low time ($t_w(RL)$).

TMS4461 262,144-BIT MULTIPOINT VIDEO RAM

JULY 1986—REVISED FEBRUARY 1988

- 65,536 × 4 Organization
- Dual-Port Accessibility — Four I/Os for Sequential Access, Four I/Os for Random Access
- One Serial Data Register Built into Each Serial I/O for Sequential-Access Applications
- Designed for Video and Non-Video Applications
- Fast Serial Ports . . . 25-MHz Shift Rate
- Mid-Scan Load — Serial Data Streams Uninterrupted by Register Reload
- TRG as Output Enable Allows Direct Connection of DQ and Address Lines to Simplify System Design
- Random-Access Port Is Compatible with the TMS4464, 64K × 4 DRAM
- Supported by TI's TMS34061 Video System Controller and TMS34010 Graphics System Processor (GSP)
- 3-State Serial I/Os Allow Easy Multiplexing of Video Data Streams
- Maximum Access Time from RAS . . . 120 ns
- Minimum Cycle Time (Read or Write) . . . 220 ns
- Long Refresh Period . . . 4 ms
- Low Refresh Overhead Time . . . As Low As 1.3% of Total Refresh Period
- All Inputs, Outputs, Clocks Fully TTL Compatible
- 3-State Unlatched Random-Access Outputs
- Common Random-Access I/O Capability with "Early Write" Feature
- High-Speed Page-Mode Operation for Faster Access

PIN NOMENCLATURE

description

The TMS4461 is a high-speed dual-ported 65,536 × 4 bit dynamic random-access memory with on-chip data registers. The random-access port makes the memory look as if it is organized as 65,536 words of four bits each, like the TMS4464. The sequential-access port is interfaced to four internal 256-bit dynamic data registers, which make the memory look as if it is organized as 256 four-bit words of up to 256 bits each that are accessed serially.

The 256K Multiport Video RAM employs state-of-the-art scaled NMOS, double-level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

TMS4461
262,144-BIT MULTIPORT VIDEO RAM

The TMS4461 features full asynchronous dual-port accessibility except when transferring data between the data register and the random-access memory.

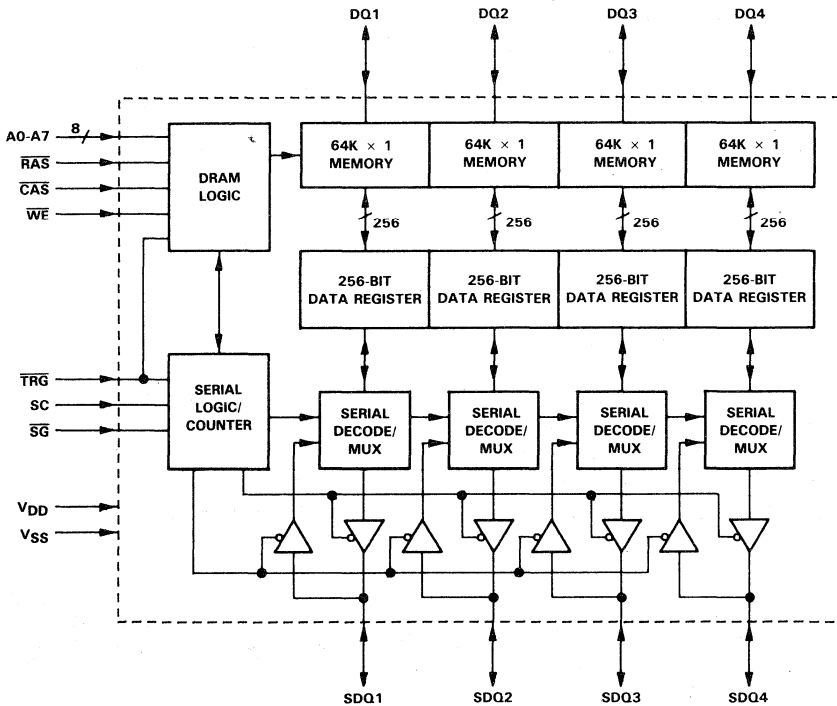

Refresh period is 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. CAS can remain high during the refresh sequence to conserve power. Note that the transfer of a row of data from the memory array to the data register also refreshes that particular row. CAS-before-RAS and hidden refresh modes are also available.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data in are latched on-chip to simplify system design. All data outs are unlatched to allow greater system flexibility.

The 256K Multiport Video RAM is offered in a 24-pin dual-in-line plastic package (N suffix) and is guaranteed for operation from 0°C to 70°C. The package is designed for insertion in mounting-hole rows on 10,16-mm (400-mil) centers.

The TMS4461 Multiport Video RAM is also offered in a 24-pin zig-zag plastic package (SD suffix), guaranteed for operation from 0°C to 70°C.

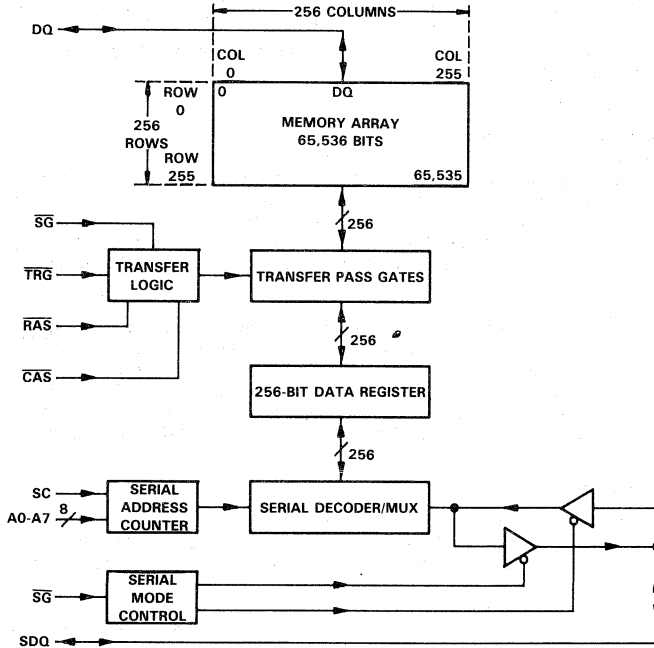

functional block diagram

random port to serial port interface

The TMS4461 Multiport Video RAM consists of a 64K × 4 DRAM port and a 256 × 4 serial port. Each of the four random (DRAM) I/Os is interfaced to a 256-bit data register that can be loaded with 256 bits in parallel from any row in that I/O channel's memory then read out sequentially starting from one of 256 selectable locations along the data register. Conversely, each of the four data registers can be loaded with data serially from the serial input (SD) and subsequently transferred, 256 bits in parallel, into any row of memory for each respective DRAM I/O channel.

block diagram showing one random and serial interface

random-access address space to sequential-address space mapping

The 256 bits in each of the four data registers correspond to the 256 column locations of each of the four random I/Os. Data can be read out of the registers starting at any of the 256 data register bit locations.

This tap location is selected by addresses A7 through A0 on the falling edge of $\overline{\text{CAS}}$ during a transfer cycle between the memory array and the data registers. All registers are read out starting from the selected tap point proceeding from the least-significant bits to the most-significant bits. The four data registers are configured as circular data registers when reading their contents to the serial outputs. After the most-significant bit (bit 255) is read out of each register, the next bit read will be 00 (see explanation under section entitled "serial data input/output").

Note that if column address bits A7 through A0 equal 00 during the last memory-to-register transfer cycle, a total of 256 bits can be sequentially read out of each of the four data registers starting from bit position 00.

operation

random-access operation

transfer register select ($\overline{\text{TRG}}$)

The $\overline{\text{TRG}}$ selects either register transfer or random-access operation as $\overline{\text{RAS}}$ falls. To use the TMS4461 in random-access mode, $\overline{\text{TRG}}$ must be held high as $\overline{\text{RAS}}$ falls. Holding $\overline{\text{TRG}}$ high as $\overline{\text{RAS}}$ falls causes the 256 storage elements of each data register to remain disconnected from the corresponding 256 bit lines of the memory array. If serial data is to be written in or read out of the data registers, the data registers must be disconnected from the bit lines. Holding $\overline{\text{TRG}}$ low as $\overline{\text{RAS}}$ falls enables the 256 switches that connect the data registers to the bit lines and indicates that a transfer will occur between the data registers and the selected memory row.

random output enable ($\overline{\text{TRG}}$)

During random-access operations, $\overline{\text{TRG}}$ functions as an output enable for the random outputs after the read access times have been satisfied (if this is a read cycle). Whenever $\overline{\text{TRG}}$ is held high, the Q outputs will be in the high-impedance state. This feature removes the possibility of an overlap between data on the address lines and data appearing on the Q outputs making it possible to connect the address lines to the data I/O lines—although use of this organization prohibits the use of the early write cycle. It also allows read-modify-write cycles to be performed by providing a three-state condition to the common I/O pins to allow write data to be driven onto the pins after output read data has been externally latched.

address (A0 through A7)

Sixteen address bits are required to decode one of 65,536 storage cell locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip on the falling edge of $\overline{\text{RAS}}$. Then the eight column-address bits are set up on pins A0 through A7 and latched onto the chip on the falling edge of $\overline{\text{CAS}}$. All row and column addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ respectively. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select, activating the device input and output buffers. $\overline{\text{CAS}}$ is also used to strobe the column address into the memory.

write-mask enable ($\overline{\text{WE}}$)

The $\overline{\text{WE}}$ pin selects the random-mode write-mask option. The TMS4461 random port is equipped with two modes of write operations. If $\overline{\text{WE}}$ is held low on the falling edge of $\overline{\text{RAS}}$ (during a random access operation), the write mask is enabled. Accordingly, a 4-bit binary code (the mask) is input to the device via the random DQ pins and is also latched on the falling edge of $\overline{\text{RAS}}$. This binary pattern determines which of the four DRAM I/Os will be written into on that access and which DRAM I/Os will not. Thus, after $\overline{\text{RAS}}$ has latched the write mask on chip, input data is driven onto the DQ pins and is latched on the falling edge of the latter of $\overline{\text{CAS}}$ or $\overline{\text{WE}}$ (for early write operation, $\overline{\text{WE}}$ can remain low for the entire $\overline{\text{RAS}}$ low period). If a 0 was strobed into a particular I/O pin on the falling edge of $\overline{\text{RAS}}$, then the write circuits for that particular I/O will be defeated and data will not be written to that I/O. If a 1 was strobed into a particular I/O pin on the falling edge of $\overline{\text{RAS}}$, then the write circuits for that particular I/O will not be defeated and data will be written to that I/O. See the corresponding timing diagrams for details.

Important: The mask operation is selected only if \overline{WE} is held low on the falling edge of \overline{RAS} . If \overline{WE} is held high on the falling edge of \overline{RAS} the mask is not enabled and the write operation is identical to standard $\times 4$ DRAMs, with all four I/Os being written by the data appearing on the DQ pins when the latter of \overline{WE} or \overline{CAS} is brought low. Thus, if it is not desired to use the mask function, then a standard DRAM timing interface can be used.

WRITE MASK FUNCTION TABLE

TRG	WE	DQ1-DQ4	MODE
1	1	X	Write enabled at DQ1-DQ4
1	0	1	Write to DQ enabled
1	0	0	Write to DQ disabled

NOTE 1: The logic states in the table above are assumed valid on the falling edge of \overline{RAS} .

write enable (\overline{WE})

The read or write mode is selected through the write-enable (\overline{WE}) input. A logic high on the \overline{WE} input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When \overline{WE} goes low prior to \overline{CAS} , data out will remain in the high-impedance state for the entire cycle.

data I/O (DQ1-DQ4)

Memory data is written during a write or read-modify-write cycle. The falling edge of \overline{WE} strobes data into the on-chip data latches. These latches can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, \overline{WE} is brought low prior to \overline{CAS} and the data is strobed in by \overline{CAS} with data setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, \overline{CAS} will already be low. Thus, the data will be strobed in by \overline{WE} with data setup and hold times referenced to this signal. The three-state output buffers provide direct TTL compatibility (no pull-up resistors required) with a fanout of two Series 74 TTL loads. Data out is the same polarity as data in. The outputs are in the high-impedance (floating) state as long as \overline{CAS} or \overline{TRG} is held high. Data will not appear at the outputs until after both \overline{CAS} and \overline{TRG} have been brought low.

Once the outputs are valid, they will remain valid while \overline{CAS} and \overline{TRG} are low. \overline{CAS} or \overline{TRG} going high will return the outputs to a high-impedance state. In an early write cycle, the outputs are always in the high-impedance state. In a delayed-write or read-modify-write cycle, the outputs will follow the sequence for the read cycle. In a register-transfer operation (memory-to-register or register-to-memory), the outputs remain in the high impedance state for the entire cycle, regardless of transitions on \overline{CAS} or \overline{TRG} .

write mask bits (DQ1-DQ4)

When the write mask is enabled (\overline{WE} low on the falling edge of \overline{RAS}), the write mask bits determine which DRAM I/Os are to be written and which of the DRAM I/Os will have their write operations internally defeated. The state of the write mask bits is latched on-chip on the falling edge of \overline{RAS} and selectively controls the internal write enable circuits of each corresponding DRAM I/O. If the write mask is not enabled (\overline{WE} high on the falling edge of \overline{RAS}), then no write enable circuits will be defeated and data appearing at the DQ1-DQ4 pins on the falling edge of \overline{RAS} will be ignored. See timing diagrams and the table under "write mask enable (\overline{WE})" for details.

refresh

A refresh operation must be performed to each row at least once every four milliseconds to retain data. Since the output buffer is in the high-impedance state unless $\overline{\text{CAS}}$ is applied, the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 256 row addresses with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power. Note that the data registers are dynamic storage elements and that the data held in the registers will be lost unless SC is clocked 2 times or else the data is reloaded from the memory array. See specifications for maximum register retention times.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is accomplished by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ (see parameter t_{CLRRL}). The external row address is ignored and the refresh address is generated internally.

column-address strobe ($\overline{\text{CAS}}$)

The $\overline{\text{CAS}}$ input latches the column addresses on-chip and also functions as an output enable for DQ1-DQ4.

page mode

Page-mode operation allows faster memory access by keeping the same row address and strobing random column addresses onto the chip. Thus, the time required to set up and strobe row addresses for the same page is eliminated. The maximum number of columns that can be addressed is determined by $t_{\text{W}}(\text{RL})$, the maximum $\overline{\text{RAS}}$ low pulse duration.

power up

After power up, the power supply must remain at its steady-state value for 1 ms. In addition, $\overline{\text{RAS}}$ must remain high for 100 μs immediately prior to initialization. Initialization consists of performing eight $\overline{\text{RAS}}$ cycles and one memory-to-register transfer cycle with an SC cycle following the rising edge of $\overline{\text{TRG}}$ before proper device operation is achieved.

sequential-access operation

transfer register select ($\overline{\text{TRG}}$)

Memory operations involving parallel use (i.e., transfer from memory to data register or data register to memory) of the data register are invoked by bringing $\overline{\text{TRG}}$ low with the address lines A0-A7 before $\overline{\text{RAS}}$ falls. This enables the switches connecting the 256 elements of each data register to the 256 bit lines of each DRAM I/O. The states of $\overline{\text{WE}}$ and $\overline{\text{SG}}$, which are also latched on the falling edge of $\overline{\text{RAS}}$, determine whether the 256-bit data transfer will be from the memory array to the data registers or from the data registers to memory array, as well as determining if the SDQs are in read or write mode (see "transfer operation logic table").

Note that the state of $\overline{\text{TRG}}$ is latched on the falling edge of $\overline{\text{RAS}}$ just like a row address, to select the mode of operation. During read or read-modify-write cycles, $\overline{\text{TRG}}$ functions as output enable after $\overline{\text{CAS}}$ falls.

transfer write enable ($\overline{\text{WE}}$)

In register transfer mode, $\overline{\text{WE}}$ determines whether a transfer will occur from the data registers to the memory array, or from the memory array to the data registers. To transfer data from the data registers to the memory array, $\overline{\text{WE}}$ and $\overline{\text{SG}}$ are held low as $\overline{\text{RAS}}$ falls. If $\overline{\text{SG}}$ were to be high during this transition, then no transfer of data from the data register to the memory array would occur, but the SDQs would be put into the write mode. This would allow serial data to be written into the register. To transfer from the memory array to the data registers, $\overline{\text{WE}}$ is held high and $\overline{\text{SG}}$ is a don't care as $\overline{\text{RAS}}$ falls. This cycle puts the SDQs into the read mode, thus allowing serial data to be read out of the data register. Note that $\overline{\text{WE}}$ and $\overline{\text{SG}}$ setup and hold times are referenced to the falling edge of $\overline{\text{RAS}}$ for this mode of operation (see "transfer operation logic table").

row address (A0 through A7)

Eight address bits are required to select one of the 256 possible rows involved in the transfer of data to or from the data registers. (The states of A0-A7, \overline{WE} , \overline{TRG} , and \overline{SG} are latched on the falling edge of \overline{RAS} .)

register column address (A0 through A7)

To select one of the 256 positions along each of the four data registers from which the first serial data will be read out, or to which the first serial data will be written, the appropriate 8-bit column address (A0-A7) must be valid when \overline{CAS} falls during the appropriate transfer cycle.

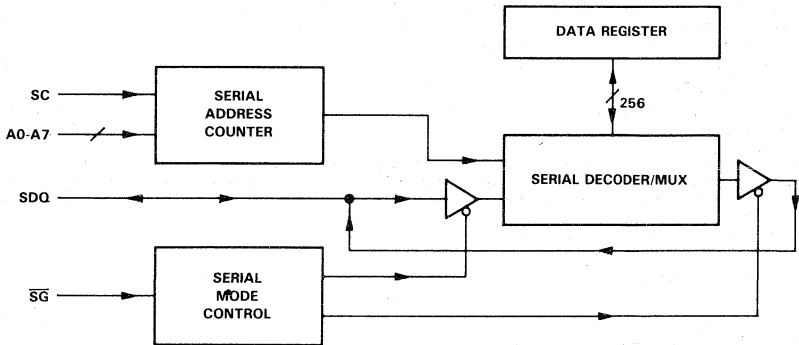

serial data clock (SC)

Data is written in or read out of the data registers on the rising edge of SC. This makes it possible to view the data registers as though they were made of 256 positive-edge-triggered D flip-flops which connect D to Q (not to be confused with the DQ random I/O pins of the TMS4461). The TMS4461 is designed to work with a wide range duty cycle clock to simplify system design.

serial data input/output (SDQ1-SDQ4)

SD and SQ share a common I/O pin. Data is written in when \overline{SG} is low during write mode, and data is read out when \overline{SG} is low during read mode (see "transfer operation logic table"). Note that when the serial address counter reaches its maximum value of 255, it is reset to 00 with the next positive transition of SC. This allows data to be read out in a continuous loop.

block diagram of one serial I/O

serial enable (\overline{SG})

The serial enable pin has two functions. First, it is used on the falling edge of \overline{RAS} , with both \overline{TRG} and \overline{WE} low. If \overline{SG} is low during this transition, then a register-to-memory cycle transfer will occur. On the other hand, if \overline{SG} were to be high as \overline{RAS} falls, then a write-mode control cycle will be performed. The function of this cycle is to switch the SDQs from the output mode to the input mode, thus allowing serial data to be written into the data register. Second, \overline{SG} is used as a SDQ enable/disable. In the write mode, \overline{SG} is used as an input enable. \overline{SG} high disables the input, and \overline{SG} low enables the input. To take the device out of the write mode and into the read mode, a memory-to-register transfer cycle must be performed. The read mode allows data to be read out of the data register. \overline{SG} high disables the output and \overline{SG} low enables the output. Note that the serial address counter will be incremented on each SC cycle regardless of the state of \overline{SG} .

TRANSFER OPERATION LOGIC TABLE

TRG	WE	SG	MODE
0	0	0	Register to memory transfer and write-mode enable
0	0	1	Write-mode enable
0	1	X	Memory-to-register transfer

NOTE 2: The logic states in the table above are assumed valid on the falling edge of \overline{RAS} . In a serial write-mode to read-mode sequence, the first positive transition of SCLK after the memory-to-register transfer will change the SDQs from three-state to output mode.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

Voltage range for any pin except V_{DD} and data out (see Note 3)	-1 to 7 V

Storage temperature range	-65°C to 150°C

†Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 3: All voltage values in this data sheet are with respect to V_{SS} .

recommended operating conditions

	MIN	NOM	MAX	UNIT
V_{DD} Supply voltage	4.5	5	5.5	V
V_{SS} Supply voltage		0		V
V_{IH} High-level input voltage	2.4		6.5	V
V_{IL} Low-level input voltage (see Note 4)	-1		0.8	V
T_A Operating free-air temperature	0	25	70	°C

NOTE 4: The algebraic convention, where the more negative (less positive) limit is designated as minimum, is used in this data sheet for logic voltage levels only.

electrical characteristics over full range of recommended operating conditions (unless otherwise noted)

CAS-before-RAS refresh

write-mode control timing

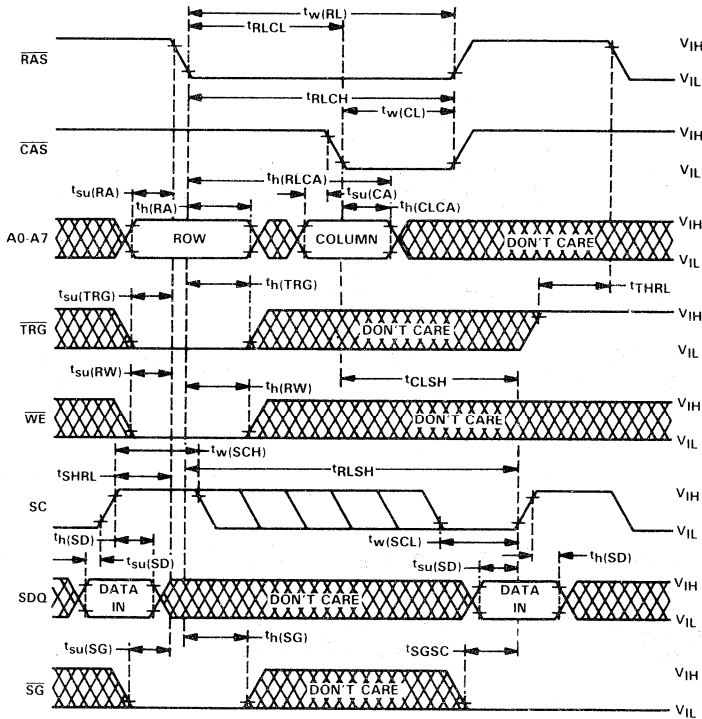

The write-mode control cycle is used to change the SDQs from the output mode to the input mode. This allows serial data to be written into the data register. The diagram below assumes that the device was originally in the serial read mode.

- NOTES: 8. Random-mode (Q outputs) remain in 3-state for the entire write-mode control.
9. SG must be high as RAS falls in order to perform a write-mode control cycle.

data-register-to-memory timing, serial input enabled

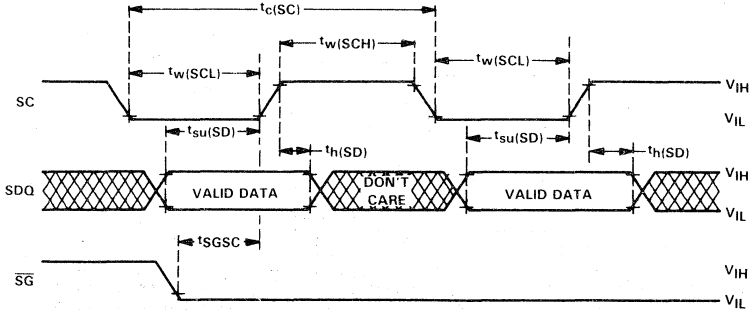

The data-register-to-memory cycle is used to transfer data from the data register to the memory array. Every one of the 256 locations in the data register is written into the 256 columns of the selected row. Note that the data that was in the data register may have arrived there either from a serial write in or from a parallel load of the data register from one of the memory array rows. The diagram below assumes that the device is presently in the serial-write mode (i.e., SD is enabled by a previous write-mode control cycle, thus allowing data to be written in).

- NOTES: 10. Random-mode (Q outputs) remain in 3-state for the entire data-register-to-memory transfer cycle.
11. \overline{SG} must be low as RAS falls in order to perform a register-to-memory transfer.

serial data-in timing

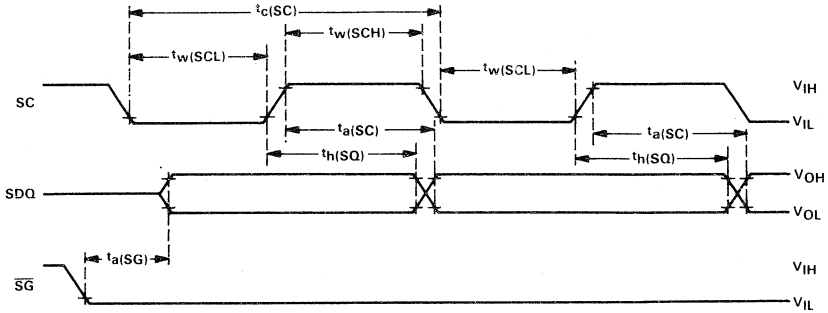

The serial data-in write cycle is used to write data into the data register. Before data can be written into the data register via SD, the device must be put into the write mode by performing a write-mode control cycle. Register-to-memory transfer cycles occurring between the write-mode control cycle and the subsequent writing in of data will not take the device out of the write mode. But, a memory-to-register transfer cycle during that time will take the device out of the write mode and put it into the read mode, thus not allowing the writing in of data.

NOTE 15: While writing data into the data register, the state of \overline{TRG} is a don't care as long as \overline{TRG} is held high when \overline{RAS} goes low. This is to avoid the initiation of a register-to-memory or memory-to-register data-transfer function.

serial data-out timing

The serial data-out read cycle is used to read data out of the data register. Before data can be read out via SQ, the device must be put into the read mode by performing a memory-to-data-register transfer cycle. Register-to-memory transfer cycles occurring between the memory-to-register transfer cycle and the subsequent reading out of data will not take the device out of the read mode. But, a write-mode control cycle at that time will take the device out of the read mode and put it in the write mode, thus not allowing the reading out of data.

NOTE 16: While reading data out of the data register, the state of \overline{TRG} is a don't care as long as \overline{TRG} is held high when \overline{RAS} goes low. This is to avoid the initiation of a register-to-memory or memory-to-register data-transfer operation.

description

The TMS4464 is a high-speed, 262,144-bit dynamic random-access memory, organized as 65,536 words of four bits each. It employs state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon/polyicide gate technology for very high performance combined with low cost and improved reliability.

This device features maximum $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, or 150 ns. Power dissipation maximums are 330 mW operating and 25 mW standby for 150-ns devices.

New SMOS technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{DD} peaks are 125 mA typical, and a –1-V input voltage undershoot can be tolerated, minimizing system noise considerations.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

TMS4464

65,536-WORD BY 4-BIT DYNAMIC RANDOM-ACCESS MEMORY

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address and data-in lines are latched on chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The TMS4464 is offered in 18-pin plastic dual-in-line and 18-lead plastic chip carrier packages. It is guaranteed for operation from 0°C to 70°C. The dual-in-line package is designed for insertion in mounting-hole rows on 7,62-mm (300-mil) centers.

operation

address (A0 through A7)

Sixteen address bits are required to decode 1 of 65,536 storage locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip by the row-address strobe (\overline{RAS}). Then the eight column-address bits are set up on pins A0 through A7 and latched onto the chip by the column-address strobe (\overline{CAS}). All addresses must be stable on or before the falling edges of \overline{RAS} and \overline{CAS} . \overline{RAS} is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. \overline{CAS} is used as a chip select activating the column decoder and the input and output buffers.

write enable (\overline{W})

The read or write mode is selected through the write-enable (\overline{W}) input. A logic high on the \overline{W} input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When \overline{W} goes low prior to \overline{CAS} , data out will remain in the high-impedance state for the entire cycle permitting common I/O operation.

data in (DQ1-DQ4)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of \overline{CAS} or \overline{W} strobes data into the on-chip data latches. These latches can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, \overline{W} is brought low prior to \overline{CAS} and the data is strobed in by \overline{CAS} with setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, \overline{CAS} will already be low, thus the data will be strobed in by \overline{W} with setup and hold times referenced to this signal. In a delayed or read-modify-write cycle, \overline{G} must be high to bring the output buffers to high impedance prior to impressing data on the I/O lines.

data out (DQ1-DQ4)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fan-out of two Series 74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until \overline{CAS} is brought low. In a read cycle the output goes active after the access time interval $t_a(C)$ that begins with the negative transition of \overline{CAS} as long as $t_a(R)$ and $t_a(G)$ are satisfied. The output becomes valid after the access time has elapsed and remains valid while \overline{CAS} and \overline{G} are low. \overline{CAS} or \overline{G} going high returns it to a high-impedance state. In a delayed-write or read-modify-write cycle, the output must be put in the high-impedance state prior to applying data to the DQ input. This is accomplished by bringing \overline{G} high prior to applying data, thus satisfying t_{GHD} .

output enable (\overline{G})

The \overline{G} input controls the impedance of the output buffers. When \overline{G} is high, the buffers will remain in the high-impedance state. Bringing \overline{G} low during a normal cycle will activate the output buffers putting them in the low-impedance state. It is necessary for both \overline{RAS} and \overline{CAS} to be brought low for the output buffers to go into the low-impedance state. Once in the low-impedance state they will remain in the low-impedance state until \overline{G} or \overline{CAS} is brought high.

refresh

A refresh operation must be performed at least once every four milliseconds to retain data. This can be achieved by strobing each of the 256 rows (A0-A7). A normal read or write cycle will refresh all bits in each row that is selected. A RAS-only operation can be used by holding CAS at the high (inactive) level, thus conserving power as the output buffer remains in the high-impedance state.

CAS-before-RAS refresh

The CAS-before-RAS refresh is utilized by bringing CAS low earlier than RAS (see parameter t_{CLRL}) and holding it low after RAS falls (see parameter t_{RLCHR}). For successive CAS-before-RAS refresh cycles, CAS can remain low while cycling RAS. The external address is ignored and the refresh address is generated internally.

hidden refresh

Hidden refresh may be performed while maintaining valid data at the output pin. This is accomplished by holding CAS at V_{IL} after a read operation and cycling RAS after a specified precharge period, similar to a CAS-before-RAS refresh cycle. The external address is also ignored during the hidden refresh cycles. The data at the output pin remains valid up to the maximum CAS low pulse duration, t_{w(CL)}.

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing random column addresses onto the chip. Thus, the time required to set up and strobe row addresses for the same page is eliminated. The maximum number of columns that can be addressed is determined by t_{w(RL)}, the maximum RAS low pulse duration.

power up

To achieve proper device operation, an initial pause of 200 μs is required after power up, followed by a minimum of eight initialization cycles.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)[†]

Voltage on any pin including V _{DD} supply (see Note 1)	-1 V to 7 V
Short circuit output current	50 mA
Power dissipation	1 W
Operating free-air temperature	0°C to 70°C
Storage temperature range	-65°C to 150°C

[†]Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: All voltage values in this data sheet are with respect to V_{SS}.

recommended operating conditions

	MIN	NOM	MAX	UNIT
V _{DD} Supply voltage	4.5	5	5.5	V
V _{SS} Supply voltage		0		V
V _{IH} High-level input voltage	2.4		V _{DD} +1	V
V _{IL} Low-level input voltage (see Note 2)	-1		0.8	V
T _A Operating free-air temperature	0		70	°C

NOTE 2: The algebraic convention, where the more negative (less positive) limit is designated as maximum, is used in this data sheet for logic voltage levels only.

ADVANCE INFORMATION

4

4-79

descripton

The TMS44C251 Multiport Video RAM is a high speed, dual ported memory device. It consists of a dynamic random-access memory (DRAM) organized as 262,144 words of 4 bits each, interfaced to a serial data register, or Serial Access Memory (SAM), organized as 512 words of 4 bits each. The TMS44C251 supports three basic types of operation: random access to and from the DRAM, serial access to and from the serial register, and bidirectional transfer of data between any row in the DRAM and the serial register. Except during transfer operations, the TMS44C251 can be accessed simultaneously and asynchronously from the DRAM and SAM ports. During transfer operation, the 512 columns of the DRAM are connected to the 512 positions in the serial data register. The 512×4 bit serial data register can be loaded from the memory row (transfer read) or else the contents of the 512×4 bit serial data register can be written to the memory row (transfer write).

The TMS44C251 is equipped with several features designed to provide higher system level bandwidth and simplify design integration on both the DRAM and SAM ports. On the DRAM port, greater pixel draw rates can be achieved by the device's novel 4×4 Block Write Mode. Block Write mode allows four bits of data present in an on-chip color data register to be written to any combination of four adjacent column address locations. As many as 16 bits of data can be written to memory during each CAS cycle time. Also on the DRAM port, a write mask register provides a persistent write per bit mode without repeated mask loading.

On the serial register, or SAM port, the TMS44C251 offers a split register transfer read (DRAM to SAM) option which enables realtime register reload implementation for truly continuous serial data streams, without critical timing requirements. The register is divided into a high half and a low half. While one half is being read out of the SAM port, the other half can be loaded from the memory array. This new realtime register reload implementation allows truly continuous serial data. For applications not requiring realtime register reload (for example, reloads done during CRT retrace periods), the single register mode of operation is retained to simplify system design. The SAM can also be configured in input mode, accepting serial data from an external device. Once the serial register within the SAM is loaded, its contents can be transferred to the corresponding column positions in any row in memory in a single memory cycle.

The SAM port is designed for maximum performance. Data can be input to or accessed from the SAM at serial rates up to 33 MHz. During split register mode of operation, internal circuitry detects when the last bit position is accessed from the active half of the register and immediately transfers control to the opposite half. A separate open drain output, designated QSF, is included to designate which half of the serial register is active at any given time in split register mode.

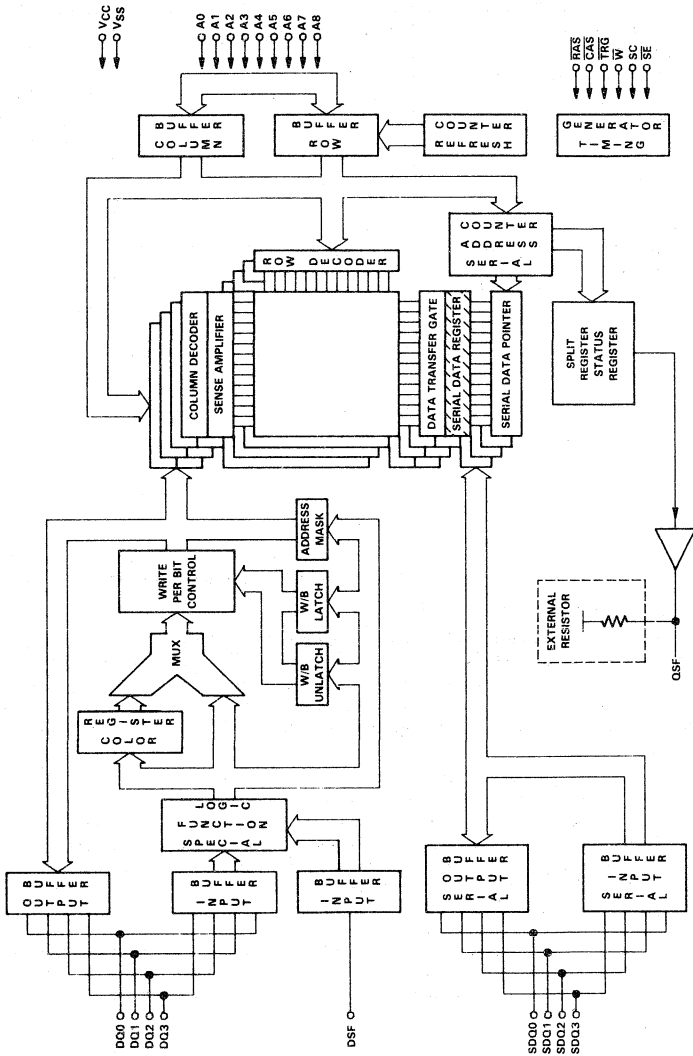

All inputs, outputs, and clock signals on the TMS44C251 are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. All data-outs are unlatched to allow greater system flexibility.

The TMS44C251 employs state-of-the-art Texas Instruments EPIC™ scaled-CMOS, double level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

The TMS44C251 is offered in a 28-pin small-outline J-leaded package (DJ suffix) for direct surface mounting in rows on 400-mil (5,08-mm) centers. It is also offered in a 400-mil, 28-pin zig-zag in-line package (SD suffix). Both packages are characterized for operation from 0°C to 70°C (L suffix).

The TMS44C251 and other Multiport Video RAMs are supported by a broad line of graphics processor and control devices from Texas Instruments, including the TMS34010 Graphics System Processor.

operation

random access operation

Refer to Table 1, Functional Truth Table, for Random Access and Transfer Operations. Random access operations are denoted by the designator "R" and transfer operations are denoted by a "T."

transfer register select and DQ enable ($\overline{\text{TRG}}$)

The $\overline{\text{TRG}}$ pin selects either register or random access operation as $\overline{\text{RAS}}$ falls. For random access (DRAM) mode, $\overline{\text{TRG}}$ must be held high as $\overline{\text{RAS}}$ falls. Asserting $\overline{\text{TRG}}$ high as $\overline{\text{RAS}}$ falls causes the 512 storage elements of each data register to remain disconnected from the corresponding 512-bit lines of the memory array. (Asserting $\overline{\text{TRG}}$ low as $\overline{\text{RAS}}$ falls connects the 512-bit positions in the serial register to the bit lines and indicates that a transfer will occur between the data registers and the selected memory row. See "Transfer Operation" for details.)

During random access operations, $\overline{\text{TRG}}$ also functions as an output enable for the random (Q) outputs. Whenever $\overline{\text{TRG}}$ is held high, the Q outputs are in the high-impedance state to prevent an overlap between the address and DRAM data. This organization allows the connection of the address lines to the data I/O lines but prohibits the use of the early write cycle. It also allows read-modify-write cycles to be performed by providing a three-state condition to the common I/O pins so that write data can be driven onto the pins after output read data has been externally latched.

addresses (A0 through A8)

Eighteen address bits are required to decode 1 of 262,144 storage cell locations. Nine row address bits are set up on pins A0 through A8 and latched onto the chip on the falling edge of $\overline{\text{RAS}}$. Then, the nine column address bits are set up on pins A0 through A8 and latched onto the chip on the falling edge of $\overline{\text{CAS}}$.

RAS and CAS address strobes and device control clocks

RAS is a control input that latches the states of the row address, \overline{W} , \overline{TRG} , \overline{SE} , \overline{CAS} , and DSF onto the chip to invoke the various DRAM and Transfer functions of the TMS44C251. RAS is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. CAS is a control input that latches the states of the column address and DSF to control various DRAM and Transfer functions. CAS also acts as an output enable for the DRAM output pins.

special function select (DSF)

The Special Function Select input is latched on the falling edges of RAS and CAS, similarly to an address, and serves four functions. First, during write cycles DSF invokes persistent write per bit operation. If $\overline{TRG} = 1$, $\overline{W} = 0$, and DSF = 0 on the falling edge of RAS, the write mask will be reloaded with the data present on the DQ pins. If DSF = 1, the mask will not be reloaded but will retain the data from the last mask reload cycle.

Second, DSF is used to change the internally stored write per bit mask register (or write mask) via the load write mask cycle. The data present on the DQ pins when \overline{W} falls is written to the write mask rather than to the addressed memory location. See "Delayed Write Cycle Timing" and the accompanying "Write Cycle State Table" in the timing diagram section. Once the write mask is loaded, it can be used on subsequent masked write per bit cycles. This feature allows systems with a common address and data bus to use the write per bit feature, eliminating the time needed for multiplexing the write mask and input data on the data bus.

Third, DSF is used to load an on-chip four-bit data, or "color," register via the Load Color Register cycle. The contents of this register can subsequently be written to any combination of four adjacent column memory locations using a 4 × 4 Block Write feature. The load color register cycle is performed using normal write cycle timing except that DSF is held high on the falling edges of RAS and CAS. Once the color register is loaded, it retains data until power is lost or until another load color register cycle is performed.

After loading the color register, the block write cycle can be enabled by holding DSF high on the falling edge of CAS. During block write cycles, only the seven most significant column addresses (A2-A8) are latched on the falling edge of CAS. The two least significant addresses (A0-A1), are replaced by the four DQ bits, which are also latched on the later of CAS or W falling. These four bits are used as an address mask and indicate which of the four column address locations addressed by A2-A8 will be written with the contents of the color register during the write cycle, and which ones will not. DQ0 enables a write to column address A1 = 0, A0 = 0; DQ1 enables a write to A1 = 0, A0 = 1; DQ2 enables a write to A1 = 1, A0 = 0; and DQ3 enables a write to A1 = 1, A0 = 1. A logic level 1 enables a write and a logic level 0 disables the write. A maximum of 16 bits can be written to memory during each CAS cycle (see Figure 1, Block Write Diagram).

Fourth, the DSF pin is used to invoke the split register transfer and serial access operation, described in the sections "Transfer Operation" and "Serial Operation."

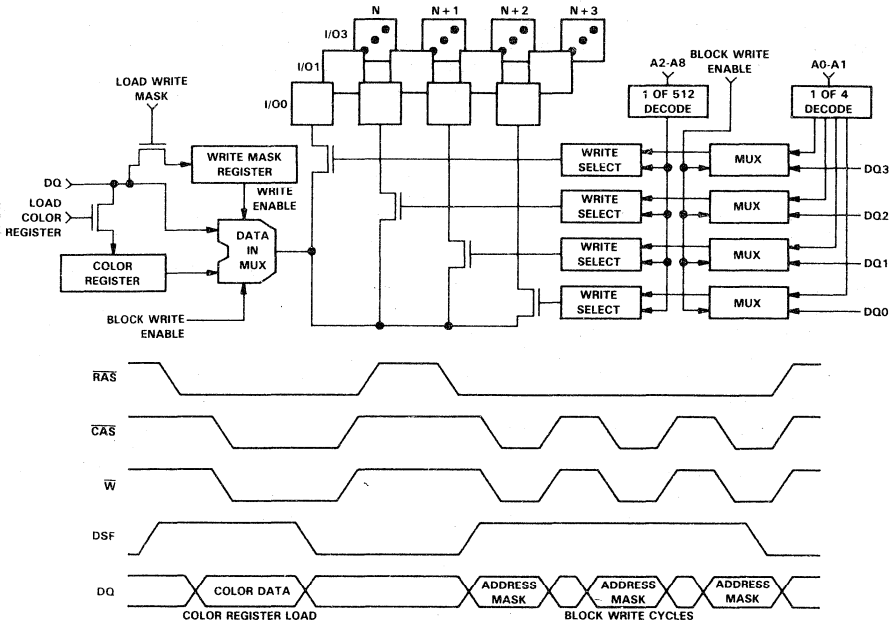

FIGURE 1. BLOCK WRITE DIAGRAM

write enable, write per bit enable (\overline{W})

The \overline{W} pin enables data to be written to the DRAM and also is used to select the DRAM write per bit mode of operation. A logic high level on the \overline{W} input selects the read mode and logic low level selects the write mode. In an Early Write cycle, \overline{W} is brought low before \overline{CAS} and the DRAM output pins (DQ) remain in the high-impedance state for the entire cycle. During DRAM write cycles, holding \overline{W} low on the falling edge of \overline{RAS} will invoke the write per bit operation. Two modes of write per bit operation are supported.

Case 1. If $DSF = 0$ on the falling edge of \overline{RAS} , the write mask is reloaded. Accordingly, a four-bit binary code (the write per bit mask) is input to the device via the random DQ pins and is latched on the falling edge of \overline{RAS} . The write per bit mask selects which of the four random I/Os are written and which are not. After \overline{RAS} has latched the write mask on-chip, input data is driven onto the DQ pins and is latched on the falling edge of the later of \overline{CAS} or \overline{W} . If a 0 was strobed into a particular I/O pin on the falling edge of \overline{RAS} , data will not be written to that I/O. If a 1 was strobed into a particular I/O pin on the falling edge of \overline{RAS} , data will be written to that I/O.

Case 2. If $DSF = 1$ on the falling edge of \overline{RAS} , the mask is not reloaded from the DQ pins but instead retains the value stored during the last write per bit mask reload. This mode of operation is known as Persistent Write per Bit, since the write per bit mask is persistent over an arbitrary number of cycles.

See the corresponding timing diagrams for details. **IMPORTANT:** The write per bit operation is invoked only if \overline{W} is held low on the falling edge of \overline{RAS} . If \overline{W} is held high on the falling edge of \overline{RAS} , write per bit is not enabled and the write operation is identical to that of standard $\times 4$ DRAMs.

data I/O (DQ0-DQ3)

DRAM data is written during a write or read-modify-write cycle. The falling edge of \overline{W} strobes data into the on-chip data latches. In an early write cycle, \overline{W} is brought low prior to \overline{CAS} and the data is strobed in by \overline{CAS} with data setup and hold times referenced to this signal. In a delayed write or read-modify-write cycle, \overline{CAS} will already be low. Thus, the data will be strobed-in by \overline{W} with data setup and hold times referenced to this signal.

The three-state output buffers provide direct TTL compatibility (no pull-up resistors required) with a fanout of two Series 74 TTL loads. Data-out is the same polarity as Data-in. The outputs are in the high impedance (floating) state as long as \overline{CAS} or \overline{TRG} is held high. Data will not appear at the outputs until after both \overline{CAS} and \overline{TRG} have been brought low. Once the outputs are valid, they remain valid while \overline{CAS} and \overline{TRG} are low. \overline{CAS} or \overline{TRG} going high returns the outputs to a high-impedance state. In an early write cycle, the outputs are always in the high-impedance state. In a register transfer operation (memory to register or register to memory), the outputs remain in the high-impedance state for the entire cycle.

enhanced page mode

Unlike conventional page-mode DRAMs, the column-address buffers in this device are activated on the falling edge of \overline{RAS} . The buffers act as transparent or flow-through latches while \overline{CAS} is high. The falling edge of \overline{CAS} latches the column addresses. This feature allows the TMS44C251 to operate at a higher data bandwidth than conventional page-mode parts, since data retrieval begins as soon as column address is valid rather than when \overline{CAS} transitions low. This performance improvement is referred to as "enhanced page mode." Valid column address may be presented immediately after row address hold time has been satisfied, usually well in advance of the falling edge of \overline{CAS} . In this case, data is obtained after $t_{a(C)}$ max (access time from \overline{CAS} low), if $t_{a(CA)}$ max (access time from column address) has been satisfied. In the event that column addresses for the next page cycle are valid at the time \overline{CAS} goes high, access time for the next cycle is determined by the later occurrence of $t_{a(C)}$ or $t_{a(CP)}$ (access time from rising edge of \overline{CAS}).

Enhanced page mode operation allows faster memory access by keeping the same row address while selecting random column addresses. The time for row address setup, row address hold, and address multiplex is thus eliminated, and a memory cycle time reduction of up to $3 \times$ can be achieved, compared to minimum $\overline{\text{RAS}}$ cycle times. The maximum number of columns that may be accessed is determined by the maximum $\overline{\text{RAS}}$ low time and page mode cycle time used. The TMS44C251 allows a full page (512 cycles) of information to be accessed in read, write, or read-modify-write mode during a single $\overline{\text{RAS}}$ low period using relatively conservative page mode cycle times.

During write per bit operations, the DQ pins are used to load the write per bit mask register using either mode of write per bit operation described above under the $\overline{\text{W}}$ pin description.

During block write operations, the DQ pins are used to load the on-chip color register during the load color register cycle and are also used as a write enable during block write cycles.

refresh

A refresh operation must be performed to each row at least once every eight milliseconds to retain data. Since the output buffer is in the high-impedance state (unless $\overline{\text{CAS}}$ is applied), the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 512 row addresses with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power.

GND

This pin is reserved for the manufacturer's test operation. It is an input and should be tied to system ground to ensure proper device operation.

IMPORTANT: GND is not connected internally to V_{SS} .

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is accomplished by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$. The external row address is ignored and the refresh address is generated internally.

random port to serial port interface

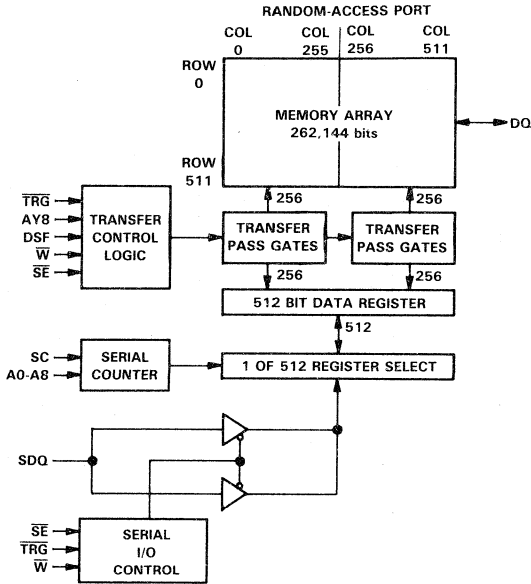

FIGURE 2. BLOCK DIAGRAM SHOWING ONE RANDOM AND ONE SERIAL I/O INTERFACE

random address space to serial address space mapping

The 512 bits in each of the four data registers of the SAM are connected to the 512 column locations of each of the four random I/Os. Data can be accessed in or out of the SAM starting at any of the 512 data bit locations. This start location is selected by addresses A0 through A8 on the falling edge of $\overline{\text{CAS}}$ during any transfer cycle. The SAM is accessed starting from the selected start address, proceeding from the lowest to the highest significant bits. After the most significant bit position (511) is accessed, the serial counter wraps around such that bit 0 is accessed on the next clock pulse. The selected start address is stored and used for all subsequent transfer cycles until $\overline{\text{CAS}}$ is again brought low during any transfer cycle. Thus, the start address can be set once and $\overline{\text{CAS}}$ held high during all subsequent transfer cycles and the start address point will not change regardless of data present on A0 through A8.

split register mode random address to serial address space mapping

In split register transfer operation, the serial data register is split into halves, the low half containing bits 0 through 255 and the high half containing bits 256 through 511. When a split register transfer cycle is performed, the tap address must be strobed in on the falling edge of $\overline{\text{CAS}}$. The most significant column address bit (A8) determines which register half will be reloaded from the memory array. The eight remaining column address bits (A0-A7) are used to select the SAM starting location for the register half selected by A8. Thus when bit 255 or 511 is reached, the next bit read out will be from the previously loaded start location.

To guarantee proper operation when using the split register read transfer feature, a non-split register transfer must precede any split register sequence. The serial start address must be supplied for every split register transfer.

transfer operations

As illustrated in Table 1, the TMS44C251 supports five basic transfer modes of operation:

1. Normal Write Transfer (SAM to DRAM)
2. Alternate Write Transfer (independent of the state of \overline{SE})
3. Pseudo Write Transfer (Switches serial port from serial out mode to serial in mode. No actual data transfer takes place between the DRAM and the SAM.)
4. Normal Read Transfer (Transfer entire contents of DRAM to SAM)
5. Split Register Read Transfer (Divides the SAM into a high and a low half. Only one half is transferred to the SAM while the other half is read from the serial I/O port.)

transfer register select (\overline{TRG})

Transfer operations between the memory array and the data registers are invoked by bringing \overline{TRG} low before \overline{RAS} falls. The states of \overline{W} , \overline{SE} , and DSF , which are also latched on the falling edge of \overline{RAS} , determine which transfer operation will be invoked. (See Table 2.)

During read transfer cycles, \overline{TRG} going high causes the addressed row of data to be transferred into the data register. Although the previous data in the data register is overwritten, the last bit of data appearing at SDQ before \overline{TRG} goes high will remain valid until the first positive transition of SC after \overline{TRG} goes high. The data at SDQ will then switch to new data beginning from the selected start, or "tap," position.

transfer write enable (\overline{W})

In register transfer mode, \overline{W} determines whether a read or a write transfer will occur. To perform a write transfer, \overline{W} and \overline{SE} are held low as \overline{RAS} falls. If \overline{SE} is high during this transition, no transfer of data from the data register to the memory array occurs, but the $SDQs$ are put into the input mode. This allows serial data to be input into the SAM. An alternative way to perform the transfer write cycle is by holding DSF high on the falling edge of \overline{RAS} . In this way, the state of \overline{SE} is a Don't Care as \overline{RAS} falls. To perform a read transfer operation, \overline{W} is held high and \overline{SE} is a Don't Care as \overline{RAS} falls. This cycle also puts the $SDQs$ into the read mode, allowing serial data to be shifted out of the data register. (See Table 2.)

column enable (\overline{CAS})

If \overline{CAS} is brought low during a control cycle, the address present on the pins $A0$ through $A8$ will become the new register start location. If \overline{CAS} is held high during a control cycle, the previous tap address will be retained from the last transfer cycle in which \overline{CAS} went low to set the tap address.

addresses ($A0$ through $A8$)

Nine address bits are required to select one of the 512 possible rows involved in the transfer of data to or from the data registers. The states of $A0$ - $A8$ are latched on the falling edge of \overline{RAS} to select one of 512 rows for the transfer operation.

To select one of the 512 positions in the SAM from which the first serial data will be read out, the appropriate 9-bit column address ($A0$ - $A8$) must be valid when \overline{CAS} falls. However, the \overline{CAS} and start (tap) position need not be supplied every cycle, only when changing to a different start position.

In split register transfer mode, the most significant column address bit ($A8$) selects which half of the register will be reloaded from the memory array. The remaining eight addresses ($A0$ - $A7$) determine the register starting location for the register to be reloaded.

special function input (DSF)

In read transfer mode, holding DSF high on the falling edge of \overline{RAS} selects the split register mode read transfer operation. This mode divides the serial data register into a high order half and a low order half; one active, and one inactive. When the cycle is initiated, a transfer occurs between the memory array and either the high half or the low half register, depending on the state of most significant column address bit (A8) that is strobed in on the falling edge of CAS. If A8 is high, the transfer is to the high half of the register. If A8 is low, the transfer is to the low half of the register. Use of the split register mode read transfer feature allows on-the-fly read transfer operation without synchronizing \overline{TRG} to the serial clock.

The transfer can be to either the active half or the inactive half register. If the transfer is to the active register, with an uninterrupted serial data stream, then the timings $t_d(SCTR)$ and $t_d(THSC)$ must be met.

In write transfer mode, holding DSF high on the falling edge of \overline{RAS} permits use of an alternate mode of transfer write. This mode allows \overline{SE} to be high on the falling edge of \overline{RAS} without performing a pseudo write transfer, with the serial port disabled during the entire transfer write cycle.

serial access operation

Refer to Tables 2 and 3 for the following discussion on serial access operation.

serial clock (SC)

Data (SDQ) is accessed in or out of the data registers on the rising edge of SC. The TMS44C251 is designed to work with a wide range of clock duty cycles to simplify system design. Since the data registers comprising the SAM are of static design, there are no SAM refresh requirements and there is no minimum SC clock operating frequency.

serial data input/output (SDQ0-SDQ3)

SD and SQ share a common I/O pin. Data is input to the device when \overline{SE} is low during write mode and data is output from the device when \overline{SE} is low during read mode. The data in the SAM will be accessed in the direction from least significant bit to most significant bit. The data registers operate modulo 512. Thus, after bit 511 is accessed, the next bits to be accessed will be bits 00, 01, 02, and so on.

serial enable (\overline{SE})

The Serial Enable pin has two functions: first, it is latched on the falling edge of \overline{RAS} , with both \overline{TRG} and \overline{W} low to select one of the transfer functions (see Table 3). If \overline{SE} is low during this transition, then a transfer write occurs. If \overline{SE} is high as \overline{RAS} falls and DSF is low, then a write mode control cycle is performed. The function of this cycle is to switch the SDQs from the output mode to the input mode, thus allowing data to be shifted into the data register. NOTE: All transfer read and serial mode enable (pseudo transfer write) operations will perform a memory refresh operation on the selected row.

Second, during serial access operations, \overline{SE} is used as an SDQ enable/disable. In the write mode, \overline{SE} is used as an input enable. \overline{SE} high disables the input and \overline{SE} low enables the input. To take the device out of the write mode and into the read mode, a transfer read cycle must be performed. The read mode allows data to be accessed from the data register. While in the read mode, \overline{SE} high disables the output and \overline{SE} low enables the output.

IMPORTANT: While \overline{SE} is held high, the serial clock is NOT disabled. Thus, external SC pulses will increment the internal serial address counter regardless of the state of \overline{SE} . This ungated serial clock scheme minimizes access time of serial output from \overline{SE} low since the serial clock input buffer and the serial address counter are not disabled by \overline{SE} .

split register active status output (QSF)

QSF is an OPEN DRAIN output pin. During the split register mode of serial access operation, QSF indicates which half of the serial register in the SAM is being accessed. If QSF is low, then the serial address pointer is accessing the low (least significant) 256 bits of the SAM. If QSF is high, then the pointer is accessing the higher (most significant) 256 bits of the SAM.

QSF changes state upon crossing the boundary between the two register halves. When the SAM is not operating in split register mode, the QSF output remains in the high-impedance state.

QSF is designed as an open drain output to allow OR-tying of QSF outputs from several chips. Thus, an external pull-up resistor is required for the zero to one transition on QSF and the output risetime is determined by the load capacitance and the value of the pull-up resistor. The specification for QSF switching time assumes a pull-up resistor of 820 ohms and a load capacitance of 50 picofarads.

TABLE 2. TRANSFER OPERATION LOGIC

TRG	W	SE	DSF	MODE
0	0	0	X	Register to memory (write) transfer

read-write/read-modify-write cycle timing

Dynamic RAMS

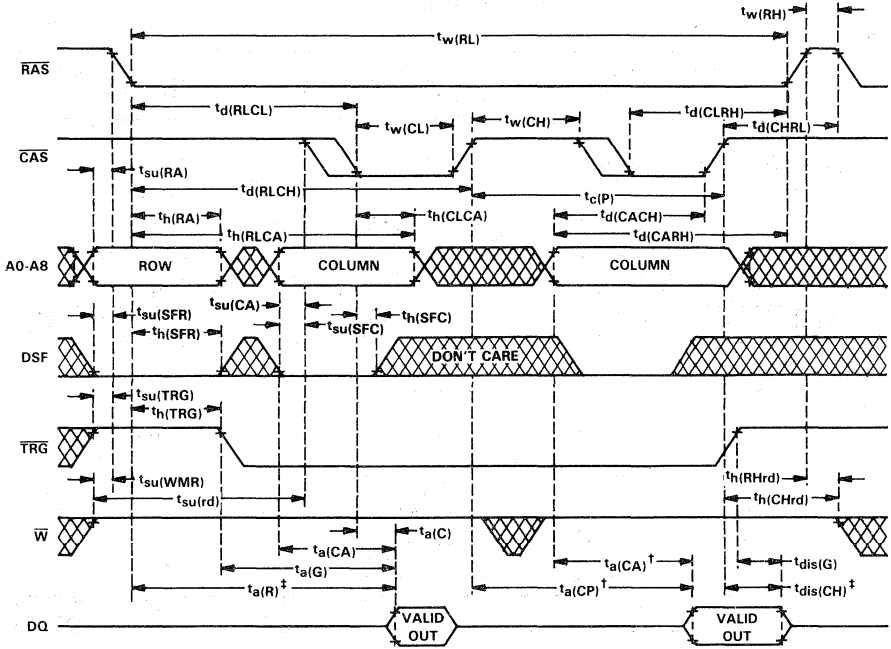

4

ADVANCE INFORMATION

NOTE 25: See "Write Cycle State Table" for logic state of "1", "2", "3", "4", and "5". Same logic as delayed write cycle.

enhanced page-mode read cycle timing

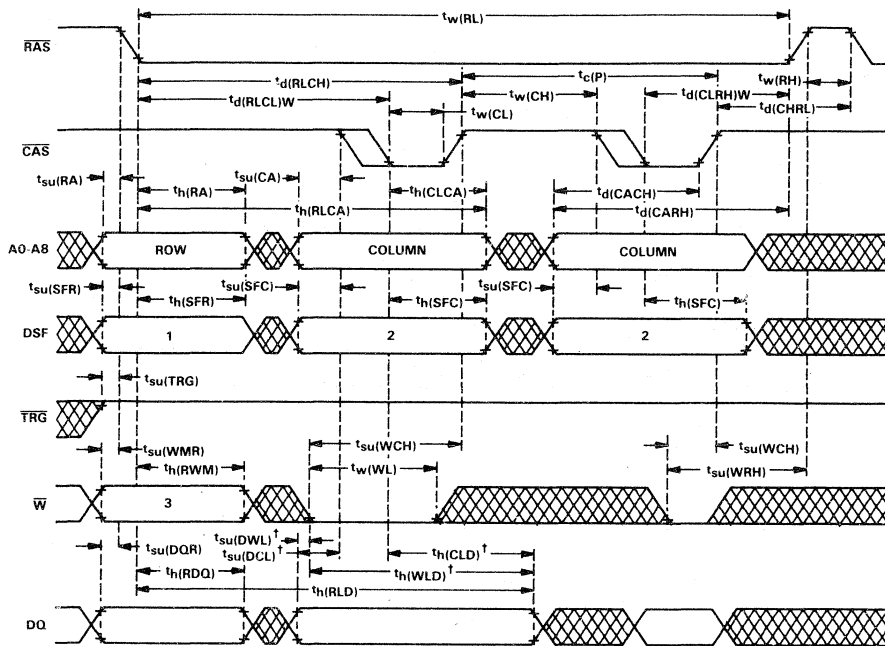

NOTE 26: A write cycle or a read-modify-write cycle can be mixed with the read cycles as long as the write and read-modify-write timing specifications are not violated and the proper polarity of DSF is selected on the falling edges of RAS and CAS to select the desired write mode (normal, block write, etc.).

† Access time is $t_a(CP)$ or $t_a(CA)$ dependent.

‡ Output may go from the high-impedance state to an invalid data state prior to the specified access time.

enhanced page mode write cycle timing

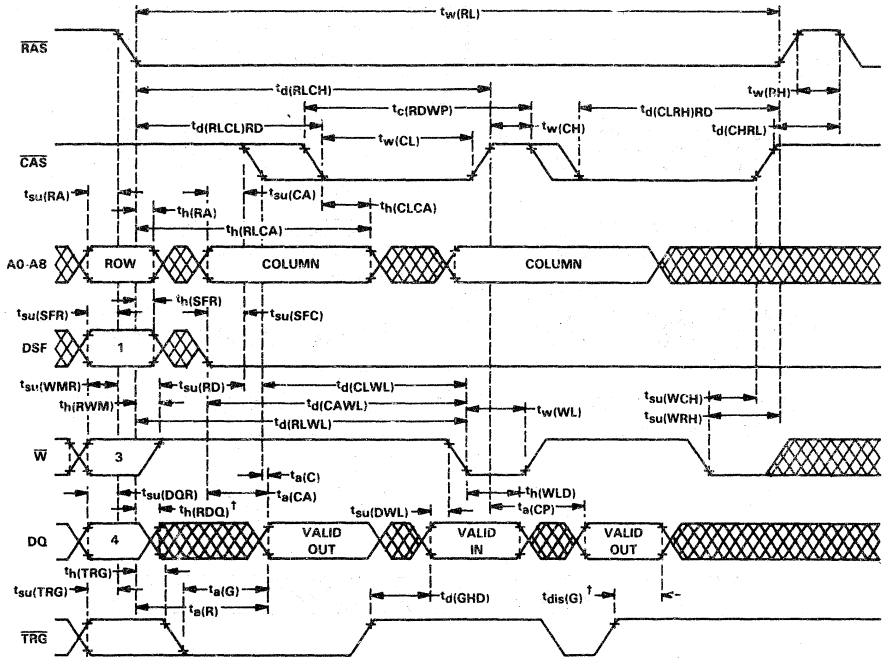

NOTES: 24. See "Write Cycle State Table" for logic state of "1", "2", "3", "4", and "5".

27. A read cycle or a read-modify-write cycle can be intermixed with write cycles, observing read and read-modify-write timing specifications. TRG must remain high throughout the entire page-mode operation if the late write feature is used, to guarantee page-mode cycle time. If the early write cycle timing is used, the state of TRG is a Don't Care after the minimum period $t_h(TRG)$ from the falling edge of RAS.

†Referenced to CAS or W, whichever occurs last.

enhanced page-mode read-modify-write cycle timing

- NOTES: 24. See "Write Cycle State Table" for logic state of "1", "2", "3", "4", and "5".
 28. A read or a write cycle can be intermixed with read-modify-write cycles as long as the read and write timing specifications are not violated.
 † Output may go from the high-impedance state to an invalid data state prior to the specified access time.

CAS-before-RAS refresh counter test timing

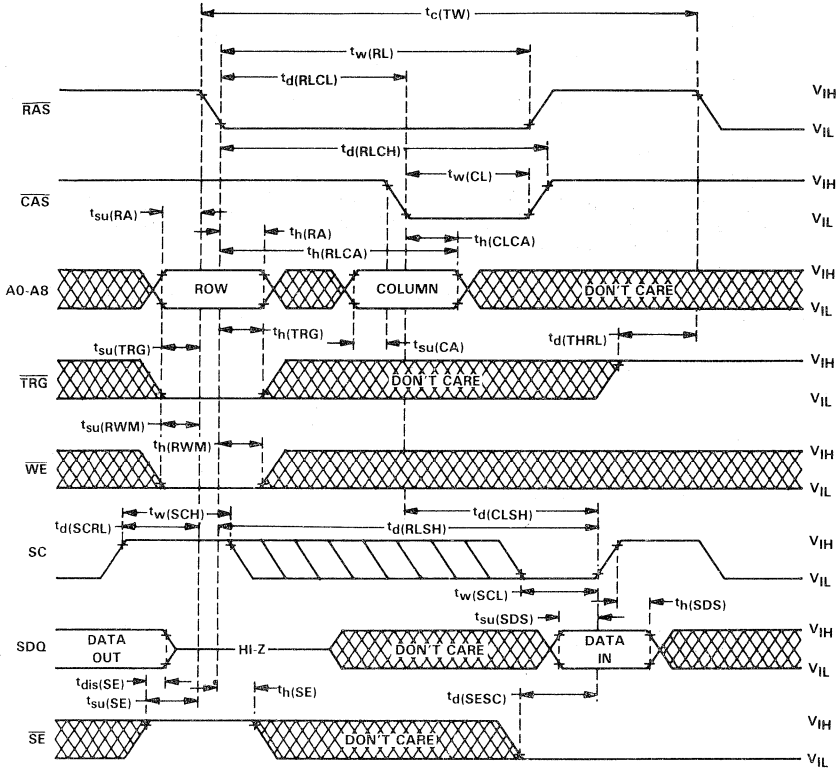

hidden refresh cycle timing

write-mode control pseudo write transfer timing

The write-mode control cycle is used to change the SDQs from the output mode to the input mode. This allows serial data to be written into the data register. The diagram below assumes that the device was originally in the serial read mode.

- NOTES: 29. Random-mode Q outputs remain in the high-impedance state for the entire write-mode control.
30. SE must be high as RAS falls in order to perform a write-mode control cycle.

data register to memory timing, serial input enabled

NOTES: 31. Random mode Q outputs remain in the high-impedance state for the entire data register to memory transfer cycle. This cycle is used to transfer data from the data register to the memory array. Every one of the 512 locations in each data register is written into the corresponding 512 columns of the selected row. Data in the data register may proceed from a serial shift-in or from a parallel load from one of the memory array rows. The above diagram assumes that the device is in the serial write mode (i.e., SD is enabled by a previous write mode control cycle, thus allowing data to be shifted-in).

32. See "Register Transfer Functions Table" for logic state of "1" and "3".

Dynamic RAMs

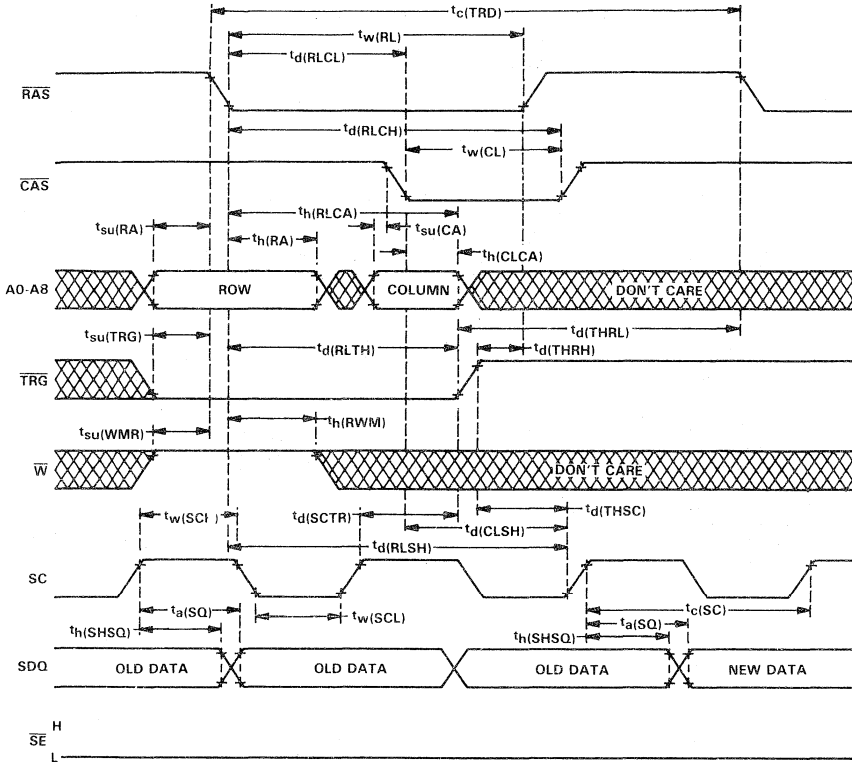

4

ADVANCE INFORMATION

alternate data register to memory timing

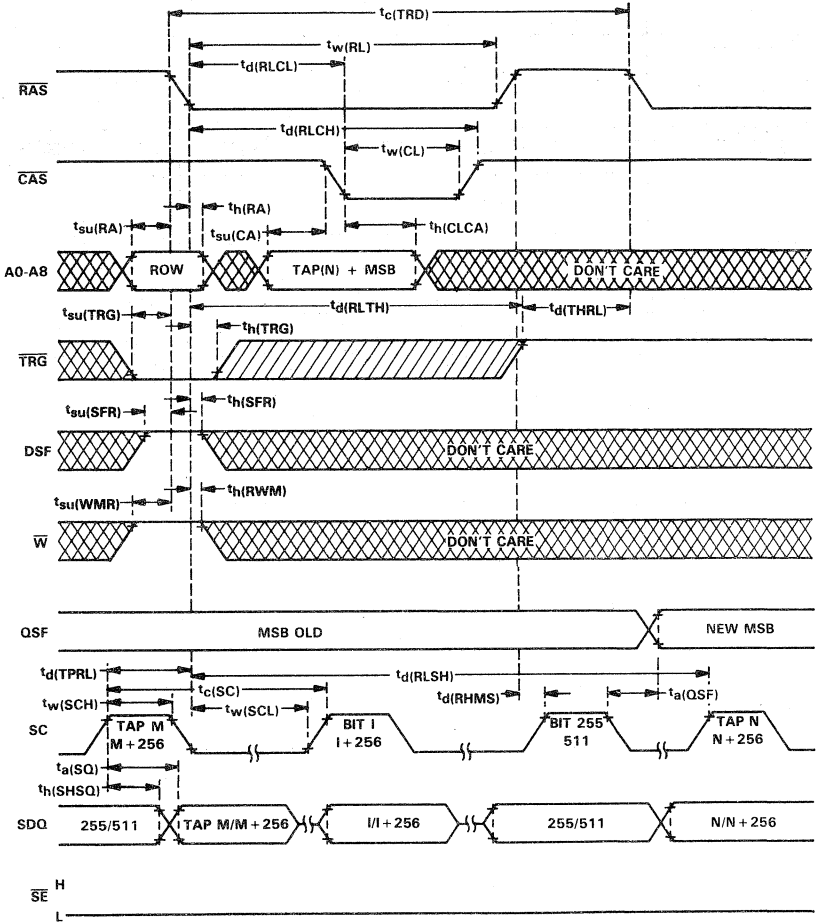

memory to data register transfer timing

NOTES: 33. Random mode (Q outputs) remain in the high-impedance state for the entire memory to data register transfer cycle. The memory to data register transfer cycle is used to load the data registers in parallel from the memory array. The 512 locations in each data register are written into from the 512 corresponding columns of the selected row. The data that is transferred into the data registers may be either shifted out or transferred back into another row.

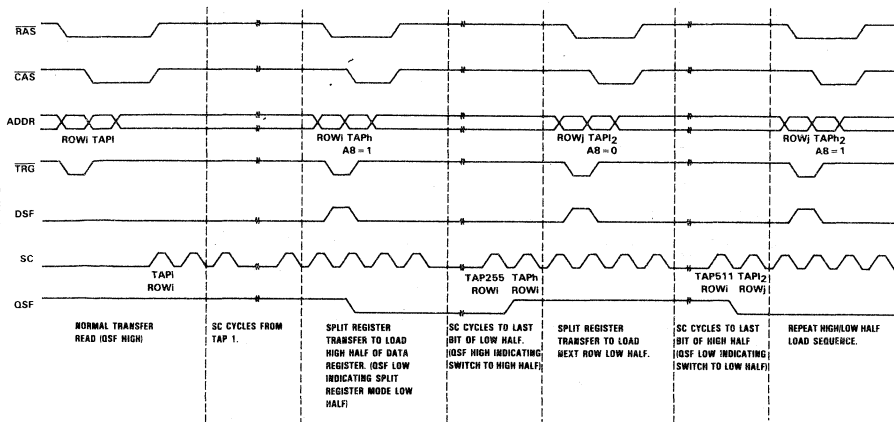

34. Once data is transferred into the data registers, the SAM is in the serial read mode (i.e., the SQ is enabled), thus allowing data to be shifted out of the registers. Also, the first bit to be read from the data register after TRG has gone high must be activated by a positive transition of SC.

split register mode read transfer timing

NOTE 35: There must be a minimum of one SC clock cycle between any two split register reload cycles.

split register operating sequence

NOTE 36: In split register mode, data can be transferred from different rows to the low and high halves of the data register.

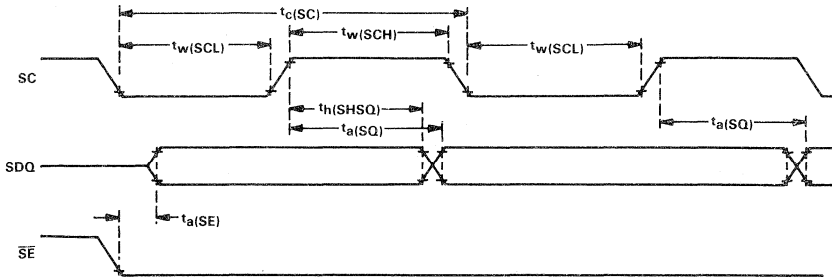

serial data-in timing

The Serial Data-in cycle is used to input serial data into the data registers. Before data can be written into the data registers via SD, the device must be put into the write mode by performing a write mode control, or pseudo-transfer, cycle. Transfer write cycles occurring between the write mode control cycle and the subsequent writing or data will not take the device out of the write mode. However, a transfer read cycle during that time will take the device out of the write mode and put it into the read mode, thus disabling the input of data. Data will be written starting at the location specified by the input address loaded on the previous transfer cycle.

While accessing data in the serial data registers, the state of \overline{TRG} is a Don't Care as long as \overline{TRG} is held high when \overline{RAS} goes low to prevent data transfers between memory and data registers.

serial data-out timing

NOTE 37: While reading data through the serial data register, the state of \overline{TRG} is a Don't Care as long as \overline{TRG} is held high when \overline{RAS} goes low. This is to avoid the initiation of a register to memory or memory to register data transfer operation.

The Serial Data-out cycle is used to read data out of the data registers. Before data can be read via SQ, the device must be put into the read mode by performing a transfer read cycle. Transfer write cycles occurring between the transfer read cycle and the subsequent shifting out of data will not take the device out of the read mode. But a write mode control cycle at that time will take the device out of the read mode and put it in the write mode, thus not allowing the reading of data.

description

The TMS44C256 and TMS44C257 series are high-speed, 1,048,576-bit Dynamic Random-Access Memories organized as 262,144 words of four bits each. They employ state-of-the-art EPIC™ (Enhanced Process Implanted CMOS) technology for high performance, reliability, and low power at a low cost.

operation

enhanced page mode (TMS44C256)

Page-mode operation allows faster memory access by keeping the same row address while selecting random column addresses. The time for row-address setup and hold and address multiplex is thus eliminated. The maximum number of columns that may be accessed is determined by the maximum RAS low time and

EPIC is a trademark of Texas Instruments Incorporated.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

†The packages shown here are for pinout reference only. The DJ package is actually 75% of the length of the N package.

262,144-WORD BY 4-BIT DYNAMIC RANDOM-ACCESS MEMORIES

the $\overline{\text{CAS}}$ page-mode cycle time used. With minimum $\overline{\text{CAS}}$ page cycle time, all 512 columns specified by column addresses A0 through A8 can be accessed without intervening $\overline{\text{RAS}}$ cycles.

Unlike conventional page-mode DRAMs, the column-address buffers in this device are activated on the falling edge of $\overline{\text{RAS}}$. The buffers act as transparent or flow-through latches while $\overline{\text{CAS}}$ is high. The falling edge of $\overline{\text{CAS}}$ latches the column addresses. This feature allows the TMS44C256 to operate at a higher data bandwidth than conventional page-mode parts, since data retrieval begins as soon as column address is valid rather than when $\overline{\text{CAS}}$ transitions low. This performance improvement is referred to as "enhanced page mode." Valid column address may be presented immediately after $t_{\text{H}}(\text{RA})$ (row address hold time) has been satisfied, usually well in advance of the falling edge of $\overline{\text{CAS}}$. In this case, data is obtained after $t_{\text{a}}(\text{C})$ max (access time from $\overline{\text{CAS}}$ low), if $t_{\text{a}}(\text{CA})$ max (access time from column address) has been satisfied. In the event that column addresses for the next page cycle are valid at the time $\overline{\text{CAS}}$ goes high, access time for the next cycle is determined by the later occurrence of $t_{\text{a}}(\text{C})$ or $t_{\text{a}}(\text{CP})$ (access time from rising edge of $\overline{\text{CAS}}$).

static column decode mode (TMS44C257)

The static column decode mode of operation allows high-speed read, write, or read-modify-write by reducing the number of required signal setup, hold, and transition timings. This is achieved by first addressing the row and column in the normal manner, but after the first access maintain $\overline{\text{CAS}}$ low. Subsequently changing the column address produces valid data at the $t_{\text{a}}(\text{CA})$. The first bit is accessed in the normal manner with read data coming out at $t_{\text{a}}(\text{C})$ time. Similarly, write or read-modify-write cycle times can be achieved with appropriate toggling of $\overline{\text{W}}$. The addresses are latched during the write operation, but at the completion of the internal write operation the addresses are unlatched.

address (A0 through A8)

Eighteen address bits are required to decode 1 of 262,144 storage cell locations. Nine row-address bits are set up on pins A0 through A8 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then nine column-address bits are set up on pins A0 through A8 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. The TMS44C256 $\overline{\text{CAS}}$ is used as a chip select activating the output buffer, as well as latching the address bits into the column-address buffers. The TMS44C257 column addresses are latched only on write cycles with the later of the $\overline{\text{CAS}}$ or $\overline{\text{W}}$ falling edge.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$ (early write), data out will remain in the high-impedance state for the entire cycle permitting a write operation with $\overline{\text{G}}$ grounded. The TMS44C257 latches the column addresses on write cycles with the later of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ falling edge.

data in (DQ1-DQ4)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal. In a delayed or read-modify-write cycle, $\overline{\text{G}}$ must be high to bring the output buffers to high impedance prior to impressing data on the I/O lines.

data out (DQ1-DQ4)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ and $\overline{\text{G}}$ are brought low. In a read cycle the output becomes valid after the access time interval $t_{a(C)}$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{a(R)}$ and $t_{a(CA)}$ are satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ and $\overline{\text{G}}$ are low. $\overline{\text{CAS}}$ or $\overline{\text{G}}$ going high returns it to a high-impedance state. This is accomplished by bringing $\overline{\text{G}}$ high prior to applying data, thus satisfying $t_d(\text{GHD})$.

output enable ($\overline{\text{G}}$)

$\overline{\text{G}}$ controls the impedance of the output buffers. When $\overline{\text{G}}$ is high, the buffers will remain in the high-impedance state. Bringing $\overline{\text{G}}$ low during a normal cycle will activate the output buffers putting them in the low-impedance state. It is necessary for both $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ to be brought low for the output buffers to go into the low-impedance state. Once in the low-impedance state, they will remain in the low-impedance state until either $\overline{\text{G}}$ or $\overline{\text{CAS}}$ is brought high.

refresh

A refresh operation must be performed at least once every eight milliseconds to retain data. This can be achieved by strobing each of the 512 rows (A0-A8). A normal read or write cycle will refresh all bits in each row that is selected. A $\overline{\text{RAS}}$ -only operation can be used by holding $\overline{\text{CAS}}$ at the high (inactive) level, thus conserving power as the output buffer remains in the high-impedance state. Externally generated addresses must be used for a $\overline{\text{RAS}}$ -only refresh. Hidden refresh may be performed while maintaining valid data at the output pin. This is accomplished by holding $\overline{\text{CAS}}$ at V_{IL} after a read operation and cycling $\overline{\text{RAS}}$ after a specified precharge period, similar to a $\overline{\text{RAS}}$ -only refresh cycle.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is utilized by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ [see parameter $t_d(\text{CLRL})_R$] and holding it low after $\overline{\text{RAS}}$ falls [see parameter $t_d(\text{RLCH})_R$]. For successive $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh cycles, $\overline{\text{CAS}}$ can remain low while cycling $\overline{\text{RAS}}$. The external address is ignored and the refresh address is generated internally. The external address is also ignored during the hidden refresh option.

power up

To achieve proper device operation, an initial pause of 200 μs followed by a minimum of eight initialization cycles is required after power up to the full V_{CC} level.

test function pin

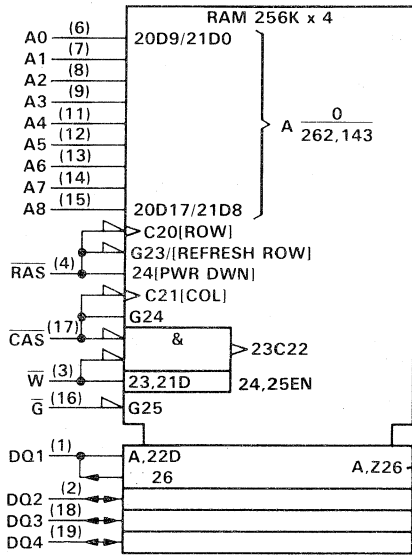

During normal device operation, the TF pin must be either disconnected or biased at a voltage less than or equal to V_{CC} .

TMS4C1024, TMS4C1025, TMS4C1027 1,048,576-BIT DYNAMIC RANDOM-ACCESS MEMORIES

description

The TMS4C1024, TMS4C1025, and TMS4C1027 are high-speed, 1,048,576-bit dynamic random-access memories, organized as 1,048,576 words of one bit each. They employ state-of-the-art EPIC™ (Enhanced Process Implanted CMOS) technology for high performance, reliability, and low power at a low cost.

These devices feature maximum \overline{RAS} access times of 100 ns, 120 ns and 150 ns. Maximum power dissipation is as low as 330 mW operating and 16.5 mW standby on 120 ns devices.

The EPIC™ technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{CC} peaks are 140 mA typical, and a -1-V input voltage undershoot can be tolerated, minimizing system noise considerations.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All addresses and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The TMS4C102_ are offered in 18-pin plastic dual-in-line (N-suffix) and 20/26-lead plastic surface mount SOJ (DJ suffix) packages. These packages are guaranteed for operation from 0°C to 70°C.

operation

enhanced page mode (TMS4C1024)

Enhanced page-mode operation allows faster memory access by keeping the same row address while selecting random column addresses. The time for row-address setup and hold and address multiplex is thus eliminated. The maximum number of columns that may be accessed is determined by the maximum \overline{RAS} low time and the \overline{CAS} page cycle time used. With minimum \overline{CAS} page cycle time, all 1024 columns specified by column addresses A0 through A9 can be accessed without intervening \overline{RAS} cycles.

Unlike conventional page-mode DRAMs, the column-address buffers in this device are activated on the falling edge of \overline{RAS} . The buffers act as transparent or flow-through latches while \overline{CAS} is high. The falling edge of \overline{CAS} latches the column addresses. This feature allows the TMS4C1024 to operate at a higher data bandwidth than conventional page-mode parts, since data retrieval begins as soon as column address is valid rather than when \overline{CAS} transitions low. This performance improvement is referred to as "enhanced page mode." Valid column address may be presented immediately after row address hold time has been satisfied, usually well in advance of the falling edge of \overline{CAS} . In this case, data is obtained after $t_{a(C)}$ max (access time from \overline{CAS} low), if $t_{a(CA)}$ max (access time from column address) has been satisfied. In the event that column addresses for the next page cycle are valid at the time \overline{CAS} goes high, access time for the next cycle is determined by the later occurrence of $t_{a(C)}$ or $t_{a(CP)}$ (access time from rising edge of \overline{CAS}).

nibble mode (TMS4C1025)

Nibble-mode operation allows high-speed read, write, or read-write-modify-write access of 1 to 4 bits of data. The first bit is accessed in the normal manner with read data coming out at $t_{a(C)}$ time as long as $t_{a(R)}$ and $t_{a(CA)}$ are satisfied. The next sequential bits can be read or written by cycling \overline{CAS} while \overline{RAS} remains low. The first bit is determined by the row and column addresses, which need to be supplied only for the first access. Row A9 and column A9 provide the two binary bits for initial selection, with row A9 being the least-significant address and column A9 being the most significant. Thereafter, the falling edge of \overline{CAS} will access the next bit of the circular 4-bit nibble in the following sequence.

Data written in a sequence of more than 4 consecutive cycles shall be capable of being read back without exiting from the nibble mode. In a sequence of consecutive nibble-mode cycles the control of the high-impedance state for the data out (Q) pin is determined by each individual cycle. This facilitates fully mixed nibble-mode cycles (e.g., read/write/read-modify-write/read etc.).

static column decode mode (TMS4C1027)

The static column decode mode of operation allows high-speed read, write, or read-modify-write by reducing the number of required signal setup, hold, and transition timings. This is achieved by first addressing the row and column in the normal manner, but after the first access, maintaining $\overline{\text{CAS}}$ low. Subsequently changing the column address produces valid data at $t_a(\text{CA})$. The first bit is accessed in the normal manner with read coming out at $t_a(\text{R})$ time. Similarly, write or read-modify-write cycle times can be achieved with appropriate toggling of $\overline{\text{W}}$. The addresses are latched during the write operation, but at the completion of the internal write operation the addresses are unlatched.

address (A0 through A9) (TMS4C1024, TMS4C1025)

Twenty address bits are required to decode 1 of 1,048,576 storage cell locations. Ten row-address bits are set up on inputs A0 through A9 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). The ten column-address bits are set up on pins A0 through A9 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select activating the output buffer, as well as latching the address bits into the column-address buffer.

address (A0 through A9) (TMS4C1027)

Twenty address bits are required to decode 1 of 1,048,576 storage cell locations. Ten row-address bits are set up on inputs A0 through A9 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). The ten column-address bits are set up on pins A0 through A9. Row addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. In a write cycle, the later of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ latches the column address bits.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$ (early write), data out will remain in the high-impedance state for the entire cycle, permitting common I/O operation.

data in (D)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal.

data out (Q)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output becomes valid after the access time interval $t_a(\text{C})$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_a(\text{R})$ and $t_a(\text{CA})$ are satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ is low; $\overline{\text{CAS}}$ going high returns it to a high-impedance state. In a delayed-write or read-modify-write cycle, the output will follow the sequence for the read cycle.

refresh

A refresh operation must be performed at least once every eight milliseconds to retain data. This can be achieved by strobing each of the 512 rows (A0-A8). A normal read or write cycle will refresh all bits in each row that is selected. A $\overline{\text{RAS}}$ -only operation can be used by holding $\overline{\text{CAS}}$ at the high (inactive) level,

TMS4C1024, TMS4C1025, TMS4C1027
1,048,576-BIT DYNAMIC RANDOM-ACCESS MEMORIES

thus conserving power as the output buffer remains in the high-impedance state. Externally generated addresses must be used for a $\overline{\text{RAS}}$ -only refresh. Hidden refresh may be performed while maintaining valid data at the output pin. This is accomplished by holding $\overline{\text{CAS}}$ at V_{IL} after a read operation and cycling $\overline{\text{RAS}}$ after a specified precharge period, similar to a $\overline{\text{RAS}}$ -only refresh cycle.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is utilized by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ [see parameter $t_d(\text{CLRL})_R$] and holding it low after $\overline{\text{RAS}}$ falls [see parameter $t_d(\text{RLCH})_R$]. For successive $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh cycles, $\overline{\text{CAS}}$ can remain low while cycling $\overline{\text{RAS}}$. The external address is ignored and the refresh address is generated internally. The external address is also ignored during the hidden refresh cycles.

power up

To achieve proper device operation, an initial pause of 200 μs followed by a minimum of eight initialization cycles is required after full V_{CC} level is achieved.

test-function pin

During normal device operation the TF pin must either be disconnected or biased at a voltage less than or equal to V_{CC} .

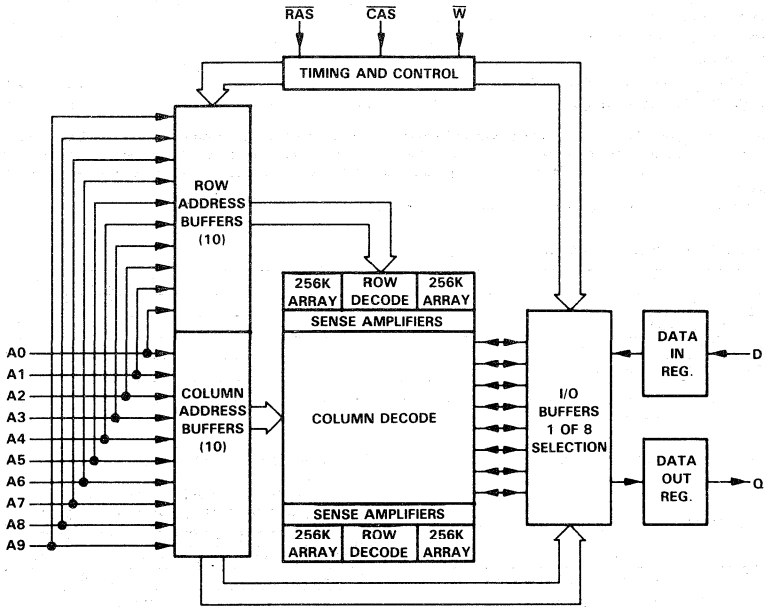

logic symbol†

NOTES:

- Timing measurements in this table are referenced to V_{IL} max and V_{IH} min.
- All cycle times assume $t_t = 5$ ns.
- To guarantee $t_{c(P)}$ min, $t_{su(CA)}$ should be greater than or equal to $t_{w(CH)}$.
- In a read-modify-write cycle, $t_d(CLWL)$ and $t_{su(WCH)}$ must be observed.
- In a read-modify-write cycle, $t_d(RLWL)$ and $t_{su(WRH)}$ must be observed.
- Referenced to the later of \overline{CAS} or \overline{W} in write operations.
- Early write operation only.
- The minimum value is measured when $t_d(RLCL)$ is set to $t_d(RLCL)$ min as a reference.
- Read-modify-write operation only.
- Maximum value specified only to guarantee access time.
- Either $t_h(RHrd)$ or $t_h(CHrd)$ must be satisfied for a read cycle.

description

The TMS4C1050 provides four-bit parallel and asynchronous serial read and write operations (first-in first-out feature) with each bit furnishing access to 262,144 words.

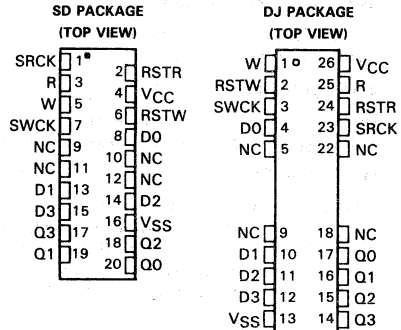

The device employs state-of-art EPIC™ (Enhanced Process Implanted CMOS) technology for high performance, reliability and lower power at low cost.

A dynamic data storage cell is employed as the main data memory to achieve high density. Arbitration logic is implemented in the TMS4C1050, supplying a refresh-free system. The built-in arbitration logic prevents any conflict between data-saving, data-loading, and memory-refresh requests.

The TMS4C1050 is offered in a 16-pin plastic dual-in-line package (N suffix) designed for insertion in mounting hole rows on 7,62-mm (300-mil) centers. This device is also offered in a 20-pin 400-mil zig-zag in-line package (SD suffix) and a 300-mil 20/26-lead plastic surface mount SOJ package (DJ suffix). The latter two versions of the TMS4C1050 are still in development, and the ADVANCE INFORMATION notices in this data sheet pertain only to the SD and DJ packaged devices.

The TMS4C1050 is guaranteed for operation from 0°C to 70°C (L suffix).

EPIC is a trademark of Texas Instruments Incorporated.

ADVANCE INFORMATION

TMS4C1050

1,048,576-BIT FIRST-IN FIRST-OUT PSEUDO-STATIC MEMORY

operation

write enable (W)

W is used as a D enable/disable. A logic high on the W input enables the input and a logic low disables the input and holds the internal write address pointer (head address). W disable time (low) can be expanded to 1 ms. In case W is held low over 1 ms, an RSTW operation will be required to achieve proper write operation. Note that W setup times are referenced to the rising edge of SWCK for D enable/disable.

reset write (RSTW)

RSTW input initializes the write address pointer (head address). RSTW setup and hold times [$t_{su}(RW)$, $t_h(RW)$] are referenced to the rising edge of SWCK.

serial write clock (SWCK)

The SWCK input latches the data inputs on chip when W is high and also increments the internal write address pointer.

data inputs (D0-D3)

Data is shifted in the data registers on the rising edge of SWCK when W is high. D setup and hold times [$t_{su}(D)$, $t_h(D)$] are referenced to the rising edge of SWCK.

read enable (R)

R is used as a Q enable/disable. A logic high on the R input enables the output and a logic low disables the output and holds the internal read address pointer. The outputs are in the high-impedance (floating) state as long as R is held low. R disable time (low) is required below 1 ms. If R is held low over 1 ms, an RSTR operation will be required to achieve the proper read operation. Note that R setup times are referenced to the rising edge of SRCK for Q enable/disable.

reset read (RSTR)

RSTR input initializes the read address pointer (head address). RSTR setup and hold times [$t_{su}(RR)$, $t_h(RR)$] are referenced to the rising edge of SRCK.

serial read clock (SRCK)

Data is shifted out of the data registers on the rising edge of SRCK when R is high during the read operation. The SRCK input increments the internal read address pointer when R is high.

data output (Q0-Q3)

The three-state output buffer provides direct TTL compatibility (no pull-up resistors required) with a fanout of two Series 74 TTL loads. Data out is the same polarity as data in. The output becomes valid after the access time interval $t_a(RC)$ that begins with the positive transition of SRCK. Q valid times [$t_v(RCH)$] are referenced to the rising edge of SRCK in the next cycle.

write cycle

The write operation is controlled by three clocks, SWCK, RSTW, and W. It is accomplished by cycling SWCK and holding W high after the write address pointer reset operation (RSTW). To transfer the last data in data register to memory array, a RSTW operation at W low is required after the write operation. The write operation must be performed by a minimum of 120 write cycles.

read cycle

The read operation is controlled by three clocks, SRCK, RSTR, and R. It is accomplished by cycling SRCK and holding R high after the read address pointer reset operation (RSTR).

power up

To achieve proper device operation, an initial pause of 100 μ s is required after each power-up to the full V_{CC} level followed by a minimum of one (1) SWCK and SRCK cycle for each write and read respectively. After power-up, write/read address pointers are not valid. RSTW and RSTR operations must be performed to initialize the write/read address pointers.

new data access

To access the new data, the SWCK must be brought high at least 600 cycles ahead of the SRCK.

old data access

To access the previously preserved data, the SWCK must be brought high less than 120 cycles ahead of the SRCK.

absolute maximum ratings over operating free air temperature range (unless otherwise noted)†

Voltage range on any pin except Q0-Q3 (see Note 1)	-1.0 V to 7.0 V
Voltage range on Q0-Q3 (see Note 1)	-1.0 V to $V_{CC} + 0.3$ V
Voltage range on V_{CC} (see Note 1)	0.0 V to 7.0 V
Short circuit output current	50 mA
Power dissipation	1.0 W
Operating free-air temperature	0°C to 70°C
Storage temperature range	-65°C to 150°C

†Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: Under absolute maximum ratings, all voltage values in this data sheet are with respect to V_{SS} .

$t_h(RR)$ RSTR hold time after SRCK high (see Note 7)		10		15		20		ns
t_t Transition time		3	30	3	30	3	30	ns

- NOTES: 1. Under absolute maximum ratings, all voltage values are with respect to V_{SS} .
2. Timing measurements are referenced to $V_{IH \text{ min}} = 2.4 \text{ V}$ and $V_{IL \text{ max}} = 0.8 \text{ V}$. t_t is measured between $V_{IH \text{ min}}$ and $V_{IL \text{ max}}$.
3. All cycle times assume $t_t = 3 \text{ ns}$.
4. No restriction for maximum value as long as the write and read address pointers are addressing the first addresses.
5. When the write and read address pointers are not addressing the first addresses, $t_{c(W)}$, $t_{c(R)}$, $t_w(WCH)$, $t_w(WCL)$, $t_w(W)$, $t_w(RCH)$, $t_w(RCL)$, and $t_w(RL)$ must be less than 1 ms. After improper operation ($t_{su(RW)}$ over 1 ms), RSTW or RSTR cycle is required to initialize the write or read address pointer.
6. Reset operation is not guaranteed in case $t_{su(RW)}$, $t_h(RW)$, $t_{su(RR)}$, and $t_h(RR)$ do not meet the specification.

- Common $\overline{\text{CAS}}$ Control with separate Data-In and Data-Out Lines
- Low Power Dissipation
- Operating Free-Air Temperature... 0 °C to 70 °C
- Decoupling Capacitors Ready Mounted on Substrate
- Downward Compatible with 64K X 4 SIPs and Upward Compatible with 1M X 4 SIPs

description

The TM425_EA4 series are 1 M dynamic random-access memory modules organized as 262,144 X 4 bits in a 22-pin single-in-line package comprising four TMS425_FML, 262,144 X 1-bit dynamic RAMs in 18-lead plastic chip carriers mounted on top of substrate together with two 0.1 μ F decoupling capacitors mounted beneath the PLCCs. The onboard capacitors eliminate the need for bypassing on the motherboard and offer superior performance over equivalent leaded capacitors due to reduced lead inductance. With the elimination of bypass capacitors on the motherboard, reduced PC board size, and fewer plated through-holes, a cost savings can be realized. Each TMS425_FML is described in the TMS425_ data sheet and is fully electrically tested and processed according to TI's MIL-SDT-883B (as

amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM425_EA4 features $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM425_EA4 series are rated for operation from 0 °C to 70 °C.

operation

The TM425_EA4 series operate as four TMS425_s connected as shown in the functional block diagram.

Refer to the appropriate TMS425_data sheet for details of its operation.

specifications

For TMS425_ electrical specifications, refer to the appropriate TMS425_ data sheet.

TM4256EC4
262,144 BY 4-BIT DYNAMIC RAM MODULE

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All addresses and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The TM4256EC4 is rated for operation from 0°C to 70°C.

operation

The TM4256EC4 operates as four TMS4256FMLs connected as shown in the functional block diagram. Refer to the TMS4256 data sheet for details of operation.

specifications

For TMS4256FML electrical specifications, refer to the TMS4256 data sheet.

single-in-line package and components

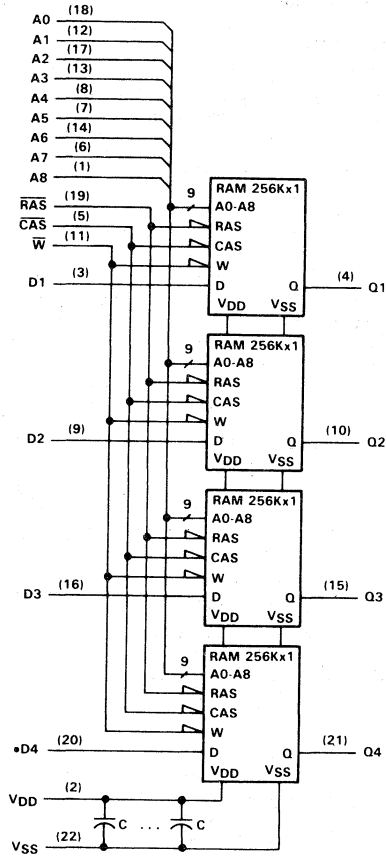

PC substrate: 0,79 mm (0.031 inch) minimum thickness

Bypass capacitors: Multilayer ceramic

Leads: Tin/lead solder coated over phosphor-bronze

description

The TM425_EK8 series are a 2,048K dynamic random-access memory module organized as 262,144 X 8 in a 30-pin single-in-line package (SIP). The SIP is composed of eight TMS425_FML, 262,144 X 1 bit dynamic RAMs, each in 18-lead plastic chip carriers, mounted on top of a substrate together with four 0.1 μF decoupling capacitors mounted beneath the PLCCs. The onboard capacitors eliminate the need for bypassing on the motherboard and offer superior performance over equivalent leaded capacitors due to reduced lead inductance. With the elimination of bypass capacitors on the motherboard, reduced PC board size, and fewer plated through-holes, a cost savings can be realized. Each TMS425_FML is described in the

data sheet and is fully electrically tested and processed according to TI MIL-STD-883B flows (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM425__EK8 features \overline{RAS} access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with \overline{RAS} in order to retain data. \overline{CAS} can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM425__EK8 series are rated for operation from 0 °C to 70 °C.

operation

The TM425__EK8 series operate as eight TMS425__FMLs connected as shown in the functional block diagram. Refer to the appropriate TMS425__ data sheet for details of its operation.

specifications

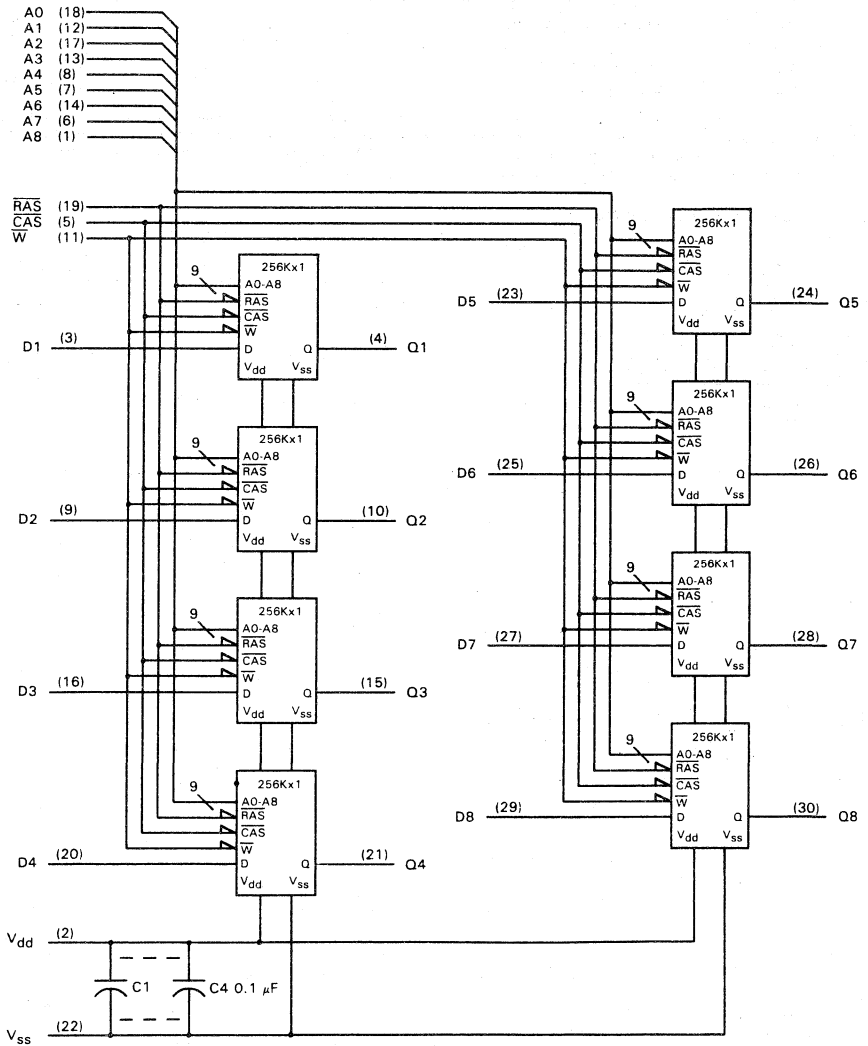

For TMS425__FML electrical specifications, refer to the TMS425__ data sheet.

description

The TM4256__8 series are 2048K, dynamic random-access memory modules organized as 262,144 × 8 bits in a 30-pin single-in-line package comprising eight TMS4256FML, 262,144 × 1 bit dynamic RAMs in 18-lead plastic chip carriers mounted on top of a substrate together with decoupling capacitors mounted beneath the chip carriers. The onboard capacitors eliminate the need for bypassing on the motherboard and offer superior performance over equivalent leaded capacitors due to reduced lead inductance. Also, with 0.3 inch board spacing, the TM4256__8 has a density of ten devices per square inch (approximately 4 × the density of DIPs). With the elimination of bypass capacitors on the motherboard, reduced PC board size, and fewer plated through-holes, a cost savings can be realized.

Each TMS4256FML is described in its data sheet and is fully electrically tested and processed according to TI MIL-STD-883B flows (as amended for commercial applications) prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed.

TM4256FL8, TM4256GU8

262,144 BY 8-BIT DYNAMIC RAM MODULES

The TM4256__8 features $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns maximum.

Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All addresses and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The TM4256__8 is rated for operation from 0°C to 70°C.

presence detect

This feature is included on the TM4256GU8 to allow for hardware presence detection of the memory module. The $\overline{\text{PRD}}$ pin for each module in the system should be pulled high through a pull-up resistor, resulting in a logic one when no module is present. When a module is present, $\overline{\text{PRD}}$ is a logic zero as this pin is connected to VSS on the module. $\overline{\text{PRD}}$ can be used only to detect a module's presence, not its functionality. In a system not requiring presence detect, it is recommended that this pin be left as a no connect; this allows the use of either type of module without adverse effects.

operation

The TM4256FL8 and TM4256GU8 operate as eight TMS4256FMLs connected as shown in the functional block diagram. Refer to the TMS4256 data sheet for details of operation.

specifications

For TMS4256FML electrical specifications, refer to the TMS4256 data sheet.

- Operating Free-Air Temperature... 0 °C to 70 °C
- Decoupling Capacitors Ready Mounted on Substrate
- Upward Compatible with 1M X 8 SIPs

description

The TM425_GB8 series are 2 M dynamic random-access memory modules organized as 262,144 X 8 bits in a 24-pin single-in-line package comprising eight TMS425_FML, 262,144 × 1-bit dynamic RAMs in 18-lead plastic chip carriers mounted on top of substrate together with four 0.1 μ F decoupling capacitors mounted beneath the PLCCs. The onboard capacitors eliminate the need for bypassing on the motherboard and offer superior performance over equivalent leaded capacitors due to reduced lead inductance. With the elimination of bypass capacitors on the motherboard, reduced PC board size, and fewer plated through-holes, a cost savings can be realized. Each TMS425_FML is described in the TMS425_ data sheet and if fully electrically tested and processed according to TI's MIL-SDT-883B (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP,

a further set of electrical tests is performed. The TM425__GB8 features $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM425__GB8 series are rated for operation from 0 °C to 70 °C.

operation

The TM425__GB8 series operate as eight TMS425__s connected as shown in the functional block diagram.

Refer to the appropriate TMS425__ data sheet for details of its operation. The common I/O feature of the TM425__GB8 dictates the use of early write cycles to prevent contention on D and Q.

specifications

For TMS425__ electrical specifications, refer to the appropriate TMS425__ data sheet. The common I/O feature of the TM425__GB8 dictates the use of early write cycles to prevent contention on D and Q.

processed according to TI's MIL-STD-883B (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM425_GV8 features RAS access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with RAS in order to retain data. CAS can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM425_GV8 series are rated for operation from 0 °C to 70 °C.

operation

The TM425_GV8 series operate as eight TMS425_s connected as shown in the functional block diagram.

Refer to the appropriate TMS425_ data sheet for details of its operation. The common I/O feature of the TM425_GV8 dictates the use of early write cycles to prevent contention on D and Q.

presence detect

This feature is included to allow for hardware presence detection of the memory module. The PRD pin for each module in the system should be pulled high through a pull-up resistor, resulting in a logic one when no module is present. When a module is present, PRD is a logic zero as this pin is connected to V_{SS} on the module. PRD can only be used to detect a module's presence, not its functionality. In a system not requiring presence detect, it is recommended that this pin be left as a no connect.

specifications

For TMS425_ electrical specifications, refer to the appropriate TMS425_ data sheet. The common I/O feature of the TM425_GV8 dictates the use of early write cycles to prevent contention on D and Q.

plated through-holes, a cost savings can be realized.

Each TMS4256FML is described in its data sheet and is fully electrically tested and processed according to TI MIL-STD-883B flows (as amended for commercial applications) prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed.

The TM4256_9 features $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns maximum.

Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All addresses and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The TM4256_9 is rated for operation from 0°C to 70°C.

presence detect

This feature is included on the TM4256GU9 to allow for hardware presence detection of the memory module. The PRD pin for each module in the system should be pulled high through a pull-up resistor, resulting in a logic one when no module is present. When a module is present, PRD is a logic zero as this pin is connected to VSS on the module. PRD can be used only to detect a module's presence, not its functionality. In a system not requiring presence detect, it is recommended that this pin be left as a no connect; this allows the use of either type of module without adverse effects.

operation

The TM4256EL9 and TM4256GU9 operate as nine TMS4256FMLs connected as shown in the functional block diagram. Refer to the TMS4256 data sheet for details of operation.

specifications

262,144 BY 9-BIT DYNAMIC RAM MODULES

through-holes, a cost savings can be realized. Each TM425_FML is described in the TM425_ data sheet and is fully electrically tested and processed according to TI's MIL-STD-883B (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM425_FN9 features $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM425_FN9 series are rated for operation from 0 °C to 70 °C.

operation

The TM425_FN9 series operate as nine TMS425_FMLs connected as shown in the functional block diagram. Refer to the appropriate TMS425_ data sheet for details of its operation.

5

specifications

For TMS425_FML electrical specifications, refer to the appropriate TMS425_ data sheet.

board capacitors eliminate the need for bypassing on the motherboard and offer superior performance over equivalent leaded capacitors due to reduced lead inductance. With the elimination of bypass capacitors on the motherboard, reduced PC board size, and fewer plated through-holes, a cost savings can be realized. Each TMS425_FML is described in the data sheet and is fully electrically tested and processed according to TI's MIL-STD-883B (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM425_GV9 and TM425_GP9 features RAS access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with RAS in order to retain data. CAS can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM425_GV9 and TM425_GP9 series are rated for operation from 0 °C to 70 °C.

operation

The TM425_GV9 and TM425_GP9 series operate as nine TMS425_s connected as shown in the functional block diagram. Refer to the appropriate TMS425_ data sheet for details of its operation. The common I/O feature of the TM425_GV9 and TM425_GP9 dictates the use of early write cycles to prevent contention on D and Q.

presence detect

This feature is included to allow for hardware presence detection of the memory module. The PRD pin for each module in the system should be pulled high through a pull-up resistor, resulting in a logic one when no module is present. When a module is present, PRD is a logic zero as this pin is connected to V_{SS} on the module. PRD can only be used to detect a module's presence, not its functionality. In a system not requiring presence detect, it is recommended that this pin be left as a no connect.

specifications

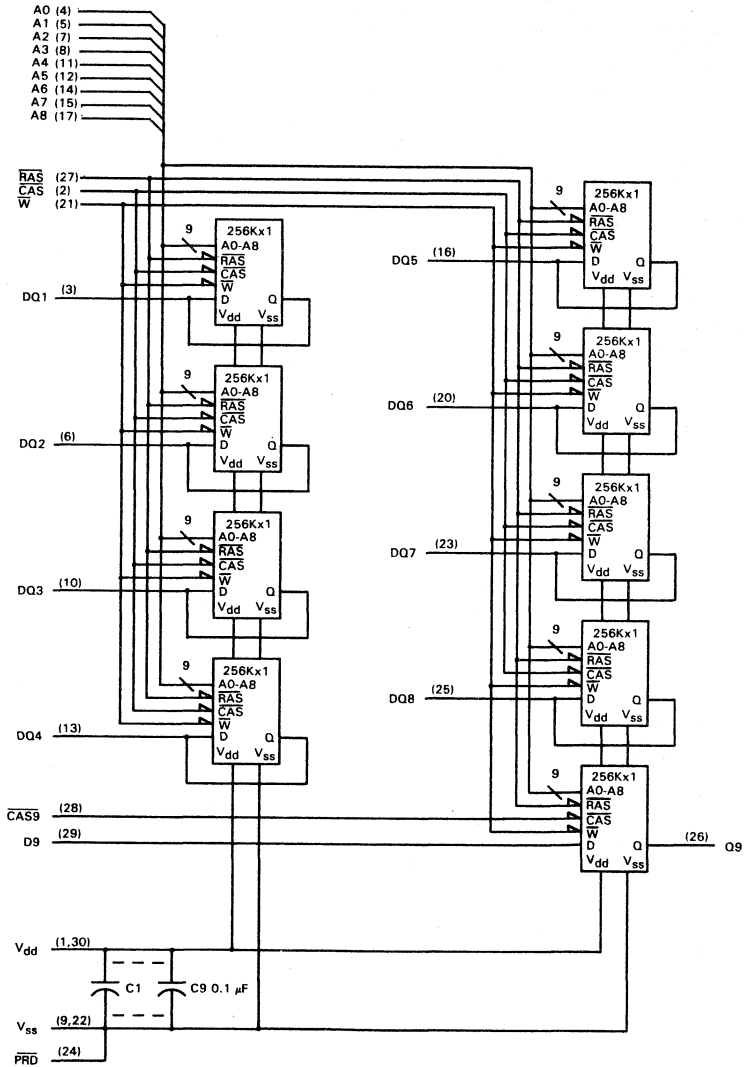

For TMS425_ electrical specifications, refer to the appropriate TMS425_ data sheet. The common I/O feature of the TM425_GV9 and TM425_GP9 dictates the use of early write cycles to prevent contention on D and Q.

tions) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM02__EAB8 features RAS access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 8 milliseconds, and during this period each of the 512 rows must be strobed with RAS in order to retain data. CAS can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM02__EAB8 series are rated for operation from 0 °C to 70 °C.

operation

The TM02__EAB8 series operate as eight TMS4C102__s connected as shown in the functional block diagram.

Refer to the appropriate TMS4C102__ data sheet for details of its operation. The common I/O feature of the TM02__EAB8 dictates the use of early write cycles to prevent contention on D and Q.

test-function pin

During normal device operation the TF pin must either be disconnected or held at a voltage less than or equal to VCC.

specifications

For TMS4C102__ electrical specifications, refer to the appropriate TMS4C102__ data sheet. The common I/O feature of the TM02__EAB8 dictates the use of early write cycles to prevent contention on D and Q.

ced PC board size, and fewer plated through-holes, a cost savings can be realized. Each TMS4C102_DJ is described in the data sheet and is fully electrically tested and processed according to TI's MIL-STD-883B (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM02_EAD8 and TM02_GAL8 features RAS access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 8 milliseconds, and during this period each of the 512 rows must be strobed with RAS in order to retain data. CAS can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM02_EAD8 and TM02_GAL8 series are rated for operation from 0 °C to 70 °C.

operation

The TM02_EAD8 and TM02_GAL8 series operate as eight TMS4C102_s connected as shown in the functional block diagram.

Refer to the appropriate TMS4C102_ data sheet for details of its operation. The common I/O feature of the TM02_EAD8 and TM02_GAL8 dictates the use of early write cycles to prevent contention on D and Q.

presence detect

This feature is included to allow for hardware presence detection of the memory module. The PRD pin for each module in the system should be pulled high through a pull-up resistor, resulting in a logic one when no module is present. When a module is present, PRD is a logic zero as this pin is connected to VSS on the module. PRD can only be used to detect a module's presence, not its functionality. In a system not requiring presence detect, it is recommended that this pin be left as a no connect.

specifications

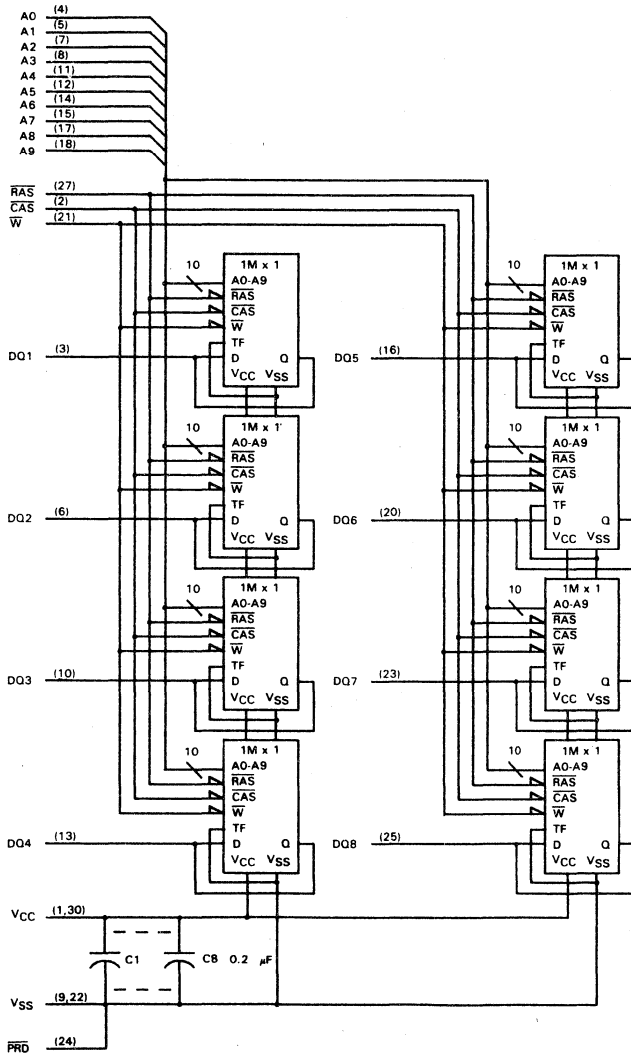

For TMS4C102_ electrical specifications, refer to the appropriate TMS4C102_ data sheet. The common I/O feature of the TM02_EAD8 and TM02_GAL8 dictates the use of early write cycles to prevent contention on D and Q.

TM024EAF9, TM025EAF9, TM027EAF9 1,048,576 BY 9-BIT DYNAMIC RAM MODULE
TM024FAF8, TM025FAF8, TM027FAF8 1,048,576 BY 8-BIT DYNAMIC RAM MODULE

TM02_FAF8 features $\overline{\text{RAS}}$ access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 8 milliseconds, and during this period each of the 512 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM02_FAF8 series are rated for operation from 0 °C to 70 °C.

operation

TM02_EAF9

The TM02_EAF9 series operate as nine TMS4C102_DJs connected as shown in the functional block diagram. Refer to the appropriate TMS4C102_ data sheet for details of its operation.

test-function pin

During normal device operation the TF pin must either be disconnected or held at a voltage less than or equal to V_{CC} .

TM02_FAF8

The TM02_FAF8 series operate as eight TMS4C102_DJs connected as shown in the functional block diagram. Refer to the appropriate TMS4C102_ data sheet for details of its operation.

test-function pin

During normal device operation the TF pin must either be disconnected or held at a voltage less than or equal to V_{CC} .

specifications

For TMS4C102_DJ electrical specifications, refer to the appropriate TMS4C102_ data sheet.

motherboard and offer superior performance over equivalent leaded capacitors due to reduced lead inductance. With the elimination of bypass capacitors on the motherboard, reduced PC board size, and fewer plated through-holes, a cost savings can be realized. Each TMS4C102_DJ is described in the data sheet and is fully electrically tested and processed according to TI's MIL-STD-883B (as amended for commercial applications) flows prior to assembly. After assembly onto the SIP, a further set of electrical tests is performed. The TM02_EAD9 and TM024_GAL9 features RAS access times of 100 ns, 120 ns, and 150 ns maximum. Refresh period is extended to 8 milliseconds, and during this period each of the 512 rows must be strobed with RAS in order to retain data. CAS can remain high during the refresh sequence to conserve power. All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data-in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. The TM02_EAD9 and TM02_GAL9 series are rated for operation from 0 °C to 70 °C.

operation

5

The TM02_EAD9 and TM02_GAL9 series operate as nine TMS4C102_s connected as shown in the functional block diagram. Refer to the appropriate TMS4C102_ data sheet for details of its operation. The common I/O feature of the TM02_EAD9 and TM02_GAL9 dictates the use of early write cycles to prevent contention on D and Q.

presence detect

This feature is included to allow for hardware presence detection of the memory module. The PRD pin for each module in the system should be pulled high through a pull-up resistor, resulting in a logic one when no module is present. When a module is present, PRD is a logic zero as this pin is connected to VSS on the module. PRD can only be used to detect a module's presence, not its functionality. In a system not requiring presence detect, it is recommended that this pin be left as a no connect.

specifications

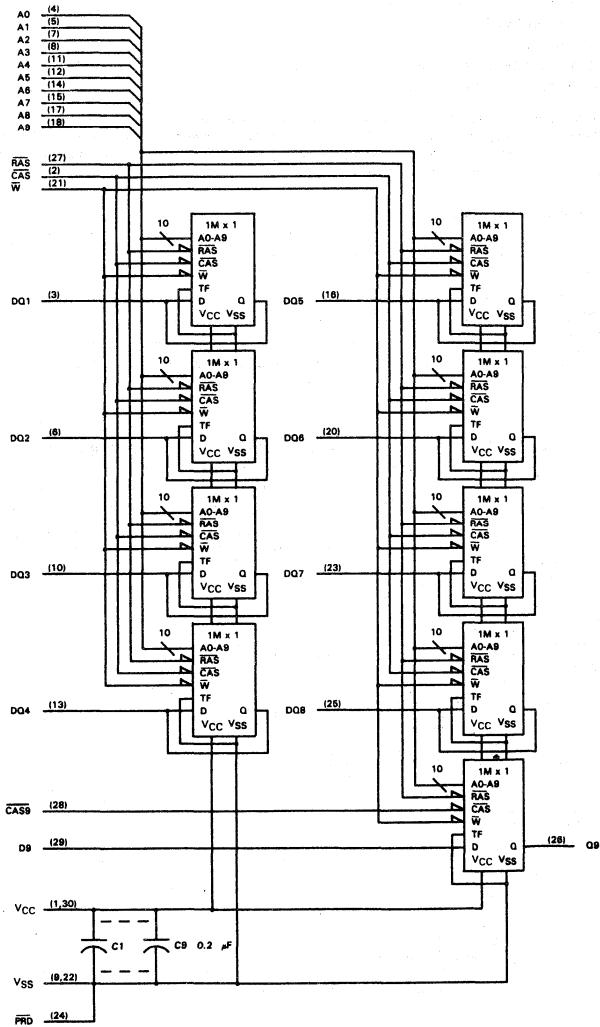

For TMS4C102_ electrical specifications, refer to the appropriate TMS4C102_ data sheet. The common I/O feature of the TM02_EAD9 and TM02_GAL9 dictates the use of early write cycles to prevent contention on D and Q.

description

The TMS27C291 and TMS27C292 series are 16,384-bit, ultraviolet-light erasable, electrically programmable read-only memories. The TMS27PC291 series are 16,384-bit, one-time, electrically programmable read-only memories. These devices are fabricated using CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits without the use of external resistors. Each output can drive eight Series 74 TTL circuits without external resistors. The data outputs are three-state for connecting multiple devices to a common bus. The J and N dual-in-line packages are pin compatible with existing 24-pin bipolar PROMs and high speed EPROMs.

The TMS27C291 and TMS27C292 are offered in dual-in-line ceramic packages (J suffix). The TMS27C291 ceramic package is designed for insertion in mounting-hole rows on 7.62-mm (300-mil) centers. The TMS27C292 ceramic package is designed for insertion in mounting-hole rows on 15.24-mm (600-mil) centers.

The TMS27PC291 PROM is offered in dual-in-line plastic package (N suffix) designed for insertion in mounting-hole rows on 7,62-mm (300-mil) centers. This version of the device is still in development, and the ADVANCE INFORMATION notices in this data sheet pertain to the N package devices. The TMS27PC291[†] PROM is also offered in a 28-lead plastic-leaded chip carrier (FN suffix) for surface mounting applications on solder lands on 1,27-mm (50-mil) centers.

All devices are guaranteed for operation from 0°C to 70°C.

operation

There are eight modes of operation for the TMS27C291, TMS27C292 and the TMS27PC291 as listed in the following table. The read mode requires a single 5-V supply. All inputs are TTL or CMOS levels except for V_{pp} during programming (13.5 V).

FUNCTION	MODE

[‡]X can be V_{IL} or V_{IH}.

[§]V_H = 12 V ± 0.5 V.

[¶](P) = Programming mode.

#Output can be disabled using any of these three methods.

read/output disable

When the outputs of two or more of these devices are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from competing outputs of the other devices. To read the output of a '27C291, '27PC291, or '27C292, a low-level signal is applied to $\overline{S}1$ and a high-level signal is applied to S2 and S3. Any other combination of logic states on these three inputs will disable the outputs. Output data is accessed at pins Q1 through Q8.

latchup immunity

Latchup immunity is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. The input/output layout approach controls latchup without compromising performance or packing density.

TMS27C291, TMS27C292 16,384-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORIES TMS27PC291 16,384-BIT PROGRAMMABLE READ-ONLY MEMORY

erasure (TMS27C291-__JL and TMS27C292-__JL)

Before programming, the '27C291 or '27C292 is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is 25 watt-seconds per square centimeter. A typical 12 milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 45 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the '27C291 or '27C292, the window should be covered with an opaque label.

programming mode pin functions

In the programming mode pins 18-20 on the dual-in-line packages or pins 22-24 on the plastic-leaded chip carrier no longer act as chip selects. Pin S1 becomes the Vpp power supply, pin S2 becomes the VFY (verify) input, and pin S3 becomes the PGM (program) input in the programming mode. Programming mode pin assignments and nomenclature are given in the figures to the right.

blank check mode

The '27C291 and '27C292 use a differential memory cell. This means that an unprogrammed device has ambiguous states in all address locations. Prior to programming, the blank check mode is used to verify that both sides of the differential cell are erased. The blank check mode is defined as S3 to VH and S1 to VL. In this mode, S2 selects between blank check 0s and 1s.

fast programming

Data is presented in parallel (eight bits) on pins Q1 through Q8. Once addresses and data are stable, PGM is pulsed. The programming mode is achieved when Vpp = 13.5 V, VCC = 5.0 V, VFY = VIH, PGM = pulsed VIL. More than one '27C291, '27C292, or '27PC291 can be programmed when the devices are connected in parallel. Locations can be programmed in any order, but it is recommended that all locations be programmed.

**TMS27C291, TMS27C292 16,384-BIT UV
ERASABLE PROGRAMMABLE READ-ONLY MEMORIES
TMS27PC291 16,384-BIT PROGRAMMABLE READ-ONLY MEMORY**

Programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 0.1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied. If correct data is not read, an additional 0.1-millisecond pulse is applied up to a maximum X of 4. The Final programming pulse is 24X long. This sequence of programming and verification is performed at $V_{CC} = 5.0\text{ V}$ and $V_{pp} = 13.5\text{ V}$. When the full Fast programming routine is complete, all bits are verified with $V_{CC} = 5\text{ V} \pm 10\%$ (see Figure 1).

program inhibit

Programming may be inhibited by maintaining a high-level input on the $\overline{\text{PGM}}$ pin.

program verify

Programmed bits may be verified with $V_{pp} = 13.5\text{ V}$ when $\overline{\text{VFY}} = V_{IL}$ and $\overline{\text{PGM}} = V_{IH}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 is forced to $12\text{ V} \pm 0.5\text{ V}$. Two identifier bytes are accessed by A0, i.e., A0 = V_{IL} accesses the manufacturer code; A0 = V_{IH} accesses device code. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is 02.

description

The TMS2732A is an ultraviolet light-erasable, electrically programmable read-only memory. It has 32,768 bits organized as 4,096 words of 8-bit length. The TMS2732A only requires a single 5-volt power supply with a tolerance of ±5%.

The TMS2732A provides two output control lines: Output Enable (\bar{G}/V_{pp}) and Chip Enable (\bar{E}). This feature allows the \bar{G}/V_{pp} control line to eliminate bus contention in multibus microprocessor systems. The TMS2732A has a power-down mode that reduces maximum power dissipation from 657 mW to 158 mW when the device is placed on standby.

This EPROM is supplied in a 24-pin dual-in-line ceramic package and is designed for operation from 0°C to 70°C. The TMS2732A is also offered in the PEP4 version with an extended guaranteed operating temperature range of -10°C to 85°C and 168 hour burn-in (TMS2732A-__JP4).

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

6

operation

The six modes of operation for the TMS2732A are listed in the following table.

FUNCTION (PINS)	MODE					
	Read	Output Disable	Power Down (Standby)	Program	Program Verification	Inhibit Programming
\bar{E} (18)	V_{IL}	X^\dagger	V_{IH}	V_{IL}	V_{IL}	V_{IH}
\bar{G}/V_{PP} (20)	V_{IL}	V_{IH}	X^\dagger	21 V	V_{IL}	21 V
V_{CC} (24)	5 V	5 V	5 V	5 V	5 V	5 V
Q1-Q8 (9 to 11, 13 to 17)	Q	HI-Z	HI-Z	D	Q	HI-Z

$^\dagger X = V_{IH}$ or V_{IL}

read/output disable

The two control pins (\bar{E} and \bar{G}/V_{PP}) must have low-level TTL signals in order to provide data at the outputs. Chip enable (\bar{E}) should be used for device selection. Output enable (\bar{G}/V_{PP}) should be used to gate data to the output pins.

power down

The power-down mode reduces the maximum power dissipation from 657 mW to 158 mW. A TTL high-level signal applied to \bar{E} selects the power-down mode. In this mode, the outputs assume a high-impedance state, independent of \bar{G}/V_{PP} .

erasure

The TMS2732A is erased by exposing the chip to shortwave ultraviolet light that has a wavelength of 253.7 nanometers (2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is fifteen watt-seconds per square centimeter. The lamp should be located about 2.5 centimeters (1 inch) above the chip during erasure. After erasure, all bits are at a high level. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS2732A, the window should be covered with an opaque label.

programming

Note that the application of a voltage in excess of 22 V to \bar{G}/V_{PP} may damage the TMS2732A.

After erasure (all bits in logic 1 state), logic 0s are programmed into the desired locations. A logic 0 can only be erased by ultraviolet light. In the program mode, \bar{G}/V_{PP} is taken from a TTL low level to 21 V and data to be programmed are applied in parallel to output pins Q1-Q8. The location to be programmed is addressed. Once data and addresses are stable, a 10-millisecond TTL low-level pulse is applied to \bar{E} . The maximum width of this pulse is 11 milliseconds. The programming pulse must be applied at each location that is to be programmed. Locations may be programmed in any order.

Several TMS2732As can be programmed simultaneously by connecting them in parallel and following the programming sequence previously described.

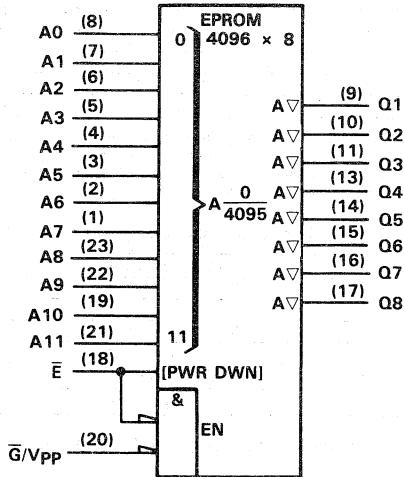

program inhibit

The program inhibit is useful when programming multiple TMS2732As connected in parallel with different data. Program inhibit can be implemented by applying a high-level signal to \bar{E} of the device that is not to be programmed.

program verify

After the EPROM has been programmed, the programmed bits should be verified. To verify bit states, \bar{G}/V_{PP} and \bar{E} are set to V_{IL} .

logic symbol†

†This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)‡

Supply voltage range, V_{CC}	-0.3 V to 7 V
Supply voltage range, V_{PP}	-0.3 V to 22 V

description

The TMS27C32 series are 32,768-bit ultraviolet-light erasable, electrically programmable read-only memories.

The TMS27PC32 series are 32,768-bit, one-time, electrically programmable read-only memories.

These devices are fabricated using power saving CMOS technology for high-speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits without the use of external pull-up resistors. Each output can drive one Series 74 TTL circuit without external resistors.

The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C32 and the TMS27PC32 are pin compatible with 24-pin 32K MOS ROMs, PROMs, and EPROMs.

The TMS27C32 EPROM is offered in a dual-in-line ceramic package (J suffix) designed for insertion in mounting hole rows on 15.2-mm (600-mil) centers. The TMS27C32 is available with two guaranteed temperature ranges of 0°C to 70°C and -40°C to 85°C (TMS27C32- JL and TMS27C32- JE, respectively). The TMS27C32 is also offered with 168 hour burn-in on both temperature ranges (TMS27C32- JL4 and TMS27C32- JE4, respectively). (See table on page 2).

ADVANCE INFORMATION documents contain information on new products in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

TMS27C32 32,768-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY
TMS27PC32 32,768-BIT PROGRAMMABLE READ-ONLY MEMORY

EPROMs/PROMs/EEPROMs

The TMS27C32 PROM is offered in a dual-in-line plastic package (N suffix) designed for insertion in mounting hole rows on 15.2-mm (600-mil) centers. The TMS27C32 is guaranteed for operation from 0°C to 70°C (NL suffix).

All package styles conform to JEDEC standards.

EPROM	SUFFIX FOR OPERATING TEMPERATURE RANGES WITHOUT PEP4 BURN-IN		SUFFIX FOR PEP4 168 ± 8 HR. BURN-IN VS TEMPERATURE RANGES	
	0°C to 70°C	-40°C to 85°C	0°C to 70°C	-40°C to 85°C
	TMS27C32-XXX	JL	JE	JL4

These 32K EPROMs and PROMs operate from a single 5-V supply (in the read mode), thus are ideal for use in microprocessor-based systems. One other 12-13 V supply is needed for programming. All programming signals are TTL level. These devices are programmable by either Fast or SNAP! Pulse programming algorithms. Fast programming uses a V_{pp} of 12.5 V and a V_{CC} of 6.0 V for a nominal programming time of two minutes. SNAP! Pulse programming uses a V_{pp} of 13.0 V and a V_{CC} of 6.5 V for a nominal programming time of 1 second. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed singly, in blocks, or at random.

6

operation

There are seven modes of operation listed in the following table. Read mode requires a single 5-V supply. All inputs are TTL level except for V_{pp} during programming (12.5 V for Fast, or 13.0 V for SNAP! Pulse) and 12 V on A9 for signature mode.

FUNCTION (PINS)	MODE						
	Read	Output Disable	Standby	Programming	Verify	Program Inhibit	Signature Mode
\bar{E} (18)	V_{IL}	V_{IL}	V_{IH}	V_{IL}	V_{IL}	V_{IH}	V_{IL}
\bar{G}/V_{PP} (20)	V_{IL}	V_{IH}	X^\dagger	V_{PP}	V_{IL}	V_{PP}	V_{IL}
V_{CC} (24)	V_{CC}	V_{CC}	V_{CC}	V_{CC}	V_{CC}	V_{CC}	V_{CC}
A9 (22)	X	X	X	X	X	X	V_{H}^\ddagger V_{H}^\ddagger
A0 (8)	X	X	X	X	X	X	V_{IL} V_{IH}
O1-Q8 (9-11, 13-17)	D _{OUT}	HI-Z	HI-Z	D _{IN}	D _{OUT}	HI-Z	CODE
							MFG DEVICE
							97 08

$^\dagger X$ Can be V_{IL} or V_{IH} .
 $^\ddagger V_{H} = 12 V \pm 0.5 V$.

TMS27C32 32,768-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY

TMS27PC32 32,768-BIT PROGRAMMABLE READ-ONLY MEMORY

read/output disable

When the outputs of two or more TMS27C32s or TMS27PC32s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of a single device, a low-level signal is applied to the \bar{E} and \bar{G}/V_{pp} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 to Q8.

latchup immunity

Latchup immunity on the TMS27C32 and TMS27PC32 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. Input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001; "Design Considerations; Latchup Immunity of the HVC MOS EPROM Family," available through TI Field Sales Offices.

power down

Active I_{CC} current can be reduced from 30 mA to 500 μ A (TTL-level inputs) or 250 μ A (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure (TMS27C32)

Before programming, the TMS27C32 EPROM is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). EPROM erasure before programming is necessary to assure that all bits are in the logic 1 (high) state. Logic 0s are programmed into the desired locations. A programmed logic 0 can be erased only by ultraviolet light. The recommended minimum ultraviolet light exposure dose (UV intensity \times exposure time) is 15 watt-seconds per square centimeter. A typical 12-milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C32, the window should be covered with an opaque label.

initializing (TMS27PC32)

The one-time programmable TMS27PC32 PROM is provided with all bits in the logic 1 state, then logic 0s are programmed into the desired locations. Logic 0s programmed into a PROM cannot be erased.

SNAP! Pulse programming

The 32K EPROM and PROM can be programmed using the TI SNAP! Pulse programming algorithm illustrated by the flowchart in Figure 1, which can reduce programming time to a nominal of one second. Actual programming time will vary as a function of the programmer used.

Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed.

The SNAP! Pulse programming algorithm uses initial pulses of 100 microseconds (μ s) followed by a byte verification to determine when the addressed byte has been successfully programmed. Up to 10 (ten) 100 μ s pulses per byte are provided before a failure is recognized.

The programming mode is achieved when $\bar{G}/V_{pp} = 13.0$ V, $V_{CC} = 6.5$ V, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order. When the SNAP! Pulse programming routine is complete, all bits are verified when $V_{CC} = 5$ V, $\bar{G}/V_{pp} = V_{IL}$, and $\bar{E} = V_{IL}$.

fast programming

The 32K EPROM and PROM can be programmed using the Fast programming algorithm illustrated by the flowchart in Figure 2. During Fast programming, data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed. The programming mode is achieved when $\bar{G}/V_{pp} = 12.5 \text{ V}$, $V_{CC} = 6.0 \text{ V}$, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Fast programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{CC} = 6.0 \text{ V}$ and $\bar{G}/V_{pp} = 12.5 \text{ V}$. When the full Fast programming routine is complete, all bits are verified when $V_{CC} = \bar{G}/V_{pp} = 5 \text{ V}$.

program inhibit

Programming may be inhibited by maintaining a high level input on the \bar{E} pin.

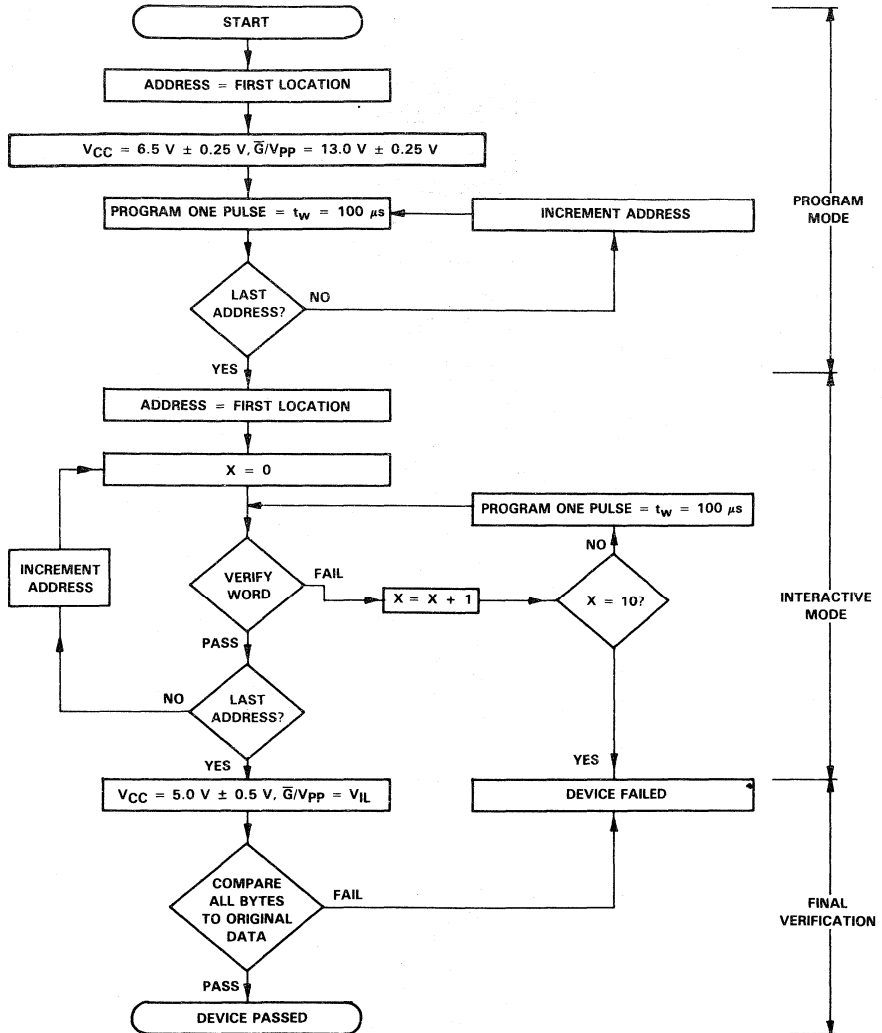

program verify

Programmed bits may be verified when \bar{G}/V_{pp} and $\bar{E} = V_{IL}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 22) is forced to $12 \text{ V} \pm 0.5 \text{ V}$. Two identifier bytes are accessed by A0 (pin 8); i.e., $A0 = V_{IL}$ accesses the manufacturer code which is output on Q1-Q8; $A0 = V_{IH}$ accesses the device code which is output on Q1-Q8. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is 08.

description

The TMS2764 is an ultraviolet-light erasable, electrically programmable read-only memory. It has 65,536 bits organized as 8,192 words of 8-bit length. The TMS2764 only requires a single 5-volt power supply with a tolerance of $\pm 5\%$.

The TMS2764 provides two output control lines: Output Enable (\bar{G}) and Chip Enable (\bar{E}). This feature allows the \bar{G} control line to eliminate bus contention in microprocessor systems. The TMS2764 has a power-down mode that reduces maximum power dissipation from 150 mA to 35 mA when the device is placed on standby.

This EPROM is supplied in a 28-pin, 15,2-mm (600-mil) dual-in-line ceramic package and is designed for operation from 0°C to 70°C. The TMS2764 is also offered in the PEP4 version with an extended guaranteed operating temperature range of -10°C to 85°C and 168 hour burn-in (TMS2764-__JP4).

operation

The six modes of operation for the TMS2764 are listed in the following table.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

V _{CC} (28)	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}
Q1-Q8 (11 to 13, 15 to 19)	D _{OUT}	HI-Z	HI-Z	D _{IN}	D _{OUT}	HI-Z

[†]X = V_{IH} or V_{IL}

read/output disable

The two control pins (\bar{E} and \bar{G}) must have low-level TTL signals in order to provide data at the outputs. Chip enable (\bar{E}) should be used for device selection. Output enable (\bar{G}) should be used to gate data to the output pins.

power down

The power-down mode reduces the maximum active current from 150 mA to 35 mA. A TTL high-level signal applied to \bar{E} selects the power-down mode. In this mode, the outputs assume a high-impedance state, independent of \bar{G} .

erasure

Before programming, the TMS2764 is erased by exposing the chip to shortwave ultraviolet light that has a wavelength of 253.7 nanometers (2537 angstroms). The recommended minimum exposure dose (UV intensity × exposure time) is fifteen watt-seconds per square centimeter. A typical 12 mW/cm² UV lamp will erase the device in approximately 20 minutes. The lamp should be located about 2.5 centimeters (1 inch) above the chip during erasure. After erasure, all bits are at a high level. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS2764, the window should be covered with an opaque label.

Fast programming

Note that the application of a voltage in excess of 22 V to V_{pp} may damage the TMS2764.

After erasure, logic 0s are programmed into the desired locations. Programming consists of the following sequence of events. With the level on V_{pp} equal to 21 V and \bar{E} at TTL low, data to be programmed is applied in parallel to output pins Q1-Q8. The location to be programmed is addressed. Once data and addresses are stable, a TTL low-level pulse is applied to PGM. Programming pulses must be applied at each location that is to be programmed. Locations may be programmed in any order.

TMS2764

65,536-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY

Programming uses two types of programming pulse: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each application, the byte being programmed is verified. If the correct data is read, the Final programming pulse is then applied. If correct data is not read, a further 1 millisecond programming pulse is applied up to a maximum X of 15. The Final programming pulse is 4X milliseconds long. This sequence of programming pulses and byte verification is done at $V_{CC} = 6.0\text{ V}$ and $V_{pp} = 21.0\text{ V}$. When the full Fast programming routine is complete, all bits are verified with $V_{CC} = V_{pp} = 5\text{ V}$. A flowchart of the Fast programming routine is shown in Figure 1.

multiple device programming

Several TMS2764s can be programmed simultaneously by connecting them in parallel and following the programming sequence previously described.

program inhibit

The program inhibit is useful when programming multiple TMS2764s connected in parallel with different data. Program inhibit can be implemented by applying a high-level signal to \bar{E} or $\overline{\text{PGM}}$ of the device that is not to be programmed.

program verify

Programmed bits may be verified with $V_{pp} = 21\text{ V}$ when $\bar{G} = V_{IL}$, $\bar{E} = V_{IL}$ and $\overline{\text{PGM}} = V_{IH}$.

description

The TMS27C49 EPROM series are 65,536-bit, ultraviolet-light erasable, electrically programmable read-only memories in ceramic packages (J or JT suffix).

The TMS27PC49 PROM series are 65,536-bit, one-time, electrically programmable read-only memories in plastic packages (N, NT, or FN suffix). These devices are fabricated using CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits without the use of external pull-up resistors. Each output can drive eight Series 74 TTL circuits without pull-up resistors.

The data outputs are three-state for connecting multiple devices to a common bus. The J, JT, N, and NT packaged devices are pin compatible with existing 24-pin high-speed EPROMs and bipolar PROMs.

The JT and NT packages are designed for insertion in mounting-hole rows on 7,62-mm (300 mil) centers. The J and N packages are designed for insertion in mounting-hole rows on 15,24-mm (600 mil) centers. The TMS27PC49 PROM is also provided in an FN plastic leaded chip carrier package for surface mounting on pads of 1,27-mm (50 mil) lead spacing.

The TMS27C49 EPROM and the TMS27PC49 PROM are guaranteed for operation from 0°C to 70°C (L suffix).

TMS27C49 65,536-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY
TMS27PC49 65,536-BIT PROGRAMMABLE READ-ONLY MEMORY

operation

There are nine modes of operation for the TMS27C49 and TMS27PC49 listed in the following table. The read mode requires a single 5-V supply. All inputs are TTL or CMOS levels except for Vpp, \bar{E} , and PGM, which can be high level voltages during specific modes.

[†]Pin assignments for program mode.

[‡]X can be V_{IL} or V_{IH}.

[§]V_H = 12 V ± 0.5 V.

[¶](P) = Programming mode.

read/output disable

When the outputs of two or more TMS27C49s or TMS27PC49s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from competing outputs of the other devices. To read the output of the selected TMS27C49 or TMS27PC49, a low-level signal is applied to \bar{E} . All other devices in the circuit should have their outputs disabled by applying a high-level signal to their \bar{E} pins. Output data is accessed at pins Q1 through Q8.

latchup immunity

Latchup immunity is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P. C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. The input/output layout approach controls latchup without compromising performance or packing density.

TMS27C49 65,536-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY

TMS27PC49 65,536-BIT PROGRAMMABLE READ-ONLY MEMORY

erasure (TMS27C49-__JL and JTL EPROMs)

Before programming, the TMS27C49 EPROMs are erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is 25 watt-seconds per square centimeter. A typical 12 milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 45 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C49 EPROM, the window should be covered with an opaque label.

programming mode pin functions

In the programming mode, A12 becomes VSEL, A11 becomes Vpp supply, \bar{E} becomes \bar{PE} (program enable), A10 becomes LAT (latch) input, A9 becomes PGM (program) input, and A8 becomes \bar{VFY} (verify) input. Latched inputs occur on pins 8 through 4 (J, JT, N, and NT packages) and on pins 9 through 5 (FN package) as A8L through A12L are multiplexed with A0 through A4 addresses on these pins.

blank check mode

The TMS27C49 and the TMS27PC49 use a differential memory cell. This means that an unprogrammed device has ambiguous states in all address locations. Prior to programming, the blank check mode is used to verify that both sides of the differential cell are erased. The blank check mode is defined as \bar{PE} to V_H; VSEL and PGM to V_{IL}(P). In this mode, Vpp selects between blank check 0s and 1s. \bar{VFY} acts as an output enable (see Figure 1).

programming mode

After erasure, logic 1s and 0s are programmed into the desired memory cells. Data is presented in parallel (eight bits) on pins Q1-Q8. High order addresses (A8L-A12L) are latched by pulsing LAT. Once addresses and data are stable, PGM is pulsed. The programming mode is achieved when Vpp = 13.5V, VCC = 6.0V, PGM = V_{IL}(P), \bar{VFY} = V_{IH}(P), \bar{PE} = V_{IL}(P), and VSEL = V_{IL}(P).

TMS27C49 65,536-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY

TMS27PC49 65,536-BIT PROGRAMMABLE READ-ONLY MEMORY

More than one TMS27C49 or TMS27PC49 can be programmed when the devices are connected in parallel. Locations can be programmed in any order, but it is recommended that all locations be programmed. The length of the programming pulse is 100 μ s; this pulse is applied X times. After each pulse the byte being programmed is verified. If it fails verify, another programming pulse is applied up to a maximum X = 25. If the part passes verify, the algorithm continues programming the remaining memory locations. This sequence of programming and verification is performed at $V_{CC} = 6.0$ V and $V_{pp} = 13.5$ V. When the programming routine is complete, all bits are verified with $V_{CC} = 5.0$ V \pm 10% (see Figure 2).

program inhibit

Programming may be inhibited by maintaining a high-level input on the \overline{PGM} or \overline{PE} pins.

program verify

The TMS27C49 and TMS27PC49 use a differential memory cell for data storage. It is composed of two FAMOS transistors. One of the FAMOS transistors in the cell must be programmed for data to be read correctly. The condition of both FAMOS transistors in a cell being erased or both being programmed results in an undefined condition on the outputs. The TMS27C49 and the TMS27PC49 use a two-pass verify to ensure that a reliable data storage margin in the differential memory cell has been achieved without the need for an overprogramming pulse. During the program verify mode, the outputs from the differential memory cell are intentionally biased, or offset, to insure that a highly reliable program margin is achieved during normal read mode operation. Verify 1s skew the differential memory cell toward zeros and are used to check for programmed 1s. Verify 0s skew the differential memory cell towards 1s and are used to check for programmed 0s. Programmed bits may be verified with $V_{pp} = 13.5$ V when $\overline{VFY} = V_{IL(P)}$, $\overline{PGM} = V_{IH(P)}$, and $VSEL = V_{IL(P)}$ (verify 0s) or $VSEL = V_{IH(P)}$ (verify 1s).

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 is forced to V_H . Two identifier bytes are accessed by A0, ie., A0 = V_{IL} accesses the manufacturer code; A0 = V_{IH} accesses device code. Addresses A1-A4 must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is F2.

description

The TMS27C64 series are 65,536-bit, ultraviolet-light erasable, electrically programmable read-only memories.

The TMS27PC64 series are 65,536-bit, one-time, electrically programmable read-only memories.

These devices are fabricated using power saving CMOS technology for high-speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits without the use of external pull-up resistors. Each output can drive one Series 74 TTL circuit without external resistors.

The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C64 and the TMS27PC64 are pin compatible with 28-pin 64K MOS ROMs, PROMs, and EPROMs.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

TMS27PC64 65,536-BIT PROGRAMMABLE READ-ONLY MEMORY

EPROMs/PROMs/EEPROMs

6

The TMS27C64 EPROM is offered in a dual-in-line ceramic package (J suffix) designed for insertion in mounting hole rows on 15,2-mm (600-mil) centers. The TMS27C64 is available with two guaranteed temperature ranges of 0°C to 70°C and -40°C to 85°C (TMS27C64-__JL and TMS27C64-__JE, respectively). The TMS27C64 is also offered with 168-hour burn-in on both temperature ranges (TMS27C64-__JL4 and TMS27C64-__JE4, respectively). (See table below).

The TMS27PC64 PROM is offered in a dual-in-line plastic package (N suffix) designed for insertion in mounting hole rows on 15,2-mm (600-mil) centers. The TMS27PC64 is guaranteed for operation from 0°C to 70°C.

All package styles conform to JEDEC standards.

EPROM	SUFFIX FOR OPERATING TEMPERATURE RANGES WITHOUT PEP4 BURN-IN		SUFFIX FOR PEP4 168 HR. BURN-IN VS TEMPERATURE RANGES	
	0°C to 70°C	-40°C to 85°C	0°C to 70°C	-40°C to 85°C
TMS27C64-XXX	JL	JE	JL4	JE4

These EPROMs and PROMs operate from a single 5-V supply (in the read mode), thus are ideal for use in microprocessor-based systems. One other 12-13 V supply is needed for programming. All programming signals are TTL level. These devices are programmable by either Fast or SNAP! Pulse programming algorithms. Fast programming uses a V_{pp} of 12.5 V and a V_{CC} of 6.0 V for a nominal programming time of two minutes. SNAP! Pulse programming uses a V_{pp} of 13.0 V and a V_{CC} of 6.5 V for a nominal programming time of one second. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed singly, in blocks, or at random.

operation

There are seven modes of operation listed in the following table. Read mode requires a single 5-V supply. All inputs are TTL level except for V_{pp} during programming (12.5 V for Fast, or 13.0 V for SNAP! Pulse) and 12 V on A9 for signature mode.

[†]X Can be V_{IL} or V_{IH}.
[‡]V_H = 12 V ± 0.5 V.

read/output disable

When the outputs of two or more TMS27C64s or TMS27PC64s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of a single device, a low-level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 through Q8.

latchup immunity

Latchup immunity on the TMS27C64 and TMS27PC64 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. Input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001; "Design Considerations; Latchup Immunity of the HVCMOS EPROM Family," available through TI Field Sales Offices.

power down

Active I_{CC} current can be reduced from 30 mA to 500 μ A (TTL-level inputs) or 250 μ A (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure (TMS27C64)

Before programming, the TMS27C64 EPROM is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). EPROM erasure before programming is necessary to assure that all bits are in the logic 1 (high) state. Logic 0s are programmed into the desired locations. A programmed logic 0 can be erased only by ultraviolet light. The recommended minimum ultraviolet light exposure dose (UV intensity × exposure time) is 15 watt-seconds per square centimeter.

TMS27C64 65,536-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY

TMS27PC64 65,536-BIT PROGRAMMABLE READ-ONLY MEMORY

A typical 12-milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C64, the window should be covered with an opaque label.

initializing (TMS27PC64)

The one-time programmable TMS27PC64 PROM is provided with all bits in the logic 1 state, then logic 0s are programmed into the desired locations. Logic 0s programmed into a PROM cannot be erased.

SNAP! Pulse programming

The 64K EPROM and PROM can be programmed using the TI SNAP! Pulse programming algorithm illustrated by the flowchart of Figure 1, which can reduce programming time to a nominal of one second. Actual programming time will vary as a function of the programmer used.

Data is presented in parallel (eight bits) on pins Q1 through Q8. Once addresses and data are stable, $\overline{\text{PGM}}$ is pulsed.

The SNAP! Pulse programming algorithm uses initial pulses of 100 microseconds (μs) followed by a byte verification to determine when the addressed byte has been successfully programmed. Up to 10 (ten) 100 μs pulses per byte are provided before a failure is recognized.

The programming mode is achieved when $V_{\text{pp}} = 13.0 \text{ V}$, $V_{\text{CC}} = 6.5 \text{ V}$, $\overline{\text{G}} = V_{\text{IH}}$, and $\overline{\text{E}} = V_{\text{IL}}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order. When the SNAP! Pulse programming routine is complete, all bits are verified with $V_{\text{CC}} = V_{\text{pp}} = 5 \text{ V}$.

Fast programming

The 64K EPROM and PROM can be programmed using the Fast programming algorithm illustrated by the flowchart in Figure 2. During Fast programming, data is presented in parallel (eight bits) on pins Q1 through Q8. Once addresses and data are stable, $\overline{\text{PGM}}$ is pulsed. The programming mode is achieved when $V_{\text{pp}} = 12.5 \text{ V}$, $V_{\text{CC}} = 6.0 \text{ V}$, $\overline{\text{G}} = V_{\text{IH}}$, and $\overline{\text{E}} = V_{\text{IL}}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Fast programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{\text{CC}} = 6.0 \text{ V}$ and $V_{\text{pp}} = 12.5 \text{ V}$. When the full Fast programming routine is complete, all bits are verified with $V_{\text{CC}} = V_{\text{pp}} = 5 \text{ V}$.

program inhibit

Programming may be inhibited by maintaining a high level input on the $\overline{\text{E}}$ or $\overline{\text{PGM}}$ pin.

program verify

Programmed bits may be verified with $V_{\text{pp}} = 12.5 \text{ V}$ when $\overline{\text{G}} = V_{\text{IL}}$, $\overline{\text{E}} = V_{\text{IL}}$, and $\overline{\text{PGM}} = V_{\text{IH}}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 is forced to $12 \text{ V} \pm 0.5 \text{ V}$. Two identifier bytes are accessed by A0; i.e., $A0 = V_{\text{IL}}$ accesses the manufacturer code, which is output on Q1-Q8; $A0 = V_{\text{IH}}$ accesses the device code, which is output on Q1-Q8. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is 07.

description

The TMS28C64 is a 65,536-bit, electrically erasable programmable read only memory. This device is fabricated using 2-μ CMOS twin-well silicon gate flotox technology for high reliability and very low power dissipation. All inputs can be driven by Series 74 TTL circuits without the use of external resistors. The data I/O are three-state for connecting multiple devices to a common bus.

The TMS28C64 EEPROM is offered in a dual-in-line ceramic package (J suffix) and a dual-in-line plastic package (N suffix) designed for insertion in mounting hole rows on 15.2-mm (600-mil) centers. The TMS28C64 EEPROM is guaranteed for operation from 0°C to 70°C (L suffix).

The TMS28C64 is organized as 8K × 8 bits. It features internal circuitry to minimize external hardware interface (single 5-V power supply, internal latch of address and data buses during write operation, data polling and ready/busy pin signaling end-of-write).

The device performs the programming operation automatically and can write a single byte or any number of bytes between 1 and 32 (page mode), which the user is able to load within a time window of 200 μs from the moment the write operation is enabled.

During a programming operation, the data polling and the ready/busy functions are enabled to notify the memory to ignore any command until the operation is completed.

The device has power-up/power-down protection to prevent inadvertent write operations.

ADVANCE INFORMATION documents contain information on new products in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

ADVANCE INFORMATION

TMS28C64
65,536-BIT ELECTRICALLY ERASABLE PROGRAMMABLE READ-ONLY MEMORY

EPPROMS/PROMS/EEPROMS

All the mode functions and the electrical conditions to access them are listed in the following table.

FUNCTIONS (PINS)	MODE			
	READ	OUTPUT DISABLE	STANDBY AND WRITE INHIBIT	WRITE
\bar{E} (20)	V_{IL}	V_{IL}	V_{IH}	V_{IL}
\bar{G} (22)	V_{IL}	V_{IH}	X	V_{IH}
A11 (25)	X	X	X	X
A9 (24)	X	X	X	X
\bar{W} (27)	V_{IH}	V_{IH}	X	V_{IL}
DQ0-DQ7 (11-13, 15-19)	DOUT	HI-Z	HI-Z	DIN

X = Don't care for $V < V_{CC}$

operation

read/output disable

When the outputs of two or more TMS28C64s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices.

To read the output of the TMS28C64, a low-level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins DQ0 to DQ7.

In word read-mode (where the word is defined as two bytes whose address is different only for A0) it is possible to read the second word byte much faster (100 ns) than the first one (250 ns).

latchup immunity

Latchup immunity on the TMS28C64 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. Input/output layout approach controls latchup without compromising performance or packing density.

power down

Active I_{CC} current can be reduced from 10 mA to 1.5 mA typical by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

write

Single byte write initiates with a \bar{W} low and \bar{G} high applied to a selected device. This performs the writing, at the location selected by address pins, of the data present at the I/O pins.

Addresses are latched on the last falling edge of \bar{E} or \bar{W} , while data is latched on the first rising edge of \bar{E} or \bar{W} .

Single byte write cycle is completed in 10 ms typical.

automatic page write

The TMS28C64 performs the write operation automatically, and 1 to 32 bytes of data can be written into the EEPROM in a single write cycle (10 ms typical).

Following a byte write signal, an internal window is open. While this window is open, the user is allowed to send up to 31 further bytes, each one of them by a new byte write signal.

After 200 μ s the part will perform the simultaneous writing of all the addressed bytes.

Total time for the entire array writing (256 pages) is 2.56 seconds typical.

During the page mode, the addresses A5 through A12 must be the same as the first byte. The bytes may be written in any order.

data polling

The TMS28C64 provides a software means (data polling) to signal that the device is performing a write operation. During the write cycle, after an attempt to read any byte, the device answers with the last received byte, except for DQ7, whose logical value is inverted.

ready/busy

The TMS28C64 also provides the possibility of signaling if the device is performing a byte or a page write cycle by the ready/busy output (low during the write cycle). Ready/busy is an open-drain output with a 10 k Ω external resistor to V_{CC}.

inadvertent write operation protection

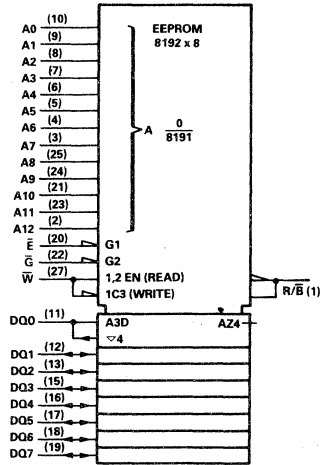

The device is protected against write command during power-up for 25 μ s typical after V_{CC} reaches 4 volts. At the end of this interval, the signals at input pins, \bar{E} , \bar{G} , and \bar{W} must be stable to avoid inadvertent write operation.

(including program data inputs) can be driven by Series 74 TTL circuits without the use of external pull-up resistors. Each output can drive one Series 74 TTL circuit without external resistors.

The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C128 and the TMS27PC128 are pin compatible with 28-pin 128K MOS ROMs, PROMs, and EPROMs.

The TMS27C128 EPROM is offered in a dual-in-line ceramic package (J suffix) designed for insertion in mounting holes on 15.2-mm (600-mil) centers and is rated for operation from 0°C to 70°C. The TMS27C128 is also offered with two guaranteed temperature ranges of 0°C to 70°C and -40°C to 85°C (TMS27C128-__JL and TMS27C128-__JE, respectively). The TMS27C128 is also offered with 168 hour burn-in on both temperature ranges (TMS27C128-__JL4 and TMS27C128-__JE4, respectively). (See table below.)

The TMS27PC128 PROM is offered in a dual-in-line plastic package (N suffix) designed for insertion in mounting hole rows on 15.2-mm (600-mil) centers. The TMS27PC128 is also supplied in a 32-lead plastic leaded chip carrier package using 1.25-mm (50-mil) lead spacing (FM suffix). The TMS27PC128 is guaranteed for operation from 0°C to 70°C.

All package styles conform to JEDEC standards.

EPROM	SUFFIX FOR OPERATING TEMPERATURE RANGES WITHOUT PEP4 BURN-IN		SUFFIX FOR PEP4 168 HR. BURN-IN VS TEMPERATURE RANGES	
	0°C TO 70°C	-40°C TO 85°C	0°C TO 70°C	-40°C TO 85°C
TMS27C128-XXX	JL	JE	JL4	JE4

These EPROMs and PROMs operate from a single 5-V supply (in the read mode), thus are ideal for use in microprocessor-based systems. One other 12-13 V supply is needed for programming. All programming signals are TTL level. These devices are programmable by either Fast or SNAP! Pulse programming algorithms. Fast programming uses a V_{pp} of 12.5 V and a V_{CC} of 6.0 V for a nominal programming time of two minutes. SNAP! Pulse programming uses a V_{pp} of 13.0 V and a V_{CC} of 6.5 V for a nominal programming time of two seconds. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed singly, in blocks, or at random.

operation

There are seven modes of operation listed in the following table. Read mode requires a single 5-V supply. All inputs are TTL level except for V_{pp} during programming (12.5 V for Fast or 13.0 V for SNAP! Pulse) and 12 V on A9 for signature mode.

FUNCTION	MODE							SIGNATURE MODE	
	Read	Output Disable	Standby	Programming	Verify	Program Inhibit	Signature Mode		
\bar{E}	V _{IL}	V _{IL}	V _{IH}	V _{IL}	V _{IL}	V _{IH}	V _{IL}		
\bar{G}	V _{IL}	V _{IH}	X [†]	V _{IH}	V _{IL}	X	V _{IL}		
PGM	V _{IH}	V _{IH}	X	V _{IL}	V _{IH}	X	V _{IH}		
V _{pp}	V _{CC}	V _{CC}	V _{CC}	V _{pp}	V _{pp}	V _{pp}	V _{CC}		
V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}		
A9	X	X	X	X	X	X	V _{IH} [‡]	V _{IH} [‡]	
A0	X	X	X	X	X	X	V _{IL}	V _{IH}	
Q1-Q8	DOUT	HI-Z	HI-Z	D _{IN}	DOUT	HI-Z	CODE		
							MFG	DEVICE	
							97	83	

[†]X Can be V_{IL} or V_{IH}.
[‡]V_{IH} = 12 V ± 0.5 V.

read/output disable

When the outputs of two or more TMS27C128s or TMS27PC128s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of a single device, a low-level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 through Q8.

latchup immunity

Latchup immunity on the TMS27C128 and TMS27PC128 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. Input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001; "Design Considerations; Latchup Immunity of the HVCMOS EPROM Family," available through TI Field Sales Offices.

power down

Active I_{CC} current can be reduced from 30 mA to 500 μ A (TTL-level inputs) or 250 μ A (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure (TMS27C128)

Before programming, the TMS27C128 EPROM is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). EPROM erasure before programming is necessary to assure that all bits are in the logic 1 (high) state. Logic 0s are programmed into the desired locations. A programmed logic 0 can be erased only by ultraviolet light. The recommended minimum ultraviolet light exposure dose (UV intensity \times exposure time) is 15 watt-seconds per square centimeter. A typical 12-milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C128, the window should be covered with an opaque label.

initializing (TMS27PC128)

The one-time programmable TMS27PC128 PROM is provided with all bits in the logic 1 state, then logic 0s are programmed into the desired locations. Logic 0s programmed into a PROM cannot be erased.

SNAP! Pulse programming

The 128K EPROM and PROM can be programmed using the TI SNAP! Pulse programming algorithm illustrated by the flowchart in Figure 1, which can reduce programming time to a nominal of two seconds. Actual programming time will vary as a function of the programmer used.

Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \overline{PGM} is pulsed.

The SNAP! Pulse programming algorithm uses initial pulses of 100 microseconds (μ s) followed by a byte verification to determine when the addressed byte has been successfully programmed. Up to 10 (ten) 100- μ s pulses per byte are provided before a failure is recognized.

The programming mode is achieved when $V_{pp} = 13.0$ V, $V_{CC} = 6.5$ V, $\bar{G} = V_{IH}$, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order. When the SNAP! Pulse programming routine is complete, all bits are verified with $V_{CC} = V_{pp} = 5$ V.

Fast programming

The 128K EPROM and PROM can be programmed using the Fast programming algorithm illustrated by the flowchart in Figure 2. During Fast programming, data is presented in parallel (eight bits) on pins Q1 through Q8. Once addresses and data are stable, $\overline{\text{PGM}}$ is pulsed. The programming mode is achieved when $V_{\text{pp}} = 12.5\text{ V}$, $V_{\text{CC}} = 6.0\text{ V}$, $\overline{\text{G}} = V_{\text{IH}}$, and $\overline{\text{E}} = V_{\text{IL}}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Fast programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{\text{CC}} = 6.0\text{ V}$ and $V_{\text{pp}} = 12.5\text{ V}$. When the full Fast programming routine is complete, all bits are verified with $V_{\text{CC}} = V_{\text{pp}} = 5\text{ V}$.

program inhibit

Programming may be inhibited by maintaining a high level input on the $\overline{\text{E}}$ or $\overline{\text{PGM}}$ pin.

program verify

Programmed bits may be verified with $V_{\text{pp}} = 12.5\text{ V}$ when $\overline{\text{G}} = V_{\text{IL}}$, $\overline{\text{E}} = V_{\text{IL}}$, and $\overline{\text{PGM}} = V_{\text{IH}}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 24) is forced to $12\text{ V} \pm 0.5\text{ V}$. Two identifier bytes are accessed by A0 (pin 10); i.e., $A0 = V_{\text{IL}}$ accesses the manufacturer code, which is output on Q1-Q8; $A0 = V_{\text{IH}}$ accesses the device code, which is output on Q1-Q8. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is 83.

NOTES: 2. V_{CC} must be applied before or at the same time as V_{pp} and removed after or at the same time as V_{pp}. The device must not be inserted into or removed from the board when V_{pp} or V_{CC} is applied.

3. V_{pp} can be connected to V_{CC} directly (except in the program mode). V_{CC} supply current in this case would be I_{CC} + I_{pp}.

description

The TMS27C256 series are 262,144-bit, ultraviolet-light erasable, electrically programmable read-only memories.

The TMS27PC256 series are 262,144-bit, one-time, electrically programmable read-only memories.

These devices are fabricated using power saving CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can

EPROMS/PROMS/EEPROMS

be driven by Series 74 TTL circuits without the use of external pull-up resistors. Each output can drive one Series 74 TTL circuit without external resistors.

The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C256 and the TMS27PC256 are pin compatible with 28-pin 256K MOS ROMs, PROMs, and EPROMs.

The TMS27C256 EPROM is offered in a dual-in-line ceramic package (J suffix) designed for insertion in mounting hole rows on 15.2-mm (600-mil) centers. The TMS27C256 is offered with two guaranteed temperature ranges of 0°C to 70°C and -40°C to 85°C (TMS27C256-__JL and TMS27C256-__JE, respectively). The TMS27C256 is also offered with 168-hour burn-in on both temperature ranges (TMS27C256-__JL4 and TMS27C256-__JE4, respectively); see table below.

The TMS27PC256 PROM is offered in a dual-in-line plastic package (N suffix) designed for insertion in mounting hole rows on 15.2-mm (600-mil) centers. The TMS27PC256 is also supplied in a 32-lead plastic leaded chip carrier package using 1.25-mm (50-mil) lead spacing (FM suffix). The TMS27PC256 is guaranteed for operation from 0°C to 70°C (NL or FML suffix).

All package styles conform to JEDEC standards.

EPROM	SUFFIX FOR OPERATING TEMPERATURE RANGES WITHOUT PEP4 BURN-IN		SUFFIX FOR PEP4 168 ± 8 HR. BURN-IN VS TEMPERATURE RANGES	
	0°C to 70°C	-40°C TO 85°C	0°C TO 70°C	-40°C TO 85°C
TMS27C256-XXX	JL	JE	JL4	JE4

These EPROMs and PROMs operate from a single 5-V supply (in the read mode), thus are ideal for use in microprocessor-based systems. One other 12-13 V supply is needed for programming. All programming signals are TTL level. These devices are programmable by either Fast or SNAP! Pulse programming algorithms. Fast programming uses a V_{pp} of 12.5 V and a V_{CC} of 6.0 V for a nominal programming time of two minutes. SNAP! Pulse programming uses a V_{pp} of 13.0 V and a V_{CC} of 6.5 V for a nominal programming time of four seconds. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed singly, in blocks, or at random.

operation

There are seven modes of operation listed in the following table. Read mode requires a single 5 V supply. All inputs are TTL level except for V_{pp} during programming (12.5 V for Fast, or 13.0 V for SNAP! Pulse) and 12 V on A9 for signature mode.

[†]X can be V_{IL} or V_{IH} .
[‡] $V_H = 12 V \pm 0.5 V$.

read/output disable

When the outputs of two or more TMS27C256s or TMS27PC256s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of a single device, a low-level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 to Q8.

latchup immunity

Latchup immunity on the TMS27C256 and TMS27PC256 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the EPROM is interfaced to industry standard TTL or MOS logic devices. Input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001; "Design Considerations; Latchup Immunity of the HVC MOS EPROM Family."

power down

Active I_{CC} current can be reduced from 30 mA to 500 μA (TTL-level inputs) or 250 μA (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure (TMS27C256)

Before programming, the TMS27C256 EPROM is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is 15 watt-seconds per square centimeter. A typical 12-milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C256, the window should be covered with an opaque label. After erasure (all bits in logic 1 state), logic 0s are programmed into the desired locations. A programmed zero can be erased only by ultraviolet light.

initializing (TMS27PC256)

The one-time programmable TMS27PC256 PROM is provided with all bits in logic 1 state, then logic 0s are programmed into the desired locations. Logic 0s programmed into a PROM cannot be erased.

SNAP! Pulse programming

The 256K EPROM and PROM can be programmed using the TI SNAP! Pulse programming algorithm as illustrated by the flowchart of Figure 1, which can reduce programming time to a nominal of 4 seconds. Actual programming time will vary as a function of the programmer used.

Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed.

The SNAP! Pulse programming algorithm uses initial pulses of 100 microseconds (μ s) followed by a byte verification to determine when the addressed byte has been successfully programmed. Up to 10 (ten) 100- μ s pulses per byte are provided before a failure is recognized.

The programming mode is achieved when $V_{pp} = 13.0$ V, $V_{CC} = 6.5$ V, $\bar{G} = V_{IH}$, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order. When the SNAP! Pulse programming routine is complete, all bits are verified with $V_{CC} = V_{pp} = 5$ V.

fast programming

The 256K EPROM and PROM can be programmed using the Fast programming algorithm illustrated by the flowchart in Figure 2. During Fast programming, data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed. The programming mode is achieved when $V_{pp} = 12.5$ V, $V_{CC} = 6.0$ V, $\bar{G} = V_{IH}$, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Fast programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{CC} = 6.0$ V and $V_{pp} = 12.5$ V. When the full Fast programming routine is complete, all bits are verified with $V_{CC} = V_{pp} = 5$ V.

program inhibit

Programming may be inhibited by maintaining a high level input on the \bar{E} pin.

program verify

Programmed bits may be verified with $V_{pp} = 12.5$ V when $\bar{G} = V_{IL}$ and $\bar{E} = V_{IH}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 is forced to 12 V \pm 0.5 V. Two identifier bytes are accessed by A0; i.e., A0 = V_{IL} accesses the manufacturer code which is output on Q1-Q8; A0 = V_{IH} accesses the device code which is output on Q1-Q8. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is 04.

description

The TMS27C512 series are 524,288-bit, ultraviolet-light erasable, electrically programmable read-only memories.

The TMS27PC512 series are 524, 288-bit, one-time, electrically programmable read-only memories.

These devices are fabricated using power-saving CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by

6

Series 74 TTL circuits without the use of external pull-up resistors. Each output can drive one Series 74 TTL circuit without external resistors.

The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C512 and the TMS27PC512 are pin compatible with 28-pin 512K MOS ROMs, PROMs, and EPROMs.

The TMS27C512 EPROM is offered in a dual-in-line ceramic package (J suffix) designed for insertion in mounting hole rows on 15,2-mm (600-mil) centers. The TMS27C512 is available with two guaranteed temperature ranges of 0°C to 70°C and -40°C to 85°C (TMS27C512-__JL and TMS27C512-__JE, respectively). The TMS27C512 is also offered with 168 hour burn-in on both temperature ranges (TMS27C512-__JL4 and TMS27C512-__JE4, respectively). (See table below.)

The TMS27PC512 PROM is offered in a dual-in-line plastic package (N suffix) designed for insertion in mounting hole rows on 15,2-mm (600-mil) centers. The TMS27PC512 is also supplied in a 32-lead plastic leaded chip carrier package using 1,25-mm (50-mil) lead spacing (FM suffix). The TMS27PC512 is guaranteed for operation from 0°C to 70°C.

All package styles conform to JEDEC standards.

EPROM	SUFFIX FOR OPERATING TEMPERATURE RANGES WITHOUT PEP4 BURN-IN		SUFFIX FOR PEP4 168 HR. BURN-IN VS TEMPERATURE RANGES	
	0°C TO 70°C	-40°C TO 85°C	0°C TO 70°	-40°C TO 85°C
	TMS27C512-XXX	JL	JE	JL4

These EPROMs and PROMs operate from a single 5-V supply (in the read mode), thus are ideal for use in microprocessor-based systems. One other 12-13 V supply is needed for programming. All programming signals are TTL level. These devices are programmable by either Fast or SNAP! Pulse programming algorithms. Fast programming uses a Vpp of 12.5 V and a VCC of 6.0V for a nominal programming time of two minutes. SNAP! Pulse programming uses a Vpp of 13.0 V and a VCC of 6.5 V for a nominal programming time of four seconds. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed singly, in blocks, or at random.

operation

There are seven modes of operation listed in the following table. Read mode requires a single 5-V supply. All inputs are TTL level except for Vpp during programming (12.5 V for Fast or 13.0 V for SNAP! Pulse) and 12 V on A9 for signature mode.

FUNCTION	MODE							Signature Mode	
	Read	Output Disable	Standby	Programming	Verify	Program Inhibit	Signature Mode		
\bar{E}	V _{IL}	V _{IL}	V _{IH}	V _{IL}	V _{IL}	V _{IH}	V _{IL}		
\bar{G}/V_{PP}	V _{IL}	V _{IH}	X [†]	V _{PP}	V _{IL}	V _{PP}	V _{IL}		
V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}	V _{CC}		
A9	X	X	X	X	X	X	V _H [‡]	V _H [‡]	
A0	X	X	X	X	X	X	V _{IL}	V _{IH}	
Q1-Q8	D _{OUT}	HI-Z	HI-Z	D _{IN}	D _{OUT}	HI-Z	CODE		
							MFG	DEVICE	
							97	85	

[†]X Can be V_{IL} or V_{IH}.
[‡]V_H = 12 V ± 0.5 V.

read/output disable

When outputs of two or more TMS27C512s or TMS27PC512s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of a single device, a low-level signal is applied to the \bar{E} and \bar{G}/V_{pp} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 through Q8.

latchup immunity

Latchup immunity on the TMS27C512 and TMS27PC512 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the devices are interfaced to industry-standard TTL or MOS logic devices. Input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001; "Design Considerations; Latchup Immunity of the HVCMOS EPROM Family," available through TI Field Sales Offices.

power down

Active I_{CC} current can be reduced from 30 mA to 500 μ A (TTL-level inputs) or 250 μ A (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure (TMS27C512)

Before programming, the TMS27C512 EPROM is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). EPROM erasure before programming is necessary to assure that all bits are in the logic 1 (high) state. Logic 0s are programmed into the desired locations. A programmed logic 0 can be erased only by ultraviolet light. The recommended minimum ultraviolet light exposure dose (UV intensity \times exposure time) is 15 watt-seconds per square centimeter. A typical 12-milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C512, the window should be covered with an opaque label.

initializing (TMS27PC512)

The one-time programmable TMS27PC512 PROM is provided with all bits in the logic 1 state, then logic 0s are programmed into the desired locations. Logic 0s programmed into a PROM cannot be erased.

SNAP! Pulse programming

The 512K EPROM and PROM can be programmed using the TI SNAP! Pulse programming algorithm illustrated by the flowchart in Figure 1, which can reduce programming time to a nominal of four seconds. Actual programming time will vary as a function of the programmer used.

Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed.

The SNAP! Pulse programming algorithm uses initial pulses of 100 microseconds (μ s) followed by a byte verification to determine when the addressed byte has been successfully programmed. Up to 10 (ten) 100- μ s pulses per byte are provided before a failure is recognized.

The programming mode is achieved when $\bar{G}/V_{pp} = 13.0$ V, $V_{CC} = 6.5$ V, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order. When the SNAP! Pulse programming routine is complete, all bits are verified when $V_{CC} = 5$ V, $\bar{G}/V_{pp} = V_{IL}$, and $\bar{E} = V_{IL}$.

TMS27C512 524,288-BIT ERASABLE PROGRAMMABLE READ-ONLY MEMORY

TMS27PC512 524,288-BIT PROGRAMMABLE READ-ONLY MEMORY

Fast programming

The 512K EPROM and PROM can be programmed using the Fast programming algorithm illustrated by the flowchart in Figure 2. During Fast programming, data is presented in parallel (eight bits) on pins Q1 through Q8. Once addresses and data are stable, \bar{E} is pulsed. The programming mode is achieved when $\bar{G}/V_{pp} = 12.5\text{ V}$, $V_{CC} = 6.0\text{ V}$, and $\bar{E} = V_{IL}$. More than one device can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Fast programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{CC} = 6.0\text{ V}$ and $\bar{G}/V_{pp} = 12.5\text{ V}$. When the full Fast programming routine is complete, all bits are verified when $V_{CC} = 5\text{ V}$ and $\bar{G}/V_{pp} = V_{IL}$.

program inhibit

Programming may be inhibited by maintaining a high level input on the \bar{E} pin.

program verify

Programmed bits may be verified when \bar{G}/V_{pp} and $\bar{E} = V_{IL}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 is forced to $12\text{ V} \pm 0.5\text{ V}$. Two identifier bytes are accessed by A0; i.e., $A0 = V_{IL}$ accesses the manufacturer code, which is output on Q1-Q8; $A0 = V_{IH}$ accesses the device code, which is output on Q1-Q8. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for these devices is 97, and the device code is 85.

description

The TMS27C010 series are 1,048,576-bit, ultraviolet-light erasable, electrically programmable read-only memories. These devices are fabricated using CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits. Each output can drive one Series 74 TTL circuit without external resistors. The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C010 is offered in a 600-mil dual-inline cerdip package (J suffix) rated for operation from 0°C to 70°C.

Since these EPROMs operate from a single 5-V supply (in the read mode), they are ideal for use in microprocessor-based systems. One other (12.5 V) supply is needed for programming. All programming signals are TTL level. For programming outside the system, existing EPROM programmers can be used.

ADVANCE INFORMATION documents contain information on new products in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

6

operation

There are nine modes of operation for the TMS27C010 which are listed in the following table. The read mode requires a single 5-V supply. All inputs are TTL level except for V_{pp} during programming (12.5 V) and V_H (12 V) on A9 for signature mode.

MODE	FUNCTION (PINS)							
	\bar{E} (22)	\bar{G} (24)	PGM (31)	V_{pp} (1)	V_{CC} (32)	A9 (26)	A0 (12)	Q1-Q8 (13-15, 17-21)
Read	V_{IL}	V_{IL}	X	V_{CC}	V_{CC}	X	X	DOUT
Output Disable	X^\dagger	V_{IH}	X	V_{CC}	V_{CC}	X	X	HI-Z
Standby	V_{IH}	X	X	V_{CC}	V_{CC}	X	X	HI-Z
Page Data Latch	V_{IH}	V_{IL}	V_{IH}	V_{pp}	V_{CC}	X	X	DIN
Programming One Byte	V_{IL}	V_{IH}	V_{IL}	V_{pp}	V_{CC}	X	X	DIN
Programming Four Byte	V_{IH}	V_{IH}	V_{IL}	V_{pp}	V_{CC}	X	X	HI-Z
Program Inhibit	X	V_{IL}	V_{IL}	V_{pp}	V_{CC}	X	X	HI-Z
	X	V_{IH}	V_{IH}					
Verify	V_{IL}	V_{IL}	V_{IH}	V_{pp}	V_{CC}	X	X	DOUT
Signature Mode	V_{IL}	V_{IL}	X	V_{CC}	V_{CC}	V_H^\ddagger	V_{IL}	MFG Code 97
							V_{IH}	Device Code 46

$^\dagger X$ can be V_{IL} or V_{IH}

$^\ddagger V_H = 12 V \pm 0.5 V$

read/output disable

When the outputs of two or more TMS27C010s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from competing outputs of the other devices. To read the output of the TMS27C010, a low level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high level signal to one of these pins.

latchup immunity

Latchup immunity on the TMS27C010 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the EPROM is interfaced to industry standard TTL or MOS logic devices. The input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001, "Design Considerations; Latchup Immunity of the HVCMOS EPROM Family", available through TI Sales Offices.

power down

Active I_{CC} supply current can be reduced from 40 mA to 500 μA for a high TTL input on \bar{E} and to 250 μA for a high CMOS input on \bar{E} . In this mode all outputs are in the high impedance state.

erasure

Before programming, the TMS27C010 is erased by exposing the chip through the transparent lid to a high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is fifteen watt-seconds per square centimeter. A typical 12 milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. After erasure, all bits are in the high state. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C010, the window should be covered with an opaque label. After erasure (all bits in logic 1 state), logic 0s are programmed into the desired locations. A programmed zero can be erased only by ultraviolet light.

32-bit programming

The device is programmed in 32-bit blocks by latching four successive bytes. The programming sequence is shown in the 32-bit programming flow chart (Figure 1).

The initial setup in the page data latch is $V_{pp} = 12.5\text{ V}$, $V_{CC} = 6.5\text{ V}$, $\bar{E} = V_{IH}$, $\bar{G} = V_{IH}$, and $\overline{PGM} = V_{IH}$. The first location is defined as any address when $A0 = \text{logic } 0$ and $A1 = \text{logic } 0$, and the first order data is the corresponding eight bits of parallel data. Subsequently, the next three bytes of data are defined when $A0 = \text{logic } 1$ and $A1 = \text{logic } 0$, $A0 = \text{logic } 0$ and $A1 = \text{logic } 1$, and $A0 = \text{logic } 1$ and $A1 = \text{logic } 1$, respectively.

Starting at the first location, the four bytes of data are presented in sequence to the data pins Q1 through Q8. For every byte, when the addresses and data are stable, \bar{G} is pulsed low (V_{IL}) and the byte is latched on the rising edge of \bar{G} . The 32-bit parallel programming is achieved when \overline{PGM} is pulsed low (V_{IL}) with a pulse duration of $t_w(\overline{PGM})$. Every location is programmed only once before going to the interactive mode.

In the interactive mode, the word is verified at $V_{pp} = 12.5\text{ V}$, $V_{CC} = 6.5\text{ V}$, $\bar{E} = V_{IL}$, $\bar{G} = V_{IL}$, and $\overline{PGM} = V_{IH}$. If the correct data is not read, 8-bit programming is performed by pulling \overline{PGM} low with a pulse duration of $t_w(\overline{PGM})$. This sequence of verification and programming is performed up to a maximum of 15 times. When the device is fully programmed, all bytes are verified with $V_{CC} = V_{pp} = 5.0\text{ V} \pm 10\%$.

8-bit programming

TMS27C010 can also be programmed by using the 8-bit programming algorithm. The programming sequence is shown in the 8-bit programming flow chart (Figure 2).

The initial setup is $V_{pp} = 12.5\text{ V}$, $V_{CC} = 6.5\text{ V}$, $\bar{E} = V_{IL}$, $\bar{G} = V_{IH}$, and $\overline{PGM} = V_{IH}$. Once the initial location is selected, the data is presented in parallel (eight bits) on pins Q1 through Q8. Once addresses and data are stable, the programming mode is achieved when \overline{PGM} is pulsed low (V_{IL}) with a pulse duration of $t_w(\overline{PGM})$. Every location is programmed only once before going to interactive mode.

In the interactive mode, the word is verified at $V_{pp} = 12.5\text{ V}$, $V_{CC} = 6.5\text{ V}$, $\bar{E} = V_{IL}$, $\bar{G} = V_{IL}$, and $\overline{PGM} = V_{IH}$. If the correct data is not read, the eight-bit programming is performed by pulling \overline{PGM} low with a pulse duration of $t_w(\overline{PGM})$. This sequence of verification and programming is performed up to a maximum of 15 times. When the device is fully programmed, all bytes are verified with $V_{CC} = V_{pp} = 5.0\text{ V} \pm 10\%$.

program inhibit

Programming may be inhibited by maintaining a high level input on both \bar{G} and \overline{PGM} pins or a low level input on both \bar{G} and \overline{PGM} pins.

program verify

Programmed bits may be verified with $V_{pp} = 12.5\text{ V}$ when $\bar{G} = V_{IL}$, $\bar{E} = V_{IL}$, and $\overline{PGM} = V_{IH}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 26) is forced to 12.0 V. Two identifier bytes are accessed by toggling A0. All addresses must be held low. The signature code for the TMS27C010 is 9746. A0 low selects the manufacturer's code 97 (Hex), and A0 high selects the device code 46 (Hex), as shown by the signature mode table below.

IDENTIFIER [†]	PINS									
	A0	Q8	Q7	Q6	Q5	Q4	Q3	Q2	Q1	HEX
MANUFACTURER CODE	V _{IL}	1	0	0	1	0	1	1	1	97
DEVICE CODE	V _{IH}	0	1	0	0	0	1	1	0	46

[†] $\bar{E} = \bar{0} = V_{IL}, A9 = V_H, V_{PP} = V_{CC}$.

logic symbol[‡]

[‡]This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

description

The TMS27C210 is a 1,048,576 bit, ultraviolet-light erasable, electrically programmable read only memory. This device is fabricated using CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits without the use of external pull-up resistors and each output can drive one Series 74 TTL circuit without external resistors. The data outputs are three-state for connecting multiple devices to a common bus. The TMS27C210 is offered in a dual-in-line cerdip package (J suffix) rated for operation from 0°C to 70°C.

ADVANCE INFORMATION documents contain information on new products in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

TMS27C210

1,048,576-BIT UV ERASABLE PROGRAMMABLE READ-ONLY MEMORY

Since this EPROM operates from a single 5-V supply (in the read mode), it is ideal for use in microprocessor-based systems. One other (12.5 V) supply is needed for programming. All programming signals are TTL level. For programming outside the system, existing EPROM programmers can be used.

operation

There are eight modes of operation for the TMS27C210 which are listed in the following table. The read mode requires a single 5-V supply. All inputs are TTL level except for V_{PP} during programming (12.5 V) and 12 V on A9 for signature mode.

MODE	FUNCTION PINS							
	\bar{E} (2)	\bar{G} (20)	PGM (39)	V_{PP} (1)	V_{CC} (40)	A9 (31)	A0 (21)	I/O (19-12) (10-3)
Read	V_{IL}	V_{IL}	X	V_{CC}	V_{CC}	X	X	Q1-Q8 Q9-Q16
Output Disable	X^\dagger	V_{IH}	X	V_{CC}	V_{CC}	X	X	HI-Z
Standby	V_{IH}	X	X	V_{CC}	V_{CC}	X	X	HI-Z
Programming	V_{IL}	V_{IH}	V_{IL}	V_{PP}	V_{CC}	X	X	D_{IN}
Verify	V_{IL}	V_{IL}	V_{IH}	V_{PP}	V_{CC}	X	X	D_{OUT}
Program Inhibit	V_{IH}	X	X	V_{PP}	V_{CC}	X	X	HI-Z
Signature Mode (Mfg)	V_{IL}	V_{IL}	X	V_{CC}	V_{CC}	V_H^\ddagger	V_{IL}	Mfg Code 0097
Signature Mode (Device)	V_{IL}	V_{IL}	X	V_{CC}	V_{CC}	V_H^\ddagger	V_{IH}	Device Code 0086

$^\dagger X$ can be V_{IL} or V_{IH} .

$^\ddagger V_H = 12 V \pm 0.5 V$.

read/output disable

When the outputs of two or more TMS27C210s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from competing outputs of the other devices. To read the output of the TMS27C210, a low level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high level signal to one of these pins.

latchup immunity

Latchup immunity on the TMS27C210 is a minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the EPROM is interfaced to industry standard TTL or MOS logic devices. The input/output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001, "Design Considerations; Latchup Immunity of the HVC MOS EPROM Family", available through TI Sales Offices.

power down

Active power dissipation can be reduced from 40 mA to 1 mA for a high TTL input on \bar{E} and to 250 μ A for a high CMOS input on \bar{E} . In this mode all outputs are in the high impedance state.

erasure

Before programming, the TMS27C210 is erased by exposing the chip through the transparent lid to a high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is fifteen watt-seconds-per-square-centimeter. A typical 12 milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. After erasure, all bits are in the high state. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the TMS27C210, the window should be covered with an opaque label.

32-bit programming

After erasure (all bits in logic 1 state), logic 0s are programmed into the desired locations. A programmed zero can be erased only by ultraviolet light. The device is programmed in 32-bit blocks. The programming sequence is shown in the 32-bit programming flow chart (Figure 1).

The initial setup in the page data latch is $V_{pp} = 12.5$ V, $V_{CC} = 6.5$ V, $\bar{E} = V_{IL}$, $\bar{G} = V_{IH}$, and $\overline{PGM} = V_{IH}$. The first location is defined as any address when $A0 = \text{logic } 0$, and the low order word data is the corresponding 16 bits of parallel data. The high order word data is the 16 bits of parallel data for any address when $A0 = \text{logic } 1$.

Once the first location is selected, the low order word data is presented to the data pins Q1 to Q16. When the address and data are stable, $A0$ is clocked from logic 0 to logic 1. The low order word is latched on the rising edge of $A0$ when $V_{pp} = 12.5$ V, $V_{CC} = 6.5$ V, $\bar{E} = V_{IL}$, $\bar{G} = V_{IH}$, and $\overline{PGM} = V_{IH}$. The high order word is then presented to the data pins. When the data is stable, the 32-bit parallel programming is achieved when \overline{PGM} is pulsed low (V_{IL}). The length of the pulse is $t_W(\overline{PGM})$. Every location is programmed once before going to the interactive mode.

The interactive mode consists of a sequence of verification and programming. In the interactive mode, two 16-bit words corresponding to low and high order word data are verified at $V_{pp} = 12.5$ V, $V_{CC} = 6.5$ V, $\bar{E} = V_{IL}$, $\bar{G} = V_{IL}$, and $\overline{PGM} = V_{IH}$. If the correct data is not read in either or both words, 32-bit bit programming is performed with $V_{pp} = 12.5$ V, $V_{CC} = 6.5$ V, $\bar{E} = V_{IL}$, $\bar{G} = V_{IH}$, and a low pulse of $t_W(\overline{PGM})$ on \overline{PGM} . This sequence of verification and programming is performed up to a maximum of 15 times for two words. When the device is fully programmed, all bits are verified with $V_{CC} = V_{pp} = 5.0$ V \pm 10%.

16-bit programming

TMS27C210 can also be programmed in 16-bit blocks if desired. The 16-bit programming flow is shown in Figure 2. The initial setup is the same as the 32-bit programming flow except $\bar{E} = V_{IH}$. Once the initial location is selected, the 16-bit word data is presented to the data pins Q1 through Q16. When the addresses and data are stable, \bar{E} is pulled low (V_{IL}). The 16-bit programming is achieved when \overline{PGM} is pulsed low (V_{IL}). The length of the pulse is $t_w(PGM)$. To program the next location, \bar{E} is pulled high (V_{IH}) and the 16-bit data is presented to the data pins. When the data and address are stable, programming is achieved with $\bar{E} = V_{IL}$ followed by a low pulse of $t_w(PGM)$ on \overline{PGM} . Every location is programmed once before going to the interactive mode.

In the interactive mode, 16-bit data corresponding to every location is verified at $V_{pp} = 12.5$ V, $V_{CC} = 6.5$ V, $\bar{E} = V_{IL}$, $\bar{G} = V_{IL}$, and $\overline{PGM} = V_{IH}$. If the correct data is not read, a 16-bit word programming is performed with $\bar{G} = V_{IH}$ and a low pulse of $t_w(PGM)$ on \overline{PGM} . This sequence of verification and programming is performed up to a maximum of 15 times for a word. When the device is fully programmed, all bits are verified with $V_{CC} = V_{pp} = 5.0$ V \pm 10%.

program inhibit

Programming may be inhibited by maintaining a high level input on the \bar{E} pin.

program verify

Programmed bits may be verified with $V_{pp} = 12.5$ V when $\bar{G} = V_{IL}$, $\bar{E} = V_{IL}$, and $\overline{PGM} = V_{IH}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 31) is forced to 12.0 V. Two identifier bytes are accessed by toggling A0. Q1-Q8 contain the valid codes. Each byte possesses odd parity on bit Q8. All other addresses must be held low. The signature code for the TMS27C210 is 9786. A0 low selects the manufacturer's code 97 (Hex), and A0 high selects the device code 86 (Hex), as shown by the signature mode table on page 7.

description

The TMX27PC010 series are 1,048,576-bit, one-time, electrically programmable read-only memories. These devices are fabricated using CMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 74 TTL circuits. Each output can drive one Series 74 TTL circuit without external resistors. The data outputs are three-state for connecting multiple devices to a common bus. The TMX27PC010 is offered in a 600-mil dual-in-line plastic package (N suffix) rated for operation from 0°C to 70°C.

Since these PROMs operate from a single 5-V supply (in the read mode), they are ideal for use in microprocessor-based systems. One other (12.5 V) supply is needed for programming. All programming signals are TTL level. For programming outside the system, existing PROM programmers can be used.

PRODUCT PREVIEW documents contain information on products in the formative or design phase of development. Characteristic data and other specifications are design goals. Texas Instruments reserves the right to change or discontinue these products without notice.

16 × 5 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORIES

D2876, MARCH 1986—REVISED MAY 1986

- Independent Asynchronous Inputs and Outputs
- 16 Words by 5 Bits Each
- Data Rates from 0 to 30 MHz
- Fall-Through Time . . . 24 ns Typ
- 3-State Outputs

description

These 80-bit memories utilize Advanced Low-Power Schottky technology and feature high speed and fast fall-through times. They are organized as 16 words by 5 bits each.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. These FIFOs are designed to process data at rates from 0 to 30 megahertz in a bit-parallel format, word by word.

Data is written into memory on a low-to-high transition at the load clock input (LDCK) and is read out on a low-to-high transition at the unload clock input (UNCK). The memory is full when the number of words clocked in exceeds by 16 the number of words clocked out. When the memory is full, LDCK signals will have no effect. When the memory is empty, UNCK signals have no effect.

Status of the FIFO memory is monitored by the $\overline{\text{FULL}}$, $\overline{\text{EMPTY}}$, $\overline{\text{FULL}} - 2$, and $\overline{\text{EMPTY}} + 2$ output flags. The $\overline{\text{FULL}}$ output will be low whenever the memory is full, and high whenever not full. The $\overline{\text{FULL}} - 2$ output will be low whenever the memory contains 14 data words. The $\overline{\text{EMPTY}}$ output will be low whenever the memory is empty, and high whenever it is not empty. The $\overline{\text{EMPTY}} + 2$ output will be low whenever 2 words remain in memory.

A low level on the reset input ($\overline{\text{RST}}$) resets the internal stack control pointers and also sets $\overline{\text{EMPTY}}$ low and sets $\overline{\text{FULL}}$, $\overline{\text{FULL}} - 2$, and $\overline{\text{EMPTY}} + 2$ high. The Q outputs are not reset to any specific logic level. The first low-to-high transition on LDCK, after either a $\overline{\text{RST}}$ pulse or from an empty condition, will cause $\overline{\text{EMPTY}}$ to go high and the data to appear on the Q outputs. It is important to note that the first word does not have to be unloaded. Data outputs are noninverting with respect to the data inputs and are at high impedance when the output enable input (OE) is low. OE does not affect the output flags. Cascading is easily accomplished in the word-width direction, but is not possible in the word-depth direction.

description

These 64-bit memories use Advanced Low-Power Schottky technology and feature high speed and fast fall-through times. They are organized as 16 words by 4 bits each.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. These FIFOs are designed to process data at rates from 0 to 30 megahertz in a bit-parallel format, word by word.

Data is written into memory on a low-to-high transition at the load clock input (LDCK) and is read out on a low-to-high transition at the unload clock input (UNCK). The memory is full when the number of words clocked in exceeds by 16 the number of words clocked out. When the memory is full, LDCK signals have no effect on the data residing in memory. When the memory is empty, UNCK signals have no effect.

Status of the FIFO memory is monitored by the $\overline{\text{FULL}}$ and $\overline{\text{EMPTY}}$ output flags. The $\overline{\text{FULL}}$ output will be low when the memory is full, and high when the memory is not full. The $\overline{\text{EMPTY}}$ output will be low when the memory is empty, and high when it is not empty.

A low level on the reset input ($\overline{\text{RST}}$) resets the internal stack control pointers and also sets $\overline{\text{EMPTY}}$ low and sets $\overline{\text{FULL}}$ high. The outputs are not reset to any specific logic levels. The first low-to-high transition on LDCK, either after a $\overline{\text{RST}}$ pulse or from an empty condition, will cause $\overline{\text{EMPTY}}$ to go high and the data to appear on the Q outputs. It is important to note that the first word does not have to be unloaded. Data outputs are noninverting with respect to the data inputs and are at high impedance when the output-enable input (OE) is low. OE does not affect either the $\overline{\text{FULL}}$ or $\overline{\text{EMPTY}}$ output flags. Cascading is easily accomplished in the word-width direction, but is not possible in the word-depth direction.

SN54ALS233A, SN74ALS233A 16 × 5 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORIES

D2876, JANUARY 1986 — REVISED MAY 1986

- Independent Asynchronous Inputs and Outputs
- Package Options Include Plastic "Small Outline" Packages, Ceramic Chip Carriers, and Standard Plastic and Ceramic 300-mil DIPs
- 16 Words by 5 Bits Each
- Data Rates from 0 to 30 MHz
- Fall-Through Time . . . 24 ns Typ
- 3-State Outputs

description

These 80-bit memories utilize Advanced Low-Power Schottky technology and feature high speed and fast fall-through times. They are organized as 16 words by 5 bits each.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. These FIFOs are designed to process data at rates from 0 to 30 megahertz in a bit-parallel format, word by word.

Data is written into memory on a low-to-high transition at the load clock input (LDCK) and is read out on a low-to-high transition at the unload clock input (UNCK). The memory is full when the number of words clocked in exceeds by 16 the number of words clocked out. When the memory is full, LDCK signals will have no effect. When the memory is empty, UNCK signals have no effect.

Status of the FIFO memory is monitored by the $\overline{\text{FULL}}$, $\overline{\text{EMPTY}}$, $\overline{\text{FULL}} - 1$, and $\overline{\text{EMPTY}} + 1$ output flags. The $\overline{\text{FULL}}$ output will be low whenever the memory is full, and high whenever not full. The $\overline{\text{FULL}} - 1$ output will be low whenever the memory contains 15 data words. The $\overline{\text{EMPTY}}$ output will be low whenever the memory is empty, and high whenever it is not empty. The $\overline{\text{EMPTY}} + 1$ output will be low whenever one word remains in memory.

A low level on the reset input ($\overline{\text{RST}}$) resets the internal stack control pointers and also sets $\overline{\text{EMPTY}}$ low and sets $\overline{\text{FULL}}$, $\overline{\text{FULL}} - 1$, and $\overline{\text{EMPTY}} + 1$ high. The Q outputs are not reset to any specific logic level. The first low-to-high transition on LDCK, after either a $\overline{\text{RST}}$ pulse or from an empty condition, will cause $\overline{\text{EMPTY}}$ to go high and the data to appear on the Q outputs. It is important to note that the first word does not have to be unloaded. Data outputs are noninverting with respect to the data inputs and are at high impedance when the output enable input (OE) is low. OE does not affect the output flags. Cascading is easily accomplished in the word-width direction, but is not possible in the word-depth direction.

logic symbol†

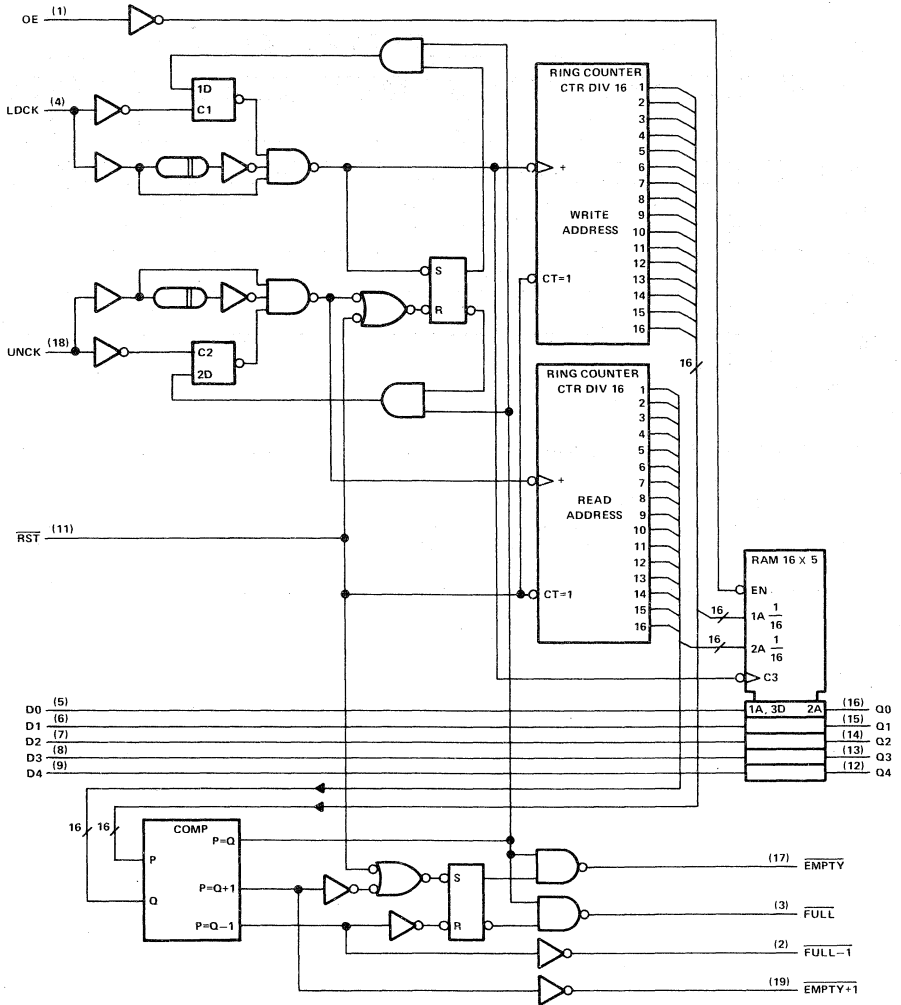

VLSI Memory Management Products

† This symbol is in accordance with ANSI/IEEE Standard 91-1984 and IEC Publication 617-12. The symbol is functionally accurate but does not show the details of implementation; for these, see the logic diagram. The symbol represents the memory as if it were controlled by a single counter whose content is the number of words stored at the time. Output data is invalid when the counter content (CT) is 0.

SN54ALS234, SN74ALS234 64 × 4 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

D2958, OCTOBER 1986

- Asynchronous Operation
- Organized as 64 Words of 4 Bits
- Data Rates from 0 to 30 MHz
- 3-State Outputs
- Similar to MMI67401B with Higher Speed and 3-State Outputs
- Dependable Texas Instruments Quality and Reliability

description

The SN54ALS234 and SN74ALS234 are 256-bit memories utilizing Advanced Low-Power Schottky IMPACT™ Technology. They feature high speed with fast fall-through times and are organized as 64 words by 4 bits.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The 'ALS234 is designed to process data at rates from 0 to 30 megahertz in a bit-parallel format, word by word.

Data is written into memory on the rising edge of the Shift In input. When Shift In goes low, the first data word ripples through to the output (see Figure 1). As the FIFO fills up, the data words stack up in the order they were written. When the FIFO is full, additional Shift In pulses have no effect. Data is shifted out of memory on the falling edge of the Shift Out input (see Figure 2). When the FIFO is empty, additional Shift Out pulses have no effect. The last data word remains at the outputs until a new word falls through or RST goes low.

Status of the 'ALS234 FIFO memory is monitored by the Output Ready (OR) and Input Ready (IR) flags. When the OR flag is high, valid data is available at the outputs. The OR flag is low when Shift Out is high and will stay low when the FIFO is empty. The IR status flag is high when the inputs are ready to receive more data. The IR flag is low when Shift In is high and stays low when the FIFO is full.

When the FIFO is empty, input data is shifted to the output automatically when Shift In goes low. If Shift Out is held high during this time, the OR flag pulses high indicating valid data at the outputs (see Figure 3).

When the FIFO is full, data can be shifted in automatically by holding Shift In high and taking Shift Out low. A propagation delay after Shift Out goes low, IR will go high. If Shift In is still high when IR goes high, data at the inputs are automatically shifted in. Since IR is normally low when the FIFO is full and Shift In is high, only a high-level pulse is seen on the IR output (see Figure 4).

SN54ALS234, SN74ALS234
64 × 4 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

description (continued)

The FIFO must be reset after power up with a low-level pulse on the Master Reset input (\overline{RST}). This sets Input Ready (IR) high and Output Ready (OR) low signifying that the FIFO is empty. Resetting the FIFO sets the outputs to a low logic level (see Figure 1). If Shift In is high when \overline{RST} goes high, the input data is shifted in and IR goes low and remains low until Shift In goes low. If Shift In goes low before \overline{RST} goes high, the input data will not be shifted in and IR goes high. Data outputs are noninverting with respect to the data inputs and are at high impedance when Output Enable (\overline{OE}) is high. \overline{OE} does not affect the IR and OR outputs.

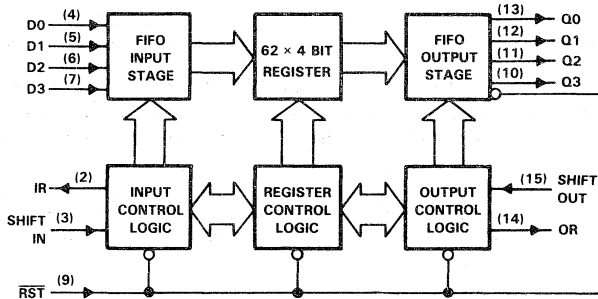

The SN54ALS234 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN74ALS234 is characterized for operation from 0°C to 70°C .

SN54ALS235, SN74ALS235 64 × 5 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

D2958, OCTOBER 1986

- Asynchronous Operation
- Organized as 64 Words of 5 Bits
- Data Rates from 0 to 25 MHz
- 3-State Outputs
- Dependable Texas Instruments Quality and Reliability

description

The SN54ALS235 and SN74ALS235 are 320-bit memories utilizing Advanced Low-Power Schottky IMPACT™ Technology. They feature high speed with fast fall-through times and are organized as 64 words by 5 bits.

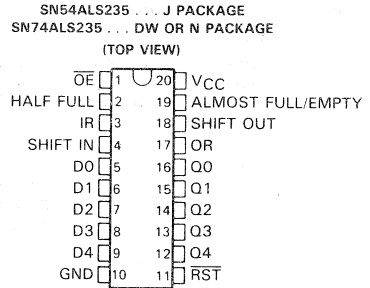

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The 'ALS235 is designed to process data at rates from 0 to 25 megahertz in a bit-parallel format, word by word.

Data is written into memory on the rising edge of the Shift In input. When Shift In goes low, the first data word ripples through to the output (see Figure 1). As the FIFO fills up, the data words stack up in the order they were written. When the FIFO is full, additional Shift In pulses have no effect. Data is shifted out of memory on the falling edge of the Shift Out input (see Figure 2). When the FIFO is empty, additional Shift Out pulses have no effect. The last data word remains at the outputs until a new word falls through or RST goes low.

Status of the 'ALS235 FIFO memory is monitored by the Output Ready (OR), Input Ready (IR), Almost Full/Empty, and Half Full flags. When the OR flag is high, valid data is available at the outputs. The OR flag is low when Shift Out is high and will stay low when the FIFO is empty. The IR status flag is high when the inputs are ready to receive more data. The IR flag is low when Shift In is high and stays low when the FIFO is full. The Almost Full/Empty flag is high when the FIFO contains eight or less words (see Figure 5), or fifty-six or more words (see Figure 6). The Almost Full/Empty flag is low when the FIFO contains between nine and fifty-five words. The Half Full flag is high when the FIFO contains thirty-two or more words, and is low when the FIFO contains thirty-one words or less (see Figure 7).

When the FIFO is empty, input data is shifted to the output automatically when Shift In goes low. If Shift Out is held high during this time, the OR flag pulses high indicating valid data at the outputs (see Figure 3).

When the FIFO is full, data can be shifted in automatically by holding Shift In high and taking Shift Out low. A propagation delay after Shift Out goes low, IR will go high. If Shift In is still high when IR goes high, data at the inputs are automatically shifted in. Since IR is normally low, when the FIFO is full and Shift In is high, only a high-level pulse is seen on the IR output.

description

The SN54ALS236 and SN74ALS236 are 256-bit memories utilizing Advanced Low-Power Schottky IMPACT™ Technology. They feature high speed with fast fall-through times and are organized as 64 words by 4 bits.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The 'ALS236 is designed to process data at rates from 0 to 30 megahertz in a bit-parallel format, word by word.

Data is written into memory on the rising edge of the Shift In input. When Shift In goes low, the first data word ripples through to the output (see Figure 1). As the FIFO fills up, the data words stack up in the order they were written. When the FIFO is full, additional Shift In pulses have no effect. Data is shifted out of memory on the falling edge of the Shift Out input (see Figure 2). When the FIFO is empty, additional Shift Out pulses have no effect. The last data word remains at the outputs until a new word falls through or RST goes low

Status of the 'ALS236 FIFO memory is monitored by the Output Ready (OR) and Input Ready (IR) flags. When the OR flag is high, valid data is available at the outputs. The OR flag is low when Shift Out is high and will stay low when the FIFO is empty. The IR status flag is high when the inputs are ready to receive more data. The IR flag is low when Shift In is high and stays low when the FIFO is full.

When the FIFO is empty, input data is shifted to the output automatically when Shift In goes low. If Shift Out is held high during this time, the OR flag pulses high indicating valid data at the outputs (see Figure 3).

When the FIFO is full, data can be shifted in automatically by holding Shift In high and taking Shift Out low. A propagation delay after Shift Out goes low, IR will go high. If Shift In is still high when IR goes high, data at the inputs are automatically shifted in. Since IR is normally low when the FIFO is full and Shift In is high, only a high-level pulse is seen on the IR output (see Figure 4).

SN54ALS236, SN74ALS236
64 × 4 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

description (continued)

The FIFO must be reset after power up with a low-level pulse on the Master Reset input (\overline{RST}). This sets Input Ready (IR) high and Output Ready (OR) low signifying that the FIFO is empty. Resetting the FIFO sets the outputs to a low logic level (see Figure 1). If Shift In is high when \overline{RST} goes high, the input data is shifted in and IR goes low and remains low until Shift In goes low. If Shift In goes low before \overline{RST} goes high, the input data will not be shifted in and IR goes high. Data outputs are noninverting with respect to the data inputs.

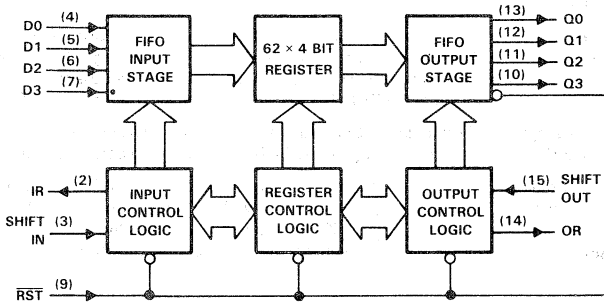

The SN54ALS236 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN74ALS236 is characterized for operation from 0°C to 70°C .

timing diagram

† The last data word shifted out of the FIFO remains at the output until a new word falls through or a \overline{RST} pulse clears the FIFO.

‡ While the output data is considered valid only when the OR flag is high, the stored data remains at the output. Any additional words written into the FIFO will stack up behind the first word and will not appear at the output until SHIFT OUT is taken low.

description

This 4608-bit memory uses Advanced CMOS Technology and features high speed and fast fall-through times. The 'ACT7201A is organized as 512 words by 9 bits each.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The function is used as a buffer to couple two buses operating at different clock rates. The 'ACT7201A is designed to process data at rates from 0 to 28.5 MHz in a bit-parallel format, word by word.

Data is written into the memory on a low-to-high transition at the Write Clock (WCLK) input, and is read out of the memory on a high-to-low transition at the Read Clock (RCLK) input, (see Figure 1). The data outputs are noninverting with respect to the data inputs and are in a high-impedance state when RCLK is high. The memory is full when the number of words clocked in exceeds by 512 the number of words clocked out. When the memory is full, write signals have no effect on the data residing in memory. When the memory is empty, read signals have no effect, and the data outputs remain in a high-impedance state.

Status of the FIFO memory is monitored by the Full Flag ($\overline{\text{FULL}}$), Empty Flag ($\overline{\text{EMPTY}}$), and Expansion Enable Out/Half Full Flag ($\overline{\text{XEO/HF}}$). The $\overline{\text{FULL}}$ output is low when the memory is full, and high when the memory is not full (see Figure 2). The $\overline{\text{EMPTY}}$ output is low when the memory is empty, and high when it is not empty (see Figure 3). When cascading two or more devices for word-depth expansion, $\overline{\text{XEO/HF}}$ functions as an Expansion Enable Out output. When the 'ACT7201A is used as a 512-word FIFO memory (no word-depth expansion), the $\overline{\text{XEO/HF}}$ output functions as a Half Full Flag. This 512-word memory mode is defined by grounding the Expansion Enable In ($\overline{\text{XEI}}$) input of the device. In this mode, $\overline{\text{XEO/HF}}$ is low whenever the FIFO contains 257 or more words, and is high whenever the FIFO contains 256 or less words (see Figure 8).

The First Load/Retransmit ($\overline{\text{FL/RT}}$) input performs two separate functions. When cascading two or more devices for word-depth expansion, $\overline{\text{FL/RT}}$ functions as a first-load input and is grounded on the first device in the daisy chain to indicate that it is the first device loaded and unloaded. When the 'ACT7201A is used as a 512-word FIFO memory, the $\overline{\text{FL/RT}}$ input performs the retransmit function. In this mode, a low-level pulse on the $\overline{\text{FL/RT}}$ input resets the read pointer to the first memory location to allow for retransmission from the beginning of data entered. The write pointer is not affected by the $\overline{\text{FL/RT}}$ input. RCLK and WCLK must be at a high level during the low-level $\overline{\text{FL/RT}}$ retransmit pulse (see Figure 4). The retransmit operation will affect the value of the Half Full Flag ($\overline{\text{XEO/HF}}$) by changing the position of the read pointer relative to the write pointer.

The retransmit feature should be used only when less than 512 writes are performed between resets, otherwise, an attempt to retransmit may cause loss of some data that has not yet been read.

EPIC is a trademark of Texas Instruments Incorporated.

512 × 9 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

description (continued)

When the FIFO is empty, a data word can be read automatically at the Q outputs by holding RCLK low when loading in the data word with a low-level pulse on the WCLK (see Figure 5).

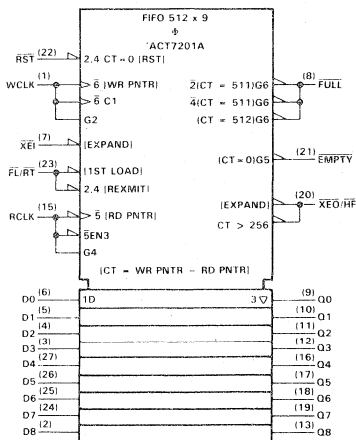

When the FIFO is full, a data word can be written automatically into memory by holding WCLK low while reading out another data word with a low-level pulse on RCLK (see Figure 6).

The FIFO must be reset after power up with a low level pulse on the Reset (\overline{RST}) input. This resets the read and write internal stack control pointers to the first memory location, and also sets EMPTY low, FULL high, and $\overline{XEO}/\overline{HF}$ high. Both the RCLK and WCLK inputs must be at a high level during reset (see Figure 7).

The $\overline{ACT7201A}$ is fully cascadable in word-width and/or word-depth over the specified temperature range. Word-width expansion (see Figure 13) is accomplished by connecting together the corresponding input control signals of the cascaded devices. The status flags (EMPTY, FULL, and $\overline{XEO}/\overline{HF}$) can be monitored from any one of the cascaded devices. The \overline{XEI} input of each device in the word-width expansion should be grounded. Word-depth expansion (see Figure 14) is also accomplished by connecting together the corresponding input control signals of the cascaded devices. The $\overline{FL}/\overline{RT}$ input, on the first device in the daisy chain, is grounded to designate it as the first device loaded and unloaded. The $\overline{FL}/\overline{RT}$ inputs of all the other devices in the daisy chain must be tied high. The Expansion Enable Out ($\overline{XEO}/\overline{HF}$) output of each device in the word-depth expansion is connected to the \overline{XEI} input of the next device in the daisy chain. After reset, the RCLK and WCLK inputs are enabled on the first device in the daisy chain. The RCLK and WCLK inputs of all the other devices are disabled. When the last word location of the first device is written into, the \overline{XEO} output pulses low, enabling the WCLK of the next device in the daisy chain. Similarly, when the last word location of the first device is read from, the \overline{XEO} output pulses low, enabling the RCLK of the next device in the daisy chain (see Figure 9). Control of read and write continues this progression through the daisy chain in a circular queue fashion. In word-depth expansion, a composite EMPTY and FULL must be generated by ORing the corresponding flags together. In addition, word-width and word-depth expansion can be applied together to create large FIFO arrays (see Figure 15).

The SN74ACT7201A is characterized for operation from 0°C to 70°C.

D4	27	I	
D5	26	I	
D6	25	I	
D7	24	I	
D8	2	I	
EMPTY	21	O	Empty flag output. The empty flag ($\overline{\text{EMPTY}}$) output is low when the FIFO memory is empty, and high when the memory is not empty. When the memory is empty, additional read operations are inhibited.
FULL	8	O	Full flag output. The full flag ($\overline{\text{FULL}}$) output is low when the FIFO memory is full, and high when the memory is not full. When the memory is full, additional write operations are inhibited.
FL/RT	23	I	First load/retransmit input. This input performs two separate functions. When cascading two or more devices for word-depth expansion, the FL/RT input is grounded on the first device in the daisy chain to indicate that it is the first device loaded and unloaded. It is connected high on the other devices. In single-device operation or in word-width expansion, the FL/RT input initiates the retransmit function. In this mode, a low-level pulse on the FL/RT input resets the read pointer to the first memory location to allow for retransmission from the beginning of data entered. The write pointer is not affected by the FL/RT input. The RCLK and WCLK must be at a high level during the low level FL/RT retransmit pulse. The retransmit feature should be used only when less than 512 writes are performed between resets, otherwise, an attempt to retransmit may cause loss of some data that has not yet been read.
GND	14		Ground
Q0	9	O	Data outputs. These outputs are in the high-impedance state when the RCLK input is high or if the memory is empty.
Q1	10		
Q2	11		
Q3	12		
Q4	16		
Q5	17		
Q6	18		
Q7	19		
Q8	13		
RCLK	15	I	Read clock input. If the FIFO is not empty (i.e., $\overline{\text{EMPTY}}$ is high), data is read from the FIFO on RCLK input high-to-low transition.
RST	22	I	Master Reset Input. A low level pulse on the Master Reset input ($\overline{\text{RST}}$) resets the FIFO. This sets the $\overline{\text{EMPTY}}$ output low and the $\overline{\text{FULL}}$ output high, indicating that the FIFO is empty. RCLK and WCLK must both be at a high level during reset.
VCC	28		Supply voltage
WCLK	1	I	Write clock input. If the FIFO is not full (i.e., $\overline{\text{FULL}}$ is high), data is written into the FIFO on a low-to-high transition at the WCLK input.
$\overline{\text{XEI}}$	7	I	Expansion Enable Input. When cascading two or more devices for word-depth expansion, the $\overline{\text{XEI}}$ input is connected to the XEO output of the previous device in the daisy chain. The $\overline{\text{XEI}}$ input is grounded when no word-depth expansion is desired.
XEO/HF	20	O	Expansion Enable Out/Half Full Flag Output. This output performs two separate functions. When cascading two or more devices for word-depth expansion, the XEO/HF output is connected to the $\overline{\text{XEI}}$ input of the next device in the daisy chain. When the FIFO is used as a 512-word memory, the XEO/HF output functions as a Half Full Flag. In this mode, XEO/HF is low whenever the FIFO contains 257 or more words, and is high whenever the FIFO contains 256 words or less.

description

This 9216-bit memory uses Advanced CMOS Technology and features high speed and fast fall-through times. The 'ACT7202 is organized as 1024 words by 9 bits each.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The 'ACT7202 is designed to process data at rates from 0 to 22 MHz in a bit-parallel format, word by word.

Data is written into the memory on a low-to-high transition at the Write Clock (WCLK) input, and is read out of the memory on a high-to-low transition at the Read Clock (RCLK) input, (see Figure 1). The data outputs are noninverting with respect to the data inputs and are in a high-impedance state when RCLK is high. The memory is full when the number of words clocked in exceeds by 1024 the number of words clocked out. When the memory is full, write signals have no effect on the data residing in memory. When the memory is empty, read signals have no effect, and the data outputs remain in a high-impedance state.

Status of the FIFO memory is monitored by the Full Flag ($\overline{\text{FULL}}$), Empty Flag ($\overline{\text{EMPTY}}$). The $\overline{\text{FULL}}$ output is low when the memory is full, and high when the memory is not full (see Figure 2). The $\overline{\text{EMPTY}}$ output is low when the memory is empty, and high when it is not empty (see Figure 3).

The First Load/Retransmit ($\overline{\text{FL/RT}}$) input performs two separate functions. When cascading two or more devices for word-depth expansion, $\overline{\text{FL/RT}}$ functions as a first-load input and is grounded on the first device in the daisy chain to indicate that it is the first device loaded and unloaded. When the 'ACT7202 is used as a 1024-word FIFO memory, the $\overline{\text{FL/RT}}$ input performs the retransmit function. This 1024-word memory mode is defined by grounding the Expansion Enable Input (XEI) of the device. In this mode, a low-level pulse on the $\overline{\text{FL/RT}}$ input resets the read pointer to the first memory location to allow for retransmission from the beginning of data entered. The write pointer is not affected by the $\overline{\text{FL/RT}}$ input. RCLK and WCLK must be at the high level during the low-level $\overline{\text{FL/RT}}$ retransmit pulse (see Figure 4).

The retransmit feature should be used only when less than 1024 writes are performed between resets, otherwise, an attempt to retransmit may cause loss of some data that has not yet been read.

When the FIFO is empty, a data word can be read automatically at the Q outputs by holding RCLK low when loading in the data word with a low-level pulse on the WCLK (see Figure 5).

When the FIFO is full, a data word can be written automatically into memory by holding WCLK low while reading out another data word with a low-level pulse on RCLK (see Figure 6).

SN74ACT7202-35, SN74ACT7202-50
1024 × 9 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

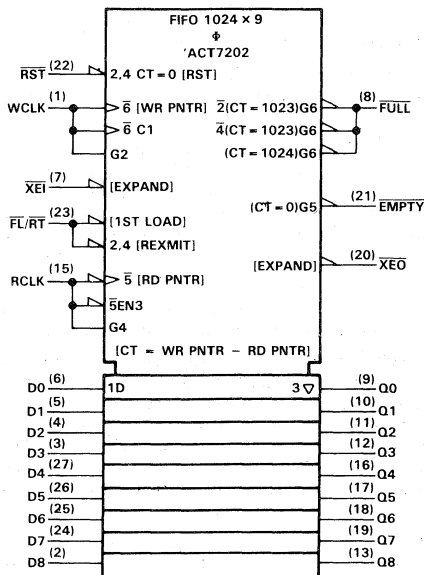

description (continued)

The FIFO must be reset after power up with a low level pulse on the Reset ($\overline{\text{RST}}$) input. This resets the read and write internal stack control pointers to the first memory location, and also sets $\overline{\text{EMPTY}}$ low and $\overline{\text{FULL}}$ high. Both the $\overline{\text{RCLK}}$ and $\overline{\text{WCLK}}$ inputs must be at a high level during reset (see Figure 7).

The 'ACT7202 is fully cascadable in word-width and/or word-depth over the specified temperature range. Word-width expansion (see Figure 10) is accomplished by connecting together the corresponding input control signals of the cascaded devices. The status flags $\overline{\text{EMPTY}}$ and $\overline{\text{FULL}}$ can be monitored from any one of the cascaded devices. The $\overline{\text{XEI}}$ input of each device in the word-width expansion should be grounded. Word-depth expansion (see Figure 11) is also accomplished by connecting together the corresponding input control signals of the cascaded devices. The $\overline{\text{FL/RT}}$ input, on the first device in the daisy chain, is grounded to designate it as the first device loaded. The $\overline{\text{FL/RT}}$ inputs of all the other devices in the daisy chain must be tied high. The Expansion Enable Out ($\overline{\text{XEO}}$) output of each device in the word-depth expansion is connected to the $\overline{\text{XEI}}$ input of the next device in the daisy chain. A composite $\overline{\text{EMPTY}}$ and $\overline{\text{FULL}}$ must be generated by ORing the corresponding flags together. In addition, word-width and word-depth expansion can be applied together to create large FIFO arrays (see Figure 12).

The SN74ACT7202 is characterized for operation from 0°C to 70°C.

- Fall-Through Time . . . 20 ns Typical
- 3-State Outputs

description

This 512-bit memory uses Advanced Low-Power Schottky IMPACT-X™ technology and features high speed and fast fall-through times. It is organized as 64 words by 8 bits.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The function is used as a buffer to couple two buses operating at different clock rates. This FIFO is designed to process data at rates from 0 to 40 MHz in a bit-parallel format, word by word.

Data is written into memory on a low-to-high transition of the load clock input (LDCK) and is read out on a low-to-high transition of the unload clock input (UNCK). The memory is full when the number of words clocked in exceeds by 64 the number of words clocked out. When the memory is full, LDCK signals have no effect on the data residing in memory. When the memory is empty, UNCK signals have no effect.

Status of the FIFO memory is monitored by the FULL and EMPTY output flags. The FULL output will be low when the memory is full, and high when the memory is not full. The EMPTY output will be low when the memory is empty, and high when it is not empty.

A low level on the reset input ($\overline{\text{RST}}$) resets the internal stack control pointers and also sets $\overline{\text{EMPTY}}$ low and FULL high. The outputs are not reset to any specific logic levels. The first low-to-high transition on LDCK, either after a $\overline{\text{RST}}$ pulse or from an empty condition, causes $\overline{\text{EMPTY}}$ to go high and the data to appear on the Q outputs. The first word does not have to be unloaded. Data outputs are noninverting with respect to the data inputs and are at a high-impedance state when the output-enable input (OE) is low. The OE input does not effect either the FULL or EMPTY output flags. Cascading is easily accomplished in the word-width direction, but is not possible in the word-depth direction.

The SN74ALS2232 is characterized for operation from 0°C to 70°C.

64 × 9 ASYNCHRONOUS FIRST-IN FIRST-OUT MEMORY

D3092, FEBRUARY 1988—REVISED APRIL 1988

- Independent Asynchronous Inputs and Outputs
- 64 Words by 9 Bits
- Data Rates from 0 to 40 MHz
- Fall-Through Time . . . 20 ns Typical
- 3-State Outputs

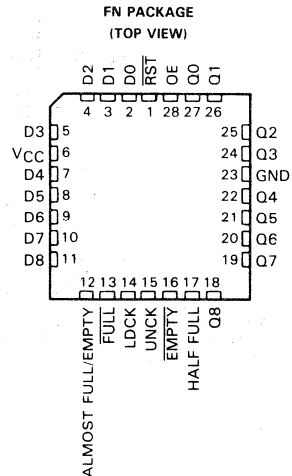

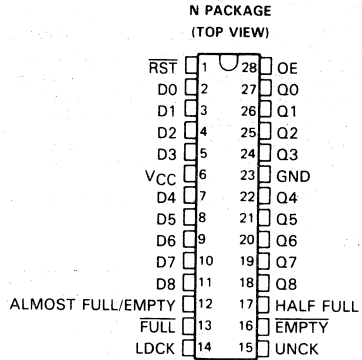

description

This 576-bit memory uses Advanced Low-Power Schottky IMPACT—X™ technology and features high speed and fast fall-through times. It is organized as 64 words by 9 bits.

A FIFO memory is a storage device that allows data to be written into and read from its array at independent data rates. The function is used as a buffer to couple two buses operating at different clock rates. This FIFO is designed to process data at rates from 0 to 40 MHz in a bit-parallel format, word by word.

Data is written into memory on a low-to-high transition of the load clock input (LDCK) and is read out on a low-to-high transition of the unload clock input (UNCK). The memory is full when the number of words clocked in exceeds by 64 the number of words clocked out. When the memory is full, LDCK signals have no effect on the data residing in memory. When the memory is empty, UNCK signals have no effect.

Status of the FIFO memory is monitored by the FULL, EMPTY, ALMOST FULL/EMPTY, and HALF FULL output flags. The FULL output will be low when the memory is full and high when the memory is not full. The EMPTY output will be low when the memory is empty and high when it is not empty. The ALMOST FULL/EMPTY flag is high when the FIFO contains eight or less words or fifty-six or more words. The ALMOST FULL/EMPTY flag is low when the FIFO contains between nine and fifty-five words. The HALF FULL flag is high when the FIFO contains thirty-two or more words, and is low when the FIFO contains thirty-one words or less.

description

The 'ALS632B, 'ALS633, 'ALS634B and 'ALS635 devices are 32-bit parallel error detection and correction circuits (EDACs) in 52-pin ('ALS632B and 'ALS633) or 48-pin ('ALS634B and 'ALS635) 600-mil packages. The EDACs use a modified Hamming code to generate a 7-bit check word from a 32-bit data word. This check word is stored along with the data word during the memory write cycle. During the memory read cycle, the 39-bit words from memory are processed by the EDACs to determine if errors have occurred in memory.

Single-bit errors in the 32-bit data word are flagged and corrected.

Single-bit errors in the 7-bit check word are flagged, and the CPU sends the EDAC through the correction cycle even though the 32-bit data word is not in error. The correction cycle will simply pass along the original 32-bit data word in this case and produce error syndrome bits to pinpoint the error-generating location.

Dual-bit errors are flagged but not corrected. These errors may occur in any two bits of the 39-bit data word from memory (two errors in the 32-bit data word, two errors in the 7-bit check word, or one error in each word). The gross-error condition of all lows or all highs from memory will be detected. Otherwise, errors in three or more bits of the 39-bit word are beyond the capabilities of these devices to detect.

 SN74ALS632B, SN74ALS633, SN54ALS634B, SN54ALS635
 32-BIT PARALLEL ERROR DETECTION AND CORRECTION CIRCUITS**

Read-modify-write (byte-control) operations can be performed with the 'ALS632B and 'ALS633 EDACs by using output latch enable, LEDB0, and the individual OEBO thru OEB3 byte control pins.

Diagnostics are performed on the EDACs by controls and internal paths that allow the user to read the contents of the DB and CB input latches. These will determine if the failure occurred in memory or in the EDAC.

[†]See Table 2 for details on check bit generation.

memory write cycle details

During a memory write cycle, the check bits (CB0 thru CB6) are generated internally in the EDAC by seven 16-input parity generators using the 32-bit data word as defined in Table 2. These seven check bits are stored in memory along with the original 32-bit data word. This 32-bit word will later be used in the memory read cycle for error detection and correction. CB0, CB1 and CB2 are odd parity bits and CB3, CB4, CB5, and CB6 are even parity bits. For example, for a data word of all zeros CB0-CB2 will be high and CB3-CB6 will be low.

CB3		X	X	X					X	X	X			X	X				X	X	X	X				X	X	X	X	X	X	X	X	X	
CB4	X	X							X	X	X	X	X	X			X	X									X	X	X	X	X	X	X	X	
CB5	X	X	X	X	X	X	X	X									X	X	X	X	X	X	X	X											
CB6	X	X	X	X	X	X	X	X																			X	X	X	X	X	X	X	X	

The seven check bits are parity bits derived from the matrix of data bits as indicated by "X" for each bit.

error detection and correction details

During a memory read cycle, the 7-bit check word is retrieved along with the actual data. In order to be able to determine whether the data from memory is acceptable to use as presented to the bus, the error flags must be tested to determine if they are at the high level.

The first case in Table 3 represents the normal, no-error conditions. The EDAC presents highs on both flags. The next two cases of single-bit errors give a high on MERR and a low on ERR, which is the signal for a correctable error, and the EDAC should be sent through the correction cycle. The last three cases of double-bit errors will cause the EDAC to signal lows on both ERR and MERR, which is the interrupt indication for the CPU.

TABLE 3. ERROR FUNCTION

TOTAL NUMBER OF ERRORS		ERROR FLAGS		DATA CORRECTION
32-BIT DATA WORD	7-BIT CHECK WORD	ERR	MERR	
0	0	H	H	Not applicable
1	0	L	H	Correction
0	1	L	H	Correction
1	1	L	L	Interrupt
2	0	L	L	Interrupt
0	2	L	L	Interrupt

Error detection is accomplished as the 7-bit check word and the 32-bit data word from memory are applied to internal parity generators/checkers. If the parity of all seven groupings of data and check bits are correct, it is assumed that no error has occurred and both error flags will be high.

If the parity of one or more of the check groups is incorrect, an error has occurred and the proper error flag or flags will be set low. Any single error in the 32-bit data word will change the state of either three or five bits of the 7-bit check word. Any single error in the 7-bit check word changes the state of only that one bit. In either case, the single error flag (ERR) will be set low while the dual error flag (MERR) will remain high.

Any two-bit error will change the state of an even number of check bits. The two-bit error is not correctable since the parity tree can only identify single-bit errors. Both error flags are set low when any two-bit error is detected.

Three or more simultaneous bit errors can cause the EDAC to believe that no error, a correctable error, or an uncorrectable error has occurred and will produce erroneous results in all three cases. It should be noted that the gross-error conditions of all lows and all highs will be detected.

† See Table 3 for error description.

‡ See Table 5 for error location.

As the corrected word is made available on the data I/O port (DB0 thru DB31), the check word I/O port (CB0 thru CB6) presents a 7-bit syndrome error code. This syndrome error code can be used to locate the bad memory chip. See Table 5 for syndrome decoding.

read-modify-write (byte control) operations

The 'ALS632B and 'ALS633 devices are capable of byte-write operations. The 39-bit word from memory must first be latched into the DB and CB input latches. This is easily accomplished by switching from the read and flag mode (S1 = H, S0 = L) to the latch input mode (S1 = H, S0 = H). The EDAC will then make any corrections, if necessary, to the data word and place it at the input of the output data latch. This data word must then be latched into the output data latch by taking $\overline{\text{LEDBO}}$ from a low to a high.

Byte control can now be employed on the data word through the $\overline{\text{OEB0}}$ through $\overline{\text{OEB3}}$ controls. $\overline{\text{OEB0}}$ controls DB0-DB7 (byte 0), $\overline{\text{OEB1}}$ controls DB8-DB15 (byte 1), $\overline{\text{OEB2}}$ controls DB16-DB23 (byte 2), and $\overline{\text{OEB3}}$ controls DB24-DB31 (byte 3). Placing a high on the byte control will disable the output and the user can modify the byte. If a low is placed on the byte control, then the original byte is allowed to pass onto the data bus unchanged. If the original data word is altered through byte control, a new check word must be generated before it is written back into memory. This is easily accomplished by taking control S1 and S0 low. Table 6 lists the read-modify-write functions.

diagnostic operations

7

The 'ALS632B, 'ALS633, 'ALS634B and 'ALS635 are capable of diagnostics that allow the user to determine whether the EDAC or the memory is failing. The diagnostic function tables will help the user to see the possibilities for diagnostic control.

In the diagnostic mode (S1 = L, S0 = H), the checkword is latched into the input latch while the data input latch remains transparent. This lets the user apply various data words against a fixed known checkword. If the user applies a diagnostic data word with an error in any bit location, the ERR flag should be low. If a diagnostic data word with two errors in any bit location is applied, the MERR flag should be low. After the checkword is latched into the input latch, it can be verified by taking \overline{OECB} low. This outputs the latched checkword. With the 'ALS632B and 'ALS633, the diagnostic data word can be latched into the output data latch and verified. It should be noted that the 'ALS634B and 'ALS635 do not have this pass-through capability because they do not contain an output data latch. By changing from the diagnostic mode (S1 = L, S0 = H) to the correction mode (S1 = H, S0 = H), the user can verify that the EDAC will correct the diagnostic data word. Also, the syndrome bits can be produced to verify that the EDAC pinpoints the error location. Table 7 ('ALS632B and 'ALS633) and Table 8 ('ALS634B and 'ALS635) list the diagnostic functions.

32-BIT PARALLEL ERROR DETECTION AND CORRECTION CIRCUITS

D2661, JANUARY 1986—REVISED JUNE 1987

- Detects and Corrects Single-Bit Errors
- Detects and Flags Dual-Bit Errors
- Built-In Diagnostic Capability
- Fast Write and Read Cycle Processing Times
- Byte-Write Capability . . . 'AS632
- Dependable Texas Instruments Quality and Reliability

DEVICE	PACKAGE	BYTE-WRITE	OUTPUT
'AS632	52-pin	yes	3-State
'AS634	48-pin	no	3-State

description

The 'AS632 and 'AS634 devices are 32-bit parallel error detection and correction circuits (EDACs) in 52-pin ('AS632) or 48-pin ('AS634) 600-mil packages. The EDACs use a modified Hamming code to generate a 7-bit check word from a 32-bit data word. This check word is stored along with the data word during the memory write cycle. During the memory read cycle, the 39-bit words from memory are processed by the EDACs to determine if errors have occurred in memory.

Single-bit errors in the 32-bit data word are flagged and corrected.

Single-bit errors in the 7-bit check word are flagged, and the CPU sends the EDAC through the correction cycle even though the 32-bit data word is not in error. The correction cycle will simply pass along the original 32-bit data word in this case and produce error syndrome bits to pinpoint the error-generating location.

Dual-bit errors are flagged but not corrected. These errors may occur in any two bits of the 39-bit data word from memory (two errors in the 32-bit data word, two errors in the 7-bit check word, or one error in each word). The gross-error condition of all lows or all highs from memory will be detected. Otherwise, errors in three or more bits of the 39-bit word are beyond the capabilities of these devices to detect.

SN74AS632, SN74AS634
32-BIT PARALLEL ERROR DETECTION AND CORRECTION CIRCUITS**

Read-modify-write (byte-control) operations can be performed with the 'AS632 EDAC by using output latch enable, LEDBO, and the individual OEBO thru OEBS byte control pins.

Diagnostics are performed on the EDACs by controls and internal paths that allow the user to read the contents of the DB and CB input latches. These will determine if the failure occurred in memory or in the EDAC.

Write	Generate check word	L L	Input	H	X	Output check bits†	L	H H

† See Table 2 for details on check bit generation.

memory write cycle details

During a memory write cycle, the check bits (CB0 thru CB6) are generated internally in the EDAC by seven 16-input parity generators using the 32-bit data word as defined in Table 2. These seven check bits are stored in memory along with the original 32-bit data word. This 32-bit word will later be used in the memory read cycle for error detection and correction. CB0, CB1 and CB2 are odd parity bits and CB3, CB4, CB5, and CB6 are even parity bits. For example, for a data word of all zeros CB0-CB2 will be high and CB3-CB6 will be low.

CB6	X	X	X	X	X	X	X	X																		X	X	X	X	X	X	

The seven check bits are parity bits derived from the matrix of data bits as indicated by "X" for each bit.

error detection and correction details

During a memory read cycle, the 7-bit check word is retrieved along with the actual data. In order to be able to determine whether the data from memory is acceptable to use as presented to the bus, the error flags must be tested to determine if they are at the high level.

The first case in Table 3 represents the normal, no-error conditions. The EDAC presents highs on both flags. The next two cases of single-bit errors give a high on MERR and a low on ERR, which is the signal for a correctable error, and the EDAC should be sent through the correction cycle. The last three cases of double-bit errors will cause the EDAC to signal lows on both ERR and MERR, which is the interrupt indication for the CPU.

TABLE 3. ERROR FUNCTION

TOTAL NUMBER OF ERRORS		ERROR FLAGS		DATA CORRECTION
32-BIT DATA WORD	7-BIT CHECK WORD	ERR	MERR	
0	0	H	H	Not applicable
1	0	L	H	Correction
0	1	L	H	Correction
1	1	L	L	Interrupt
2	0	L	L	Interrupt
0	2	L	L	Interrupt

Error detection is accomplished as the 7-bit check word and the 32-bit data word from memory are applied to internal parity generators/checkers. If the parity of all seven groupings of data and check bits are correct, it is assumed that no error has occurred and both error flags will be high.

If the parity of one or more of the check groups is incorrect, an error has occurred and the proper error flag or flags will be set low. Any single error in the 32-bit data word will change the state of either three or five bits of the 7-bit check word. Any single error in the 7-bit check word changes the state of only that one bit. In either case, the single error flag (ERR) will be set low while the dual error flag (MERR) will remain high.

Any two-bit error will change the state of an even number of check bits. The two-bit error is not correctable since the parity tree can only identify single-bit errors. Both error flags are set low when any two-bit error is detected.

Three or more simultaneous bit errors can cause the EDAC to believe that no error, a correctable error, or an uncorrectable error has occurred and will produce erroneous results in all three cases. It should be noted that the gross-error conditions of all lows and all highs will be detected.

TABLE 4. READ, FLAG, AND CORRECT FUNCTION

MEMORY CYCLE	EDAC FUNCTION	CONTROL		DATA I/O	DB CONTROL	DB OUTPUT LATCH ('AS632) LEDBO	CHECK I/O	CB CONTROL	ERROR FLAGS	
		S1	S0		$\overline{\text{OEBn}}$ OR $\overline{\text{OEDB}}$			$\overline{\text{OECB}}$	$\overline{\text{ERR}}$	$\overline{\text{MERR}}$
Read	Read & flag	H	L	Input	H	X	Input	H	Enabled †	
Read	Latch input data & check bits	H	H	Latched input data	H	L	Latched input check word	H	Enabled †	
Read	Output corrected data & syndrome bits	H	H	Output corrected data word	L	X	Output syndrome bits ‡	L	Enabled †	

†See Table 3 for error description.

‡See Table 5 for error location.

As the corrected word is made available on the data I/O port (DB0 thru DB31), the check word I/O port (CB0 thru CB6) presents a 7-bit syndrome error code. This syndrome error code can be used to locate the bad memory chip. See Table 5 for syndrome decoding.

diagnostic operations

7

The 'AS632 and 'AS634 are capable of diagnostics that allow the user to determine whether the EDAC or the memory is failing. The diagnostic function tables will help the user to see the possibilities for diagnostic control.

In the diagnostic mode (S1 = L, S0 = H), the checkword is latched into the input latch while the data input latch remains transparent. This lets the user apply various data words against a fixed known checkword. If the user applies a diagnostic data word with an error in any bit location, the ERR flag should be low. If a diagnostic data word with two errors in any bit location is applied, the MERR flag should be low. After the checkword is latched into the input latch, it can be verified by taking $\overline{OE}CB$ low. This outputs the latched checkword. With the 'AS632, the diagnostic data word can be latched into the output data latch and verified. It should be noted that the 'AS634 does not have this pass-through capability because they do not contain an output data latch. By changing from the diagnostic mode (S1 = L, S0 = H) to the correction mode (S1 = H, S0 = H), the user can verify that the EDAC will correct the diagnostic data word. Also, the syndrome bits can be produced to verify that the EDAC pinpoints the error location. Table 7 ('AS632) and Table 8 ('AS634) list the diagnostic functions.

32-BIT PARALLEL ERROR DETECTION AND CORRECTION CIRCUITS

TABLE 7. 'AS632 DIAGNOSTIC FUNCTION

EDAC FUNCTION	CONTROL S1 S0	DATA I/O	DB BYTE CONTROL OEBn	DB OUTPUT LATCH LEDBO	CHECK I/O	CB CONTROL OECB	ERROR FLAGS	
							ERR	MERR
Read & flag	H L	Input correct data word	H	X	Input correct check bits	H	H	H
Latch input check word while data input latch remains transparent	L H	Input diagnostic data word [†]	H	L	Latched input check bits	H		Enabled

description

The 'ACT2151 and 'ACT2153 cache address comparators consist of a high-speed 1K × 12 static RAM array, parity generator, parity checker, and 12-bit high-speed comparator. They are fabricated using advanced silicon-gate CMOS technology for high speed and simple interface with bipolar TTL circuits. These cache address comparators are easily cascadable for wider tag addresses or deeper tag memories. Significant reductions in cache memory component count, board area, and power dissipation can be achieved with these devices. The 'ACT2151 has a totem-pole match output while the 'ACT2153 has an open-drain MATCH output for easy AND-tying.

If \bar{S} is low and \bar{W} is high, the cache address comparator compares the contents of the memory location addressed by A0-A9 with the data D0-D10 plus generated parity. An equality is indicated by a high level on the MATCH output. A low-level output on \bar{PE} signifies a parity error in the internal RAM data. \bar{PE} is an N-channel open-drain output for easy OR-tying. During a write cycle (\bar{S} and \bar{W} low), data on D0-D10 plus generated odd parity are written in the 12-bit memory location addressed by A0-A10. Also during write, a parity error may be forced by holding \bar{PE} low.

A reset input is provided for initialization. When \bar{RESET} is taken low, all 1K × 12 RAM locations are cleared to zero (with valid parity) and the MATCH output is forced high. If an input data word of zero is compared to any memory location that has not been written into since reset, MATCH will be high indicating that input data, plus generated parity, is equal to the reset memory location. \bar{PE} will be high after reset for every addressed memory location, indicating no parity error in the RAM data. By tying a single data input pin high, this bit will function as a valid bit and a match will not occur unless data has been written into the addressed memory location. When cascading in the width direction, only one bit must be tied high regardless of the address width.

EPIC is a trademark of Texas Instruments Incorporated.

SN74ACT2151, SN74ACT2153 1K×12 CACHE ADDRESS COMPARATORS

These cache address comparators operate from a single 5-V supply and are offered in 28-pin 600-mil ceramic side-brazed, plastic dual-in-line, or PLCC packages.

The SN74ACT2151 and SN74ACT2153 are characterized for operation from 0°C to 70°C.

MATCH OUTPUT DESCRIPTION

MATCH = V_{OH} if: (A0-A9) = D0-D10 + parity,

or: $\overline{\text{RESET}} = V_{IL}$,

or: $\overline{S} = V_{IH}$,

or: $\overline{W} = V_{IL}$

MATCH = V_{OL} if: (A0-A9) \neq D0-D10 + parity,

with $\overline{\text{RESET}} = V_{IH}$,

$\overline{S} = V_{IL}$, and $\overline{W} = V_{IH}$

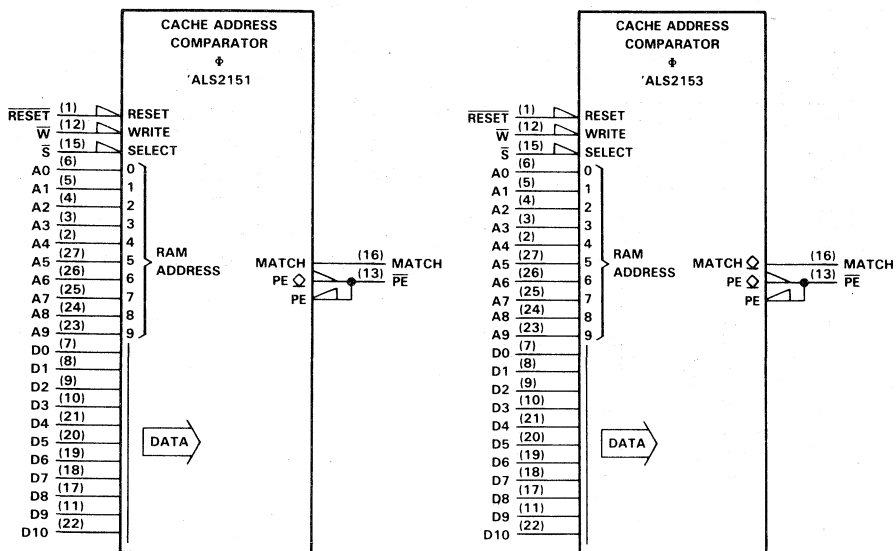

FUNCTION TABLE

INPUTS			OUTPUTS		FUNCTION
\overline{W}	\overline{S}	RESET	MATCH	PE	
			L	L	Parity error
H	L	H	L	H	Not equal
			H	L	Undefined error
			H	H	Equal
L	L	H	H	IN	Write

A5	27	
A6	26	
A7	25	
A8	24	
A9	23	
D0	7	Data inputs. Compared with memory locations addressed by A0-A9 when \bar{W} is at V_{IH} and \bar{S} is at V_{IL} . Provides input data to the RAM when \bar{W} and \bar{S} are at V_{IL} .
D1	8	
D2	9	
D3	10	
D4	21	
D5	20	
D6	19	
D7	18	
D8	17	
D9	11	
D10	22	
GND	14	Ground
MATCH	16	When MATCH output is at V_{OH} during a compare cycle, D0-D10 plus generated parity equals the contents of the 12-bit memory location addressed by A0-A10. MATCH is also driven high during deselect and reset. Since the ACT2153 features an open-drain MATCH output, an external pull-up resistor of 220 Ω minimum is required.
$\bar{P}\bar{E}$	13	Parity error input/output. During compare cycles, $\bar{P}\bar{E}$ at V_{OL} indicates a parity error in the stored data. During write cycles, $\bar{P}\bar{E}$ can force a parity error into the 12th-bit location specified by A0-A9 when $\bar{P}\bar{E}$ is taken to V_{IL} . $\bar{P}\bar{E}$ is an open-drain output so an external pull-up resistor of 220 Ω minimum is required.
RESET	1	Reset input. Asynchronously clears entire RAM array to zero and forces MATCH high when RESET is at V_{IL} .
\bar{S}	15	Chip select input. Enables device when \bar{S} is at V_{IL} . Deselects device and forces MATCH and $\bar{P}\bar{E}$ high when \bar{S} is at V_{IH} .
V_{CC}	28	Supply voltage
\bar{W}	12	Write control input. Writes D0-D0 and generated parity into RAM and forces MATCH high when \bar{W} and \bar{S} are at V_{IL} . Places selected device in compare mode when \bar{W} is at V_{IH} .

$t_h(\text{WH-D})$	Data hold time after $\overline{\text{W}}$ high	5			5			ns
$t_h(\text{WL-D})$	Data hold time after $\overline{\text{W}}$ low with MATCH high, (see Note 4)	10			10			ns
$t_h(\text{P})$	PE hold time after $\overline{\text{W}}$ high	0			0			ns
$t_h(\text{S})$	Chip select hold time after $\overline{\text{W}}$ high	0			0			ns
t_{AVWH}	Address valid to write enable high	15			15			ns

- NOTES:
- Parameters $t_w(\text{WL})$ and $t_{su}(\text{P})$ apply only during the write cycle timing when writing a parity error.
 - $t_h(\text{WL-D})$ guarantees that when $\overline{\text{W}}$ is taken low during a compare cycle with MATCH high, match will remain high without a glitch low. (As shown in the function table, $\overline{\text{W}}$ low forces MATCH high). $t_h(\text{WL-D})$ is guaranteed indirectly by $t_v(\text{D-M})$ and $t_p(\text{W-MH})$.

TYPICAL APPLICATION INFORMATION

cascading the 'ACT2151 and 'ACT2153

The 'ACT2151 and 'ACT2153 are easily cascaded in width and depth. Wider addresses can be compared by driving the A0-A9 inputs of each device with the same index and applying the additional address bits to the D0-D10 inputs. The select (S) input allows these devices to be cascaded in depth. When a device is deselected, the MATCH output is driven high. It should be noted that a decoder can be used to drive the select inputs since the propagation delay from select to match is much faster than from address to match. MATCH on the 'ACT2153 is an open-drain output for easy AND-tying. Figure 4 shows the 'ACT2153 cascaded.

cache coherency through bus watching

When cache designs are implemented, the problem of cache coherency is always a concern. One solution to this problem is to implement bus-watching using the 'ACT2151 or 'ACT2153. By storing the same tags in the bus-watcher RAM as are stored in the cache tag RAM, the bus-watcher will indicate a hit every time a cache address passes down the main address bus. If data is being modified in main memory, the index can be passed to the cache tag RAM for invalidation. Figure 5 shows a possible bus-watcher implementation.

application

Due to the high-performance switching characteristics of the 'ACT2151 and 'ACT2153, it is necessary that the address inputs not be allowed to float in the three-state condition. Proper termination techniques should be employed. It is recommended that the RC time constant associated with the address inputs (63.2% of rise time at A0-A9) not exceed 60 ns.

D3050, SEPTEMBER 1987—REVISED NOVEMBER 1987

- Fast Address to Match Delay
25 or 35 ns Max
- Common I/O with Read Feature
- On-Chip Address/Data Comparator
- On-Chip Parity Generator and Checking
- Parity Error Output, Force Parity Error Input
- Easily Expandable
- Choice of Open-Drain or Totem-Pole MATCH Output
- EPIC™ (Enhanced Performance Implanted CMOS) 1- μ m Process
- Fully TTL-Compatible

description

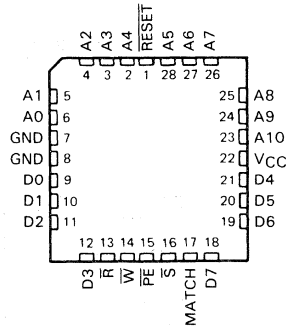

The 'ACT2152 and 'ACT2154 cache address comparators consist of a high-speed 2K × 9 static RAM array, parity generator, parity checker, and 9-bit high-speed comparator. They are fabricated using advanced silicon-gate CMOS technology for high speed and simple interface with bipolar TTL circuits. These cache address comparators are easily cascadable for wider tag addresses or deeper tag memories. Significant reductions in cache memory component count, board area, and power dissipation can be achieved with these devices. The 'ACT2152 has a totem-pole MATCH output while the 'ACT2154 has an open-drain MATCH output for easy AND-tying.

If \bar{S} is low and \bar{W} and \bar{R} are high, the cache address comparator compares the contents of the memory location addressed by A0-A10 with the data D0-D7 plus generated parity. An equality is indicated by a high level on the MATCH output. A low-level output on \bar{PE} signifies a parity error in the internal RAM data. \bar{PE} is an N-channel open-drain output for easy OR-tying. During a write cycle (\bar{S} and \bar{W} low), data on D0-D7 plus generated odd parity are written in the 9-bit memory location addressed by A0-A10. Also during write, a parity error may be forced by holding \bar{PE} low.

SN74ACT2152, SN74ACT2154
2K × 8 CACHE ADDRESS COMPARATORS

A read mode is provided with the 'ACT2152 and 'ACT2154, which allows the contents of RAM to be read at the D0-D7 pins. The read mode is selected when \bar{R} and \bar{S} are low, and \bar{W} is high.

A reset input is provided for initialization. When $\overline{\text{RESET}}$ is taken low, all $2K \times 9$ RAM locations are cleared to zero (with valid parity) and the MATCH output is forced high. If an input data word of zero is compared to any memory location that has not been written into since reset, MATCH will be high indicating that input data, plus generated parity, is equal to the reset memory location. \bar{PE} will be high after reset for every addressed memory location, indicating no parity error in the RAM data. By tying a single data input pin high, this bit will function as a valid bit and a match will not occur unless data has been written into the addressed memory location. When cascading in the width direction, only one bit must be tied high regardless of the address width.

These cache address comparators operate from a single +5-V supply and are offered in 28-pin 600-mil ceramic side-brazed, plastic dual-in-line, or PLCC packages.

The 'ACT2152 and 'ACT2154 are characterized for operation from 0°C to 70°C.

MATCH OUTPUT DESCRIPTION

MATCH = V_{OH} if: [A0-A10] = D0-D7 + parity,
 or: $\overline{\text{RESET}} = V_{IL}$,
 or: $\bar{S} = V_{IH}$,
 or: $\bar{W} = V_{IL}$

MATCH = V_{OL} if: [A0-A10] \neq D0-D7 + parity,
 with $\overline{\text{RESET}} = V_{IH}$,
 $\bar{S} = V_{IL}$, and $\bar{W} = V_{IH}$

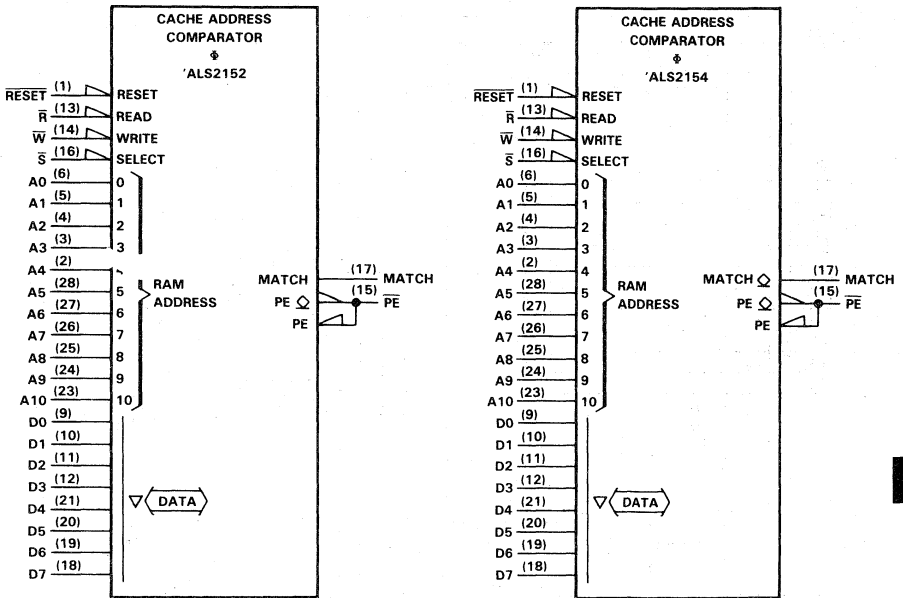

FUNCTION TABLE

SN74ACT2152, SN74ACT2154
2K × 8 CACHE ADDRESS COMPARATORS

PIN		DESCRIPTION
NAME	NO.	
A0	6	Address inputs. Addresses 1 of 2048 random access memory locations. Must be stable for the duration of the write cycle.
A1	5	
A2	4	
A3	3	
A4	2	
A5	28	
A6	27	
A7	26	
A8	25	
A9	24	
A10	23	
D0	9	Data inputs/outputs. D0-D7 are data inputs during the compare and write modes. D0-D7 are data outputs during the read mode.
D1	10	
D2	11	
D3	12	
D4	21	
D5	20	
D6	19	
D7	18	
GND	7,8	Ground
MATCH	17	When MATCH output is at V_{OH} during a compare cycle, D0-D7 plus generated parity equals the contents of the 9-bit memory location addressed by A0-A10. MATCH is also driven high during deselect, reset, and read. Since the 'ACT2154 features an open-drain MATCH output, an external pull-up resistor of 220 Ω minimum is required.
\overline{PE}	15	Parity error input/output. During compare cycles, \overline{PE} at V_{OL} indicates a parity error in the stored data. During write cycles, \overline{PE} can force a parity error into the 9th-bit location specified by A0-A10 when \overline{PE} is taken to V_{IL} . \overline{PE} is an open-drain output so an external pull-up resistor of 220 Ω minimum is required.
\overline{R}	13	Read input. When \overline{R} and \overline{S} are at V_{IL} and \overline{W} is at V_{IH} , addressed data is output to the D0-D7 pins and the MATCH and \overline{PE} outputs are forced high.
RESET	1	Reset input. Asynchronously clears entire RAM array to zero and forces MATCH high when RESET is at V_{IL} .
\overline{S}	16	Chip select input. Enables device when \overline{S} is at V_{IL} . Deselects device and forces MATCH and \overline{PE} high when \overline{S} is at V_{IH} .
VCC	22	Supply voltage
\overline{W}	14	Write control input. Writes D0-D7 and generated parity into RAM and forces MATCH high when \overline{W} and \overline{S} are at V_{IL} . Places selected device in compare mode when \overline{W} and \overline{R} are at V_{IH} .

SN74ACT2152, SN74ACT2154 2K × 8 CACHE ADDRESS COMPARATORS

TYPICAL APPLICATION INFORMATION

cascading the 'ACT2152 and 'ACT2154

The 'ACT2152 and 'ACT2154 are easily cascaded in width and depth. Wider addresses can be compared by driving the A0-A10 inputs of each device with the same index and applying the additional address bits to the D0-D7 inputs. The select (\bar{S}) input allows these devices to be cascaded in depth. When a device is deselected, the MATCH output is driven high. It should be noted that a decoder can be used to drive the select inputs since the propagation delay from select to match is much faster than from address to match. MATCH on the 'ACT2154 is an open-drain output for easy AND-tying. Figure 4 shows the 'ACT2154 cascaded.

cache coherency through bus watching

When cache designs are implemented, the problem of cache coherency is always a concern. One solution to this problem is to implement bus-watching using the 'ACT2152 or 'ACT2154. By storing the same tags in the bus-watcher RAM as are stored in the cache tag RAM, the bus-watcher will indicate a hit every time a cache address passes down the main address bus. If data is being modified in main memory, the index can be passed to the cache tag RAM for invalidation. Figure 5 shows a possible bus-watcher implementation.

application

Due to the high-performance switching characteristics of the 'ACT2152 and 'ACT2154, it is necessary that the address inputs not be allowed to float in the three-state condition. Proper termination techniques should be employed. It is recommended that the RC time constant associated with the address inputs (63.2% of rise time at A0-A10) not exceed 60 ns.

description

This 8-bit-slice cache address comparator consists of a high-speed 512 × 9 static RAM array, parity generator, parity checker, and 9-bit high-speed comparator. It is fabricated using Advanced CMOS technology for high-speed, low-power interface with bipolar TTL circuits. The cache address comparator is easily cascadable for wider tag addresses or deeper tag memories. Significant reductions in cache memory component count, board area, and power dissipation can be achieved with this device.

When \bar{S} is low and \bar{W} is high, the cache address comparator compares the contents of the memory location addressed by A0-A8 with the data on D0-D7 plus generated parity. An equality is indicated by the high level on the MATCH output. A low-level output from PE signifies a parity error in the internal RAM data. PE is an N-channel open-drain output for easy OR-tying. During a write cycle (\bar{S} and \bar{W} low), data on D0-D7 plus generated even parity are written in the 9-bit memory location addressed by A0-A8. Also during write, a parity error may be forced by holding PE low.

A reset input is provided for initialization. When RESET is taken low, all 512 × 9 RAM locations are cleared to zero (with valid parity) and the MATCH output is forced high. If an input data word of zero is compared to any memory location that has not been written into since reset, MATCH will be high indicating that input data, plus generated parity, is equal to the reset memory location. PE will be high for every addressed memory location after reset indicating no parity error in the RAM data. By tying a single data input pin high, this bit will function as a valid bit and a match will not occur unless data has been written into the addressed memory location. When cascading in the width direction, only one bit needs to be tied high regardless of the address width.

The TACT2150 operates from a single 5-V supply and is offered in a 24-pin 300-mil ceramic side-brazed or plastic dual-in-line packages and plastic "Small Outline" packages. The device is fully TTL compatible and is characterized for operation from 0°C to 70°C.

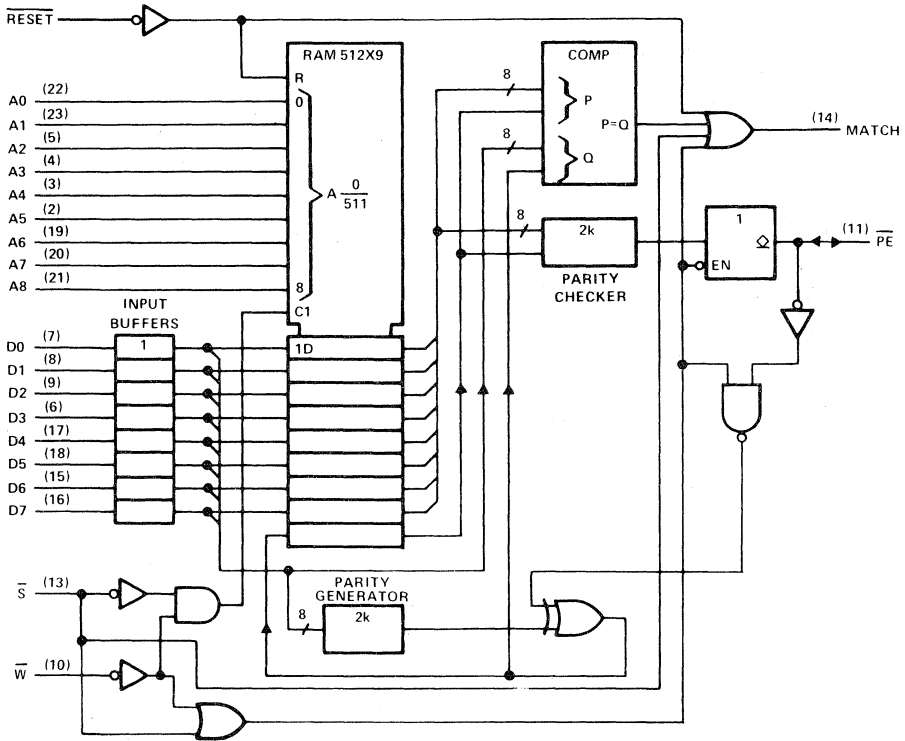

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

PIN FUNCTIONAL DESCRIPTION

PIN		DESCRIPTION
NAME	NO.	
A0	22	Address inputs. Address 1 of 512-by-9-bit random-access memory locations. Must be stable for the duration of the write cycle.
A1	23	
A2	5	
A3	4	
A4	3	
A5	2	
A6	19	
A7	20	
A8	21	
D0	7	Data inputs. Compared with memory location addressed by A0-A8 when \overline{W} is at V_{IH} and \overline{S} is at V_{IL} . Provide input data to RAM when \overline{W} is at V_{IL} and \overline{S} is at V_{IL} .
D1	8	
D2	9	
D3	6	
D4	17	
D5	18	
D6	15	
D7	16	
GND	12	Ground
MATCH	14	When MATCH output is at V_{OH} during a compare cycle, D0 through D7 plus parity equal the contents of the 9-bit memory location addressed by A0 through A8.
\overline{PE}	11	Parity error input/output. During write cycles, \overline{PE} can force a parity error into the 9-bit location specified by A0 through A8 when \overline{PE} is at V_{IL} . For compare cycles, \overline{PE} at V_{OL} indicates a parity error in the stored data. \overline{PE} is an open-drain output so an external pull-up resistor is required.
\overline{RESET}	1	\overline{RESET} input. Asynchronously clears entire RAM array and forces MATCH high when \overline{RESET} is at V_{IL} and \overline{W} is at V_{IH} .
\overline{S}	13	Chip select input. Enables device when \overline{S} is at V_{IL} . Deselects device and forces MATCH high when \overline{S} is at V_{IH} .
VCC	24	5-V supply voltage
\overline{W}	10	Write control input. Writes D0 through D7 and generated parity into RAM and forces MATCH high when \overline{W} is at V_{IL} and \overline{S} is at V_{IL} . Places selected device in compare mode if \overline{W} is at V_{IH} .

SN74ALS2967, SN74ALS2968 DYNAMIC MEMORY CONTROLLERS

D2900, JANUARY 1986 — REVISED MARCH 1988

- Provides Control for 16K, 64K, and 256K Dynamic RAMs
- Highest-Order Two-Address Bits Select One of Four Banks of RAMs
- Supports Scrubbing Operations and Nibble-Mode Access
- Separate Output Enable for Multi-Channel Access to Memory
- 48-Pin Dual-In-Line Package

description

The 'ALS2967 and 'ALS2968 dynamic memory controllers (DMCs) are designed for use in today's high-performance memory systems. The DMC acts as the address controller between any processor and dynamic memory array.

Two versions are provided that help simplify interfacing to the system dynamic timing controller. The 'ALS2967 offers active-low Row Address Strobe Input (RAS \bar{I}) and Column Address Strobe Input (CAS \bar{I}), while the 'ALS2968 offers active-high Row Address Strobe Input (RAS I) and Column Address Strobe Input (CAS I) inputs.

Using two 9-bit address latches, the DMC will hold the row and column addresses for any DRAM up to 256K. These latches and the two row/column refresh address counters feed into a 9-bit, 4-input MUX for output to the dynamic RAM address lines. A 2-bit bank select latch is provided to select one of the four \overline{RAS} and \overline{CAS} outputs. The two bits are normally obtained from the two highest-order address bits.

The 'ALS2967 and 'ALS2968 have two basic modes of operation, read/write and refresh. During normal read/write operations, the row and column addresses are multiplexed to the dynamic RAM, with the corresponding RAS and CAS signals activated to strobe the addresses into the RAM. In the refresh mode, the two counters cycle through the refresh addresses. If memory scrubbing is not being implemented, only the row counter is used. When memory scrubbing is being performed, both the row and column counters are used to perform read-modify-write cycles. In this mode all \overline{RAS} outputs will be active (low) while only one CAS output is active at a time.

The SN74ALS2967 and SN74ALS2968 are characterized for operation from 0°C to 70°C.

logic diagram (positive logic)

**SN74ALS2967, SN74ALS2968
DYNAMIC MEMORY CONTROLLERS**

TABLE 1. PIN FUNCTION

PIN NAME	DESCRIPTION
A0-A17	Address Inputs. A0-A8 are latched in as the nine-bit row address for the DRAM. These inputs drive Q0-Q8 when the DMC is in the read/write mode and MSEL is low. A9-A17 are latched in as the column address, and will drive Q0-Q8 when MSEL is high and the DMC is in the read/write mode. The addresses are latched when the Latch Enable (LE) input signal is low.
SELO, SEL1	Bank Select. These two inputs are normally the two highest-order address bits and are used in the read/write mode to select which bank of memory will be receiving the RAS and CAS signals after RAS $\bar{1}$ ('ALS2967) or RAS1 ('ALS2968) and $\bar{C}AS\bar{1}$ ('ALS2967) or CAS1 ('ALS2968) go active.
LE	Latch Enable. This active-high input causes the row, column, and bank select latches to become transparent, allowing the latches to accept new input data. A low input on LE latches the input data.
MSEL	Multiplexer Select. This input determines whether the row or column address will be sent to the memory address inputs. When MSEL is high, the column address is selected, while the row address is selected when MSEL is low. The address may come from either the address latch or refresh address counter depending on MCO and MC1 (see Mode Control Function Table).
$\bar{C}S$	Chip Select. This active-low input is used to enable the DMC. When $\bar{C}S$ is active, the DMC operates normally in all four modes. When $\bar{C}S$ goes high, the device will not enter the read/write mode. This allows other devices to access the same memory that the DMC is controlling.
$\bar{O}E$	Output Enable. This active-low input enables/disables the output signals. When $\bar{O}E$ is high, the outputs of the DMC enter the high-impedance state.
MCO-MC1	Mode Controls. These inputs determine in which of the four modes the DMC operates. The description of each of the four operating modes is given in Table 2.
Q0-Q8	Address Outputs. These address outputs feed the DRAM address inputs and provide drive for memory systems having capacitance of up to 500 picofarads.
RAS $\bar{1}$ or RAS1	Row Address Strobe Input. During the normal memory cycles, the decoded RASn output (RAS0, RAS $\bar{1}$, RAS2, or RAS3) is forced low after receipt of an active Row Address Strobe Input signal. In either Refresh mode, all four $\bar{R}AS$ outputs will be low while the Row Address Strobe Input signal is active. The $\bar{R}AS\bar{1}$ on the 'ALS2967 is an active-low input while on the 'ALS2968, RAS1 is an active-high input. (For more details see timing diagrams).
RAS0-RAS3	Row Address Strobe. Each of the Row Address Strobe outputs provides a $\bar{R}AS$ signal to one of the four banks of dynamic memory. Each RASn output will go low when selected by SELO and SEL1 after $\bar{R}AS\bar{1}$ ('ALS2967) or RAS1 ('ALS2968) goes active. All four go low in response to $\bar{R}AS\bar{1}$ ('ALS2967) or RAS1 ('ALS2968) while in the refresh mode.
CAS $\bar{1}$ or CAS1	Column Address Strobe Input. This input going active causes the selected $\bar{C}AS$ output to be forced low. The $\bar{C}AS\bar{1}$ input on the 'ALS2967 is active low input while on the 'ALS2968, CAS1 is active high input. (For more details see timing diagrams.)
$\bar{C}AS0$ - $\bar{C}AS3$	Column Address Strobe. During normal Read/Write cycles the two selected bits (SELO, SEL1) determine which $\bar{C}AS$ output will go active following $\bar{C}AS\bar{1}$ ('ALS2967) or CAS1 ('ALS2968) going active. When memory scrubbing is being performed, only the $\bar{C}ASn$ signal selected will be active. For non-scrubbing cycles, all four $\bar{C}AS$ outputs will remain high.

TABLE 2. MODE-CONTROL FUNCTION TABLE

MC1	MCO	OPERATING MODE
L	L	Refresh Mode without Scrubbing. Refresh cycles are performed with only the row counter being used to generate the addresses. In this mode, all four \overline{RAS} outputs are active while the four \overline{CAS} outputs remain high.
L	H	Refresh with Scrubbing/Initialize. During this mode, refresh cycles are done with both the row and column counters generating the addresses. MSEL is used to select either the row or the column counter. All four \overline{RAS} outputs go low in response to \overline{RASi} ('ALS2967) or \overline{RASi} ('ALS2968), while only one \overline{CASn} output goes low in response to \overline{CASi} ('ALS2967) or \overline{CASi} ('ALS2968). The bank counter keeps track of which \overline{CAS} output goes active. This mode can also be used during system power-up so that the memory can be written with a known data pattern.
H	L	Read/Write. This mode is used to perform read/write cycles. Both the Row and Column addresses are multiplexed to the address output lines using MSEL. SEL0 and SEL1 are decoded to determine which \overline{RASn} and \overline{CASn} outputs will be active. The refresh counter is disabled while in this mode.
H	H	Clear Refresh Counters. This mode clears the three refresh counters (row, column, and bank) on the inactive transition of \overline{RASi} ('ALS2967) or \overline{RASi} ('ALS2968), putting them at start of the refresh sequence (see timing diagrams for more detail). In this mode, all four \overline{RAS} outputs are driven low after the active edge of \overline{RASi} ('ALS2967) or \overline{RASi} ('ALS2968) so that DRAM wake-up cycles may also be performed.

[†] If LE is low, outputs will be the levels entered when LE was last high. If LE is high, outputs will follow address inputs as selected by MSEL.

[‡] For 'ALS2967, clearing occurs on the low-to-high transition of RASI; for 'ALS2968, clearing occurs on the high-to-low transition of RASI.

read/write operation details

During normal read/write operations, the row and column addresses are multiplexed to the dynamic RAM controlled by the MSEL input. The corresponding RASn and CASn output signals strobe the addresses into memory. The block diagram in Figure 1 shows a typical system interface for a one-megaword dynamic memory. The DMC is used to control the four banks of 256K memory.

For systems where addresses and data are multiplexed onto a single bus, the DMC uses latches, (row, column, and bank) to hold the address information. Figure 5 shows a typical timing diagram using the input latches. The twenty input latches are transparent when latch enable (LE) is high, and latch the input data whenever LE is taken low. For systems in which the processor has separate address and data buses, LE may be permanently high (see timing diagram in Figure 4).

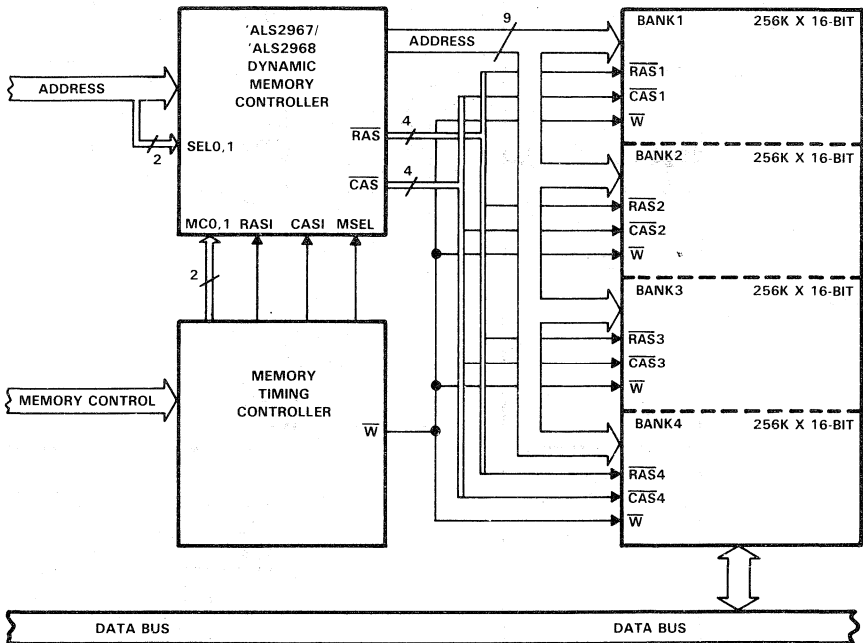

FIGURE 1. 1-MEGAWORD X 16-BIT DYNAMIC MEMORY

**SN74ALS2967, SN74ALS2968
DYNAMIC MEMORY CONTROLLERS**

read/write operations (continued)

The DMC is designed with heavy-duty outputs that are capable of driving four banks of 16-bit words, including six checkbits used for error detection and correction.

In addition to heavy-duty output drivers, the outputs are designed with balanced output impedances (25 Ω both high and low). This feature optimizes the drive low characteristics, based on safe undershoot, while providing symmetrical drive high characteristics. It also eliminates the external resistors required to pull the outputs up to the MOS V_{OH} level ($V_{CC} - 1.5 V$).

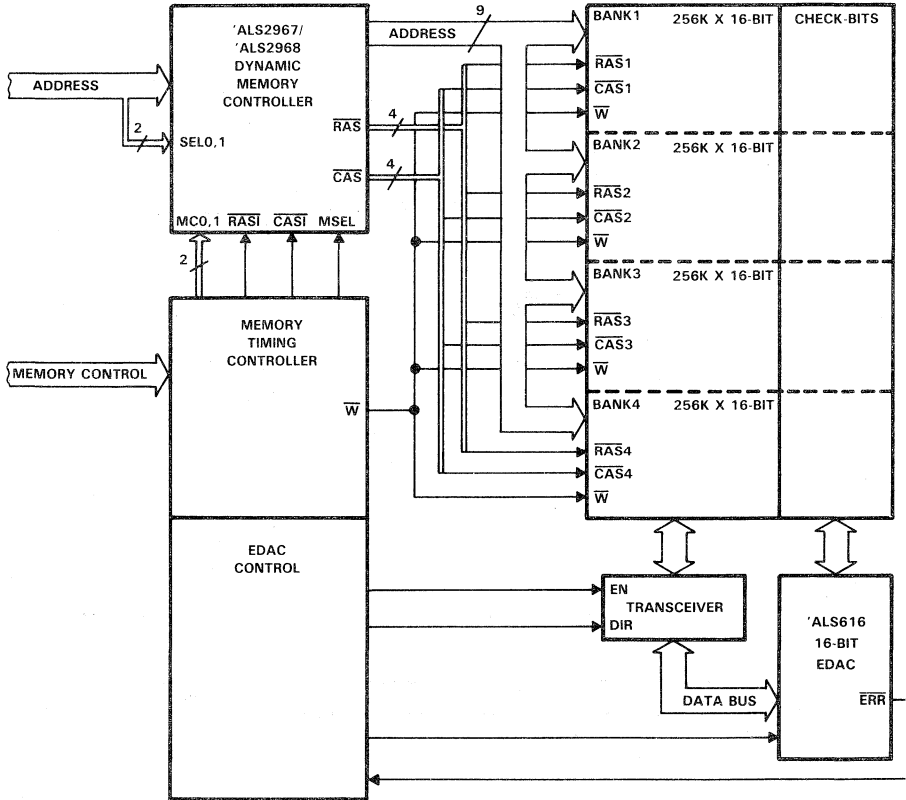

FIGURE 2. 1-MEGAWORD X 16-BIT DYNAMIC MEMORY WITH ERROR DETECTION AND CORRECTION

memory expansion

With a 9-bit address path, the DMC can control up to one megaword when using 256K dynamic RAMs. If a larger memory size is desired, the DMC's chip select (\overline{CS}) makes it easy to expand the memory size by using additional DMCs. A four-megaword memory system is shown in Figure 3.

To maintain maximum performance in 32-bit applications, it is recommended that individual bus drivers be used for each bank.

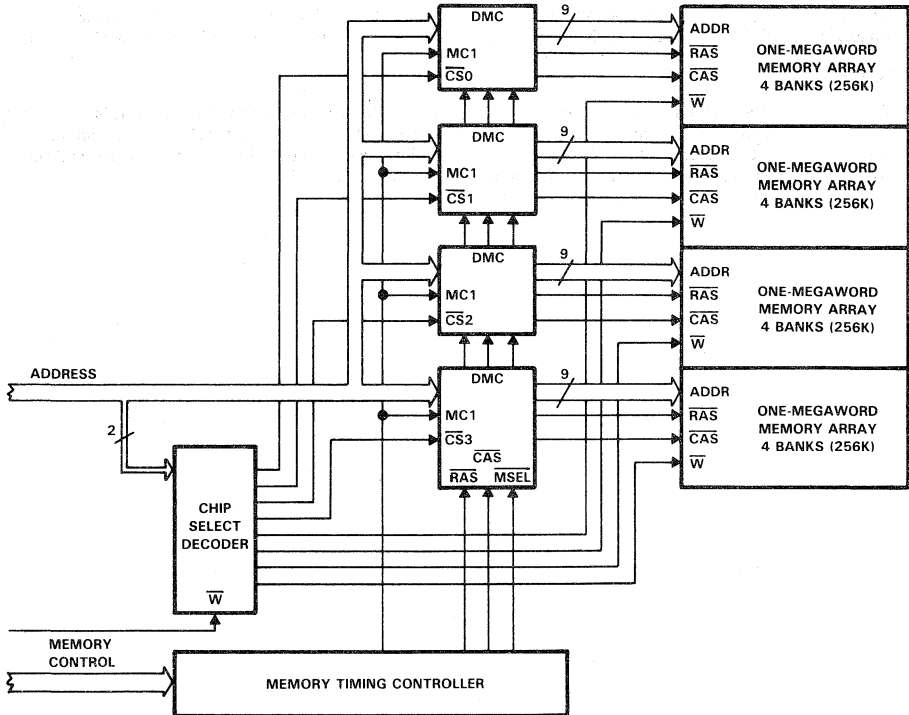

FIGURE 3. 4-MEGAWORD X 16-BIT DYNAMIC MEMORY

SN74ALS2967, SN74ALS2968 DYNAMIC MEMORY CONTROLLERS

refresh operations

The two 9-bit counters in the 'ALS2967 and 'ALS2968 support 128-, 256-, and 512-line refresh operations. Transparent, burst, synchronous, or asynchronous refresh modes are all possible. The refresh counters are advanced on the low-to-high transition of $\overline{\text{RAS}}\overline{\text{I}}$ on the 'ALS2967, and on the high-to-low transition of $\overline{\text{RAS}}\overline{\text{I}}$ on the 'ALS2968. The refresh counters are reset to zero on the low-to-high transition of $\overline{\text{RAS}}\overline{\text{I}}$ on the 'ALS2967, and on the high-to-low transition of $\overline{\text{RAS}}\overline{\text{I}}$ on the 'ALS2968, if MC1 and MCO are at a high logic level. See Figure 8 for additional timing details.

When performing refresh cycles without memory scrubbing (MC1 and MCO both low), all four $\overline{\text{RAS}}$ outputs go low, while all $\overline{\text{CAS}}$ outputs are driven high. Typical timing for this mode of operation is shown in Figure 6.

decoupling

Due to the high switching speed and high drive capability of the 'ALS2967 and 'ALS2968, it is necessary to decouple the device for proper operation. Multilayer ceramic 0.1 μF to 1 μF capacitors are recommended for decoupling. It is important to mount the capacitors as close as possible to the power pins (V_{CC} and GND) to minimize lead inductance and noise. A ground plane is recommended.

D2900, JANUARY 1986—REVISED MARCH 1988

- Provides Control for 16K, 64K, 256K, and 1M Dynamic RAMs
- Highest-Order Two-Address Bits Select One of Four Banks of RAMs
- Supports Scrubbing Operations and Nibble-Mode Access
- Separate Output Enable for Multi-Channel Access to Memory
- 52-Pin Dual-In-Line Package

description

The 'ALS6301 and 'ALS6302 dynamic memory controllers (DMCs) are designed for use in today's high-performance memory systems. The DMC acts as the address controller between any processor and dynamic memory array.

Two versions are provided that help simplify interfacing to the system dynamic timing controller. The 'ALS6301 offers active-low Row Address Strobe Input (RASI) and Column Address Strobe Input (CASI), while the 'ALS6302 offers active-high Row Address Strobe Input (RAS) and Column Address Strobe Input (CAS) inputs.

Using two 10-bit address latches, the DMC will hold the row and column addresses for any DRAM up to 1M. These latches and the two row/column refresh address counters feed into a 10-bit, 4-input MUX for output to the dynamic RAM address lines. A 2-bit bank select latch is provided to select one of the four RAS and CAS outputs. The two bits are normally obtained from the two highest-order address bits.

The 'ALS6301 and 'ALS6302 have two basic modes of operation, read/write and refresh. During normal read/write operations, the row and column addresses are multiplexed to the dynamic RAM, with the corresponding RAS and CAS signals activated to strobe the addresses into the RAM. In the refresh mode, the two counters cycle through the refresh addresses. If memory scrubbing is not being implemented, only the row counter is used. When memory scrubbing is being performed, both the row and column counters are used to perform read-modify-write cycles. In this mode all RAS outputs will be active (low) while only one CAS output is active at a time.

The SN74ALS6301 and SN74ALS6302 are characterized for operation from 0°C to 70°C.

TABLE 1. PIN FUNCTION

PIN NAME	DESCRIPTION
A0-A19	Address Inputs. A0-A9 are latched in as the nine-bit row address for the DRAM. These inputs drive Q0-Q9 when the DMC is in the read/write mode and MSEL is low. A10-A19 are latched in as the column address, and will drive Q0-Q9 when MSEL is high and the DMC is in the read/write mode. The addresses are latched when the Latch Enable (LE) input signal is low.
SEL0, SEL1	Bank Select. These two inputs are normally the two highest-order address bits and are used in the read/write mode to select which bank of memory will be receiving the \overline{RAS} and \overline{CAS} signals after \overline{RAS} ('ALS6301) or RASI ('ALS6302) and \overline{CAS} ('ALS6301) or CASI ('ALS6302) go active.
LE	Latch Enable. This active-high input causes the row, column, and bank select latches to become transparent, allowing the latches to accept new input data. A low input on LE latches the input data.
MSEL	Multiplexer Select. This input determines whether the row or column address will be sent to the memory address inputs. When MSEL is high, the column address is selected, while the row address is selected when MSEL is low. The address may come from either the address latch or refresh address counter depending on MCO and MC1 (see Mode Control Function Table).
\overline{CS}	Chip Select. This active-low input is used to enable the DMC. When \overline{CS} is active, the DMC operates normally in all four modes. When \overline{CS} goes high, the device will not enter the read/write mode. This allows other devices to access the same memory that the DMC is controlling.
\overline{OE}	Output Enable. This active-low input enables/disables the output signals. When \overline{OE} is high, the outputs of the DMC enter the high-impedance state.
MCO-MC1	Mode Controls. These inputs determine in which of the four modes the DMC operates. The description of each of the four operating modes is given in Table 2.
Q0-Q9	Address Outputs. These address outputs feed the DRAM address inputs and provide drive for memory systems having capacitance of up to 500 picofarads.
\overline{RAS} or RASI	Row Address Strobe Input. During the normal memory cycles, the decoded \overline{RASn} output ($\overline{RAS0}$, $\overline{RAS1}$, $\overline{RAS2}$, or $\overline{RAS3}$) is forced low after receipt of an active Row Address Strobe Input signal. In either Refresh mode, all four \overline{RAS} outputs will be low while the Row Address Strobe Input signal is active. The \overline{RAS} on the 'ALS6301 is an active-low input while on the 'ALS6302, RASI is an active-high input. (For more details see timing diagrams).
$\overline{RAS0}$ - $\overline{RAS3}$	Row Address Strobe. Each of the Row Address Strobe outputs provides a \overline{RAS} signal to one of the four banks of dynamic memory. Each \overline{RASn} output will go low when selected by SEL0 and SEL1 after \overline{RAS} ('ALS6301) or RASI ('ALS6302) goes active. All four go low in response to \overline{RAS} ('ALS6301) or RASI ('ALS6302) while in the refresh mode.
CASI or CASI	Column Address Strobe Input. This input going active causes the selected \overline{CAS} output to be forced low. The CASI input on the 'ALS6301 is active low input while on the 'ALS6302, CASI is active high input. (For more details see timing diagrams.)
$\overline{CAS0}$ - $\overline{CAS3}$	Column Address Strobe. During normal Read/Write cycles the two selected bits (SEL0, SEL1) determine which CAS output will go active following \overline{CAS} ('ALS6301) or CASI ('ALS6302) going active. When memory scrubbing is being performed, only the \overline{CASn} signal selected will be active. For non-scrubbing cycles, all four \overline{CAS} outputs will remain high.
TP	This active-low test input asynchronously sets the row and column input latches high, while forcing the two bank select latches low. In normal operation, TP is tied high.

**SN74ALS6301, SN74ALS6302
DYNAMIC MEMORY CONTROLLERS**

TABLE 2. MODE-CONTROL FUNCTION TABLE

MC1	MC0	OPERATING MODE
L	L	Refresh Mode without Scrubbing. Refresh cycles are performed with only the row counter being used to generate the addresses. In this mode, all four \overline{RAS} outputs are active while the four \overline{CAS} outputs remain high.
L	H	Refresh with Scrubbing/Initialize. During this mode, refresh cycles are done with both the row and column counters generating the addresses. MSEL is used to select either the row or the column counter. All four \overline{RAS} outputs go low in response to \overline{RASi} ('ALS6301) or $RASi$ ('ALS6302), while only one \overline{CASn} output goes low in response to \overline{CASi} ('ALS6301) or $CASi$ ('ALS6302). The bank counter keeps track of which \overline{CAS} output goes active. This mode can also be used during system power-up so that the memory can be written with a known data pattern.
H	L	Read/Write. This mode is used to perform read/write cycles. Both the Row and Column addresses are multiplexed to the address output lines using MSEL. SELO and SEL1 are decoded to determine which \overline{RASn} and \overline{CASn} outputs will be active. The refresh counter is disabled while in this mode.
H	H	Clear Refresh Counters. This mode clears the three refresh counters (row, column, and bank) on the inactive transition of \overline{RASi} ('ALS6301) or $RASi$ ('ALS6302), putting them at start of the refresh sequence (see timing diagrams for more detail). In this mode, all four \overline{RAS} outputs are driven low after the active edge of \overline{RASi} ('ALS6301) or $RASi$ ('ALS6302) so that DRAM wake-up cycles may also be performed.

[†] If \overline{TP} is low, the row and column address latch will be high. If \overline{TP} is high, the row and column address latch will be at the levels entered when LE was last high.

[‡] For 'ALS6301, clearing occurs on the low-to-high transition of \overline{RASI} ; for 'ALS6302, clearing occurs on the high-to-low transition of RASI.

read/write operation details

During normal read/write operations, the row and column addresses are multiplexed to the dynamic RAM controlled by the MSEL input. The corresponding \overline{RAS}_n and \overline{CAS}_n output signals strobe the addresses into memory. The block diagram in Figure 1 shows a typical system interface for a four-megaword dynamic memory. The DMC is used to control the four banks of 1M memory.

For systems where addresses and data are multiplexed onto a single bus, the DMC uses latches, (row, column, and bank) to hold the address information. Figure 5 shows a typical timing diagram using the input latches. The twenty-two input latches are transparent when latch enable (LE) is high, and latch the input data whenever LE is taken low. For systems in which the processor has separate address and data buses, LE may be permanently high (see timing diagram in Figure 4).

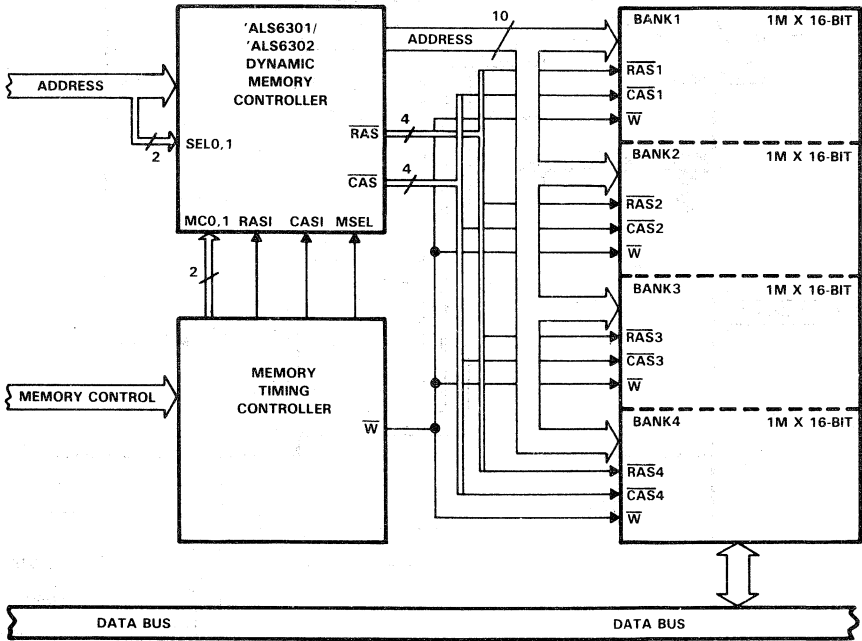

FIGURE 1. 4-MEGAWORD X 16-BIT DYNAMIC MEMORY

**SN74ALS6301, SN74ALS6302
DYNAMIC MEMORY CONTROLLERS**

read/write operations (continued)

The DMC is designed with heavy-duty outputs that are capable of driving four banks of 16-bit words, including six checkbits used for error detection and correction.

In addition to heavy-duty output drivers, the outputs are designed with balanced output impedances (25 Ω both high and low). This feature optimizes the drive low characteristics, based on safe undershoot, while providing symmetrical drive high characteristics. It also eliminates the external resistors required to pull the outputs up to the MOS V_{OH} level ($V_{CC} - 1.5 V$).

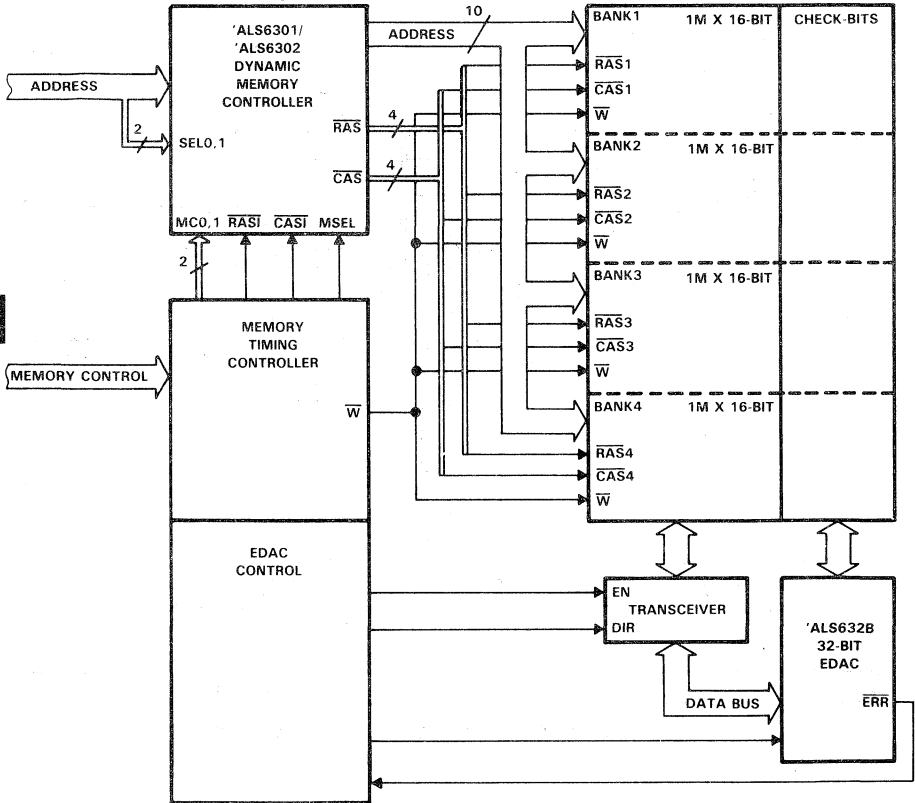

FIGURE 2. 4-MEGAWORD X 16-BIT DYNAMIC MEMORY WITH ERROR DETECTION AND CORRECTION

SN74ALS6301, SN74ALS6302 DYNAMIC MEMORY CONTROLLERS

memory expansion

With a 10-bit address path, the DMC can control up to four megaword when using 1M dynamic RAMs. If a larger memory size is desired, the DMC's chip select (\overline{CS}) makes it easy to expand the memory size by using additional DMCs. A sixteen-megaword memory system is shown in Figure 3.

To maintain maximum performance in 32-bit applications, it is recommended that individual bus drivers be used for each bank.

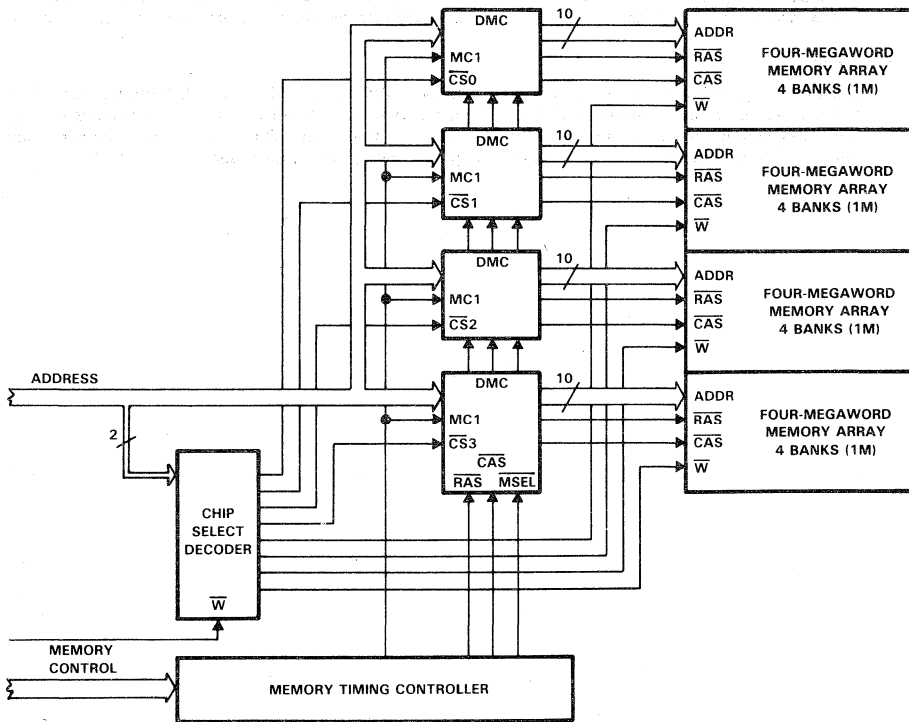

FIGURE 3. 16-MEGAWORD X 16-BIT DYNAMIC MEMORY

SN74ALS6301, SN74ALS6302 DYNAMIC MEMORY CONTROLLERS

refresh operations

The two 10-bit counters in the 'ALS6301 and 'ALS6302 support 128-, 256-, 512-, and 1024-line refresh operations. Transparent, burst, synchronous, or asynchronous refresh modes are all possible. The refresh counters are advanced on the low-to-high transition of $\overline{\text{RAS}}_1$ on the 'ALS6301, and on the high-to-low transition of $\overline{\text{RAS}}_1$ on the 'ALS6302. The refresh counters are reset to zero on the low-to-high transition of $\overline{\text{RAS}}_1$ on the 'ALS6301, and on the high-to-low transition of $\overline{\text{RAS}}_1$ on the 'ALS6302, if MC1 and MC0 are at a high logic level. See Figure 8 for additional timing details.

When performing refresh cycles without memory scrubbing (MC1 and MC0 both low), all four $\overline{\text{RAS}}$ outputs go low, while all $\overline{\text{CAS}}$ outputs are driven high. Typical timing for this mode of operation is shown in Figure 6.

decoupling

Due to the high switching speed and high drive capability of the 'ALS6301 and 'ALS6302, it is necessary to decouple the device for proper operation. Multilayer ceramic 0.1- μF to 1- μF capacitors are recommended for decoupling. It is important to mount the capacitors as close as possible to the power pins (V_{CC} and GND) to minimize lead inductance and noise. A ground plane is recommended.

THCT4502B DYNAMIC RAM CONTROLLER

D2989, JUNE 1987

- Inputs are TTL- and CMOS-Voltage Compatible
- Controls Operation of 64K and 256K Dynamic RAMs
- Creates Static RAM Appearance
- One Package Contains Address Multiplexer, Refresh Control, and Timing Control
- Directly Addresses and Drives Up to 2 Megabytes of Memory Without External Drivers
- Operates from Microprocessor Clock
 - No Crystals, Delay Lines, or RC Networks
 - Eliminates Arbitration Delays
- Refresh May Be Internally or Externally Initiated
- Versatile
 - Strap-Selected Refresh Rate
 - Synchronous, Predictable Refresh
 - Selection of Distributed, Transparent, and Cycle-Steal Refresh Modes
 - Interfaces Easily to Popular Microprocessors
 - Asynchronous RESET Function Provided in FK and FN Packages
- High-Performance Si-Gate CMOS Technology
- Strap-Selected Wait State Generation for Microprocessor/Memory Speed Matching
- Ability to Synchronize or Interleave Controller with the Microprocessor System (Including Multiple Controllers)
- 3-State Outputs Allow Multiport Memory Configuration
- Performance Range:
 - 115 ns ALE low to CAS low
- Functionally Equivalent to TMS4500A/B and to VTI VL4500A and VL4502
- Available in Plastic and Ceramic Chip Carriers in Addition to Plastic and Ceramic DIPs
- Dependable Texas Instruments Quality and Reliability

THCT4502B
DYNAMIC RAM CONTROLLER

description

The THCT4502B is a monolithic DRAM system controller providing address multiplexing, timing, control and refresh/access arbitration functions to simplify the interface of dynamic RAMs to microprocessor systems.

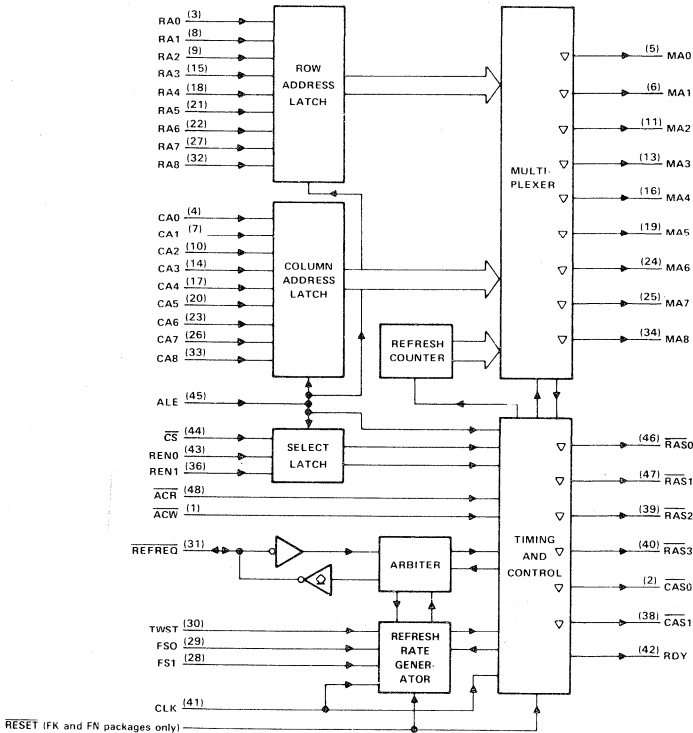

The controller contains an 18-bit multiplexer that generates the address lines for the memory device from the 18 system address bits and provides the strobe signals required by the memory to decode the address. A 9-bit refresh counter generates up to 512 row addresses required to refresh.

A refresh timer is provided to generate the necessary timing to refresh the dynamic memories and ensure data retention.

The THCT4502B also contains refresh/access arbitration circuitry to resolve conflicts between access requests and memory-refresh cycles.

The THCT4502B is characterized for operation from 0°C to 70°C.

functional block diagram

Pin numbers shown are for JD and N packages.

pin descriptions

RA0-RA8	Input	Row Address — These address inputs are used to generate the row address for the multiplexer.
CA0-CA8	Input	Column Address — These address inputs are used to generate the column address for the multiplexer.
MA0-MA8	Output	Memory Address — These three-state outputs are designed to drive the addresses of the dynamic RAM array.
ALE	Input	Address Latch Enable — This input is used to latch the 18 address inputs, \overline{CS} , RENO, and REN1. This also initiates an access cycle if \overline{CS} is low. The rising edge (low level to high level) of ALE returns all \overline{RAS} outputs to the high level.
\overline{CS}	Input	Chip Select — A low on this input enables an access cycle. The trailing edge of ALE latches the chip select input.
RENO, REN1	Inputs	\overline{RAS} Enable 0 and 1 — These inputs are used to select one of four banks of RAM when \overline{CS} is low. When REN1 is low, the lower banks are enabled via $\overline{CAS0}$, $\overline{RAS0}$, and $\overline{RAS1}$. When REN1 is high, the higher banks are enabled via $\overline{CAS1}$, $\overline{RAS2}$ and $\overline{RAS3}$. RENO selects $\overline{RAS0}$ and $\overline{RAS2}$ when low, or $\overline{RAS1}$ and $\overline{RAS3}$ when high. (see Table 2).
\overline{ACR} , \overline{ACW}	Input	Access Control, Read; Access Control, Write — A low on either of these inputs causes the column address to appear on MA0-MA8 and a low-going pulse from CAS. The rising edge of \overline{ACR} or \overline{ACW} terminates the cycle by forcing \overline{RAS} and CAS high. When \overline{ACR} and \overline{ACW} are both low, MA0-MA8, $\overline{RAS0}$, $\overline{RAS1}$, $\overline{RAS2}$, $\overline{RAS3}$, $\overline{CAS0}$ and $\overline{CAS1}$ go into a high-impedance (floating) state.
CLK	Input	System Clock — This input provides the master timing to generate refresh cycle timings and refresh rate. Refresh rate is determined by the TWST, FS1, and FSO inputs.
\overline{REFREQ}	I/O	Refresh Request — This input should be driven by an open-collector or open-drain output. On input, a low-going edge initiates a refresh cycle and will cause the internal refresh timer to be reset on the next falling edge of the CLK. As an output, a low-going edge signals an internal refresh request and that the refresh timer will be reset on the next low-going edge of CLK. \overline{REFREQ} will remain low until the refresh cycle is in progress and the current refresh address is present on MA0-MA8. (Note: \overline{REFREQ} contains an internal active pullup with a nominal resistance of 10 k Ω , which is disabled when \overline{REFREQ} is low).
$\overline{RAS0}$, $\overline{RAS1}$ $\overline{RAS2}$, $\overline{RAS3}$	Output	Row Address Strobe — These three-state outputs are used to latch the row address into the bank of DRAMs selected by RENO and REN1. On refresh, all \overline{RAS} signals are active.
$\overline{CAS0}$, $\overline{CAS1}$	Output	Column Address Strobe — These three-state outputs are used to latch the column address into the DRAM array.
RDY	Output	Ready — This totem-pole output synchronizes memories that are too slow to guarantee microprocessor access time requirements. This output is also used to inhibit access cycles during refresh when in cycle-steal mode.

THCT4502B
DYNAMIC RAM CONTROLLER

pin descriptions (continued)

TWST	Input	Timing/Wait Strap — A high on this input indicates a wait state should be added to each memory cycle. In addition it is used in conjunction with FS0 and FS1 to determine refresh rate and timing or initialize the controller.
FS0, FS1	Inputs	Frequency Select 0; Frequency Select 1 — These are strap inputs to select Mode and Frequency of operation as shown in Table 1.
$\overline{\text{RESET}}^\dagger$	Input	$\overline{\text{RESET}}$ — Active-low input to initialize the controller asynchronously. Refresh Address is set to IFF16, internal refresh requests, synchronizer, and frequency divider are cleared. (Note: $\overline{\text{RESET}}$ contains an internal pullup resistor with a nominal resistance of 100 k Ω , which allows this pin to be left open.)

[†]This function is available only in the FK and FN packages.

TABLE 1. STRAP CONFIGURATION

STRAP INPUT MODES			WAIT STATES FOR MEMORY ACCESS	REFRESH RATE	MINIMUM CLOCK FREQUENCY (MHz)	REFRESH FREQUENCY (kHz)	CLOCK CYCLES FOR EACH REFRESH
TWST	FS1	FS0					
L	L	L [†]	0	EXTERNAL	—	REFREQ	4
L	L	H	0	EXTERNAL	—	REFREQ	3
L	H	L	0	CLK \div 61	3.904	64-95 [‡]	3
L	H	H	0	CLK \div 91	5.824	64-88 [§]	4
H	L	L	1	CLK \div 61	3.904	64-95 [‡]	3
H	L	H	1	CLK \div 91	5.824	64-75 [‡]	4
H	H	L	1	CLK \div 106	6.784	64-73 [‡]	4
H	H	H	1	CLK \div 121	7.744	64-83 [¶]	4

[†]This strap configuration resets the Refresh Timer Circuitry.

[‡]Upper figure in refresh frequency is the frequency that is produced if the minimum clock frequency of the next select state is used.

[§]Refresh frequency if clock frequency is 8 MHz.

[¶]Refresh frequency if clock frequency is 10 MHz.

TABLE 2. OUTPUT STROBE SELECTION

CONTROL INPUT		SELECTED OUTPUT					
REN1	RENO	RAS0	RAS1	RAS2	RAS3	CAS0	CAS1
L	L	X				X	
L	H		X			X	
H	L			X			X
H	H				X		X

NOTE: Changing the logic value of REN1 after a low-to-high transition of ALE and before $\overline{\text{ACX}}$ rises causes the other $\overline{\text{CAS}}$ to fall. Both $\overline{\text{CAS}}$ signals remain low until $\overline{\text{ACX}}$ rises.

functional description

The THCT4502B consists of six basic blocks: address and select latches, refresh rate generator, refresh counter, the multiplexer, the arbiter, and the timing and control block.

address and select latches

The address and select latches allow the DRAM controller to be used in systems that multiplex address and data on the same lines without external latches. The row address latches are transparent, meaning that while ALE is high, the output at MA0-MA8 follows the inputs RA0-RA8.

refresh rate generator

The refresh rate generator is a counter that indicates to the arbiter that it is time for a refresh cycle. The counter divides the clock frequency according to the configuration straps as shown in Table 1. The counter is reset when a refresh cycle is requested or when TWST, FS1, and FS0 are low. The configuration straps allow the matching of memories to the system access time. Upon power-up it is necessary to provide a reset signal by driving all three straps to the controller (or RESET for devices in the FK and FN packages only) low. A systems power-on reset (RESET) can be used to do this by connecting it to those straps that are desired high during operation. During this reset period, at least four clock cycles should occur.

refresh counter

The refresh counter contains the address of the row to be refreshed. The counter is decremented after each refresh cycle. A low-to-high transition on TWST sets the refresh counter to 1FF₁₆ (511₁₀).

multiplexer

The multiplexer provides the DRAM array with row, column, and refresh addresses at the proper times. Its inputs are the address latches and the refresh counter. The outputs provide up to 18 multiplexed addresses on nine lines.

arbiter

The arbiter provides two operational cycles: access and refresh. The arbiter resolves conflicts between cycle requests and cycles in execution, and schedules the inhibited cycle when used in cycle-steal mode.

timing and control block

The timing and control block executes the operational cycle at the request of the arbiter. It provides the DRAM array with RAS and CAS signals. It provides the CPU with a RDY signal. It controls the multiplexer during all cycles. It resets the refresh rate generator and decrements the refresh counter during refresh cycles.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)[†]

Supply voltage range, V _{CC} (See Note 1)	-1.5 V to 7 V
Input diode current, I _{IK} (V _I < 0, V _I > V _{CC})	±20 mA
Output diode current, I _{OK} (V _O < 0, V _O > V _{CC})	±20 mA
Continuous output current, I _O (V _O = 0 to V _{CC})	±35 mA
Continuous current through V _{CC} or GND pins	±70 mA
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds: FK or JD package	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: FN or N package	260°C

[†] Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is stress rating only, and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
NOTE 1: Voltage values are with respect to network ground.

[‡] This parameter, I_{OZ}, the high impedance-state output current, applies only for three-state outputs and transceiver I/O pins.

[§] This is the increase in supply current for each input that is at one of the specified TTL voltage levels rather than 0 V or V_{CC}.

THCT4502B DYNAMIC RAM CONTROLLER

timing requirements over recommended ranges of supply voltage and operating free-air temperature (unless otherwise noted)

PARAMETER		THCT4502B-115		UNIT
		MIN	MAX	
$t_{c(C)}$	CLK cycle time	100		ns
$t_{w(CH)}$	CLK high pulse duration	45		ns
$t_{w(CL)}$	CLK low pulse duration	45		ns
t_{AEL-CL}	Time delay, ALE low to CLK starting low (see Note 1)	15		ns
t_{CL-AEL}	Time delay, CLK low to ALE starting low (see Note 1)	15		ns
t_{CL-AEH}	Time delay, CLK low to ALE	15		ns
$t_{w(AEH)}$	Pulse width ALE high	45		ns
t_{AV-AEL}	Time delay, address RENO, REN1, \overline{CS} valid to ALE low	10		ns
t_{AEL-AX}	Time delay, ALE low to address not valid	15		ns
$t_{AEL-ACL}$	Time delay, ALE low to \overline{ACX} low (see Notes 3, 4, 5, and 6)	$t_{h(RA)} + 30$		ns
t_{ACH-CL}	Time delay, \overline{ACX} high to CLK low (see Notes 3 and 7)	30		ns
t_{ACL-CH}	Time delay, \overline{ACX} low to CLK starting high (to remove RDY)	30		ns
t_{RQL-CL}	Time delay, \overline{REFREQ} low to CLK starting low (see Note 8)	35		ns
$t_{w(RQL)}$	Pulse width \overline{REFREQ} low	30		ns
$t_{w(ACL)}$	\overline{ACX} low width (see Note 9)	120		ns
t_{reset}	Power-up reset	$4t_{c(CLK)}$		ns

- NOTES:
- Coincidence of the trailing edge of CLK and the trailing edge of ALE should be avoided as the refresh/access occurs on the trailing CLK edge.
 - If ALE rises before \overline{ACX} and a refresh request is present, the falling edge of CLK after t_{CL-AEH} will output the refresh address to MA0-MA7 and initiate a refresh cycle.
 - These specifications relate to system timing and do not directly reflect device performance.
 - On the access grant cycle following refresh, the occurrence of \overline{CAS} low depends on the relative occurrence of ALE low to \overline{ACX} low. If \overline{ACX} occurs prior to or coincident with ALE, then \overline{CAS} is timed from the CLK high transition that causes \overline{RAS} low. If \overline{ACX} occurs 20 ns or more after ALE, then \overline{CAS} is timed from the CLK low transition following the CLK high transition causing \overline{RAS} low.
 - For maximum speed access (internal delays on both access and access grant cycles), \overline{ACX} should occur prior to or coincident with ALE.
 - $t_{h(RA)}$ is the dynamic memory row address hold time. \overline{ACX} should follow ALE by $t_{AEL-CEL}$ in systems where the required $t_{h(RA)}$ is greater than $t_{REL-MAX}$ minimum.
 - The minimum of 30 ns is specified to ensure arbitration will occur on falling CLK edge, t_{ACH-CL} also affects precharge time such that the minimum t_{ACH-CL} should be equal or greater than: $t_{w(RH)} - t_{w(CL)} + 30$ ns (for a cycle where \overline{ACX} high occurs prior to ALE high) where $t_{w(RH)}$ is the DRAM \overline{RAS} precharge time.
 - This parameter is necessary only if refresh arbitration is to occur on this low-going CLK edge (in systems where refresh is synchronized to external events).
 - The specification $t_{w(ACL)}$ is designed to allow a \overline{CAS} pulse. This assures normal operation of the device in testing and system operation.

^t ACh-MAX Column address valid after \overline{ACX} high	$C_L = 360$ pF	5		ns
^t Ch-RYH Time delay, CLK high to RDY starting high (after \overline{ACX} low) (see Note 11)	$C_L = 40$ pF		42	ns
^t RFL-RFL Time delay, \overline{REFREQ} external till supported by \overline{REFREQ} internal	$C_L = 40$ pF		35	ns
^t Ch-RFL Time delay, CLK high till \overline{REFREQ} internal starting low	$C_L = 40$ pF		50	ns
^t CL-MAV Time delay, CLK low till refresh address valid	$C_L = 360$ pF		70	ns
^t Ch-RRL Time delay, CLK high till refresh \overline{RAS} starting low	$C_L = 180$ pF	5	50	ns
^t MAV-RRL Time delay, refresh address valid till refresh \overline{RAS} low	$C_L = 180$ pF	5		ns
^t CL-RFH Time delay, CLK low to \overline{REFREQ} starting high (3 cycle refresh)	$C_L = 40$ pF		50	ns
^t Ch-RFH Time delay, CLK high to \overline{REFREQ} starting high (4 cycle refresh)	$C_L = 40$ pF		50	ns
^t Ch-RRH Time delay, CLK high to refresh \overline{RAS} starting high	$C_L = 180$ pF	5	30	ns
^t Ch-MAX Refresh address valid after CLK high	$C_L = 360$ pF	10		ns

- NOTES: 10. The falling edge of \overline{CAS} occurs when both ALE low to \overline{CAS} low time delay (^tAEL-CEL) and \overline{ACX} low to \overline{CAS} low time delay (^tACL-CEL) have elapsed, i.e., if \overline{ACX} goes low prior to (^tAEL-CEL - ^tACL-CEL) after the falling edge of ALE, the falling edge of \overline{CAS} is measured from the falling edge of ALE (^tAEL-CEL). Otherwise, the access time increases and the falling edge of \overline{CAS} is measured from the falling edge of \overline{ACX} (^tACL-CEL).
11. RDY returns high on the rising edge of CLK. If TWST = 0, then on an access grant cycle RDY goes high on the same edge that causes access \overline{RAS} low. If TWST = 1, then RDY goes to the high level on the first rising CLK edge after \overline{ACX} goes low on access cycles and on the next rising edge after the edge that causes access \overline{RAS} low on access grant cycles (assuming \overline{ACX} low).

switching characteristics over recommended supply voltage range and operating free-air temperature range (see Figure 1) (continued)

PARAMETER	TEST CONDITIONS	THCT4502B-115		UNIT
		MIN	MAX	
t _{CH-REL}	Time delay, CLK high till access \overline{RAS} starting low	C _L = 180 pF	45	ns
t _{CL-CEL}	Time delay, CLK low to access \overline{CAS} starting low (see Note 12)	C _L = 360 pF	70	ns
t _{CL-MAX}	Row address valid after CLK low	C _L = 360 pF	15	ns
t _{REL-MAX}	Row address valid after \overline{RAS} low	C _L = 360 pF	20	ns
t _{AEH-MAX}	Column address valid after ALE high	C _L = 360 pF	10	ns
t _{dis}	Output disable time (3-state outputs)	C _L = 360 pF	90	ns
t _{en}	Output enable time (3-state outputs)	C _L = 360 pF	55	ns
t _{CAV-CEL}	Time delay, column address valid to \overline{CAS} starting low after refresh (see Note 12)	C _L = 360 pF	0	ns
t _{CH-CEL}	Time delay, CLK high to access \overline{CAS} starting low (see Note 13)	C _L = 360 pF	140	ns
t _{t(CEL)}	\overline{CAS} fall time	C _L = 360 pF	20	ns
t _{t(CEH)}	\overline{CAS} rise time	C _L = 360 pF	30	ns
t _{t(REL)}	\overline{RAS} fall time	C _L = 180 pF	20	ns

TMS4500A DYNAMIC-RAM CONTROLLER

D2674, JANUARY 1982 - REVISED AUGUST 1985

- Controls Operation of 8K, 16K, 32K, and 64K Dynamic RAMs
- Creates Static RAM Appearance
- One Package Contains Address Multiplexer, Refresh Control, and Timing Control
- Directly Addresses and Drives Up to 256K Bytes of Memory Without External Drivers
- Operates from Microprocessor Clock
 - No Crystals, Delay Lines, or RC Networks
 - Eliminates Arbitration Delays
- Refresh May Be Internally or Externally Initiated
- Versatile
 - Strap-Selected Refresh Rate
 - Synchronous, Predictable Refresh
 - Selection of Distributed, Transparent, and Cycle-Steal Refresh Modes
 - Interfaces Easily to Popular Microprocessors
- Strap-Selected Wait-State Generation for Microprocessor/Memory Speed Matching
- Ability to Synchronize or Interleave Controller with the Microprocessor System (including Multiple Controllers)
- 3-State Outputs Allow Multiport Memory Configuration
- Performance Ranges of 150 ns, 200 ns, or 250 ns

description

The TMS4500A is a monolithic DRAM system controller designed to provide address multiplexing, timing, control and refresh/access arbitration functions to simplify the interface of dynamic RAMs to microprocessor systems.

The controller contains a 16-bit multiplexer that generates *the address lines for the memory device from the 16 system address bits and provides the strobe signals required by the memory to decode the address. An 8-bit refresh counter generates the 256-row addresses required for refresh.

A refresh timer is provided that generates the necessary timing to refresh the dynamic memories and assure data retention.

The TMS4500A also contains refresh/access arbitration circuitry to resolve conflicts between memory access requests and memory refresh cycles. The TMS4500A is offered in a 40-pin, 600-mil dual-in-line plastic package and 44-pin, 650-mil square plastic chip carrier package. It is characterized for operation from 0°C to 70°C.

TMS4500A
DYNAMIC-RAM CONTROLLER

BLOCK DIAGRAM

pin descriptions

RA0-RA7	Input	Row Address - These address inputs are used to generate the row address for the multiplexer.
CA0-CA7	Input	Column Address - These address inputs are used to generate the column address for the multiplexer.
MA0-MA7	Output	Memory Address - These three-state outputs are designed to drive the addresses of the dynamic RAM array.
ALE	Input	Address Latch Enable - This input is used to latch the 16 address inputs, \overline{CS} and REN1. This also initiates an access cycle if chip select is valid. The rising edge (low level to high level) of ALE returns RAS to the high level.
\overline{CS}	Input	Chip Select - A low on this input enables an access cycle. The trailing edge of ALE latches the chip select input.

pin descriptions (continued)

REN1	Input	RAS Enable 1 — This input is used to select one of two banks of RAM via the $\overline{\text{RAS0}}$ and RAS1 outputs when chip select is present. When it is low, $\overline{\text{RAS0}}$ is selected; when it is high, RAS1 is selected.
$\overline{\text{ACR}}$, $\overline{\text{ACW}}$	Input	Access Control, Read; Access Control, Write — A low on either of these inputs causes the column address to appear on MA0—MA7 and the column address strobe. The rising edge of $\overline{\text{ACR}}$ or $\overline{\text{ACW}}$ terminates the cycle by ending $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ strobes. When $\overline{\text{ACR}}$ and $\overline{\text{ACW}}$ are both low, MA0—MA7, RAS0 , RAS1 , and CAS go into a high-impedance (floating) state.
CLK	Input	System Clock — This input provides the master timing to generate refresh cycle timings and refresh rate. Refresh rate is determined by the TWST, FS1, FS0 inputs.
$\overline{\text{REFREQ}}$	Input/Output	Refresh Request — (This input should be driven by an open-collector output.) On input, a low-going edge initiates a refresh cycle and will cause the internal refresh timer to be reset on the next falling edge of the CLK. As an output, a low-going edge signals an internal refresh request and that the refresh timer will be reset on the next low-going edge of CLK. $\overline{\text{REFREQ}}$ will remain low until the refresh cycle in progress and the current refresh address is present on MA0—MA7. (Note: $\overline{\text{REFREQ}}$ contains an internal pull-up resistor with a nominal resistance of 10 kilohms.)
$\overline{\text{RAS0}}$, $\overline{\text{RAS1}}$	Output	Row Address Strobe — These three-state outputs are used to latch the row address into the bank of DRAMs selected by REN1. On refresh both signals are driven.
$\overline{\text{CAS}}$	Output	Column Address Strobe — This three-state output is used to latch the column address into the DRAM array.
RDY	Output	Ready — This totem-pole output synchronizes memories that are too slow to guarantee microprocessor access time requirements. This output is also used to inhibit access cycles during refresh when in cycle-steal mode.
TWST	Input	Timing/Wait Strap — A high on this input indicates a wait state should be added to each memory cycle. In addition it is used in conjunction with FS0 and FS1 to determine refresh rate and timing.
FS0, FS1	Input	Frequency Select 0; Frequency Select 1 — These are strap inputs to select Mode and Frequency of operation as shown in Table 1.

**TMS4500A
DYNAMIC-RAM CONTROLLER**

TABLE 1. STRAP CONFIGURATION

STRAP INPUT MODES			WAIT STATES FOR MEMORY ACCESS	REFRESH RATE	MINIMUM CLK FREQ. (MHz)	REFRESH FREQ. (kHz)	CLOCK FOR EACH FOR EACH REFRESH
TWST	FS1	FS0					
L	L	L [†]	0	EXTERNAL	—	REFREQ	4
L	L	H	0	CLK + 31	1,984	64.95 [‡]	3
L	H	L	0	CLK + 46	2,944	64.85 [‡]	3
L	H	H	0	CLK + 61	3,904	64.82 [§]	4
H	L	L	1	CLK + 46	2,944	64.85 [‡]	3
H	L	H	1	CLK + 61	3,904	64.80 [‡]	4
H	H	L	1	CLK + 76	4,864	64.77 [‡]	4
H	H	H	1	CLK + 91	5,824	64.88 [¶]	4

[†] This strap configuration resets the Refresh Timer circuitry.

[‡] The highest frequency in the refresh frequency column is the frequency that is produced if the minimum CLK frequency of the next select state is used.

[§] The highest frequency in the refresh column is the refresh frequency if the CLK frequency is 5 MHz.

[¶] The highest frequency in the refresh column is the refresh frequency if the CLK frequency is 8 MHz.

functional description

TMS4500A consists of six basic blocks; address and select latches, refresh rate generator, refresh counter, the multiplexer, the arbiter, and timing and control block.

7

address and select latches

The address and select latches allow the DRAM controller to be used in systems that multiplex address and data on the same lines without external latches. The row address latches are transparent, meaning that while ALE is high, the output at MA0—MA7 follows the inputs RAO—RA7.

refresh rate generator

The refresh rate generator is a counter that indicates to the arbiter that it is time for a refresh cycle. The counter divides the clock frequency according to the configuration straps as shown in Table 1. The counter is reset when a refresh cycle is requested or when TWST, FS1 and FS0 are low. The configuration straps allow the matching of memories to the system access time.

Upon Power-Up it is necessary to provide a reset signal by driving all three straps to the controller low to initialize internal counters. A system's low-active, power-on reset (RESET) can be used to accomplish this by connecting it to those straps that are desired high during operation. During this reset period, at least four clock cycles should occur.

refresh counter

The refresh counter contains the address of the row to be refreshed. The counter is decremented after each refresh cycle. [A low-to-high transition on TWST sets the refresh counter to FF₁₆ (255₁₀).]

multiplexer

The multiplexer provides the DRAM array with row, column, and refresh addresses at the proper times. Its inputs are the address latches and the refresh counter. The outputs provide up to 16 multiplexed addresses on eight lines.

arbiter

The arbiter provides two operational cycles: access and refresh. The arbiter resolves conflicts between cycle requests and cycles in execution, and schedules the inhibited cycle when used in cycle-steal mode.

timing and control block

The timing and control block executes the operational cycle at the request of the arbiter. It provides the DRAM array with RAS and CAS signals. It provides the CPU with a RDY signal. It controls the multiplexer during all cycles. It resets the refresh rate generator and decrements the refresh counter during refresh cycles.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

Supply voltage range, V_{CC} (see Note 1)	-1.5 V to 7 V
Input voltage range (any input)	-1.5 V to 7 V
Continuous power dissipation	1.2 W
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C

† Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: Voltage values are with respect to the ground terminal.

recommended operating conditions

$t_{w(ACL)}$	\overline{ACX} low duration (see Note 9)	110		140		175		

- NOTES:
1. Coincidence of the trailing edge of CLK and the trailing edge of ALE should be avoided as the refresh/access occurs on the trailing CLK edge. A trailing edge of CLK should occur during the interval from \overline{ACX} high to ALE low.
 2. If ALE rises before \overline{ACX} and a refresh request is present, the falling edge of CLK after t_{CL-AEH} will output the refresh address to MA0-MA7 and initiate a refresh cycle.
 3. These specifications relate to system timing and do not directly reflect device performance.
 4. On the access grant cycle following refresh, the occurrence of \overline{CAS} low depends on the relative occurrence of ALE low to \overline{ACX} low. If \overline{ACX} occurs prior to or coincident with ALE then \overline{CAS} is timed from the CLK high transition that causes \overline{RAS} low. If \overline{ACX} occurs 20 ns or more after ALE then \overline{CAS} is timed from the CLK low transition following the CLK high transition causing \overline{RAS} low.
 5. For maximum speed access (internal delays on both access and access grant cycles), \overline{ACX} should occur prior to or coincident with ALE.
 6. $t_{h(RA)}$ is the dynamic memory row address hold time. \overline{ACX} should follow ALE by $t_{AEL-CEL}$ in systems where the required $t_{h(RA)}$ is greater than $t_{REL-MAX}$ minimum.
 7. The minimum of 20 ns is specified to ensure arbitration will occur on falling CLK edge. t_{ACH-CL} also affects precharge time such that the minimum t_{ACH-CL} should be equal or greater than: $t_{w(RH)} - t_{w(CL)} + 30$ ns (for a cycle where \overline{ACX} high occurs prior to ALE high) where $t_{w(RH)}$ is the DRAM \overline{RAS} precharge time.
 8. This parameter is necessary only if refresh arbitration is to occur on this low-going CLK edge (in systems where refresh is synchronized to external events).
 9. The specification $t_{w(ACL)}$ is designed to allow a \overline{CAS} pulse. This assures normal operation of the device in testing and system operation.

$t_{ACH-MAX}$ Column address valid after ACX high		10		15		15			
t_{CH-RYH} Time delay, CLK high to RDY starting high (after ACX low) (see Note 11)		$C_L = 40$ pF	40		45		60		
$t_{RFL-RFL}$ Time delay, REFREQ external till supported by REFREQ internal*			30		35		35		
t_{CH-RFL} Time delay, CLK high till REFREQ internal starting low	30		35		45				
t_{CL-MAV} Time delay, CLK low till refresh address valid	$C_L = 160$ pF	75		100		125			
t_{CH-RRL} Time delay, CLK high till refresh RAS starting low		10	50	15	60	20	80		
$t_{MAV-RRL}$ Time delay, refresh address valid till refresh RAS low		5		5		5			
t_{CL-RFH} Time delay, CLK low to REFREQ starting high (3 cycle refresh)		50		55		75			
t_{CH-RFH} Time delay, CLK high to REFREQ starting high (4 cycle refresh)		50		55		75			
t_{CH-RRH} Time delay, CLK high to refresh RAS starting high		5	35	10	45	10	60		
t_{CH-MAX} Refresh address valid after CLK high		15		20		25			

- NOTES: 10. The falling edge of CAS occurs when both ALE low to CAS low time delay ($t_{AEL-CEL}$) and ACX low to CAS low time delay ($t_{ACL-CEL}$) have elapsed, i.e., if ACX goes low prior to ($t_{AEL-CEL} - t_{ACL-CEL}$) after the falling edge of ALE, the falling edge of CAS is measured from the falling edge of ALE ($t_{AEL-CEL}$). Otherwise, the access time increases and the falling edge of CAS is measured from the falling edge of ACX ($t_{ACL-CEL}$).
11. RDY returns high on the rising edge of CLK. If TWST = 0, then on an access grant cycle RDY goes high on the same edge that causes access RAS low. If TWST = 1, then RDY goes to the high level on the first rising CLK edge after ACX goes low on access cycles and on the next rising edge after the edge that causes access RAS low on access grant cycles (assuming ACX low).

ready timing (ACX during CLK high) (see notes 13 thru 16)

RDY starting high is timed from \overline{ACX} low ($t_{ACL-RYH}$) for the condition \overline{ACX} going low while CLK high.

ready timing (ACX during CLK low) (see notes 13 thru 16)

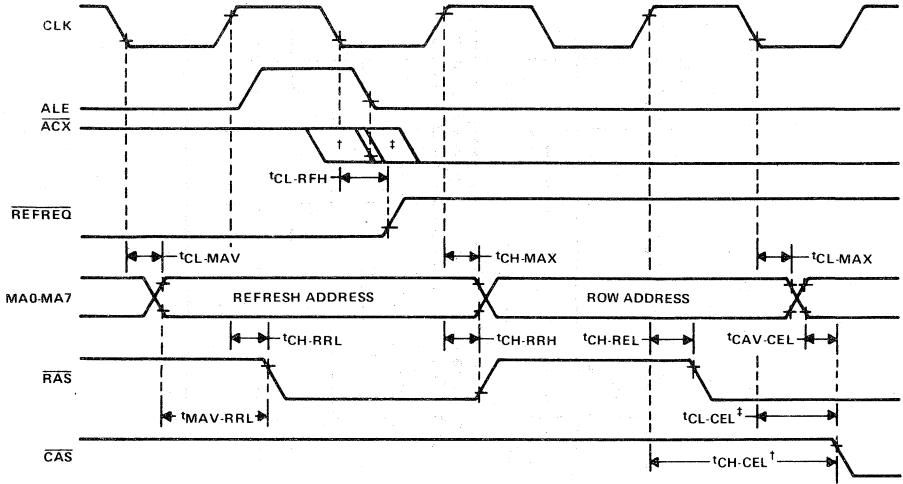

RDY starting high is timed from CLK high (t_{CH-RYH}) for the condition ACX going low while CLK low.

- NOTES: 13. For RDY high transition (during normal access) to be timed from the rising edge of CLK, \overline{ACX} must occur t_{CL-ACL} after the falling edge of CLK.
14. For \overline{ACX} prior to the falling edge of CLK by t_{ACL-CL} , the RDY high transition will be $t_{ACL-RYH}$.
15. t_{ACL-CL} is a limiting parameter for control of RDY to be dependent upon \overline{ACX} low.
16. During the interval for $t_{ACL-CL} < \text{MINIMUM}$ to $t_{ACL-CL} > \text{MINIMUM}$, the control of RDY may vary between the rising clock edge or falling edge of \overline{ACX} .

SN74ALS6310, SN74ALS6311 STATIC COLUMN AND PAGE-MODE ACCESS DETECTORS

D3020, JUNE 1987—REVISED APRIL 1988

- Detects Present Row Equal to Last Row Address
- High-Performance Compare:
 'ALS6310 CLK to HSA = 18 ns
 'ALS6311 Address to HSA = 14 ns
- Compatible with 16K to 1M DRAMs
- Easily Interfaced with Microprocessor and Memory Timing Controller
- Dependable Texas Instruments Quality and Reliability

description

The 'ALS6310 and 'ALS6311 are high-performance address comparators designed for implementing static column and page-mode access cycles.

When interfaced with the memory timing controller, these devices will detect if the present row being accessed is the same as the last row accessed. This is the fundamental requirement for implementing static column decode or page-mode access cycles.

The 'ALS6310 features two 14-bit registers and a high-speed address comparator. The first register is used to save the present row address while the second register is used to save the previous row address. On the high-to-low transition of CLK, the first register loads the new row address present on A0-A9. At the same time, the second register loads the address previously saved in the first register. The two row addresses are then compared. The High-Speed Access outputs (HSA and HSA) will signal if the two addresses are equal.

The B0-B1 inputs are provided to monitor access cycles to different banks of memory. When used in conjunction with the 'ALS2968 and 'ALS6302 series DRAM controllers, the 'ALS6310 and 'ALS6311 can monitor up to 16 banks of memory. The CLK input on the 'ALS6310 can typically be interfaced with the microprocessor's Address Latch Enable (ALE) or Address Strobe (AS) outputs. This configuration simplifies the memory timing controller interface. Refer to the typical application diagram for further information.

The 'ALS6311 features one 14-bit register feeding a high-speed address comparator. This architecture offers a faster address match time, but does require the memory timing controller to generate the CLK input. Typically, the 14-bit register would only be updated if there was a change in row or bank address. Refer to the application diagram for further information.

More information on static column DRAM access can be found in the Texas Instruments application report *System Solutions for Static Column Decode*.

The SN74ALS6310 and SN74ALS6311 are characterized for operation from 0°C to 70°C.

description

These 10-bit buffers and bus drivers are specifically designed to drive the capacitive input characteristics of MOS DRAMs. They provide high-performance bus interface for wide data paths or buses carrying parity.

The three-state control gate is a 2-input positive NOR gate so if either $\overline{G1}$ or $\overline{G2}$ is high, all 10 outputs are in the high-impedance state.

The SN74BCT2827A provides true data and the SN74BCT2828A provides inverted data at the outputs.

These devices are characterized for operation from 0°C to 70°C.

ADVANCE INFORMATION documents contain information on new products in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

D2977, APRIL 1987—REVISED MAY 1988

- BICMOS Design Substantially Reduces Standby Current
- Functionally Equivalent to AM29827, AM29828, SN74ALS29827, and SN74ALS29828
- 3-State Outputs Drive Bus Lines or Buffer Memory Address Registers
- P-N-P Inputs Reduce DC Loading
- Data Flow-Thru Pinout (All Inputs on Opposite Side from Outputs)
- Power-Up High-Impedance State
- Package Options Include Plastic Chip Carriers, in Addition to Plastic and Ceramic DIPs
- BiCMOS Process with TTL Inputs and Outputs
- Dependable Texas Instruments Quality and Reliability

description

These 10-bit buffers and bus drivers provide high-performance bus interface for wide data paths or buses carrying parity.

The 3-state control gate is a 2-input positive NOR gate so if either $\bar{G}1$ or $G2$ is high, all 10 outputs are in the high-impedance state. The outputs are also in the high-impedance state during power-up and power-down conditions. The outputs remain in the high-impedance state while the device is powered-down.

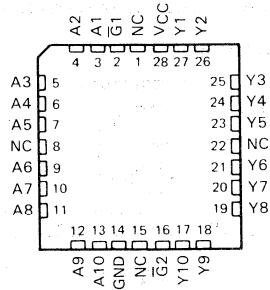

The SN74BCT29827A provides true data and the SN74BCT29828A provides inverted data at the outputs.

The SN74BCT29827A and SN74BCT29828A are characterized for operation from 0°C to 70°C.

SMJ4161 65,536-BIT MULTI-PORT VIDEO RAM

JUNE 1985 — REVISED FEBRUARY 1988

- MIL-STD-883C High-Reliability Processed and -55°C to 100°C (S Designator) Temperature Range, 20-Pin 300-Mil Ceramic Sidebrazed Package
- Dual Accessibility — One Port Sequential Access, One Port Random Access
- Four Cascaded 64-Bit Serial Shift Registers for Sequential Access Applications
- Designed for both Video and Non-Video Applications
- Fast Serial Port . . . Can Be Configured for Video Data Rates in Excess of 150 MHz
- $\overline{TR}/\overline{QE}$ as Output Enable Allows Direct Connection of D, Q, and Address Lines to Simplify System Design
- Random-Access Port Looks Exactly Like a SMJ4164
- Separate Serial In and Serial Out to Allow Simultaneous Shift In and Out
- 65,536 × 1 Organization
- Supported by TI's Video System Controller (VSC)
- Maximum Access Time from \overline{RAS} Less Than 150 ns
- Minimum Cycle Time (Read or Write) Less Than 240 ns
- Long Refresh Period . . . 4 ms
- Low Refresh Overhead Time . . . As Low As 1.7% of Total Refresh Period
- All Inputs, Outputs, Clocks Fully TTL Compatible
- 3-State Unlatched Outputs for Both Random and Serial Access
- Common I/O Capability with Early Write Feature
- Page-Mode Operation for Faster Access
- Low Power Dissipation (SMJ4161-15)
 - Operating . . . 250 mW (Typical)
 - Standby . . . 80 mW (Typical)
- New SMOS (Scaled-MOS) N-Channel Technology
- \overline{SOE} Simplifies Multiplexing of Serial Data Streams

SMJ4161
65,536-BIT MULTIPOINT VIDEO RAM

description

The SMJ4161 is a high-speed, dual-access 65,536-bit dynamic random-access memory. The random-access port makes the memory look like it is organized as 65,536 words of one bit each, like the SMJ4164. The sequential access port is interfaced to an internal 256-bit dynamic shift register organized as four cascaded 64-bit shift registers which makes the memory look like it is organized as up to 256 words of up to 256 bits each which are accessed serially. One, two, three, or four 64-bit shift registers can be sequentially read out after a transfer cycle, depending on a two-bit code applied to the two most significant column address inputs. The SMJ4161 employs state-of-the-art SMOS (Scaled-MOS) N-channel double-level polysilicon gate technology for very high performance combined with low cost and improved reliability.

The SMJ4161 features full asynchronous dual access capability except when transferring data between the shift register and the memory array.

Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power. Note that the transfer of a row of data from the memory array to the shift register also refreshes that row.

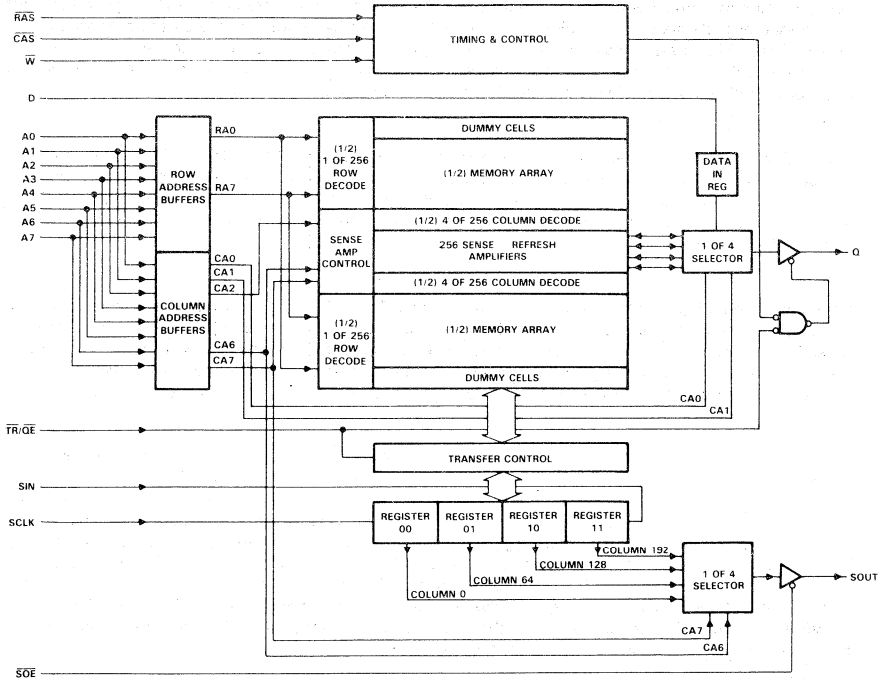

All inputs and outputs, including clocks, are compatible with Series 54 TTL. All address lines and data in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The SMJ4161 is offered in a 20-pin ceramic dual-in-line package. It is guaranteed for operation from $T_A = -55^\circ\text{C}$ to $T_C = 100^\circ\text{C}$. The dual-in-line package is designed for insertion in mounting-hole rows on 7,62-mm (300-mil) centers.

random access address space to sequential address space mapping

The SMJ4161 is designed with each row divided into four, 64-column sections (see functional block diagram). The first column section to be shifted out is selected by the two most significant column address bits. If the two bits represent binary 00, then one to four registers can be shifted out in order. If the two bits represent binary 01, then only 1 to 3 (the most significant) registers can be shifted out in order. If the two bits represent binary 10, then one to two of the most significant registers can be shifted out in order. Finally, if the two bits represent 11, only the most significant registers can be shifted out. All registers are shifted out with the least significant bit (bit 0) first and the most significant bit (bit 63) last. Note that if the two column address bits equal 00 during the last register transfer cycle (TR/OE at logic level 0 as $\overline{\text{RAS}}$ falls) a total of 256 bits can be sequentially read out.

functional block diagram

random-access operation

$\overline{TR/QE}$

The $\overline{TR/QE}$ pin has two functions. First, it selects either register transfer or random-access operation as \overline{RAS} falls, and second, if this is a random-access operation, it functions as an output enable after \overline{CAS} falls.

To use the SMJ4161 in the random-access mode, $\overline{TR/QE}$ must be high as \overline{RAS} falls. Holding $\overline{TR/QE}$ high as \overline{RAS} falls keeps the 256 elements of the shift registers disconnected from the corresponding 256 bit lines of the memory array. If data is to be transferred, the shift registers must be connected to the bit lines. Holding $\overline{TR/QE}$ low as \overline{RAS} falls enables the 256 switches that connect the shift register to the bit lines and indicates that a transfer will occur between the shift registers and one of the memory rows.

During random-access operation, once \overline{CAS} has been pulled low, $\overline{TR/QE}$ controls when the data will appear at the Q output (if this is a read cycle). Whenever $\overline{TR/QE}$ is held high during random-access operation, the Q output will be in the high-impedance state. This feature removes the possibility of an overlap between data on the address lines and data appearing on the Q output, making it possible to connect the address lines to the Q and D lines (use of this organization prohibits the use of the early write cycle).

address (A0 through A7)

Sixteen address bits are required to decode 1 of 65,536 storage cell locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the eight column-address bits are set up on pins A0 through A7 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state for the entire cycle permitting common I/O operation.

data in (D)

Data is written during a write or read-modify-write cycle. The falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. This latch can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal.

data out (Q)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 54 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state as long as $\overline{\text{CAS}}$ or $\overline{\text{TR/}\overline{\text{OE}}}$ is held high. Data will not appear on the output until after both $\overline{\text{CAS}}$ and $\overline{\text{TR/}\overline{\text{OE}}}$ have been brought low. In a read cycle, the guaranteed maximum output enable access time is valid only if t_{CQE} is greater than $t_{\text{CQE MAX}}$ and t_{RLCL} is greater than $t_{\text{RLCL MAX}}$. Likewise, $t_{\text{a(C) MAX}}$ is valid only if t_{RLCL} is greater than $t_{\text{RLCL MAX}}$. Once the output is valid, it will remain valid while $\overline{\text{CAS}}$ and $\overline{\text{TR/}\overline{\text{OE}}}$ are both low; $\overline{\text{CAS}}$ or $\overline{\text{TR/}\overline{\text{OE}}}$ going high will return the output to a high-impedance state. In an early write cycle, the output is always in a high-impedance state. In a delayed write or read-modify-write cycle, the output will follow the sequence for the read cycle. In a register transfer cycle, the output will always be in a high-impedance state.

refresh

A refresh operation must be performed at least every four milliseconds to retain data. Since the output buffer is in high-impedance state unless $\overline{\text{CAS}}$ is applied, the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 256 row addresses (A0 through A7) with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power.

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address strobing successive column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. To extend beyond the 256 column locations on a single RAM, the row address and $\overline{\text{RAS}}$ are applied to multiple 64K RAMs. $\overline{\text{CAS}}$ is then decoded to select the proper RAM.

power up

After power up, the power supply must remain at its steady-state value for 1 ms. In addition, $\overline{\text{RAS}}$ must remain high for 100 μs immediately prior to initialization. Initialization consists of performing eight $\overline{\text{RAS}}$ cycles before proper device operation is achieved.

sequential access operation

$\overline{\text{TR}}/\overline{\text{QE}}$

Memory transfer operations involving parallel use of the shift register are first indicated by bringing $\overline{\text{TR}}/\overline{\text{QE}}$ low before $\overline{\text{RAS}}$ falls low. This enables the switches connecting the 256 elements of the shift register to the 256 bit lines of the memory array. The $\overline{\text{W}}$ line determines whether the data will be transferred from or to the shift registers.

write enable ($\overline{\text{W}}$)

In the sequential access mode, $\overline{\text{W}}$ determines whether a transfer will occur from the shift registers to the memory array, or from the memory array to the shift registers. To transfer from the shift registers to the memory array, $\overline{\text{W}}$ is held low as $\overline{\text{RAS}}$ falls, and, to transfer from the memory array to the shift registers, $\overline{\text{W}}$ is held high as $\overline{\text{RAS}}$ falls. Thus, reads and writes are always with respect to the memory array. The write setup and hold times are referenced to the falling edge of $\overline{\text{RAS}}$ for this mode of operation.

row address (A0 through A7)

Eight address bits are required to select one of the 256 possible rows involved in the transfer of data to or from the shift registers. A0-A7, $\overline{\text{W}}$, and $\overline{\text{TR}}/\overline{\text{QE}}$ are latched on the falling edge of $\overline{\text{RAS}}$.

register column address (A7, A6)

To select one of the four shift registers (transfer from memory to register only), the appropriate 2-bit column address (A7, A6) must be valid when $\overline{\text{CAS}}$ falls. However, the $\overline{\text{CAS}}$ and register address signals need not be supplied every cycle, only when it is desired to change or select a new register.

SCLK

Data is shifted in and out on the rising edge of SCLK. This makes it possible to view the shift registers as though they were made of 256 rising edge D flip-flops connected D to Q. The SMJ4161 is designed to work with a wide range duty cycle clock to simplify system design. Note that data will appear at the SOUT pin not only on the rising edge of SCLK but also after an access time of $t_{a}(\text{RSO})$ from $\overline{\text{RAS}}$ high during a parallel load of the shift registers.

SIN and SOUT

Data is shifted in through the SIN pin and is shifted out through the SOUT pin. The SMJ4161 is designed such that it requires 3 ns hold time on SIN as SCLK rises. SOUT is guaranteed not to change for at least 6 ns after SCLK rises. These features make it possible to easily connect SMJ4161s together, to allow SOUT to be connected to SIN, and to give external circuitry a full SCLK cycle time to allow manipulation of the serial data. If SOUT is connected to SIN, the SCLK cycle time must include $t_{su}(\text{SI})$. When loading data into the shift register from the serial input in preparation for a shift-register-to-memory transfer operation, the serial clock must be clocked an even number of times. To guarantee proper serial clock sequence after power up, a transfer cycle must be initiated before a serial data stream is applied at SIN.

SOE

The serial output enable pin controls the impedance of the serial output, allowing multiplexing of more than one bank of SMJ4161 memories into the same external video circuitry. When $\overline{\text{SOE}}$ is at a logic low level, SOUT will be enabled and the proper data read out. When $\overline{\text{SOE}}$ is at a logic high level, SOUT will be disabled and be in the high-impedance state.

refresh

The shift registers are also dynamic storage elements. The data held in the registers will be lost unless SCLK goes high to shift the data one bit position, a transfer write operation is invoked, or the data is reloaded from the memory array. See specifications for maximum register data retention times.

SMJ4161
65,536-BIT MULTIPORT VIDEO RAM

absolute maximum ratings over operating temperature range (unless otherwise noted)†

Voltage on any pin except V _{DD} and data out (see Note 1)	-1.5 V to 10 V
Voltage on V _{DD} supply and data out with respect to V _{SS}	-1 V to 6 V
Short circuit output current	50 mA
Power dissipation	1 W
Minimum operating free-air temperature	-55 °C
Operating case temperature	100 °C
Storage temperature range	-65 °C to 150 °C

†Stress beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: All voltage values in this data sheet are with respect to V_{SS}.

recommended operating conditions

	MIN	NOM	MAX	UNIT
V _{DD} Supply voltage	4.75	5	5.25	V
V _{SS} Supply voltage		0		V
V _{IH} High-level input voltage	2.4		V _{DD} +0.3	V
V _{IL} Low-level input voltage (see Notes 2 and 3)	-0.6		0.8	V
T _A Operating free-air temperature	-55			°C
T _C Operating case temperature			100	°C

NOTES: 2. The algebraic convention, where the more negative (less positive) limit is designated as maximum, is used in this data sheet for logic voltage levels only.

3. Due to input protection circuitry, the applied voltage may begin to clamp at -0.6 V; test conditions must comprehend this occurrence.

electrical characteristics over full range of recommended operating conditions (unless otherwise noted)

Continued next page.

NOTES: 4. $t_{c(SCLK)}$ min is tested by connecting SIN to SOUT and test conditions include $t_{su(SI)}$; see paragraph entitled SIN and SOUT on page 5.

5. Timing measurements are made at the 10% and 90% points of input and clock transitions. In addition, V_{IL} max and V_{IH} min must be met at the 10% and 90% points.

6. System transition times (rise and fall) for \overline{RAS} , \overline{CAS} , and SCLK are to be a minimum of 3 ns and a maximum of 50 ns.

[†]All cycle times assume $t_f = 5$ ns except $t_{c(SCLK)}$ which assumes $t_f = 3$ ns.

[‡]Multiple transfer write cycles require separation by either a 1- μ s \overline{RAS} -precharge interval or any other active \overline{RAS} -cycle.

[§]Page-mode only.

[¶]In a read-modify-write cycle, t_{CLWL} and $t_{su(WCH)}$ must be observed. Depending on the user's transition times, this may require additional \overline{CAS} low time ($t_w(CL)$). This applies to page-mode read-modify-write also.

[#]In a read-modify-write cycle, t_{RLWL} and $t_{su(WRH)}$ must be observed. Depending on the user's transition times, this may require additional \overline{RAS} low time ($t_w(RL)$).

^{||}This parameter is guaranteed but not tested.

$t_{rf}(MA)$ Refresh time interval, memory array	t_{REF1}		4		4	ms
$t_{rf}(SR)$ Refresh time interval, shift register [§]	t_{REF2}		50,000		50,000	ns

NOTE 5: Timing measurements are made at the 10% and 90% points of input and clock transitions. In addition, V_{IL} max and V_{IH} min must be met at the 10% and 90% points.

[†] This parameter is guaranteed but not tested.

[‡] SCLK may be high or low during $t_{w}(RL)$, but there cannot be any positive edge transitions on SCLK for a minimum of 10 ns prior to \overline{RAS} going low with $\overline{TR}/\overline{QE}$ low (i.e., before a transfer cycle).

[§] See "refresh" on page 5.

PARAMETER MEASUREMENT INFORMATION

FIGURE 1. EQUIVALENT LOAD CIRCUIT

early write cycle timing

write cycle timing

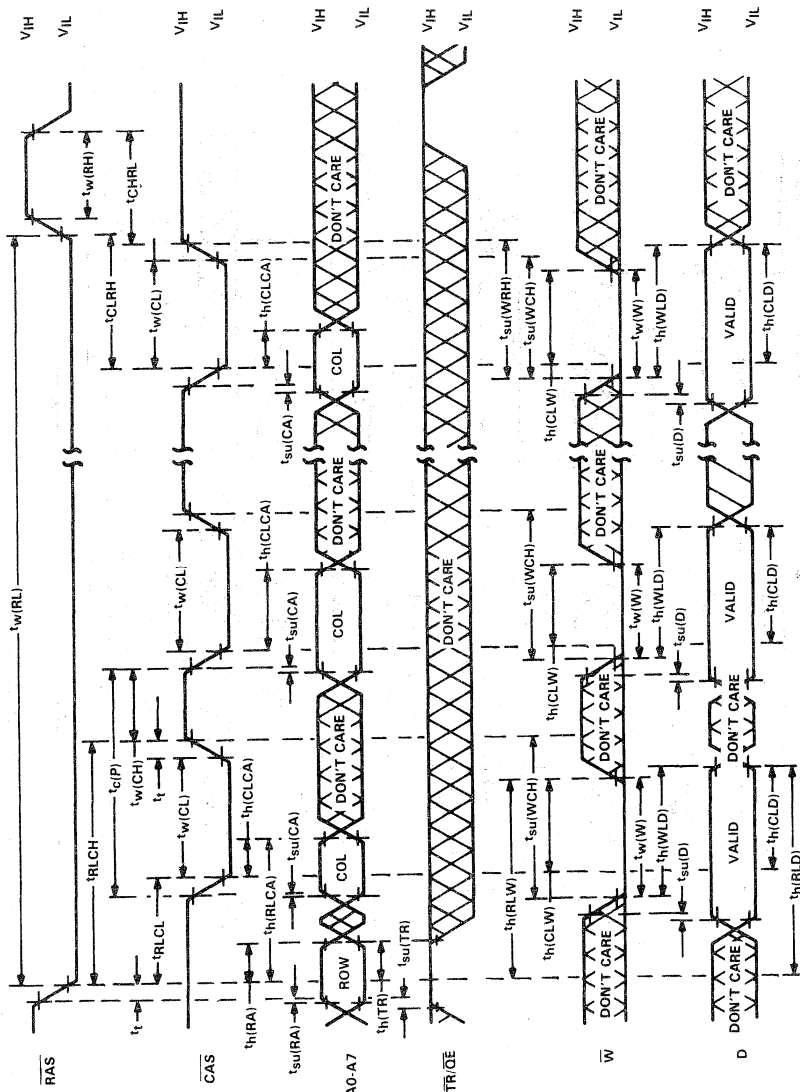

[†]The enable time (t_{en}) for a write cycle is equal in duration to the access time from \overline{CAS} ($t_{a}(C)$) in a read cycle; but the active levels at the output are invalid.

8

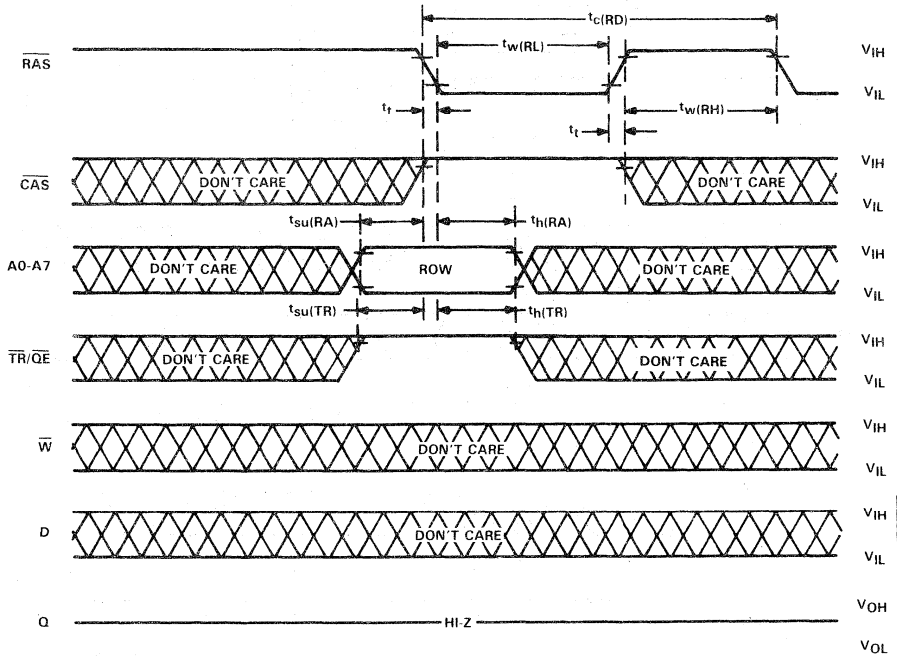

Military Products

page-mode write cycle timing

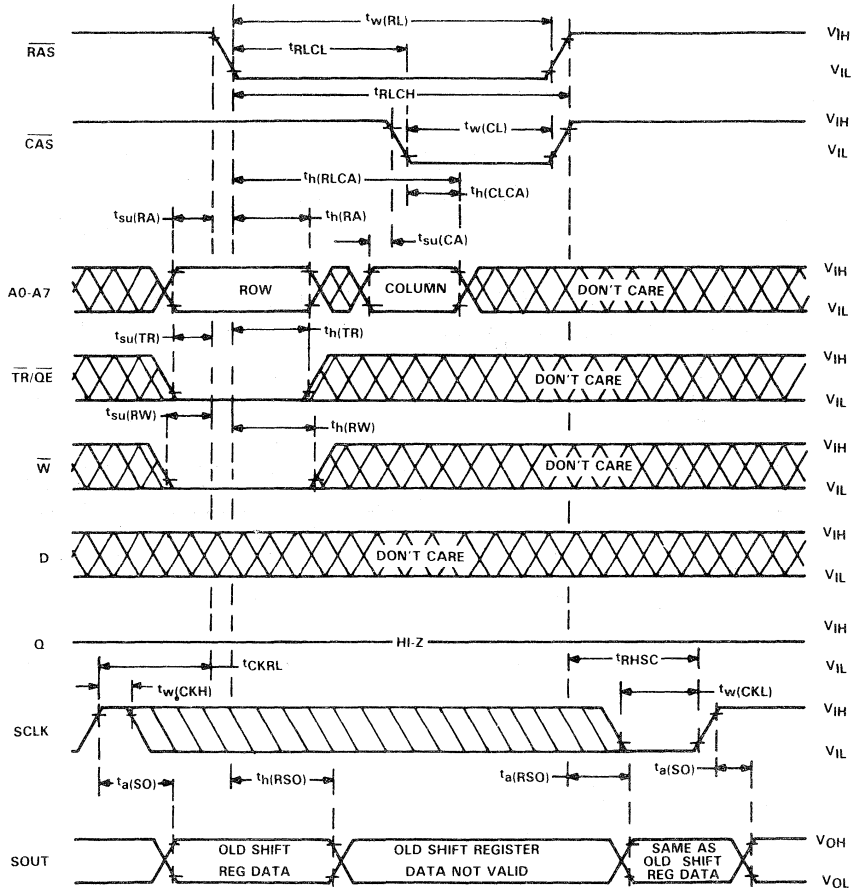

NOTES: 7. Timing is for non-multiplexed D, O, and Address lines.
9. A read cycle or a read-modify-write cycle can be intermixed with write cycles as long as the read and read-modify-write timing specifications are not violated.

RAS-only refresh timing

8
Military Products

shift register to memory timing

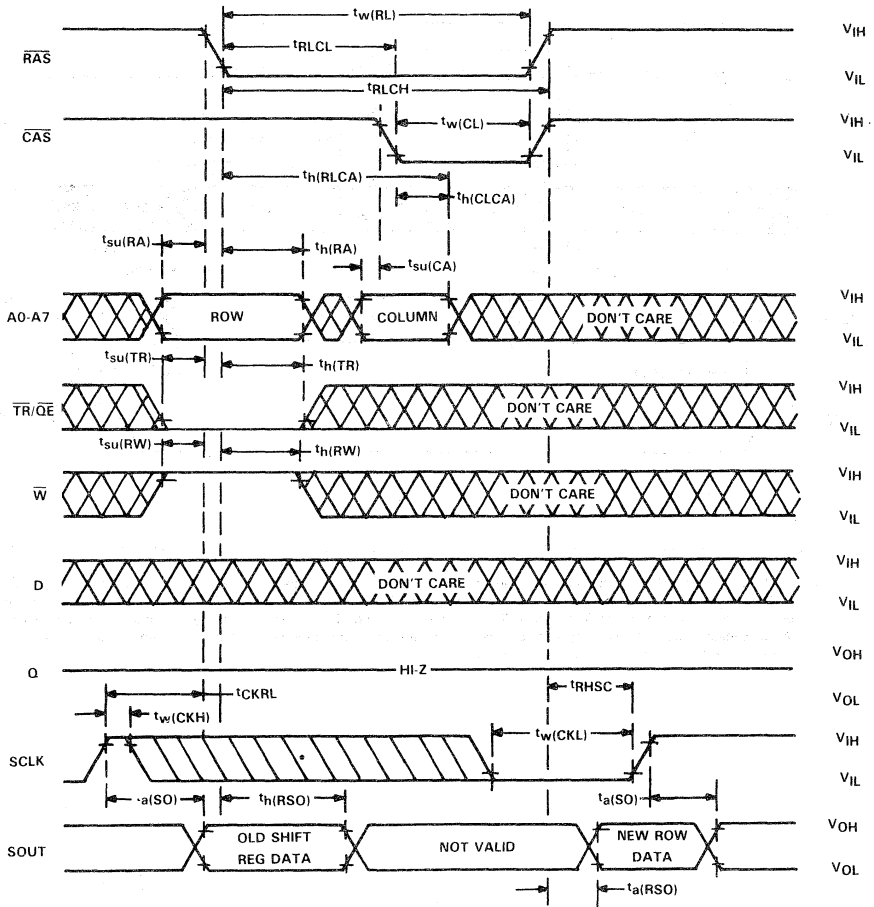

- NOTES: 11. The shift register to memory cycle is used to transfer data from the shift register to the memory array. Every one of the 256 locations in the shift register is written into the 256 columns of the selected row. Note that the data that was in the shift register may have resulted either from a serial shift in or from a parallel load of the shift register from one of the memory rows.
12. \overline{SOE} assumed low.
13. $SCLK$ may be high or low during $t_w(RL)$.
14. Multiple transfer write cycles require either a 1- μs \overline{RAS} -precharge interval or any other active \overline{RAS} cycle before initiation of the transfer write cycles and separation between any two consecutive transfer write cycles.

8

Military Products

memory to shift register timing

NOTES: 12. \overline{SOE} assumed low.

13. SCLK may be high or low during $t_w(RL)$.

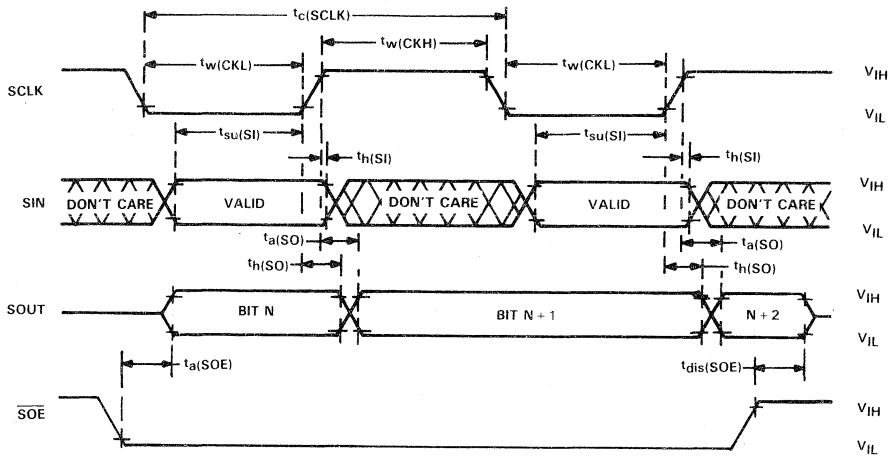

14. Multiple transfer write cycles require either a 500-ns \overline{RAS} -precharge interval or any other active \overline{RAS} cycle before initiation of the transfer write cycles and separation between any two consecutive transfer write cycles.

15. The memory to shift register cycle is used to load the shift register in parallel from the memory array. Every one of the 256 locations in the shift register are written into from the 256 columns of the selected row. Note that the data that is loaded into the shift register may be either shifted out or written back into another row.

8
Military Products

serial data shift timing

8

NOTES: 4. $t_c(\text{SCLK})$ min is tested by connecting SIN to SOUT and test conditions include $t_{su}(\text{SI})$; see paragraph entitled SIN and SOUT on page 5.

16. While shifting data through the serial shift register, the state of $\overline{\text{TR}}/\overline{\text{OE}}$ is a don't care as long as $\overline{\text{TR}}/\overline{\text{OE}}$ is held high when $\overline{\text{RAS}}$ goes low and $t_{su}(\text{TR})$ and $t_h(\text{TR})$ timings are observed. This requirement avoids the initiation of a register-to-memory or memory-to-register data transfer operation. The serial data transfer cycle is used to shift data in and/or out of the shift register.
17. When loading data into the shift register from the serial input in preparation for a shift-register-to-memory transfer operation, the serial clock must be clocked an even number of times.

shift register to memory multiple timing

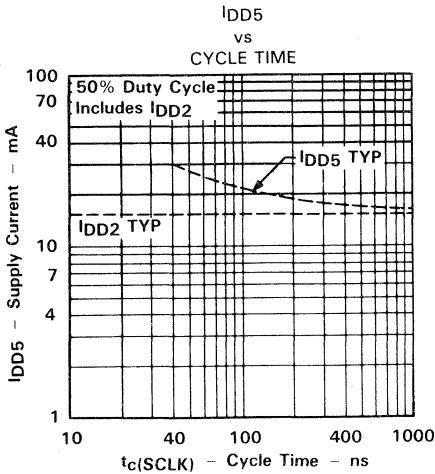

t_{CAS} and register address need not be supplied every cycle, only when it is desired to change or select a new register length.

NOTES: 12. t_{SOE} assumed low.

18. The shift register to memory multiple cycle is used to write the shift register data to more than one row of the memory array. An application of this could be clearing all memory. To do this, the SIN line would be held at 0 to fill all locations in the shift register with 0s. The shift register would then be written into all 256 rows of the memory array in 256 cycles. The random output port Q will be in a high-impedance state as long as register transfer cycles are selected.

19. $SCLK$ is a don't care except that no positive transitions on $SCLK$ can occur for a period equal to t_{CKRL} prior to \overline{RAS} falling with $\overline{TR}/\overline{OE}$ low.

description

The SMJ4164 is a Military high-speed, 65,536-bit, dynamic random-access memory, organized as 65,536 words of one bit each. It employs state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon gate technology for very high performance combined with low cost and improved reliability.

The SMJ4164 features $\overline{\text{RAS}}$ access times of 120 ns, 150 ns, and 200 ns maximum. Power dissipation is 125 mW typical operating and 17.5 mW typical standby.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

POST OFFICE BOX 225012 • DALLAS, TEXAS 75265

Copyright © 1985, Texas Instruments Incorporated

SMJ4164

65,536-BIT DYNAMIC RANDOM-ACCESS MEMORY

Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power.

All inputs and outputs, including clocks, are compatible with Series 54/74 TTL. All address lines and data in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility. Pin 1 has no internal connection to allow compatibility with other 64K RAMs that use this pin for an additional function.

The SMJ4164 is offered in a 16-pin dual-in-line ceramic sidebrazed package (JD suffix) and in a leadless ceramic chip carrier package (FG suffix). The JD package is designed for insertion in mounting-hole rows on 7.62-mm (300-mil) centers, whereas the FG package is intended for surface mounting on solder lands on 1.27-mm (0.050-inch) centers. The FG package is a three-layer, 18-pad, rectangular ceramic chip carrier with dimensions of 7.37 × 10.8 × 1.65 mm (0.290 × 0.425 × 0.065 inches).

operation

address (A0 through A7)

Sixteen address bits are required to decode 1 of 65,536 storage cell locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the eight column-address bits are set up on pins A0 through A7 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data-out will remain in the high-impedance state for the entire cycle, permitting common I/O operation.

data in (D)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. This latch can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal.

data out (Q)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 54/74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output goes active after the access time interval $t_{a(C)}$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{a(R)}$ is satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ is low; $\overline{\text{CAS}}$ going high returns it to a high-impedance state. In an early write cycle, the output is always in the high-impedance state. In a delayed-write or read-modify-write cycle, the output will follow the sequence for the read cycle.

refresh

A refresh operation must be performed at least every four milliseconds to retain data. Since the output buffer is in the high-impedance state unless $\overline{\text{CAS}}$ is applied, the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 256 row addresses (A0 through A7) with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power.

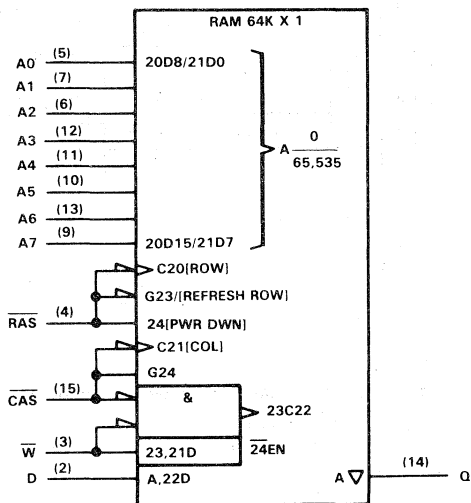

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing successive column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. To extend beyond the 256 column locations on a single RAM, the row address and RAS are applied to multiple 64K RAMs. CAS is then decoded to select the proper RAM.

power up

After power up, the power supply must remain at its steady-state value for 1 ms. In addition, $\overline{\text{RAS}}$ must remain high for 100 μs immediately prior to initialization. Initialization consists of performing eight RAS cycles before proper device operation is achieved.

logic symbol†

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12. Pin numbers shown are for the dual-in-line package.

recommended operating conditions

		S VERSION			L VERSION			UNIT
		MIN	NOM	MAX	MIN	NOM	MAX	
V _{DD}	Supply voltage	4.5	5	5.5	4.5	5	5.5	V

description

The SMJ4416 is a Military high-speed, 65,536-bit, dynamic random-access memory organized as 16,384 words of 4 bits each. It employs state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon gate technology for very high performance combined with low cost and improved reliability.

The SMJ4416 features \bar{RAS} access times to 150 ns maximum. Power dissipation is 200 mW typical operating, 17.5 mW typical standby.

SMOS technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{DD} peaks have been reduced to 60 mA typical, and a -1 V input voltage undershoot can be tolerated, minimizing system noise considerations. Input clamp diodes are used to ease system design.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

SMJ4416

16,384-WORD BY 4-BIT DYNAMIC RAM

Refresh period is extended to 4 milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power.

All inputs and outputs, including clocks, are compatible with Series 54/74 TTL. All address lines and data in are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The SMJ4416 is offered in 18-pin 300-mil ceramic side-braze dual-in-line package. It is available in -55°C to 100°C and 0°C to 70°C temperature ranges. Dual-in-line packages are designed for insertion in mounting-hole rows on 7,62 mm (300-mil) centers.

operation

address (A0 through A7)

Fourteen address bits are required to decode 1 of 16,384 storage locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the six column-address bits are set up on pins A1 through A6 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state allowing a write cycle with $\overline{\text{G}}$ grounded.

data in (DQ1 through DQ4)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latches. These latches can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal. In delayed write or read-modify-write, $\overline{\text{G}}$ must be high to bring the output buffers to high impedance prior to impressing data on the I/O lines.

data out (DQ1 through DQ4)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 54/74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output goes active after the access time interval $t_{a(C)}$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{a(R)}$ and $t_{a(E)}$ are satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ and $\overline{\text{G}}$ are low. $\overline{\text{CAS}}$ or $\overline{\text{G}}$ going high returns it to a high-impedance state. In an early write cycle, the output is always in the high-impedance state. In a delayed-write or read-modify-write cycle, the output must be put in the high-impedance state prior to applying data to the DQ input. This is accomplished by bringing $\overline{\text{G}}$ high prior to applying data, thus satisfying t_{GHD} .

output enable ($\overline{\text{G}}$)

The $\overline{\text{G}}$ signal controls the impedance of the output buffers. When $\overline{\text{G}}$ is high, the buffers will remain in the high-impedance state. Bringing $\overline{\text{G}}$ low during a normal cycle will activate the output buffers, putting them in the low-impedance state. It is necessary for both $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ to be brought low for the output buffers to go into the low-impedance state. Once in the low-impedance state, they will remain in the low-impedance state until $\overline{\text{G}}$ or $\overline{\text{CAS}}$ is brought high.

refresh

A refresh operation must be performed at least every four milliseconds to retain data. Since the output buffer is in the high-impedance state unless $\overline{\text{CAS}}$ is applied, the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 256 row addresses (A0 through A7) with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power.

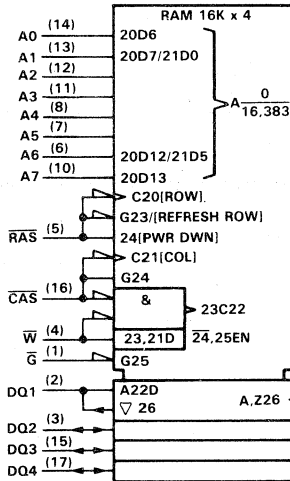

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing successive column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. To extend beyond the 64 column locations on a single RAM, the row address and $\overline{\text{RAS}}$ are applied to multiple $16\text{K} \times 4$ RAMs. $\overline{\text{CAS}}$ is then decoded to select the proper RAM.

power up

After power up, the power supply must remain at its steady-state value for 1 ms. In addition, the $\overline{\text{RAS}}$ input must remain high for $100 \mu\text{s}$ immediately prior to initialization. Initialization consists of performing eight $\overline{\text{RAS}}$ cycles before proper device operation is achieved.

logic symbol†

† This symbol is in accordance with ANSI/IEEE Std. 91-1984 and IEC Publication 617-12. Pin numbers shown are for the dual-in-line package.

refresh

A refresh operation must be performed at least every four milliseconds to retain data. Since the output buffer is in the high-impedance state unless $\overline{\text{CAS}}$ is applied, the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 256 row addresses (A0 through A7) with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power.

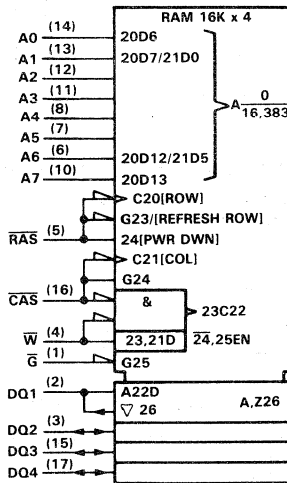

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing successive column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. To extend beyond the 64 column locations on a single RAM, the row address and $\overline{\text{RAS}}$ are applied to multiple 16K x 4 RAMs. $\overline{\text{CAS}}$ is then decoded to select the proper RAM.

power up

After power up, the power supply must remain at its steady-state value for 1 ms. In addition, the $\overline{\text{RAS}}$ input must remain high for 100 μs immediately prior to initialization. Initialization consists of performing eight $\overline{\text{RAS}}$ cycles before proper device operation is achieved.

logic symbol†

†This symbol is in accordance with ANSI/IEEE Std. 91-1984 and IEC Publication 617-12. Pin numbers shown are for the dual-in-line package.

SMJ4256

262,144-BIT DYNAMIC RANDOM-ACCESS MEMORY

NOVEMBER 1985 — REVISED MARCH 1988

- 262,144 × 1 Organization
- Single 5-V Supply
- JEDEC Standardized Pinout
- Upward Pin Compatible with SMJ4164 (64K Dynamic RAM)
- Performance Ranges:

	ACCESS TIME	ACCESS TIME	READ OR WRITE CYCLE (MIN)
	ROW ADDRESS (MAX)	COLUMN ADDRESS (MAX)	
SMJ4256-12	120 ns	65 ns	230 ns
SMJ4256-15	150 ns	80 ns	260 ns
SMJ4256-20	200 ns	100 ns	330 ns

- Long Refresh Period . . . 4 ms (Max)
- Low Refresh Overhead Time . . . As Low As 1.3% of Total Refresh Period
- On-Chip Substrate Bias Generator
- All Inputs, Outputs, and Clocks Fully TTL Compatible
- 3-State Unlatched Output
- Common I/O Capability with "Early Write" Feature
- Power Dissipation as Low As
 - Operating . . . 300 mW (Typ)
 - Standby . . . 12.5 mW (Typ)
- MIL-STD-883C Class B High-Reliability Processing
- RAS-Only Refresh Mode
- Hidden Refresh Mode
- CAS-Before-RAS Refresh Mode
- Full Military DRAM Temperature Range Operation . . . -55°C to 110°C

description

The SMJ4256 is a high-speed, 262,144-bit dynamic random-access memory, organized as 262,144 words of one bit each. It employs state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

The SMJ4256 features maximum RAS access times of 120 ns, 150 ns, or 200 ns. Typical power dissipation is as low as 300 mW operating and 12.5 mW standby.

New SMOS technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{DD} peaks are 125 mA typical, and a -0.5-V input voltage undershoot can be tolerated, minimizing system noise considerations.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

SMJ4256

262,144-BIT DYNAMIC RANDOM-ACCESS MEMORY

All inputs and outputs, including clocks, are compatible with Series 54 TTL. All address and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

The SMJ4256 is offered in 16-pin 300-mil ceramic side-braze dual-in-line and 18-pad ceramic chip carrier packages. It is guaranteed for operation from -55°C to 110°C . The dual-in-line package is designed for insertion in mounting-hole rows on 7,62-mm (300-mil) centers.

operation

address (A0 through A8)

Eighteen address bits are required to decode 1 of 262,144 storage cell locations. Nine row-address bits are set up on pins A0 through A8 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the nine column-address bits are set up on pins A0 through A8 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edge of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state for the entire cycle, permitting common I/O operation.

data in (D)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. This latch can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal.

data out (Q)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 54 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output goes active after the access time interval $t_{a(C)}$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{a(R)}$ is satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ is low; $\overline{\text{CAS}}$ going high returns it to a high-impedance state. In a read-modify-write cycle, the output will follow the sequence for the read cycle.

refresh

A refresh operation must be performed at least once every four milliseconds to retain data. This can be achieved by strobing each of the 256 rows (A0-A7). A normal read or write cycle will refresh all bits in each row that is selected. A $\overline{\text{RAS}}$ -only operation can be used by holding $\overline{\text{CAS}}$ at the high (inactive) level, thus conserving power as the output buffer remains in the high-impedance state.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

The $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is utilized by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ (see parameter $t_{\text{CLR L}}$) and holding it low after $\overline{\text{RAS}}$ falls (see parameter t_{RLCHR}). For successive $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh cycles, $\overline{\text{CAS}}$ can remain low while cycling $\overline{\text{RAS}}$. The external address is ignored and the refresh address is generated internally.

hidden refresh

Hidden refresh may be performed while maintaining valid data at the output pin. This is accomplished by holding $\overline{\text{CAS}}$ at V_{IL} after a read operation and cycling $\overline{\text{RAS}}$ after a specified precharge period, similar to a "RAS-only" refresh cycle. The external address is also ignored during the hidden refresh cycles.

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing random column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. The maximum number of columns that can be addressed is determined by $t_{W(RL)}$, the maximum $\overline{\text{RAS}}$ low pulse duration.

power-up

To achieve proper device operation, an initial pause of 200 μs is required after power up followed by a minimum of eight initialization cycles.

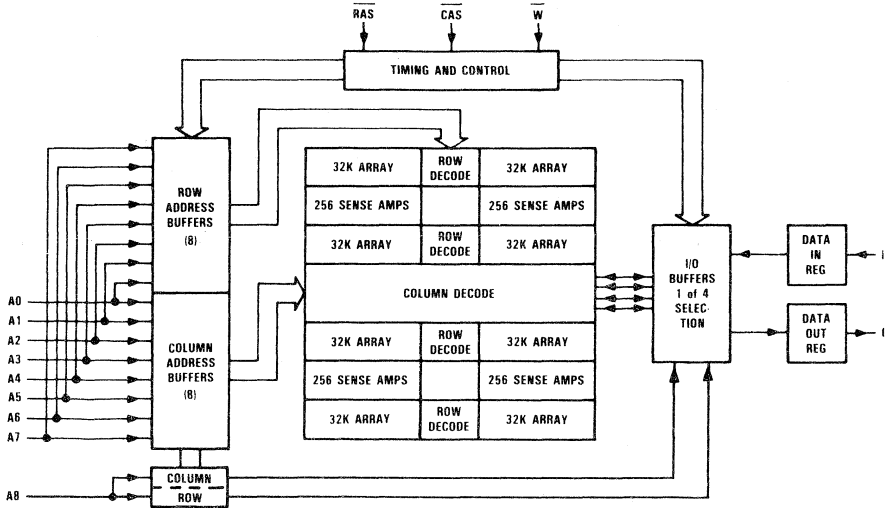

logic symbol†

description

The SMJ4461 is a high-speed dual-ported 65,536 × 4 bit dynamic random-access memory with on-chip data registers. The two ports are the random-access port and the sequential-access port. The random-access port makes the memory appear to be organized as 65,536 words of four bits each, similar to the

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

SM/SMJ4461
262,144-BIT MULTI-PORT VIDEO RAM

SMJ4464. The sequential-access port is interfaced to four internal 256-bit dynamic data registers which make the memory appear to be organized as 256 four-bit words of up to 256 bits each which are accessed serially.

The 256K Multiport Video RAM employs state-of-the-art scaled NMOS, double-level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

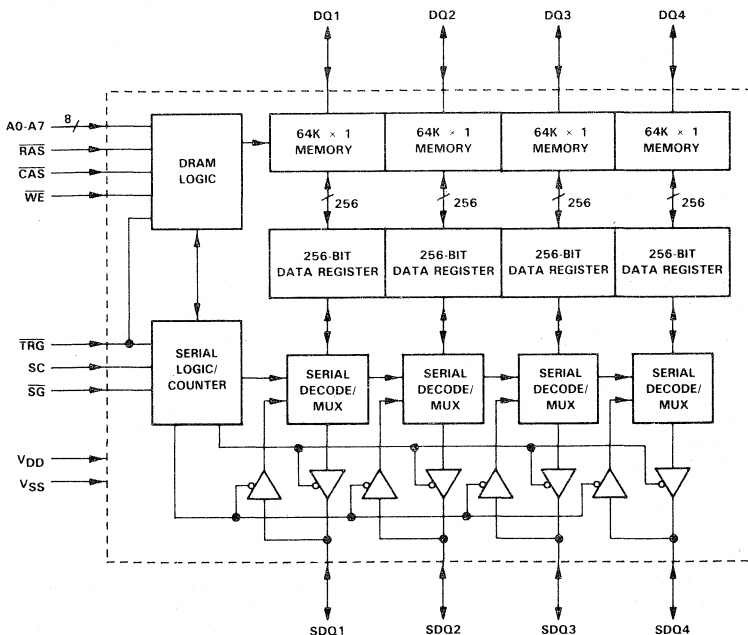

The SMJ4461 features full asynchronous dual-port accessibility except when transferring data between the data register and the random-access memory.

The refresh period is four milliseconds, and during this period each of the 256 rows must be strobed with $\overline{\text{RAS}}$ in order to retain data. $\overline{\text{CAS}}$ can remain high during the refresh sequence to conserve power. Note that the transfer of a row of data from the memory array to the data register also refreshes that particular row. $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ and hidden refresh modes are also available.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address lines and data in are latched on-chip to simplify system design. All data outs are unlatched to allow greater system flexibility.

The 256K Multiport Video RAM is offered in a 24-pin dual-in-line ceramic package and is guaranteed for operation from -55°C to 110°C . Packages are designed for insertion in mounting-hole rows on 10, 16-mm (400-mil) centers.

functional block diagram

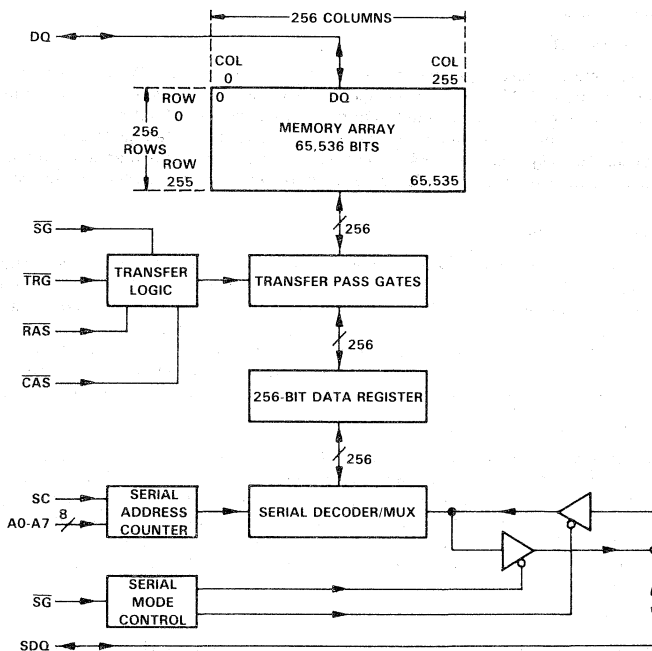

8
Military Products

random port to serial port interface

The 256K Multiport Video RAM consists of a 64K × 4 DRAM port and a 256 × 4 serial port. Each of the four random (DRAM) I/Os is interfaced to a 256-bit data register, which can be loaded with 256 bits in parallel from any row in that I/O channel's memory and then read out sequentially, starting from one of 256 selectable locations along the data register. Conversely, each of the four data registers can be loaded serially with data from the serial input (SD) and subsequently transferred, 256 bits in parallel, into any row of memory for each respective DRAM I/O channel.

block diagram showing one random and serial interface

random-access address space to sequential-address space mapping

The 256 bits in each of the four data registers correspond to the 256 column locations of each of the four random I/Os. Data can be read out of the registers starting at any of the 256 data register bit locations.

SM/SMJ4461 262,144-BIT MULTIPOINT VIDEO RAM

This tap location is selected by addresses A7 through A0 on the falling edge of $\overline{\text{CAS}}$ during a transfer cycle between the memory array and the data registers. All registers are read out starting from the selected tap point proceeding from the least-significant bits to the most-significant bits. The four data registers are configured as circular data registers when reading their contents to the serial outputs. After the most-significant bit (bit 255) is read out of each register, the next bit read will be bit 00 (see explanation under section entitled "serial data input/output").

Note that if column address bits A7 through A0 equal 00 during the last memory-to-register transfer cycle, a total of 256 bits can be sequentially read out of each of the four data registers starting from bit position 00.

operation

random-access operation

transfer register select ($\overline{\text{TRG}}$)

The $\overline{\text{TRG}}$ selects either register transfer or random-access operation as $\overline{\text{RAS}}$ falls. To use the SMJ4461 in random-access mode, $\overline{\text{TRG}}$ must be held high as $\overline{\text{RAS}}$ falls. This causes the 256 storage elements of each data register to remain disconnected from the corresponding 256 bit lines of the memory array. If serial data is to be written in or read out of the data registers, the data registers must be disconnected from the bit lines. Holding TRG low as RAS falls enables the 256 switches that connect the data registers to the bit lines and indicates that a transfer will occur between the data registers and the selected memory row.

random output enable ($\overline{\text{TRG}}$)

During random-access operations, $\overline{\text{TRG}}$ functions as an output enable for the random outputs after the read access times have been satisfied (if this is a read cycle). Whenever $\overline{\text{TRG}}$ is held high, the Q outputs will be in the high-impedance state. This feature removes the possibility of an overlap between data on the address lines and data appearing on the Q outputs, making it possible to connect the address lines to the data I/O lines — although use of this organization prohibits the use of the early write cycle. It also allows read-modify-write cycles to be performed by providing a three-state condition to the common I/O pins to allow write data to be driven onto the pins after output read data has been externally latched.

address (A0 through A7)

Sixteen address bits are required to decode one of 65,536 storage cell locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip on the falling edge of $\overline{\text{RAS}}$. Then the eight column-address bits are set up on pins A0 through A7 and latched onto the chip on the falling edge of $\overline{\text{CAS}}$. All row and column addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ respectively. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select, activating the device input and output buffers. $\overline{\text{CAS}}$ is also used to strobe the column address into the memory.

write-mask enable ($\overline{\text{WE}}$)

The $\overline{\text{WE}}$ pin selects the random-mode write-mask option. The SMJ4461 random port is equipped with two modes of write operations. If $\overline{\text{WE}}$ is held low on the falling edge of $\overline{\text{RAS}}$ (during a random access operation), the write mask is enabled. Accordingly, a 4-bit binary code (the mask) is input to the device via the random D/Q pins and is also latched on the falling edge of $\overline{\text{RAS}}$. This binary pattern determines which of the four DRAM I/Os will be written into on that access and which DRAM I/Os will not. Thus,

after $\overline{\text{RAS}}$ has latched the write mask on chip, input data is driven onto the DQ pins and is latched on the falling edge of the latter of $\overline{\text{CAS}}$ or $\overline{\text{WE}}$ (for early write operation, $\overline{\text{WE}}$ can remain low for the entire $\overline{\text{RAS}}$ low period). If a 0 was strobed into a particular I/O pin on the falling edge of $\overline{\text{RAS}}$, then the write circuits for that particular I/O will be defeated and data will not be written to that I/O. If a 1 was strobed into a particular I/O pin on the falling edge of $\overline{\text{RAS}}$, then the write circuits for that particular I/O will not be defeated and data will be written to that I/O. See the corresponding timing diagrams for details.

Important: The mask operation is selected only if $\overline{\text{WE}}$ is held low on the falling edge of $\overline{\text{RAS}}$. If $\overline{\text{WE}}$ is held high on the falling edge of $\overline{\text{RAS}}$, the mask is not enabled and the write operation is identical to standard $\times 4$ DRAMs, with all four I/Os being written by the data appearing on the DQ pins when the latter of $\overline{\text{WE}}$ or $\overline{\text{CAS}}$ is brought low. Thus, if it is not desired to use the mask function, then a standard DRAM timing interface can be used.

WRITE MASK FUNCTION TABLE

TRG	WE	DQ1-DQ4	MODE
1	1	X	Write enabled at DQ1-DQ4
1	0	1	Write to DQ enabled
1	0	0	Write to DQ disabled

NOTE 1: The logic states in the table above are assumed valid on the falling edge of $\overline{\text{RAS}}$.

write enable ($\overline{\text{WE}}$)

The read or write mode is selected through the write-enable ($\overline{\text{WE}}$) input. A logic high on the $\overline{\text{WE}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{WE}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state for the entire cycle.

data I/O (DQ1-DQ4)

Memory data is written during a write or read-modify-write cycle. The falling edge of $\overline{\text{WE}}$ strobes data into the on-chip data latches. These latches can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{WE}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with data setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low. Thus, the data will be strobed in by $\overline{\text{WE}}$ with data setup and hold times referenced to this signal. The three-state output buffers provide direct TTL compatibility (no pull-up resistors required) with a fanout of two Series 74 TTL loads. Data out is the same polarity as data in. The outputs are in the high-impedance (floating) state as long as $\overline{\text{CAS}}$ or $\overline{\text{TRG}}$ is held high. Data will not appear at the outputs until after both $\overline{\text{CAS}}$ and $\overline{\text{TRG}}$ have been brought low.

Once the outputs are valid, they will remain valid while $\overline{\text{CAS}}$ and $\overline{\text{TRG}}$ are low. $\overline{\text{CAS}}$ or $\overline{\text{TRG}}$ going high will return the outputs to a high-impedance state. In an early write cycle, the outputs are always in the high-impedance state. In a delayed-write or read-modify-write cycle, the outputs will follow the sequence for the read cycle. In a register-transfer operation (memory-to-register or register-to-memory), the outputs remain in the high-impedance state for the entire cycle, regardless of transitions on $\overline{\text{CAS}}$ or $\overline{\text{TRG}}$.

write mask bits (DQ1-DQ4)

When the write mask is enabled ($\overline{\text{WE}}$ low on the falling edge of $\overline{\text{RAS}}$), the write mask bits determine which DRAM I/Os are to be written and which of the DRAM I/Os will have their write operations internally defeated. The states of the write mask bits are latched on-chip on the falling edge of $\overline{\text{RAS}}$ and selectively control the internal write enable circuits of each corresponding DRAM I/O. If the write mask is not enabled ($\overline{\text{WE}}$ high on the falling edge of $\overline{\text{RAS}}$), then no write enable circuits will be defeated and data appearing at the DQ1-DQ4 pins on the falling edge of $\overline{\text{RAS}}$ will be ignored. See timing diagrams and the table under "write mask enable ($\overline{\text{WE}}$)" for details.

refresh

A refresh operation must be performed to each row at least once every four milliseconds to retain data. Since the output buffer is in the high-impedance state unless $\overline{\text{CAS}}$ is applied, the $\overline{\text{RAS}}$ -only refresh sequence avoids any output during refresh. Strobing each of the 256 row addresses with $\overline{\text{RAS}}$ causes all bits in each row to be refreshed. $\overline{\text{CAS}}$ can remain high (inactive) for this refresh sequence to conserve power. Note that the data registers are dynamic storage elements and that the data held in the registers will be lost unless $\overline{\text{SC}}$ is clocked two times or else the data is reloaded from the memory array. See specifications for maximum register retention times.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is accomplished by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ (see parameter t_{CLRL}). The external row address is ignored and the refresh address is generated internally.

column-address strobe ($\overline{\text{CAS}}$)

The $\overline{\text{CAS}}$ input latches the column addresses on-chip and also functions as an output enable for DQ1-DQ4.

power up

After power up, the power supply must remain at its steady-state value for one millisecond. In addition, $\overline{\text{RAS}}$ must remain high for 100 μs immediately prior to initialization. Initialization consists of performing eight $\overline{\text{RAS}}$ cycles and one memory-to-register transfer cycle with an $\overline{\text{SC}}$ cycle following the rising edge of $\overline{\text{TRG}}$ before proper device operation is achieved.

sequential-access operation

transfer register select ($\overline{\text{TRG}}$)

Memory operations involving parallel use (i.e., transfer from memory to data register or data register to memory) of the data register are invoked by bringing $\overline{\text{TRG}}$ low with the address lines A0-A7 before $\overline{\text{RAS}}$ falls. This enables the switches connecting the 256 elements of each data register to the 256 bit lines of each DRAM I/O. The states of $\overline{\text{WE}}$ and $\overline{\text{SG}}$, which are also latched on the falling edge of $\overline{\text{RAS}}$, determine whether the 256-bit data transfer will be from the memory array to the data registers or from the data registers to memory array, as well as determining if the SDQs are in read or write mode (see "transfer operation logic table").

Note that the state of $\overline{\text{TRG}}$ is latched on the falling edge of $\overline{\text{RAS}}$ just like a row address to select the mode of operation. During read or read-modify-write cycles, $\overline{\text{TRG}}$ functions as output enable after $\overline{\text{CAS}}$ falls.

transfer write enable ($\overline{\text{WE}}$)

In register transfer mode, $\overline{\text{WE}}$ determines whether a transfer will occur from the data registers to the memory array, or from the memory array to the data registers. To transfer data from the data registers to the memory array, $\overline{\text{WE}}$ and $\overline{\text{SG}}$ are held low as $\overline{\text{RAS}}$ falls. If $\overline{\text{SG}}$ were to be high during this transition, then no transfer of data from the data register to the memory array would occur, but the SDQs would be put into the write mode. This would allow serial data to be written into the register. To transfer from the memory array to the data registers, $\overline{\text{WE}}$ is held high and $\overline{\text{SG}}$ is a don't care as $\overline{\text{RAS}}$ falls. This cycle puts the SDQs into the read mode, thus allowing serial data to be read out of the data register. Note that $\overline{\text{WE}}$ and $\overline{\text{SG}}$ setup and hold times are referenced to the falling edge of $\overline{\text{RAS}}$ for this mode of operation (see "transfer operation logic" table).

row address (A0 through A7)

Eight address bits are required to select one of the 256 possible rows involved in the transfer of data to or from the data registers. (The states of A0-A7, $\overline{\text{WE}}$, $\overline{\text{TRG}}$, and $\overline{\text{SG}}$ are latched on the falling edge of $\overline{\text{RAS}}$).

register column address (A0 through A7)

To select one of the 256 positions along each of the four data registers from which the first serial data will be read out, or to which the first serial data will be written, the appropriate 8-bit column address (A0-A7) must be valid when $\overline{\text{CAS}}$ falls during the appropriate transfer cycle.

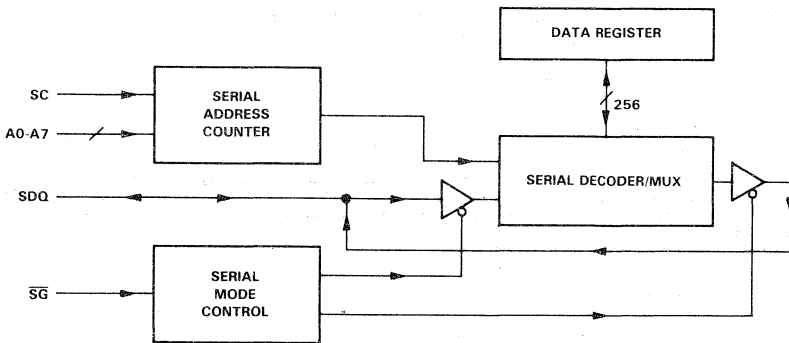

serial data clock (SC)

Data is written in or read out of the data registers on the rising edge of SC. This makes it possible to view the data registers as though they were made of 256 positive-edge-triggered D flip-flops connected D to Q (not to be confused with the DQ random I/O pins of the SMJ4461). The SMJ4461 is designed to work with a wide range duty cycle clock to simplify system design.

serial data input/output (SDQ1-SDQ4)

SD and SQ share a common I/O pin. Data is written in when $\overline{\text{SG}}$ is low during write mode and data is read out when $\overline{\text{SG}}$ is low during read mode (see "transfer operation logic table"). Note that when the serial address counter reaches its maximum value of 255, it is reset back to 00 with the next positive transition of SC. This allows data to be read out in a continuous loop.

block diagram of one serial I/O

serial enable (\overline{SG})

The serial enable pin has two functions. First, it is used on the falling edge of \overline{RAS} , with both \overline{TRG} and \overline{WE} low. If \overline{SG} is low during this transition, then a register-to-memory transfer will occur. On the other hand, if \overline{SG} were to be high as \overline{RAS} falls, then a write-mode control cycle will be performed. The function of this cycle is to switch the SDQs from the output mode to the input mode, thus allowing serial data to be written into the data register. Second, \overline{SG} is used as a SDQ enable/disable. In the write mode, \overline{SG} is used as an input enable. \overline{SG} high disables the input, and \overline{SG} low enables the input. To take the device out of the write mode and into the read mode, a memory-to-register transfer cycle must be performed. The read mode allows data to be read out of the data register. \overline{SG} high disables the output and \overline{SG} low enables the output. Note that the serial address counter will be incremented on each SC cycle regardless of the state of \overline{SG} .

TRANSFER OPERATION LOGIC TABLE

\overline{TRG}	\overline{WE}	\overline{SG}	MODE
0	0	0	Register-to-memory transfer
0	0	1	Write-mode enable
0	1	X	Memory-to-register transfer

NOTE 2: The logic states in the table above are assumed valid on the falling edge of \overline{RAS} .

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

Voltage range for any pin except V_{DD} and data out (see Note 3)	-1.0 V to 7 V
Voltage range for V_{DD} supply with respect to V_{SS}	-1 V to 7 V
Voltage range for data out with respect to V_{SS}	-1 V to $V_{DD} + 0.3$ V
Short circuit output current per output	50 mA
Power dissipation	1 W
Operating temperature range	-55°C to 110°C
Storage temperature range	-65°C to 150°C

†Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 3: All voltage values in this data sheet are with respect to V_{SS} .

recommended operating conditions

		MIN	NOM	MAX	UNIT
V_{DD}	Supply voltage	4.5	5	5.5	V
V_{SS}	Supply voltage	0			V
V_{IH}	High-level input voltage	All inputs except SC		5.5	V
		SC		5.5	
V_{IL}	Low-level input voltage (see Note 4)	-1	0.8		V
T_A	Operating free-air temperature	-55			°C
T_C	Operating case temperature	110			°C

NOTE 4: The algebraic convention where the more negative (less positive) limit is designated as minimum is used in this data sheet for logic voltage levels only.

Continued next page.

NOTE 5: Timing measurements are referenced to V_{IL} max and V_{IH} min.

[†] $\overline{\text{TRG}}$ must disable the output buffers prior to applying data to the device.

[#] $\overline{\text{TRG}}$ may be brought high early during a memory-to-register transfer cycle as long as the $t_h(\text{TRG})$, t_{SHTH} , and t_{RLSH} specifications are met.

[‡] In a register-to-memory transfer cycle, the state of SC when $\overline{\text{RAS}}$ falls is a don't care condition. However, to guarantee proper sequencing of the internal clock circuitry there can be no positive transitions of SC for at least 40 ns prior to when $\overline{\text{RAS}}$ goes low. See the section entitled "sequential access operation" for a complete explanation of the transfer operation.

^{*} In a memory-to-register transfer cycle, the state of SC when $\overline{\text{TRG}}$ rises is a don't care condition. However, to guarantee proper sequencing of the internal clock circuitry there can be no positive transitions of SC for at least 10 ns prior to when $\overline{\text{TRG}}$ goes high. See the section entitled "sequential access operation" for a complete explanation of the transfer operation.

This parameter is guaranteed but not tested.

CAS-before-RAS refresh

write-mode control timing

The write-mode control cycle is used to change the SDQs from the output mode to the input mode. This allows serial data to be written into the data register. The diagram below assumes that the device was originally in the serial read mode.

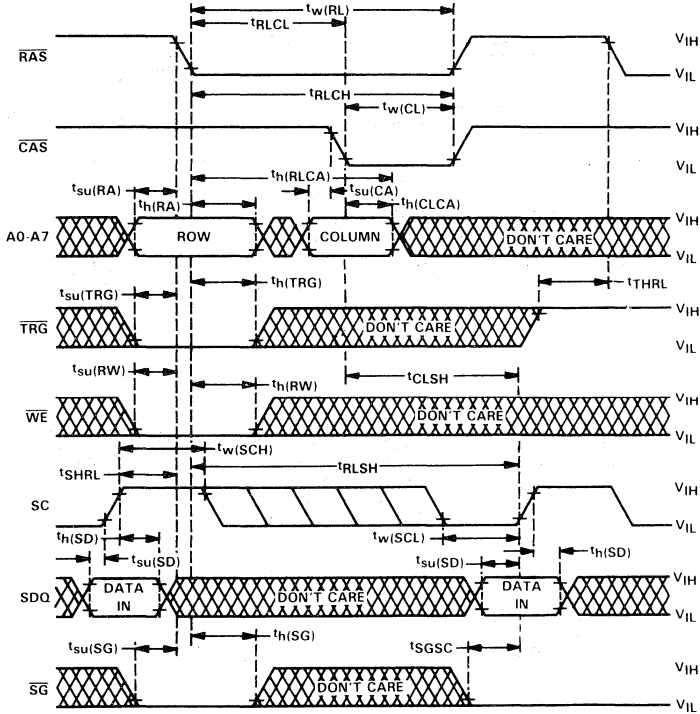

- NOTES: 9. Random-mode (Q outputs) remain in 3-state for the entire write-mode control cycle.
10. SG must be high as RAS falls in order to perform a write-mode control cycle.

8

Military Products

data-register-to-memory timing, serial input enabled

The data-register-to-memory cycle is used to transfer data from the data register to the memory array. Every one of the 256 locations in the data register is written into the 256 columns of the selected row. Note that the data that was in the data register may have arrived there either from a serial write in or from a parallel load of the data register from one of the memory array rows. The diagram below assumes that the device is presently in the serial-write mode (i.e., SD is enabled by a previous write-mode control cycle, thus allowing data to be written in).

- NOTES: 11. Random-mode (Q outputs) remain in 3-state for the entire data-register-to-memory transfer cycle.
12. SG must be high as RAS falls in order to perform a register-to-memory transfer.

memory-to-data-register timing

The memory-to-data-register cycle is used to load the data register in parallel from the memory array. Every one of the 256 locations in the data register are written into from the 256 columns of the selected row. Note that the data that is loaded into the data register may be either read out or written back into another row. This cycle puts the device into the serial read mode (i.e., the SQ is enabled, thus allowing data to be read out of the register).

Also, the first bit to be read from the data register after $\overline{\text{TRG}}$ has gone high must be activated by a positive transition of SC.

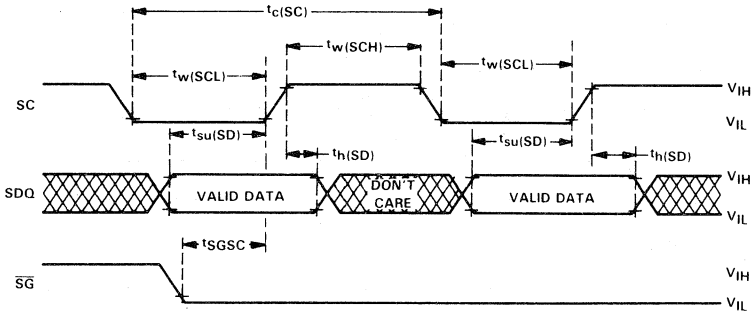

- NOTES: 13. Random-mode (Q outputs) remain in 3-state for the entire memory-to-data-register transfer cycle.
 14. Column address must be supplied to load register start address on every transfer cycle.
 15. The first positive transition of SC after $\overline{\text{TRG}}$ has gone high during a memory-to-register transfer cycle is used to read the first bit of new data.

8

Military Products

serial data-in timing

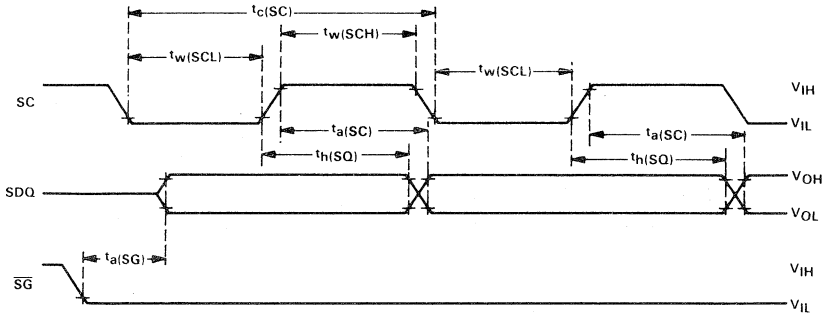

The serial data-in write cycle is used to write data into the data register. Before data can be written into the data register via SD, the device must be put into the write mode by performing a write-mode control cycle. Register-to-memory transfer cycles occurring between the write-mode control cycle and the subsequent writing in of data will not take the device out of the write mode. But a memory-to-register transfer cycle during that time will take the device out of the write mode and put it into the read mode, thus not allowing the writing in of data.

NOTE 16: While writing data into the data register, the state of \overline{TRG} is a don't care as long as \overline{TRG} is held high when \overline{RAS} goes low. This is to avoid the initiation of a register-to-memory or memory-to-register data-transfer function.

serial-data-out timing

The serial data-out read cycle is used to read data out of the data register. Before data can be read out via SQ, the device must be put into the read mode by performing a memory-to-data-register transfer cycle. Register-to-memory transfer cycles occurring between the memory-to-register transfer cycle and the subsequent reading out of data will not take the device out of the read mode. But, a write-mode control cycle at that time will take the device out of the read mode and put it in the write mode, thus not allowing the reading out of data.

NOTE 17: While reading data out of the data register, the state of \overline{TRG} is a don't care as long as \overline{TRG} is held high when \overline{RAS} goes low. This is to avoid the initiation of a register-to-memory or memory-to-register data-transfer operation.

description

The SMJ4464 is a high-speed, 262,144-bit dynamic random-access memory, organized as 65,536 words of four bits each. It employs state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

This device features maximum \overline{RAS} access times of 120 ns, 150 ns, or 200 ns. Typical power dissipation is as low as 275 mW operating and 12.5 mW standby.

New SMOS technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{DD} peaks of 125 mA are typical, and a -0.7-V input voltage undershoot can be tolerated, minimizing system noise considerations.

All inputs and outputs, including clocks, are compatible with Series 54 TTL. All address and data-in lines are latched on-chip to simplify system design. Data out is unlatched to allow greater system flexibility.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

POST OFFICE BOX 225012 • DALLAS, TEXAS 75265

Copyright © 1987, Texas Instruments Incorporated

The SMJ4464 is offered in 18-pin 300-mil ceramic side-braze dual-in-line and 18-pad leadless ceramic chip carrier packages. It is guaranteed for operation from -55°C to 110°C for the S version and from 0°C to 70°C for the L version. The dual-in-line package is designed for insertion in mounting-hole rows on 7,62-mm (300-mil) centers).

operation

address (A0 through A7)

Sixteen address bits are required to decode 1 of 65,536 storage locations. Eight row-address bits are set up on pins A0 through A7 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the eight column-address bits are set up on pins A0 through A7 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select, activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state for the entire cycle, permitting common I/O operation.

data in (DQ1-DQ4)

Data is written during a write or a read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latches. These latches can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed-write or a read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal. In a delayed or read-modify write cycle, $\overline{\text{G}}$ must be high to bring the output buffers to high impedance prior to impressing data on the I/O lines.

data out (DQ1-DQ4)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fanout of two Series 54 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output goes active after the access time interval $t_{a(C)}$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{a(R)}$ and $t_{a(G)}$ are satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ and $\overline{\text{G}}$ are low. $\overline{\text{CAS}}$ or $\overline{\text{G}}$ going high returns it to a high-impedance state. In a delayed-write or read-modify-write cycle, the output must be put in the high-impedance state prior to applying data to the DQ input. This is accomplished by bringing $\overline{\text{G}}$ high prior to applying data, thus satisfying t_{GHD} .

output enable ($\overline{\text{G}}$)

The $\overline{\text{G}}$ input controls the impedance of the output buffers. When $\overline{\text{G}}$ is high, the buffers will remain in the high-impedance state. Bringing $\overline{\text{G}}$ low during a normal cycle will activate the output buffers, putting them in the low-impedance state. It is necessary for both $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ to be brought low for the output buffers to go into the low-impedance state. Once in the low-impedance state they will remain in the low-impedance state until $\overline{\text{G}}$ or $\overline{\text{CAS}}$ is brought high.

refresh

A refresh operation must be performed at least once every four milliseconds to retain data. This can be achieved by strobing each of the 256 rows (A0-A7). A normal read or write cycle will refresh all bits in each row that is selected. A $\overline{\text{RAS}}$ -only operation can be used by holding $\overline{\text{CAS}}$ at the high (inactive) level, thus conserving power as the output buffer remains in the high-impedance state.

SMJ4464
65,536-WORD BY 4-BIT DYNAMIC RANDOM-ACCESS MEMORY

operation (continued)

CAS-before-RAS refresh

The CAS-before-RAS refresh is utilized by bringing CAS low earlier than RAS (see parameter t_{CLRL}) and holding it low after RAS falls (see parameter t_{RLCHR}). For successive CAS-before-RAS refresh cycles, CAS can remain low while cycling RAS. The external address is ignored and the refresh address is generated internally.

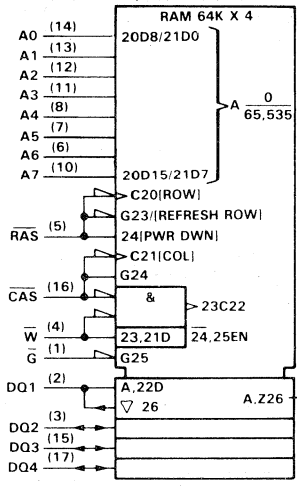

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing random column addresses onto the chip. Thus, the time required to set up and strobe sequential row addresses for the same page is eliminated. The maximum number of columns that can be addressed is determined by $t_w(RL)$, the maximum RAS low pulse duration.

power up

To achieve proper device operation, an initial pause of 200 μs is required after power up, followed by a minimum of eight initialization cycles.

logic symbol†

† This symbol is in accordance with ANSI/IEEE Std. 91-1984 and IEC Publication 617-12. Pin numbers shown are for the dual-in-line package.

description

The SMJ44C256 is a high-speed, 1,048,576-bit dynamic random-access memory organized as 262,144 words of four bits each. It employs state-of-the-art EPIC™ (Enhanced Process Implanted CMOS) technology for high performance, reliability, and low power at a low cost.

operation

enhanced page mode

Page-mode operation allows faster memory access by keeping the same row address while selecting random column addresses. The time for row-address setup and hold, and address multiplex is thus eliminated. The maximum number of columns that may be accessed is determined by the maximum RAS low time and the CAS page cycle time used. With minimum CAS page cycle time, all 1024 columns specified by column addresses A0 through A9 can be accessed without intervening RAS cycles.

EPIC is a trademark of Texas Instruments Incorporated.

description

The SMJ27C128 series are 131,072-bit, ultraviolet-light erasable, electrically programmable read-only memories. These devices are fabricated using HVC MOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 54 TTL circuits without the use of external pull-up resistors, and each output can drive one Series 54 TTL circuit without external resistors. The data outputs are three state for connecting multiple devices to a common bus. The SMJ27C128 is pin compatible with existing 28-pin ROMs and EPROMs. It is offered in a dual-in-line ceramic package (J suffix) rated for operation from -55°C to 125°C.

Since these EPROMs operate from a single 5-V supply (in the read mode), they are ideal for use in microprocessor-based systems. One other (12.5 V) supply is needed for programming, but all programming signals are TTL level. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed individually, in blocks, or at random.

operation

There are seven modes of operation for the SMJ27C128 listed on the following page. Read mode requires a single 5-V supply. All inputs are TTL level except for V_{pp} during programming (12.5 V) and 12 V on A9 for signature mode.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

$^{\dagger}X$ can be V_{IL} or V_{IH} .
 $^{\dagger}V_H = 12 V \pm 0.5 V$.

read/output disable

When the outputs of two or more SMJ27C128's are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of the SMJ27C128, a low-level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 to Q8.

power down

Active I_{CC} current can be reduced from 40 mA to 500 μA (TTL-level inputs) or 300 μA (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure

Before programming, the SMJ27C128 is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is fifteen watt-seconds per square centimeter. A typical 12 milliwatt per square centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. After erasure, all bits are in the high state. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the SMJ27C128, the window should be covered with an opaque label.

fast programming

After erasure (all bits in logic '1' state), logic '0's are programmed into the desired locations. A programmed '0' can only be erased by ultraviolet light. Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, PGM is pulsed. The programming mode is achieved when $V_{pp} = 12.5 V$, $V_{CC} = 6.0 V$, $\bar{G} = V_{IH}$, $PGM = V_{IL}$, and $\bar{E} = V_{IL}$. More than one SMJ27C128 can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified.

8

Military Products

If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{CC} = 6.0\text{ V}$ and $V_{pp} = 12.5\text{ V}$. When the full fast programming routine is complete, all bits are verified with $V_{CC} = V_{pp} = 5\text{ V}$ (see Figure 1).

program inhibit

Programming may be inhibited by maintaining a high level input on the \overline{E} pin or \overline{PGM} pin.

program verify

Programmed bits may be verified with $V_{pp} = 12.5\text{ V}$ when $\overline{G} = V_{IL}$, $\overline{E} = V_{IL}$, and $\overline{PGM} = V_{IH}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 24) is forced to $12\text{ V} \pm 0.5\text{ V}$. Two identifier bytes are accessed by A0 (pin 10) i.e., A0 = V_{IL} - manufacturer; A0 = V_{IH} - device. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for this device is 97, and the device code is 04.

read/output disable

When the outputs of two or more SMJ27C256's are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of the SMJ27C256, a low-level signal is applied to the \bar{E} and \bar{G} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 to Q8.

power down

Active I_{CC} current can be reduced from 40 mA to 500 μ A (TTL-level inputs) or 300 μ A (CMOS-level inputs) by applying a high TTL signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure

Before programming, the SMJ27C256 is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is fifteen watt-seconds per square centimeter. A typical 12 milliwatt per square centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. After erasure, all bits are in the high state. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the SMJ27C256, the window should be covered with an opaque label.

fast programming

After erasure (all bits in logic '1' state), logic '0's are programmed into the desired locations. A programmed '0' can only be erased by ultraviolet light. Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed. The programming mode is achieved when $V_{PP} = 12.5 V$, $V_{CC} = 6.0 V$, $\bar{G} = V_{IH}$, and $\bar{E} = V_{IL}$. More than one SMJ27C256 can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional

1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{CC} = 6.0\text{ V}$ and $V_{pp} = 12.5\text{ V}$. When the full fast programming routine is complete, all bits are verified with $V_{CC} = V_{pp} = 5\text{ V}$ (see Figure 1).

program inhibit

Programming may be inhibited by maintaining a high level input on the \bar{E} pin.

program verify

Programmed bits may be verified with $V_{pp} = 12.5\text{ V}$ when $\bar{G} = V_{IL}$, and $\bar{E} = V_{IH}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 24) is forced to $12\text{ V} \pm 0.5\text{ V}$. Two identifier bytes are accessed by A0 (pin 10) i.e., A0 = V_{IL} - manufacturer; A0 = V_{IH} - device. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for this device is 97, and the device code is 04.

G/Vpp	12.5-V Power Supply/ Output Enable

description

The SMJ27C512 series is a 524,288-bit, ultraviolet-light erasable, electrically programmable read-only memory. This device is fabricated using HVCMOS technology for high speed and simple interface with MOS and bipolar circuits. All inputs (including program data inputs) can be driven by Series 54 TTL circuits without the use of external pull-up resistors, and each output can drive one Series 54 TTL circuit without external resistors. The data outputs are three-state for connecting multiple devices to a common bus. The SMJ27C512 is pin compatible with existing 28-pin ROMs and EPROMs. It is offered in a dual-in-line ceramic package (J suffix) rated for operation from –55°C to 125°C.

Since this EPROM operates from a single 5-V supply (in the read mode), it is ideal for use in microprocessor-based systems. One other (12.5 V) supply is needed for programming, but all programming signals are TTL level. For programming outside the system, existing EPROM programmers can be used. Locations may be programmed singly, in blocks, or at random.

operation

There are seven modes of operation for the SMJ27C512 listed on the following page. Read mode requires a single 5-V supply. All inputs are TTL level except for Vpp during programming (12.5 V) and 12 V on A9 for signature mode.

PRODUCTIO . . . DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

							97	85	

[†]X Can be V_{IL} or V_{IH} .
[‡] $V_H = 12 V \pm 0.5 V$.

read/output disable

When the outputs of two or more SMJ27C512s are connected in parallel on the same bus, the output of any particular device in the circuit can be read with no interference from the competing outputs of the other devices. To read the output of the SMJ27C512, a low-level signal is applied to the \bar{E} and \bar{G}/V_{PP} pins. All other devices in the circuit should have their outputs disabled by applying a high-level signal to one of these pins. Output data is accessed at pins Q1 to Q8.

power down

Active I_{CC} current can be reduced from 50 mA to 500 μA (TTL-level inputs) or 350 μA (CMOS-level inputs) by applying a high logic signal to the \bar{E} pin. In this mode all outputs are in the high-impedance state.

erasure

Before programming, the SMJ27C512 is erased by exposing the chip through the transparent lid to high intensity ultraviolet light (wavelength 2537 angstroms). The recommended minimum exposure dose (UV intensity \times exposure time) is 15 watt-seconds-per-square-centimeter. A typical 12 milliwatt-per-square-centimeter, filterless UV lamp will erase the device in 21 minutes. The lamp should be located about 2.5 centimeters above the chip during erasure. After erasure, all bits are in the high state. It should be noted that normal ambient light contains the correct wavelength for erasure. Therefore, when using the SMJ27C512, the window should be covered with an opaque label.

fast programming

After erasure (all bits in logic 1 state), logic 0s are programmed into the desired locations. A programmed 0 can be erased only by ultraviolet light. Data is presented in parallel (eight bits) on pins Q1 to Q8. Once addresses and data are stable, \bar{E} is pulsed. The programming mode is achieved when $\bar{G}/V_{PP} = 12.5 V$, $V_{CC} = 6.0 V$, and $\bar{E} = V_{IL}$. More than one SMJ27C512 can be programmed when the devices are connected in parallel. Locations can be programmed in any order.

Programming uses two types of programming pulses: Prime and Final. The length of the Prime pulse is 1 millisecond; this pulse is applied X times. After each Prime pulse, the byte being programmed is verified. If the correct data is read, the Final programming pulse is applied; if correct data is not read, an additional 1 millisecond pulse is applied up to a maximum X of 25. The Final programming pulse is 3X long. This sequence of programming and verification is performed at $V_{CC} = 6.0 V$. When the full Fast programming routine is complete, all bits are verified with $V_{CC} = 5 V$ (see Figure 1).

program inhibit

Programming may be inhibited by maintaining a high level input on the \bar{E} pin.

program verify

Programmed bits may be verified with \bar{G}/V_{pp} and $\bar{E} = V_{IL}$.

signature mode

The signature mode provides access to a binary code identifying the manufacturer and type. This mode is activated when A9 (pin 24) is forced to $12\text{ V} \pm 0.5\text{ V}$. Two identifier bytes are accessed by A0 (pin 10); i.e., $A0 = V_{IL}$ accesses the manufacturer code; $A0 = V_{IH}$ accesses the device code. All other addresses must be held at V_{IL} . Each byte possesses odd parity on bit Q8. The manufacturer code for this device is 97, and the device code is 85.

latchup immunity

Latchup immunity on the SMJ27C512 is minimum of 250 mA on all inputs and outputs. This feature provides latchup immunity beyond any potential transients at the P.C. board level when the EPROM is interfaced to industry standard TTL or MOS logic devices. Input-output layout approach controls latchup without compromising performance or packing density.

For more information see application report SMLA001; "Design Considerations; Latchup Immunity of the HVCMOS EPROM Family," available through TI Field Sales Offices.

description

The '61CD16 is a separate I/O, 16,384-bit static random-access memory organized as 16,384 words by 1 bit. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six transistor cell) memory array. The six transistor cell provides for inherently lower soft error rates, improved stability across the operating temperature range, and extremely low standby power compared to the four transistor/two poly load cell making it ideal for military applications.

The '61CD16's static design and control signals (\bar{E} and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip-enable pin allows for easy memory expansion and automatic power-down. Access time from either address or chip enable is a maximum of 25, 35, or 45 ns, allowing speed upgrades for new and existing designs.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

8-167

SM61CD16, SMJ61CD16

16,384-WORD BY 1-BIT STATIC RAMS

operation

addresses (A0-A13)

The 14 address inputs select one of the 16,384 -bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL with no external pull-up resistors.

chip enable/power down (\bar{E})

The chip enable/power down terminal, which can be driven directly by standard TTL circuits, affects the data-in and data-out terminals and the internal functioning of the chip itself. Whenever the chip enable/power down is low (enabled), the device is operational, input and output terminals are enabled, and data can be read or written. When the chip enable/power down terminal is high (disabled), the device is deselected and put into a reduced-power standby mode. Data is retained during standby.

write enable (\bar{W})

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or \bar{E} must be high when changing addresses to prevent inadvertently writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

data in (D)

Data can be written into a selected device when the write-enable input is low. The input terminal can be driven directly from standard TTL circuits. Data on the input pin (D) is written into the memory location specified on the address pins (A0-A13).

data out (Q)

The three-state output buffer provides direct TTL compatibility with a fanout of two Series 54 TTL gates, one Series 54S TTL gate, or eight Series 54LS TTL gates. The output terminal is in the high-impedance state when chip enable (\bar{E}) is high or whenever a write operation is being performed. Data out is the same polarity as data in.

description

The '64C16 is a common I/O, 16,384-bit static random-access memory organized as 4096 words by 4 bits. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six-transistor cell) memory array. The six-transistor cell provides for inherently lower soft error rates, improved stability across the operating temperature range, and extremely low standby power compared to the four-transistor/two-poly load cell, making it ideal for military applications.

The '64C16's static design and control signals (\bar{E} and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip enable pin provides for easy memory expansion and for an automatic powerdown feature. Access time from either address or chip enable is a maximum of 25, 35, or 45 ns.

ADVANCE INFORMATION

Military Products

SMS4C16, SMJ64C16
4096-WORD BY 4-BIT STATIC RAMS

operation

addresses (A0-A11)

The 12 address inputs select one of the 4096 4-bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL with no external pull-up resistors.

chip enable/power down (\bar{E})

The chip enable/power down terminal, which can be driven directly by standard TTL circuits, affects the data-in and data-out terminals and the internal functioning of the chip itself. Whenever the chip enable/power down is low (enabled), the device is operational, input and output terminals are enabled, and data can be read or written. When the chip enable/power down terminal is high (disabled), the device is deselected and put into a reduced-power standby mode. Data is retained during standby.

write enable (\bar{W})

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or \bar{E} must be high when changing addresses to prevent erroneously writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

data in/data out (DQ1-DQ4)

Data can be written into a selected device when the write-enable input is low. The DQ terminals can be driven directly from standard TTL circuits. The three-state output buffer provides direct TTL compatibility with a fanout of two Series 54 TTL gates, one Series 54S TTL gate, or eight Series 54LS TTL gates. The DQ terminals are in the high-impedance state when chip enable (\bar{E}) is high or whenever a write operation is being performed. Data out is the same polarity as data in.

logic symbol†

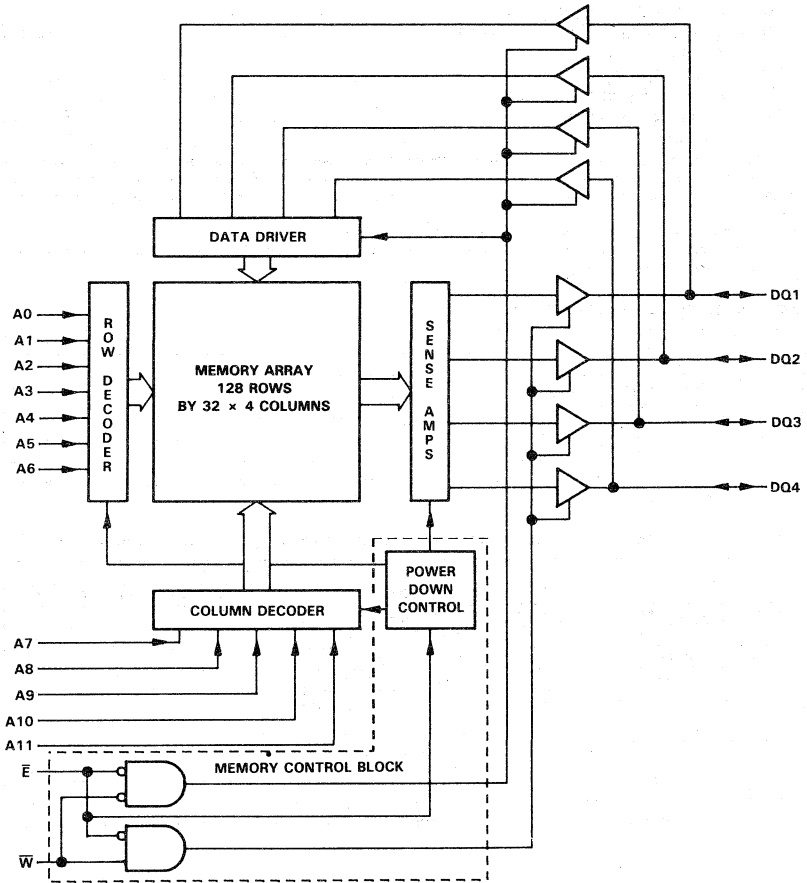

FUNCTION TABLE

ADVANCE INFORMATION

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

Supply voltage range (see Note 1)	−0.5 V to 7 V
Input voltage range (see Note 2)	−1 V to 7 V
Output voltage range in high-impedance state	−0.5 V to 7 V
Output current	20 mA
Minimum operating free-air temperature	−55 °C
Maximum operating case-temperature	125 °C
Storage temperature range	−65 °C to 150 °C
Latch-up current	200 mA

†Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

- NOTES: 1. All voltage values in this data sheet are with respect to GND.
 2. V_{IL} (min) of −3 V for short pulse durations. Prolonged operation at V_{IL} levels below −1 V will result in excessive currents that may damage the part.

description

The '68CE16 is a common I/O, 16,384-bit static random-access memory organized as 2048 words by 8 bits. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six transistor cell) memory array.

The '68CE16's static design and control signals (\bar{E} , \bar{G} , and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip-enable pin allows for easy memory expansion and automatic power-down. This feature, in conjunction with the full CMOS array, allows for low standby power operation when the memory is deselected, greatly reducing the overall memory power requirements. The output-enable pin minimizes bus contention problems and adds flexibility.

SM68CE16, SMJ68CE16
2048-WORD BY 8-BIT STATIC RAMS

Access time from either address or chip enable is a maximum of 25, 35, or 45 ns, allowing speed upgrades for new and existing designs.

operation

addresses (A0-A10)

The 11 address inputs select one of the 2048 8-bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL with no external pull-up resistors.

chip enable/power down (\bar{E})

The chip enable/power down terminal, which can be driven directly by standard TTL circuits, affects the data-in and data-out terminals and the internal functioning of the chip itself. Whenever the chip enable/power down is low (enabled), the device is operational, input and output terminals are enabled, and data can be read or written. When the chip enable/power down terminal is high (disabled), the device is deselected and put into a reduced-power standby mode. Data is retained during standby.

write enable (\bar{W})

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or \bar{E} must be high when changing addresses to prevent inadvertently writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

output enable (\bar{G})

The output-enable terminal affects only the data-out terminals. When output enable is at a logic high level, the output terminals are disabled to the high-impedance state. Output enable provides greater output control flexibility, simplifying data bus design.

data in/data out (DQ1-DQ8)

Data can be written into a selected device when the write-enable input is low. The DQ terminals can be driven directly from standard TTL circuits. The three-state output buffer provides direct TTL compatibility with a fanout of twenty Series 54LS or 54ALS TTL gates, sixteen Series 54AS TTL gates, or thirteen Series 54F TTL gates. The DQ terminals are in the high-impedance state when chip enable (\bar{E}) is high or whenever a write operation is being performed. Data out is the same polarity as data in.

description

The '61CD64 is a separate I/O, 65,536-bit static random-access memory organized as 65,536 words by 1 bit. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six-transistor cell) memory array. The six-transistor cell provides for inherently lower soft error rates, improved stability across the operating temperature range, and low standby power compared to the four-transistor/two-poly load cell, making it ideal for military applications.

The '61CD64's static design and control signals (\bar{E} and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip-enable pin provides for easy memory expansion and for automatic power-down. This feature, in conjunction with the full CMOS array, greatly reduces the overall memory power requirements.

Access time from either address or chip enable is a maximum of 25, 35, or 45 ns, allowing speed enhancements for new and existing designs.

65,536-WORD BY 1-BIT STATIC RAMS

operation

addresses (A0-A15)

The 16 address inputs select one of the 65,536 1-bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL with no external pull-up resistors.

chip enable/power down (\bar{E})

The chip enable/power down terminal, which can be driven directly by standard TTL circuits, affects the data-in and data-out terminals and the internal functioning of the chip itself. Whenever the chip enable/power down is low (enabled), the device is operational, input and output terminals are enabled, and data can be read or written. When the chip enable/power down terminal is high (disabled), the device is deselected and put into a reduced-power standby mode. Data is retained during standby.

write enable (\bar{W})

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or \bar{E} must be high when changing addresses to prevent inadvertently writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

data in (D)

Data can be written into a selected device when the write-enable input is low. The input terminal can be driven directly from standard TTL circuits. Data on the input pin (D) is written into the memory location specified on the address pins (A0-A15).

data out (Q)

The three-state output buffer provides direct TTL compatibility with a fanout of twenty Series 54LS or 54ALS TTL gates, sixteen Series 54AS TTL gates, or thirteen Series 54F TTL gates. The output terminal is in the high-impedance state when chip enable (\bar{E}) is high or whenever a write operation is being performed. Data out is the same polarity as data in.

description

The '64C64 is a common I/O, 65,536-bit static random-access memory organized as 65,536 words by 4 bits. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six transistor cell) memory array. The six transistor cell provides for inherently lower soft error rates, improved stability across the operating temperature range, and low standby power compared to the four-transistor/two-poly load cell, making it ideal for military applications.

The '64C64's static design and control signals (\bar{E} and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip-enable pin provides for easy memory expansion and for automatic powerdown. This feature, in conjunction with the full CMOS array, greatly reduces the overall memory power requirements. Access time from either address or chip enable is a maximum of 25, 35, or 45 ns, allowing speed enhancements for new and existing designs.

ADVANCE INFORMATION documents contain information on new products in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

SM64C64, SMJ64C64 16,384-WORD BY 4-BIT STATIC RAMS

operation

addresses (A0-A13)

The 14 address inputs select one of the 16,384 4-bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL with no external pull-up resistors.

chip enable/power down (\bar{E})

The chip enable/power down terminal, which can be driven directly by standard TTL circuits, affects the data-in and data-out terminals and the internal functioning of the chip itself. Whenever the chip enable/power down is low (enabled), the device is operational, input and output terminals are enabled, and data can be read or written. When the chip enable/power down terminal is high (disabled), the device is deselected and put into a reduced-power standby mode. Data is retained during standby.

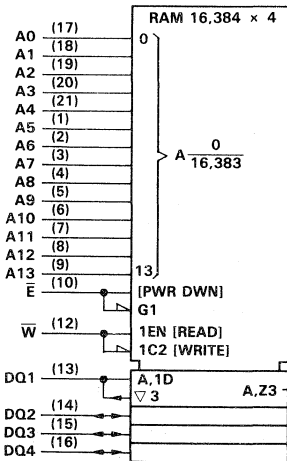

write enable (\bar{W})

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or \bar{E} must be high when changing addresses to prevent inadvertently writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

data in/data out (DQ1-DQ4)

Data can be written into a selected device when the write-enable input is low. The DQ terminals can be driven directly from standard TTL circuits. The three-state output buffer provides direct TTL compatibility with a fanout of twenty Series 54LS or 54ALS TTL gates, sixteen Series 54AS TTL gates, or thirteen Series 54F TTL gates. The DQ terminals are in the high-impedance state when chip enable (\bar{E}) is high or whenever a write operation is being performed. Data out is the same polarity as data in.

write cycle timing controlled by write enable†

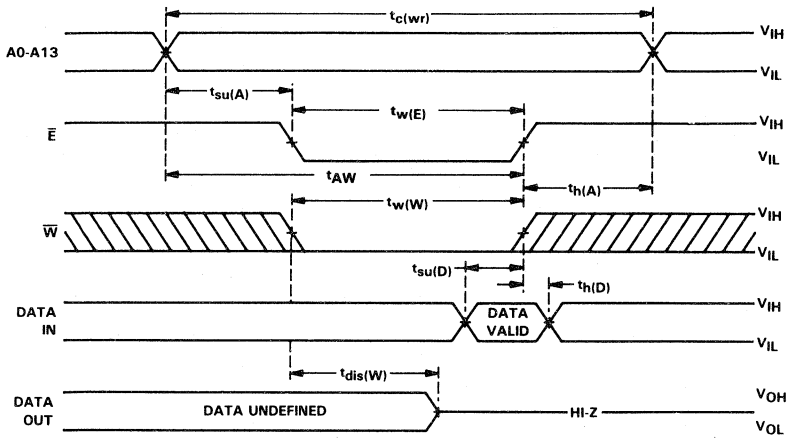

†E or \bar{W} must be high during address transitions.

NOTE: For both \bar{W} -controlled and \bar{E} -controlled Write operations, the internal write time of the memory is defined by the overlap of \bar{E} low and \bar{W} low. Both signals must be low to initiate a write, and either signal can terminate a write by going high. The data input setup and hold times should be referenced to the edge that terminates the write.

description

The '68CE64 is a common I/O, 65,536-bit static random-access memory organized as 8192 words by 8 bits. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six transistor cell) memory array. Access time from chip enable or address is available for 25, 35, or 45 ns cycle times, while maximum power dissipation is less than 660 mW. This reduces to 55 mW (TTL Inputs) or 5.5 mW (CMOS Inputs) during standby operation.

The '68CE64's static design and control signals ($\bar{E}1$, E2, \bar{G} , and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The two enable pins add flexibility and simplify memory expansion/design. The output-enable pin minimizes bus contention problems.

ADVANCE INFORMATION

Military Products

SM68CE64, SMJ68CE64

8192-WORD BY 8-BIT STATIC RAMS

The '68CE64 static RAM provides single 5-V operation with all inputs and outputs compatible with standard TTL and CMOS voltage levels.

operation

addresses (A0-A12)

The 13 address inputs select one of the 8192 8-bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL without external pull-up resistors.

chip enable/power down ($\bar{E}1$)

The chip enable/power down terminal ($\bar{E}1$) can be driven directly by standard TTL circuits, and affects the powerdown/deselect function of the chip. Whenever $\bar{E}1$ is high (disabled), the device is put into a reduced power standby mode. Data is retained during the standby mode.

chip enable (E2)

The chip enable terminal (E2) affects the chip deselect function. Whenever chip enable (E2) is high (enabled), and chip enable/powerdown ($\bar{E}1$) is low (enabled) the device is operational, and data may be written or read provided input and output terminals are enabled. Whenever chip enable (E2) is low and chip enable/powerdown ($\bar{E}1$) is low, the device is in the powered-up deselected state.

write enable (W)

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or $\bar{E}1$ must be high or E2 must be low when changing addresses to prevent inadvertently writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

output enable (\bar{G})

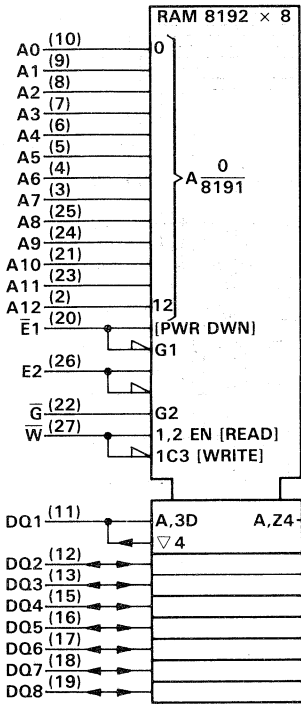

The output-enable terminal, which can be driven directly from standard TTL circuits, affects only the data-out terminals. When output enable is at a logic high level, the output terminals are disabled to the high-impedance state. Output enable provides greater output control flexibility, simplifying data bus design.

data in/data out (DQ1-DQ9)

Data can be written into a selected device when the write-enable (\bar{W}) input is low, chip enable/powerdown ($\bar{E}1$) is low, and chip enable (E2) is high. Data can be read when write enable (\bar{W}) is high, chip enable/powerdown ($\bar{E}1$) is low, chip enable (E2) is high, and output enable (\bar{G}) is low. The DQ terminals can be driven directly from standard TTL circuits. The three-state output buffers provide direct TTL compatibility with a fanout of twenty Series 54LS or 54ALS TTL gates, sixteen Series 54AS TTL gates, or thirteen Series 54F TTL gates.

description

The '69CE72 is a common I/O, 73,728-bit static random-access memory organized as 8192 words by 9 bits. Bit nine is generally used for parity bit storage for improved system reliability. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six transistor cell) memory array. Access time from chip enable or address is available for 25, 35, or 45 ns cycle times, while maximum power dissipation is less than 660 mW. This reduces to 55 mW (TTL Inputs) or 5.5 mW (CMOS Inputs) during standby operation.

SM69CE72, SMJ69CE72 8192-WORD BY 9-BIT STATIC RAMS

The '69CE72's static design and control signals ($\bar{E}1$, E2, \bar{G} and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The two enable pins add flexibility and simplify memory expansion/design. The output-enable pin minimizes bus contention problems.

The '69CE72 static RAM provides single 5-V operation with all inputs and outputs fully compatible with standard TTL and CMOS voltage levels.

operation

addresses (A0-A12)

The 13 address inputs select one of the 8192 9-bit words in the RAM. The address inputs must be stable for the duration of a read or write cycle. The address inputs can be driven directly from standard Series 54/74 TTL without external pull-up resistors.

chip enable/power down ($\bar{E}1$)

The chip enable/power down terminal ($\bar{E}1$) can be driven directly by standard TTL circuits, and affects the powerdown/deselect function of the chip. Whenever $\bar{E}1$ is high (disabled), the device is put into a reduced power standby mode. Data is retained during the standby mode.

chip enable (E2)

The chip enable terminal (E2) affects the chip deselect function. Whenever chip enable (E2) is high (enabled), and chip enable/powerdown ($\bar{E}1$) is low (enabled) the device is operational, and data may be written or read provided input and output terminals are enabled. Whenever chip enable (E2) is low and chip enable/powerdown ($\bar{E}1$) is low, the device is in the powered-up deselected state.

write enable (\bar{W})

The read or write mode is selected through the write-enable terminal. A logic high selects the read mode; a logic low selects the write mode. \bar{W} or $\bar{E}1$ must be high or E2 must be low when changing addresses to prevent inadvertently writing data into a memory location. The \bar{W} input can be driven directly from standard TTL circuits.

output enable (\bar{G})

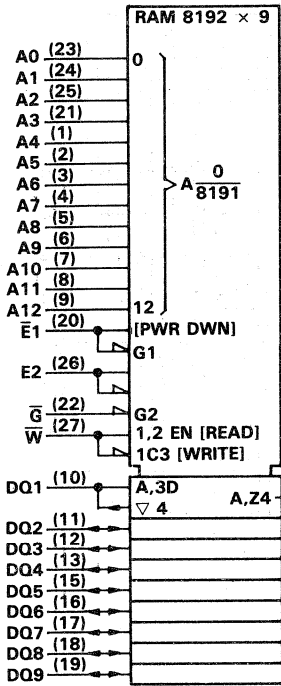

The output-enable terminal, which can be driven directly from standard TTL circuits, affects only the data-output terminals. When output enable is at a logic high level, the output terminals are disabled to the high-impedance state. Output enable provides greater output control flexibility, simplifying data bus design.

data in/data out (DQ1-DQ9)

Data can be written into a selected device when the write-enable (\bar{W}) input is low, chip enable/powerdown ($\bar{E}1$) is low, and chip enable (E2) is high. Data can be read when write enable (\bar{W}) is high, chip enable/powerdown ($\bar{E}1$) is low, chip enable (E2) is high, and output enable (\bar{G}) is low. The DQ terminals can be driven directly from standard TTL circuits. The three-state output buffers provide direct TTL compatibility with a fanout of twenty Series 54LS or 54ALS TTL gates, sixteen Series 54AS TTL gates, or thirteen Series 54F TTL gates.

description

The '61CD256 is a separate I/O, 262,144-bit static random-access memory organized as 262,144 words by 1 bit. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six-transistor cell) memory array. The six-transistor cell provides inherently lower soft error rates, improved stability over the operating temperature range, and very low standby power compared to the four-transistor/two-poly load cell, making it ideal for military applications.

The '61CD256's static design and control signals (\bar{E} and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip-enable pin provides for easy memory expansion and for automatic power-down. This feature, in conjunction with the full CMOS array, provides for very low standby power operation when the memory is deselected, greatly reducing the overall memory power requirements.

Access time from either address or chip enable is a maximum of 35, 45, or 55 ns, allowing speed enhancements for new and existing designs.

The '69CE288 is a common I/O, 294,912-bit static random-access memory organized as 32,768 words by 9 bits. This memory is fabricated using complementary MOS technology utilizing a full CMOS (six-transistor cell) memory array. The six-transistor cell provides for inherently lower soft error rates, improved stability over the operating temperature range, and very low standby power compared to the four-transistor/two-poly load cell, making it ideal for military applications.

The '69CE288's static design and control signals (\bar{E} , \bar{G} , and \bar{W}) remove the need for refresh circuitry and simplify timing requirements. The chip-enable pin provides for simplified memory expansion/design and for automatic poweredown. Access time from either address or chip enable is a maximum of 35, 45, or 55 ns. The output enable-pin minimizes bus contention problems.

PIN NOMENCLATURE	
A0-A14	Address Inputs
DQ1-DQ9	Data In/Data Out
\bar{E}	Chip Enable/Power Down
GND	Ground
VCC	5-V Supply
\bar{W}	Write Enable
\bar{G}	Output Enable
NC	No Connection

SMJ9914A GPIB CONTROLLER

JUNE 1986 -- REVISED MARCH 1988

- Handles All IEEE-488 1975/78 Functions
- Compatible with IEEE-488A 1980 Supplement
- Maximum Transfer Rate . . . Greater Than 360 Kilobytes/Second
- Talker and Listener Function (T, TE, L, LE)
- Automatic Source and Acceptor Handshakes (SH, AH)
- Controller with Pass Control
- System Controller Capabilities
- Device Trigger and Device Clear Capabilities (DT, DC)
- Optional Automatically Cleared 'Request Service Bit'
- Parallel and Serial Poll Facilities (PP)
- Remote/Local Function with Local Lockout (RL)
- Single or Dual Primary Addressing
- Secondary Address Capabilities
- Direct Interface to SN75160/161/162 Bus Transceivers with No Additional Logic
- Compatible with Most Microprocessors
- Direct-Memory-Access Facilities
- Memory-Mapped Microprocessor Interface
- Temperature Range . . . -55°C to 110°C (S Suffix)

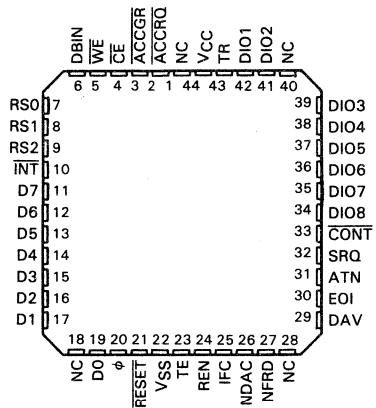

description

The SMJ9914A provides an interface between a Microprocessor System and the General Purpose Interface Bus (GPIB) specified in the IEEE-488 1975/78 standards and the IEEE-488A 1980 supplement. The device is controlled and configured through 8-bit memory-mapped registers and enables all aspects of the standards to be implemented, including talker, listener and controller. The functional block diagram is shown on page 3.

SMJ9914A GPIB CONTROLLER

The GPIB is designed to allow up to 15 instruments within a localized area to communicate with each other over a common bus. Each device has a unique address, read from external switches at power-on, to which it responds. Information is transmitted by byte-serial bit-parallel format and may consist of either device-dependent data or interface messages, commonly referred to as data or command, respectively. A typical application is shown in Figure 1. Auxiliary commands are listed in Table 1.

Device data may be sent by any one device (the talker) and received by a number of other devices (listeners). Instructions, such as select range, select function, or measurement data for processing or printout, may be sent in this way.

The SMJ9914A performs the interface function between the microprocessor and GPIB bus and relieves the processor of the task of maintaining the IEEE protocol. By utilizing the interrupt capabilities of the device, the bus does not have to be continually polled, and fast responses to changes in the interface configuration can be achieved.

The GPIB input/output pins are connected to the IEEE-488 bus via bus transceivers. The direction of data flow is controlled by the TE and $\overline{\text{CONT}}$ outputs generated on the SMJ9914A. The SN75160, 75161 and 75162 bus transceivers are designed specifically for use with a GPIB interface. The TE and $\overline{\text{CONT}}$ signals are routed within the devices so that the buffers on particular lines are controlled as required by the SMJ9914A. Other buffers may be used, but they may require a small amount of external logic, particularly around the EOI line buffer.

SMJ9914A GPIB CONTROLLER

pin descriptions

PIN		I/O	DESCRIPTION
NO.	NAME	(TYPE)	
1	ACCRO	O [†]	Access Request. This pin becomes active (low) to request a direct memory access.
2	ACCGR	I	Access Granted. When received from the direct-memory-access control logic, this enables the byte onto the data bus. ACCGR must be high when not participating in DMA transfer.
3	CE	I	Chip Enable. CE allows access of read and write registers. If CE is high, D0-D7 are in high impedance unless ACCGR is low.
4	WE	I	Write Enable. When active (low), indicates to the SMJ9914A that data is being written to one of its registers.
5	DBIN	I	Data Bus In. An active (high) state indicates to the SMJ9914A that a read is about to be carried out by the MPU.
6	RS0	I	Register Select Lines. Determine which register is addressed by the MPU during a read or write operation.
7	RS1	I	
8	RS2	I	
9	INT	O [‡]	Interrupt. Sent to the MPU to cause a branch to a service routine.
17-10	D0-D7	I/O [†]	Data transfer lines on the MPU side of the device. D0 is the most-significant bit.
18	φ	I	Clock Input. 500 kHz to 5 MHz. Need not be synchronous to system clock.
19	RESET [§]	I	Initializes the SMJ9914A at power-on.
20	VSS		Ground reference voltage.
21	TE	O [†]	Talk Enable. Controls the direction of the transfer of the line transceivers. Logically, it is: [CACS + TACS + EIO.ATN.(CIDS + CADS) SWRST].
22	REN	I/O [†]	Remote Enable. Sent by system controller to select control either from the front panel or from the IEEE bus.
23	IFC	I/O [†]	Interface Clear. Sent by the system controller to set the interface system into a known quiescent state. The system controller becomes the controller in charge.
24	NDAC	I/O [†]	Not Data Accepted. Handshake line. Acceptor sets this false (high) when it has latched the data from the I/O lines.
25	NRFD	I/O [†]	Not Ready For Data. Handshake line. Sent by acceptor to indicate readiness for the next byte.
26	DAV	I/O [†]	Data Valid. Handshake line controlled by source to show acceptors when valid data is present to the bus.
27	EOI	I/O [†]	End Or Identify. If ATN is false (high), this indicates the end of a message block. If ATN is true (low), the controller is requesting a parallel poll.
28	ATN	I/O [†]	Attention. Sent by controller in charge. When true (low), interface commands are being sent over the DIO lines. When false (high), these lines carry data.
29	SRQ	I/O [†]	Service Request. Set true (low) by a device to indicate a need for service.
30	CONT	O [†]	Indicates (low) if a device is controller in charge. It is used to control direction of SRQ and ATN in pass control systems. Logically, it is (CIDS + CADS).
31-38	DIO8-DIO1	I/O [†]	DIO8 through DIO1 are the data input/output lines on the GPIB side. These pins connect to the IEEE-488 bus via non-inverting transceivers.
39	TR	O [†]	Trigger. Activated when the GET command is received over the interface or the fget command is given by the MPU.
40	VCC		Supply voltage (5 V nominal).

[†]Push-pull output

[‡]Open-drain output with no internal pullup

[§]The hardware RESET pin has the following effect on the SMJ9914A:

- Serial and Parallel Poll registers cleared
- All clear/set auxiliary commands cleared except 'swrst'
- 'swrst' auxiliary command set. This holds the SMJ9914A in known states.

[†]Open-drain output with internal pullup

Communication between the microprocessor and SMJ9914A is carried out via memory-mapped registers. There are 13 registers within the SMJ9914A, 6 of which are read and 7 are write. These registers both pass control data to and get status information from the device. These registers are listed in Table 2 and shown in Figure 2.

The three least-significant address lines from the MPU are connected to register select lines RS0, RS1, and RS2 and determine the particular register selected. The high-order address lines are decoded by external logic to cause the \overline{CE} input to the SMJ9914A to be pulled low when any one of eight consecutive addresses are selected. Thus the internal registers appear to be situated at eight consecutive locations within the MPU address space. Reading or writing to these locations transfers information between the SMJ9914A and the microprocessor. Note that reading and writing to the same location will not access the same register within the SMJ9914A since they are either read-only or write-only registers. For example, a read operation with RS2-RS0 = 011 gives the current status of the GPIB interface control lines, whereas a write to this location loads the auxiliary-command register.

Each device on the bus interface is given a 5-bit address enabling it to be addressed as a talker or listener. This address is set on an external DIP switch (usually at the rear of an instrument) before power-on.

Typical SMJ9914A configuration utilizes registers 100 or 101 as an address switch register (see Table 2.). This register may consist of a DIP switch which drives the data lines via 3-state buffers when one of these addresses is read. This allows the host MPU to read a device address which is manually set and write this address into the address register of the SMJ9914A for device identification on the bus. The SMJ9914A responds by causing a My Address (MA) interrupt and entering the required addressed state when this address is detected on the GPIB data lines.

TABLE 1. AUXILIARY COMMANDS

MNEMONIC	DESCRIPTION	CLEAR	SET	C/S
				NA CODE
dacr	Release DAC holdoff	01	81	
dai	Disable all interrupts	13	93	
feoi	Send EOI with next byte			08
fget	Force group execute trigger	06	86	
gts	Go to standby			0B
hdfa	Holdoff on all data	03	83	
hdfe	Holdoff on EOI only	04	84	
lon	Listen only	09	89	
nbafe	New byte available false			05
pts	Pass through next secondary			14
rhdf	Release RFD holdoff			02
rlc	Release control			12
rpp	Request parallel poll	0E	8E	
rqc	Request control			11
rsv2	Request service bit 2	18	98	
rtl	Return to local	07	87	
shdw	Shadow handshake	16	96	
sic	Send interface clear	0F	8F	
sre	Send remote enable	10	90	
std1	Short T1 settling time	15	95	
tca	Take control			
	asynchronously			0C
tcs	Take control			
	synchronously			0D
ton	Talk only	0A	8A	
vstd1	Very short T1 delay	17	97	

TABLE 2. REGISTER ADDRESSES

ADDRESS			READ	WRITE
RS2	RS1	RS0	REGISTERS	REGISTERS
0	0	0	Interrupt Status 0	Interrupt Mask 0
0	0	1	Interrupt Status 1	Interrupt Mask 1
0	1	0	Address Status	+
0	1	1	Bus Status	Auxiliary Command
1	0	0	↑	Address
1	0	1	↑	Serial Poll
1	1	0	Command Pass Thru	Parallel Poll
1	1	1	Data In	Data Out

†The SMJ9914A host interface data lines will remain in the high-impedance state when these register locations are addressed. An Address Switch Register may therefore be included in the address space of the device at these locations.

‡This address is not decoded by the SMJ9914A. A write to this location will have no effect on the device, as if a write had not occurred.

clock cycle timing

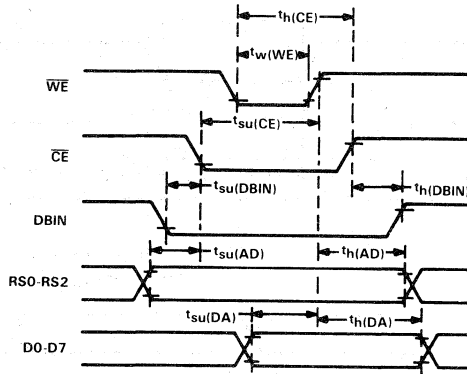

read cycle timing

Military Products

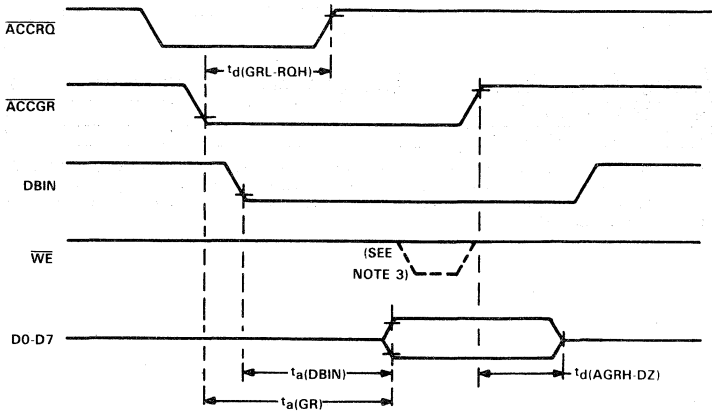

8

write cycle timing

NOTE 2: $t_h(AD)$ and $t_h(DA)$ are shown measured from the rising edge of \overline{WE} . This is the correct reference point in this figure, since the measurements should be from the rising edge of \overline{WE} or \overline{CE} – whichever comes first.

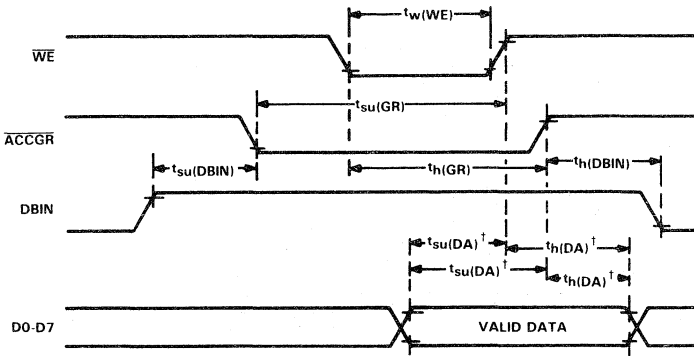

DMA read operation

NOTE 3: A write-enable pulse may occur in a DMA read operation. A write-enable pulse may therefore be provided for system memory and need not be suppressed at the SMJ9914A.

**SMJ9914A
 GPIB CONTROLLER**

DMA write operation

[†] $t_{su}(DA)$ and $t_{th}(DA)$ are only applicable to the first signal to become inactive, whether it is \overline{WE} or \overline{ACCGR} .

source handshake timing characteristics over full range of operating conditions (see Note 4)

PARAMETER	TEST CONDITIONS	MIN	MAX	UNIT
td1 Delay of DAV true from end of write operation to data out register	Normal T_1 (see Note 5)	$12(\phi)^\dagger$	$12(\phi)^\dagger + 310$	ns
	Short T_1 (see Note 5)	$8(\phi)^\dagger$	$8(\phi)^\dagger + 310$	ns
	Very short T_1 (see Note 5)	$4(\phi)^\dagger$	$4(\phi)^\dagger + 310$	ns
td2 Delay of valid GPIB data lines from end of write cycle			140	ns
td3 Delay of BO interrupt from DAC true	BO interrupt unmasked		300	ns
td4 Delay of \overline{ACCGR} DAC true			300	ns
td5 Delay of DAV false from DAC true			160	ns

- NOTES: 4. The timing of the source handshake is the same whether ATN is true or false; i.e., whether the device is in TACS, CACS, or SPAS.
 5. A very short bus settling time (T_1) occurs on the second and subsequent data byte when ATN is false if the "vstd1" feature is set. A slightly longer bus settling time takes place if "std1" is set unless there is a very short bus settling time. In all other instances, a normal bus settling time occurs.

acceptor handshake timing characteristics over full range of operating conditions

PARAMETER		TEST CONDITIONS	MIN	MAX	UNIT
t _{d6}	Delay of BI interrupt from DAV true	BI interrupt unmasked, ATN = false, device in LACS	2(φ)↑	2(φ)↑ + 415	ns
t _{d7}	Delay of $\overline{\text{ACCRQ}}$ from DAV true	ATN = false, device is in LACS	2(φ)↑	2(φ)↑ + 290	ns
t _{d8}	Delay of NDAC false from DAV true	ATN = false, device in LACS	3(φ)↑	3(φ)↑ + 445	ns
t _{d9}	Delay of NRFD false from end of read operation of Data-In register	ATN = false, device is in LACS		220	ns
t _{d10}	Delay of interface message interrupt from DAV true	ATN = false, device not in CACS, all interface message interrupts (except UNC)	2(φ)↑	2(φ)↑ + 415	ns
		UNC interrupt only	5(φ)↑	5(φ)↑ + 415	ns
t _{d11}	Delay of NDAC false from DAV true	ATN = true, device not in CACS, no DAC holdoff	7(φ)↑	7(φ)↑ + 415	ns
t _{d12}	Delay of NDAC false from end of write operation			230	ns
t _{d13}	Delay of NRFD false from DAV false	ATN = true, device not in CACS		180	ns

NOTE 6: The interrupts generated by interface messages are shown in Table 3-15 of the TMS9914A General Purpose Interface Bus (GPIO) Controller Data Manual (MP033A).

ATN, EOI, and IFC timing characteristics over full range of operating conditions

PARAMETER		TEST CONDITIONS	MIN	MAX	UNIT
t _{d14}	Delay of NDAC true from ATN true	Device is not in CACS		195	ns
t _{d15}	Delay of TE high from EOI true	Device is not in CACS		125	ns
t _{d16}	Delay of valid data from EOI true	Device is not in CACS		140	ns
t _{d17}	Delay of TE low from EOI false	Device is not in CACS		125	ns

Designing and Manufacturing Surface Mount Assemblies

Elizabeth Gunther, Charles Hutchins, and Paul Peterson

The competitive nature of the semiconductor industry has driven vendors to minimize the size of electronic components, so that more functions can be achieved in a given volume. In addition, improved electrical performance, decreased mass, and the potential for lower system cost are all by-products of compacted packaging and circuitry which hold interest to component manufacturers and users alike.

Surface Mount Technology (SMT) offers an excellent method of reducing component size. A typical memory array can be reduced to 50 percent of its original PWB size with single-sided mounting, and 25 to 30 percent with double-sided mounting. Logic designs cannot achieve the same dramatic reduction, but decreases up to 40 to 60 percent can be achieved for single-sided and double-sided assemblies respectively.

The key design and manufacturing process issues must be understood in order to fully reap the benefits of Surface Mount Technology. This article gives a general overview of the key aspects of design, process, and manufacturing of surface mounted assemblies, and offers surface mount as an opportunity to lower a system's cost without sacrificing reliability.

Components

Most surface mount components are at least one-third the size of the comparable through-hole mounted device (Figure 1). The 68-pin chip carrier is approximately one square inch, while the 64-pin DIP is approximately three square inches. The 20-pin chip carrier is slightly larger than 0.1 square inch, while the 20-pin DIP is 0.3 square inch. Similarly, other IC packages are reduced to approximately one-third the size of comparable lead count packages. The passive components

Figure 1. Component Site Reduction

occupy approximately one-tenth the board area, and this is why they have been used in most small consumer products built in the last couple of years.

There were many references in the recent past to problems with component availability, cost, and standardization. This area of SMT has probably received more attention than any other. Several recent magazine articles now state that significantly more components (particularly actives) are now available and that cost parity has been achieved on most of them. The effort by various industry committees on standardization has also been effective.

Thus, although more needs to be accomplished in these areas, a designer can begin a project with confidence that there will be no insurmountable barriers in this area. There are several consultants and subcontract assembly companies to assist in this effort. It is strongly recommended that all new designs utilize some form of SMT, particularly when space is an important consideration.

Process

The process to manufacture a surface mount assembly (SMA) is very simple. It consists of four basic steps, as shown in Figure 2. First, the solder paste is screened on the PWB. Then the component is placed on the board, with due care to get it positioned correctly. Typical geometries require placement accuracy of less than plus/minus 4 mils. Next the solder is reflowed with either a vapor phase or infrared system. Finally, the assembly is cleaned and is now ready for test. This process, although simple in concept, relies on board and component planarity and solderability. These are easily achievable with the chip carriers and memory modules we will discuss later.

Texas Instruments has installed a Surface Mount Technology Center at its plant in Houston, Texas. At this center, we have a complete and flexible engineering line to assist our customers in converting to Surface Mount Technology.

The engineering line is equipped with a screen printer, pick and place system, vapor phase reflow, and clean-up station that will easily handle PWBs up to 9" x 10". Larger boards up to 14" x 16" can be processed with some additional care. TI uses this engineering line to produce its prototype and demo boards. It is also available to any of TI's customers, free of charge, for use in building test or prototype boards.

The effectiveness of the assembly process can be characterized by the number of unacceptable solder joints formed during the process. Unacceptable joints are defined by their electrical and mechanical (strength and reliability) characteristics. The major problem is open solder joints, followed by bridging and misregistration.

Figure 2. Basic Process Steps

Open circuits are detected at electrical test and are the first defects detected after soldering. At Texas Instruments, 10 PPM or less is the desirable defect level. Several factors that contribute to open solder joints were identified during production start-up. Lead tip planarity of the J-leaded plastic chip carriers is the most important factor in obtaining acceptable process yields. Lead position, lead finish, solder paste composition, and PWB solderability affect process yield as well.

Experiments in which lead tip planarity was confined to specific limits between 1 to 7 mils indicate that a 2 mil planarity requirement produces acceptable results with the process currently in use. Little gain in yield was noted at a 1 mil planarity requirement.

Another interesting result showed that silver in the process, either as a lead finish or in the solder paste, improves yields significantly. One explanation may have to do with the dynamics of the solder during the reflow process as they are affected by the different surface forces acting in the silver and non-silver process.

Design

The design of the PWB, in addition to providing the component interconnections, will provide the proper amount and correct placement of solder paste for a strong fillet formation. The wave soldering process, by comparison, provides a semi-infinite amount of solder, whereas the SMT process will provide only a predetermined amount. Thus, the component connection pad must be correctly placed and be of the proper size.

Further, consideration must be given for inspection, testing, and rework. The density achievable can lead to severe problems at these points if understanding and due care are not exercised in the design. The project team should include members from manufacturing, testing, QA, and purchasing, in addition to the design engineers, from the start. The design and processing of test boards is strongly recommended to provide experience and direction for the major project.

A very practical set of design guidelines is given in Figure 3. These have been used on a number of SMT designs and have given good results. With proper manufacturing techniques as described later, a high yield can be achieved. Component spacings should be approximately equal to the height of the tallest component. This allows an angle of 45 degrees for visual inspection of test probes.

Figure 4 shows the standard footprint for all Small Outline (SO) packages. The larger and more important fillet of an SO package is on the inside of the gull-wing lead. The solder pad, or land, should therefore be designed to extend

slightly under the body of the package in order to optimize this fillet. From Table 1 we can see all packages have 50 mil centers with 25 mil spacings between lands. This allows the designer enough space to put traces between pads, and also reduces the occurrence of solder bridging of adjacent lands. Table 1 also summarizes the suggested land lengths and placement, depending on the terminal count of the SO. While not an absolute solution, these land sizes offer a conservative design solution that will meet most vendors' specifications and provide a mechanically and electrically sound solder joint.

Figure 3. PWB Design Guidelines

Manufacturing

The SMT manufacturing area must have the following basic equipment:

- Solder Paste Printer
- Component Pick and Place Machine
- Solder Paste Reflow Machine
- Clean-up System
- Inspection/Process Control Aids
- Electrical Test

The criteria for choosing the above is determined mainly by the size(s) and quantity of PWBs per month, the gross number of components per PWB, and the number of different components per PWB.

The size of the largest PWB is an important criterion in the choice of all of the major items. The printer, pick and place, reflow, and clean-up must all be able to handle it with no difficulty or process nonuniformity. The number and size of the various PWBs that may be produced will secondarily be considered for ease of set up and changeover in the printer and pick and place. The pick and place machine(s) will

probably be the most expensive item in the list above and therefore, should get the most attention.

The gross number of components and PWBs will provide data for choosing the pick and place. Component per hour placement speed should be checked in actual operation, as the interrelationship may affect ultimate speed. The number of different components per board will determine how many feeders and what types of feeders will be required. This is a very key issue, as well as the accuracy of placement.

Reflow

The solder reflow is easily achieved with any of the commercially available equipment. Subtle differences between vapor phase, either batch or in-line, and infrared are overshadowed by the choice of solder paste and the solderability/planarity issue. A batch vapor phase is extremely flexible for different sizes of boards with different component counts. The in-line vapor phase is a good choice for a more automated processing line with standard or similar sized boards. The infrared has the advantage of being less expensive to operate, but requires more alteration to set up the time-temperature profile for a different size PWB. This would be a minimal problem on a manufacturing line building high volumes of the same board.

Clean-up

The most popular flux for SMT is the mildly activated rosin flux (RMA). This was developed in the days of vacuum tube assembly when clean-up was next to impossible. It is noncorrosive but provides sufficient fluxing action for good quality components and PWBs. Thus it is the preferred choice for SMAs with small spacings under most passives and SOICs, where complete cleaning is difficult. A mild solvent, such as Freon TMS, is generally sufficient to achieve a good visual cleanup, and there are several systems available that provide hot vapor, spray, or ultrasonic de-fluxing.

Reliability

With the smaller surface mount packages, there is some concern about component reliability. Texas Instruments addressed the overall DRAM reliability issue several years ago. Through an extensive task force effort, the major problems of the life test, humidity performance, and temperature cycle were identified. The best solutions to these problems required several changes in the design and process of the silicon chip. In doing so, the reliability of the DRAM chip became independent of the package used. Thus, the 64K DRAM in the plastic chip carrier package performs equivalently to the same chip in a DIP as shown in Figure 5. Similar data is available on most semiconductor ICs.

An additional reliability concern originates in the surface mount solder reflow process, which submits components to higher reflow temperatures more suddenly than the wave-soldering methods of DIP components, with oftentimes repeated reflow cycles for rework and repair.

The best method for resolving this issue involves comparing the temperature-time differential of the vapor phase or infrared solder reflow process to the standard temperature

cycling reliability tests to which surface mount components are routinely submitted. Figures 6 and 7 show temperature profiles of the vapor phase and infrared solder reflow processes. In the vapor phase process, the maximum temperature change with time is:

$$\frac{215^{\circ}\text{C} - 25^{\circ}\text{C}}{45 \text{ sec}} = \frac{190^{\circ}\text{C}}{45 \text{ sec}}$$

equating approximately 4°C/sec. The infrared solder reflow method submits the ICs to a similar, yet less severe temperature over time change of 3°C/second. Comparing these temperature profile ramp-ups to that which a surface mount component undergoes in a temperature cycling reliability test proves that there should be no concern over damage to the component during reflow. In the temp cycling test, the surface mount components were submitted to 1000 cycles of sudden cycling from 150°C to -65°C within three seconds. This represents a temperature-time differential of:

$$\frac{150^{\circ}\text{C} - (-65^{\circ}\text{C})}{3} = \frac{215^{\circ}\text{C}}{3 \text{ sec}} = \frac{70^{\circ}\text{C}}{\text{sec}}$$

with less than 0.5 percent failures.

Figure 6. Typical Temperature Profile for In-Line Vapor Phase Reflow

Figure 7. Typical IR Reflow System Profile

Since the surface mounted components were able to withstand a 70°C/second temperature change of 1000 cycles, they should be able to withstand the less severe conditions of a 4°C/second damage during reflow without reliability degradation.

Another concern in the solder reflow processing of surface mount components is the dwell time in reflow temperatures of 215°C or above. The dwell time for a small PWB populated with surface mount devices is about 20 seconds. For a larger board of about 10"×12" up to 50 seconds is needed for reflow. A generalized component degradation curve, relating accumulated time and temperature, can be assumed to exist. The shape of the curve for this discussion is assumed to be a decaying parabolic for simplicity and conservatism. There are two generally known points of this curve. The flame retardant mold compound (FRMC) of a plastic package starts to break down at 300°C in two to three seconds. Also, the molding and curing of a surface mount device is performed over several hours at 175°C. These two points are shown on the generalized curve shown in Figure 8, with the "safe" region being the area under the curve. Two points that fall within this region are the industry standard practice of solder dipping leads of several types of ICs, and of the soldering plastic devices on the bottom with Type III surface mount assembly, each submerges the component for three to four seconds in a solder wave.

Figure 8. General Plastic Degradation Curve

Summary

Surface mount assembly techniques provide a significant advantage in cost, volume, and reliability over the current "thru-hole" technology. These are well documented, and the manufacturing equipment and related products are becoming readily available to support new production lines. Also, as experience grows, improved products and ideas are developed from the cooperative efforts of vendors and users in standardization organizations and in problem-solving sessions. The broad selection of package types and product technologies available now are sufficient to begin conversion of existing electronic system products for size reduction or feature enhancement. Definitely, new products should be designed with surface mount technology.

2 Memory Timing Controllers

2.1 Introduction

As processor and memory speeds increase, so do dynamic memory controller requirements. Typical processor speeds today range from 8 to 10 MHz. This increase in processor speed has created a need for faster memories, as well as faster memory timing controllers. The 'ALS2967, 'ALS2968, 'ALS6301, and 'ALS6302 are Memory Timing Controllers that are designed to meet the need of high performance memory systems.

In addition to offering better system performance, a faster memory controller typically allows the designer to use slower-rated dynamic random access memories (DRAMs). This results in significant cost savings because of the large number of DRAMs required. In other words, a faster dynamic memory controller can reduce overall dynamic memory costs.

The 'ALS2967, 'ALS2968, 'ALS6301, and 'ALS6302 feature address multiplexing, memory bank selection, and an address latch for systems which multiplex both data and address on the same bus. A row counter is provided for normal refresh operations. Column and bank counters are available for systems which use memory scrubbing.

This Section describes the functional operation of the 'ALS2967, 'ALS2968, 'ALS6301, and 'ALS6302 and shows how they can be interfaced to a typical processor. For illustration purposes, a simple timing controller generated from programmable logic is used to interface both the 'ALS2967 and the 'ALS6301 to the microprocessor. The 'ALS2967 is interfaced with an Intel 8086 and the 'ALS6301 is interfaced with a Motorola 68000.

This Section also presents a circuit configuration which interfaces the MC68000 to DRAM memory using the THCT4502B dynamic RAM Controller. The memory array is organized as 4 banks of 256K memory (TMS4256/4257) providing a 1M byte deep system architecture.

2.2 Memory Timing Controllers Using the SN54/74ALS2967, SN54/74ALS2968

2.2.1 Functional Description

The 'ALS2967 and 'ALS2968 are capable of controlling 16K, 64K, and 256K DRAMs. The two devices typically operate in a read/write or a refresh mode. During normal read/write operations, the row and column addresses are multiplexed to the DRAM, and the corresponding \overline{RAS} and \overline{CAS} signals are activated to strobe the addresses into memory. In the refresh mode, the two counters cycle through the refresh addresses. If memory scrubbing is not being implemented, only the row counter is used. When memory scrubbing is being performed, both the row and column counters are used to perform read-modify-write cycles using an error detection and correction circuit such as the 'ALS632A. In this mode, all \overline{RAS} outputs will be active (low) while only one \overline{CAS} output is active at a time.

Two device types are offered to help simplify interfacing with the system dynamic timing controller. The 'ALS2967 offers active-low row address strobe input (\overline{RASI}) and column address strobe input (\overline{CASI}) signals, while the 'ALS2968 offers active-high $RASI$ and $CASI$ inputs. Figure 2-1 is a functional block diagram of the two devices.

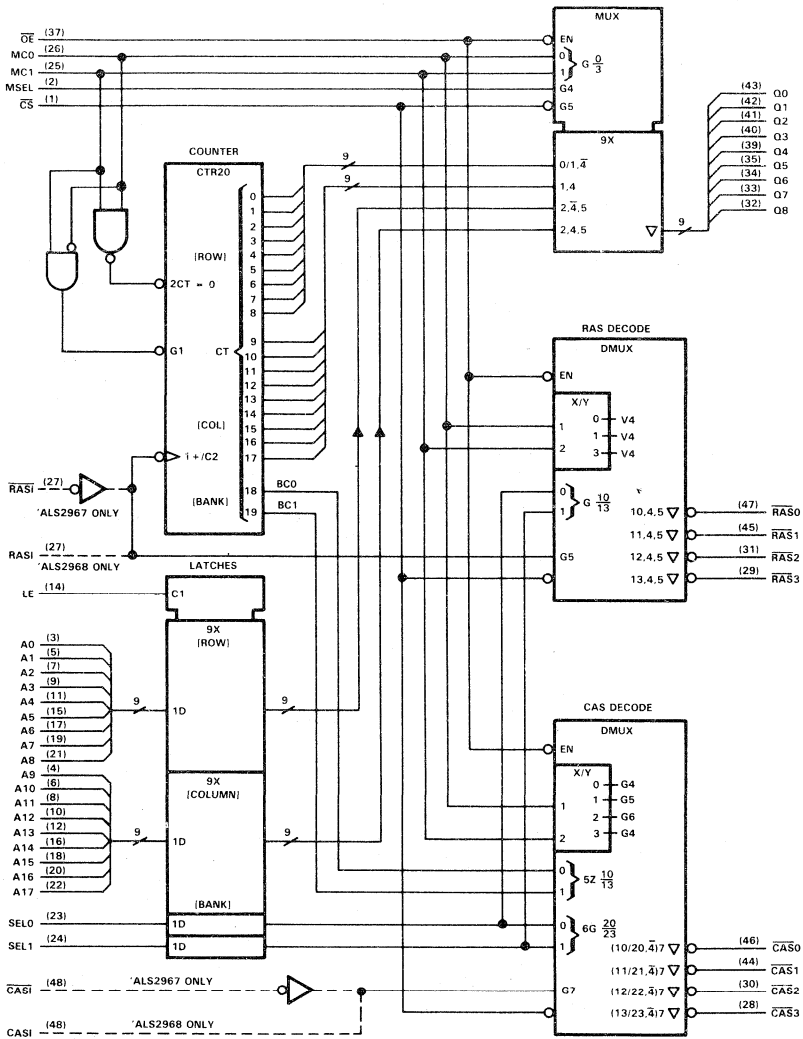

Figure 2-1. 'ALS2967, 'ALS2968 Functional Block Diagram

Table 2-1 describes the four operating modes of the 'ALS2967 and 'ALS2968 as controlled by inputs MCO and MC1. During normal read/write operations, the row and column addresses are multiplexed to the DRAM. When MSEL is high, the column address is selected; when MSEL is low, the row address is selected. The corresponding $\overline{\text{RAS}}_n$ and $\overline{\text{CAS}}_n$ output signals strobe the addresses into the selected memory bank or banks. A single 'ALS2967 or 'ALS2968 can control as many as four banks of 256K memory. Additional banks of memory can be controlled by using additional 'ALS2967 or 'ALS2968 devices and decoding each chip select ($\overline{\text{CS}}$) input.

Table 2-1. 'ALS2967, 'ALS2968 Mode-Control Function Table

SIGNAL		MODE SELECTED
MC1	MCO	
L	L	Refresh without Scrubbing. Refresh cycles are performed using the row counter to generate the addresses. In this mode, all four $\overline{\text{RAS}}$ outputs are active while the four $\overline{\text{CAS}}$ outputs remain high.
L	H	Refresh with Scrubbing/Initialize. Refresh cycles are performed using both the row and column counters to generate the addresses. MSEL selects the row or the column counter. All four $\overline{\text{RAS}}$ outputs go low in response to $\overline{\text{RAS}}_i$ ('ALS2967) or $\overline{\text{RAS}}_i$ ('ALS2968), while only one $\overline{\text{CAS}}_n$ output goes low in response to $\overline{\text{CAS}}_i$ ('ALS2967) or $\overline{\text{CAS}}_i$ ('ALS2968). The bank counter keeps track of which $\overline{\text{CAS}}$ output goes active. This mode can also be used during system power-up so that the memory can be written with a known data pattern.
H	L	Read/Write. This mode is used to perform read/write cycles. Both the row and column addresses are multiplexed to the address output lines using MSEL. SEL0 and SEL1 are decoded to determine which $\overline{\text{RAS}}_n$ and $\overline{\text{CAS}}_n$ outputs will be active.
H	H	Clear Refresh Counters. This mode clears the three refresh counters (row, column, and bank) on the inactive transition of $\overline{\text{RAS}}_i$ ('ALS2967) or $\overline{\text{RAS}}_i$ ('ALS2968), putting them at the beginning of the refresh sequence. In this mode, all four $\overline{\text{RAS}}$ outputs are driven low after the active edge of $\overline{\text{RAS}}_i$ ('ALS2967) or $\overline{\text{RAS}}_i$ ('ALS2968) so that DRAM wake-up cycles can also be performed.

In systems where addresses and data are both multiplexed onto a single bus, the 'ALS2967 and 'ALS2968 use latches (row, column and bank) to hold the address information. The 20 input latches are transparent when the latch enable input (LE) is high; the input data is latched whenever LE goes low. For systems in which the processor has separate address and data buses, LE may be tied high.

The two 9-bit counters in the 'ALS2967 and 'ALS2968 support 128, 256, and 512 line refresh operations. Transparent, burst, synchronous, or asynchronous refresh modes are all possible as determined by the memory timing controller. The refresh counters are advanced on the low-to-high transition of $\overline{\text{RAS}}_i$ on the 'ALS2967, and on the high-to-low transition of $\overline{\text{RAS}}_i$ on the 'ALS2968. This is true in either refresh mode. In the clear refresh counter mode, the refresh counters (row, column, and bank) can be reset to zero on the low-to-high transition of $\overline{\text{RAS}}_i$ on the 'ALS2967 or on the high-to-low transition of $\overline{\text{RAS}}_i$ on the 'ALS2968.

2.2.2 Typical Implementation

Figure 2-2 shows a system interface using the 'ALS2967 between an Intel 8086 and four banks of 256K DRAMs. Addresses A18 and A19 are used to select one of the four memory banks. Since members of the 8086 processor family multiplex both data and addresses onto the same data bus, input latches on the 'ALS2967 must be used to store the row, column, and bank information. The ALE signal from the 8086 can be directly connected to the latch enable (LE) input on the 'ALS2967.

The $\overline{\text{RAS}}$, $\overline{\text{CAS}}$, MSEL and mode control (MC0, MC1) inputs on the 'ALS2967 must be generated by the memory timing controller. The memory timing controller functions as an arbitrator between refresh cycles and 8086 access cycles. It also guarantees that timing requirements of the DRAM will be met.

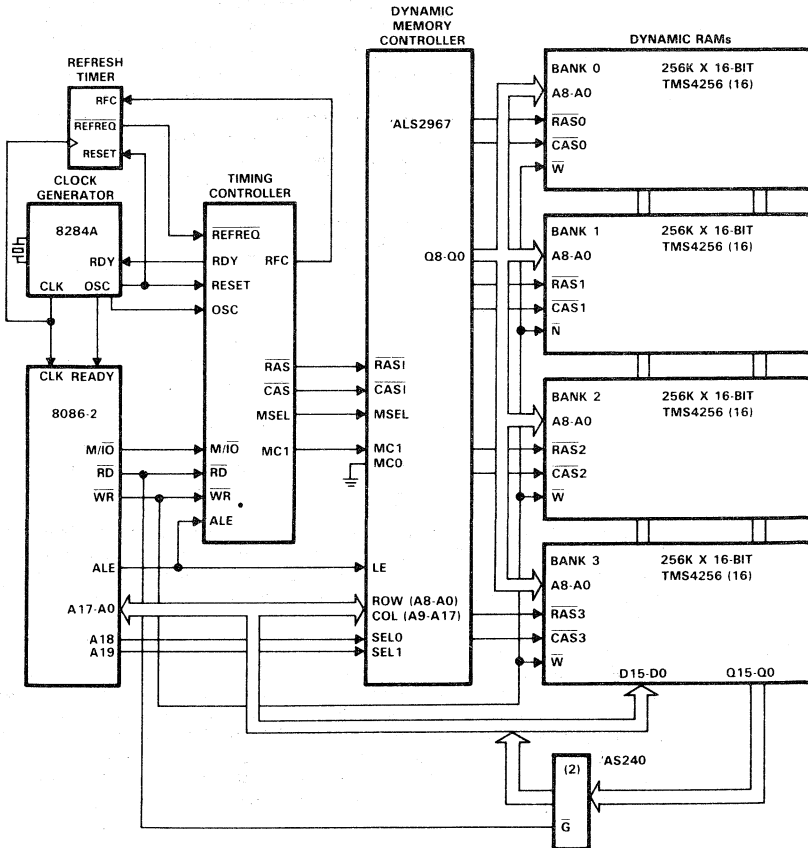

Figure 2-2. 'ALS2967, 'ALS2968 Timing Controller Interface

2.2.3 Timing Controller Details

Figure 2-3 is a timing diagram for a typical 8086 access cycle. The 'ALS2967 control signals required to execute the access cycle are also shown. Control signals for the 'ALS2967 are referenced from the OSC output of the 8284A clock generator. The timing controller in this example is generated from a state machine referenced from the OSC output of the 8284A. In critical timing situations, it may be necessary to tightly control the phase relationship of the system clock to the OSC signal. This can be accomplished by using a phase lock loop or similar method to generate the OSC signal.

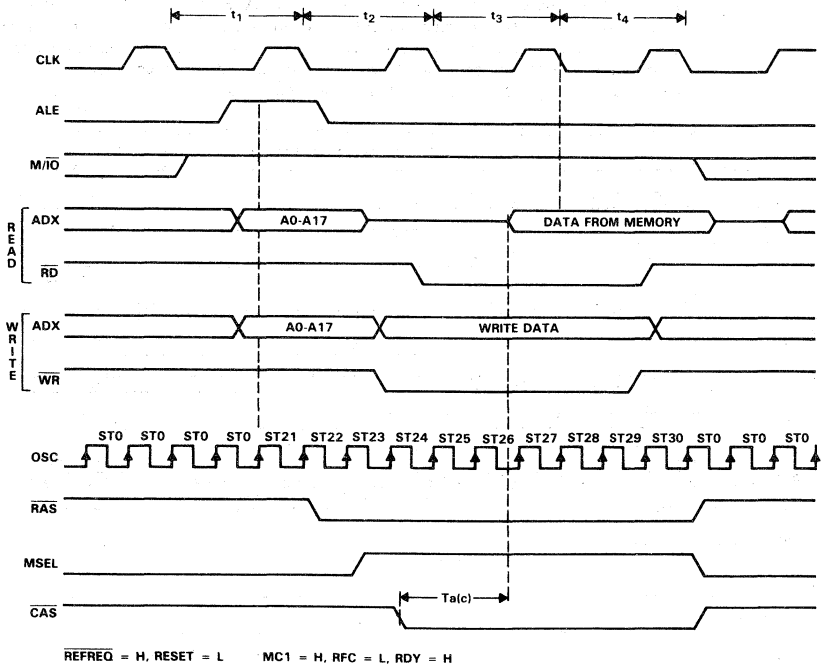

Figure 2-3. 8086 Access Cycle

In this example, refresh requests ($\overline{\text{REFREQ}}$) are generated every 122 clock cycles. The timing controller will perform the refresh cycle ($\overline{\text{RAS}}$ only) immediately if the processor is not in the middle of an access cycle. If the controller is in the middle of an access cycle, the refresh cycle will be delayed until the access cycle is complete. If the controller is asked to perform an access cycle during a refresh, the controller will place the processor in a wait state (RDY low) until the refresh is complete. Figure 2-4 shows the timing diagram for a refresh/access cycle as explained above. To implement memory scrubbing, the controller must execute a read/write cycle during the refresh cycle and then place the 'ALS2967 in the memory scrubbing mode (This example executes RAS only refresh).

Figure 2-5 is a flow chart for the timing controller. ABEL™ and CUPL™ software was used to generate fuse maps from the present state of the inputs and present condition of the state machine. These fuse maps were then used in programming the field programmable logic devices. The files used to generate the fuse maps have been included for reference at the end of this application note.

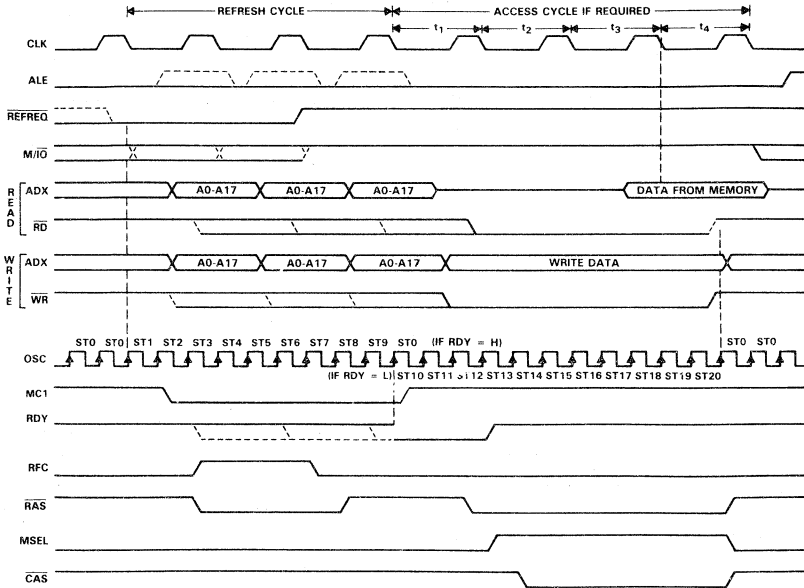

Figure 2-4. Refresh/Access Cycle

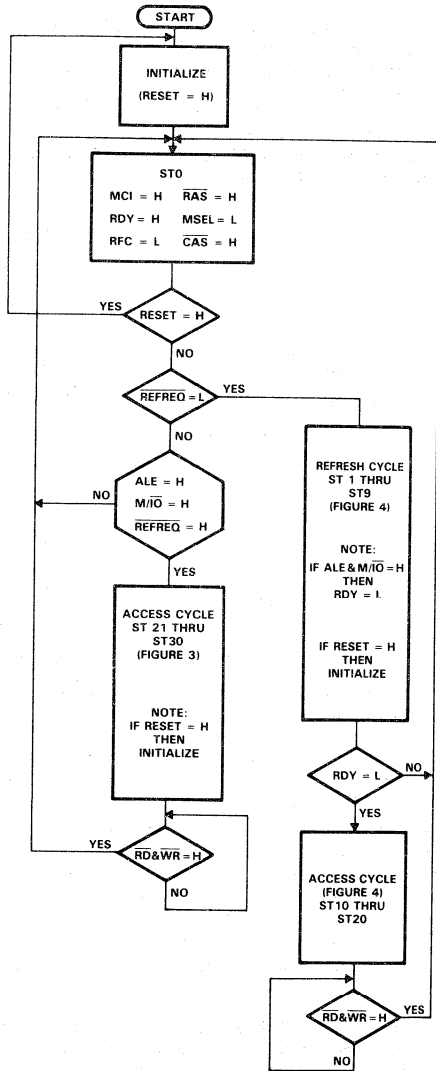

Figure 2-5. 'ALS2967, 'ALS2968 Memory Timing Controller Flow Chart

Figure 2-6 shows the actual circuit implementation of the refresh and memory timing controller. The refresh timer signals the controller whenever it is time to execute a refresh cycle. As required by memory, every row (256 on the TMS4256 DRAM) must be addressed every 4 ms. This implies that one row should be refreshed at least once every 15.6 μ s. With an 8-MHz system clock, the refresh timer should use approximately a division factor of 122. This results in a refresh request every 15.3 μ s. The refresh complete input (RFC) is used to signal the refresh timer that the refresh has been completed. It is important that the timer not stop so that the 4-ms memory requirement is maintained.

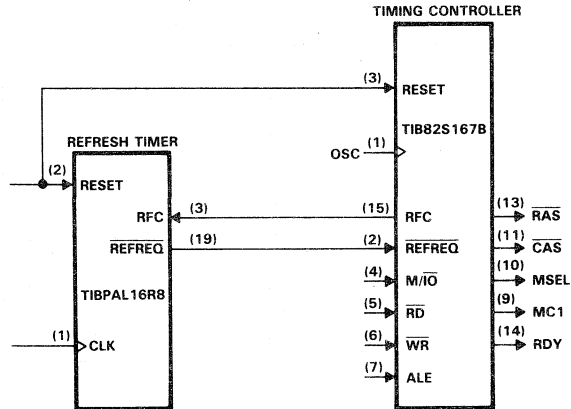

Figure 2-6. Refresh/Memory Timing Controller

The TIBPAL16R8 circuit shown in Figure 2-6 is used to generate the refresh request signal every 122 clock cycles. The refresh request signal (active low) will remain active (low) until a refresh complete (RFC) signal is received from the timing controller. During a system reset, the refresh request output is set to a high-logic level. When using different clock rates or memory sizes, the division circuit in the refresh timer should be adjusted accordingly.

The TIB82S167B field programmable sequencer shown in Figure 2-6 is configured as a state machine to execute the flow chart shown in Figure 2-5. In cases with different system timings, the CUPL™ file can be modified to fit the processor requirements. In addition, a slight modification to the file will allow an 'ALS2968 to be used instead of an 'ALS2967.

A preprogrammed sample of the refresh and timing controllers shown in Figure 2-6 can be obtained by calling PAL/PROM Applications, 214/995-2980.

2.2.4 Summary

The 'ALS2967 and 'ALS2968, coupled with programmable logic, offer the system designer a solution to high-speed dynamic memory requirements. Programmable logic allows the designer to tailor the timing controller to a selected processor and memory. In many cases, the generation of a high-speed timing controller from programmable logic will allow the designer to use slower DRAMs without affecting system speed. This results in lower total system cost because of the large number of memory devices used.

2.3 Memory Timing Controllers Using the SN54/74ALS6301, SN54/74ALS6302

2.3.1 Functional Description

The 'ALS6301 and 'ALS6302 are capable of controlling any DRAM up to 1M. The two devices typically operate in a read/write or a refresh mode. During normal read/write operations, the row and column addresses are multiplexed to the DRAM, and the corresponding \overline{RAS} and \overline{CAS} signals are activated to strobe the addresses into memory. In the refresh mode, the two counters cycle through the refresh addresses. If memory scrubbing is not being implemented, only the row counter is used. When memory scrubbing is being performed, both the row and column counters are used to perform read-modify-write cycles using an error detection and correction circuit such as the 'ALS632A. In this mode, all \overline{RAS} outputs will be active (low) while only one \overline{CAS} output is active at a time.

Two device types are offered to help simplify interfacing with the system dynamic timing controller. The 'ALS6301 offers active-low row address strobe input (\overline{RASi}) and column address strobe input (\overline{CASi}) signals, while the 'ALS6302 offers active-high \overline{RASi} and \overline{CASi} inputs. Figure 2-7 is a functional block diagram of the two devices.

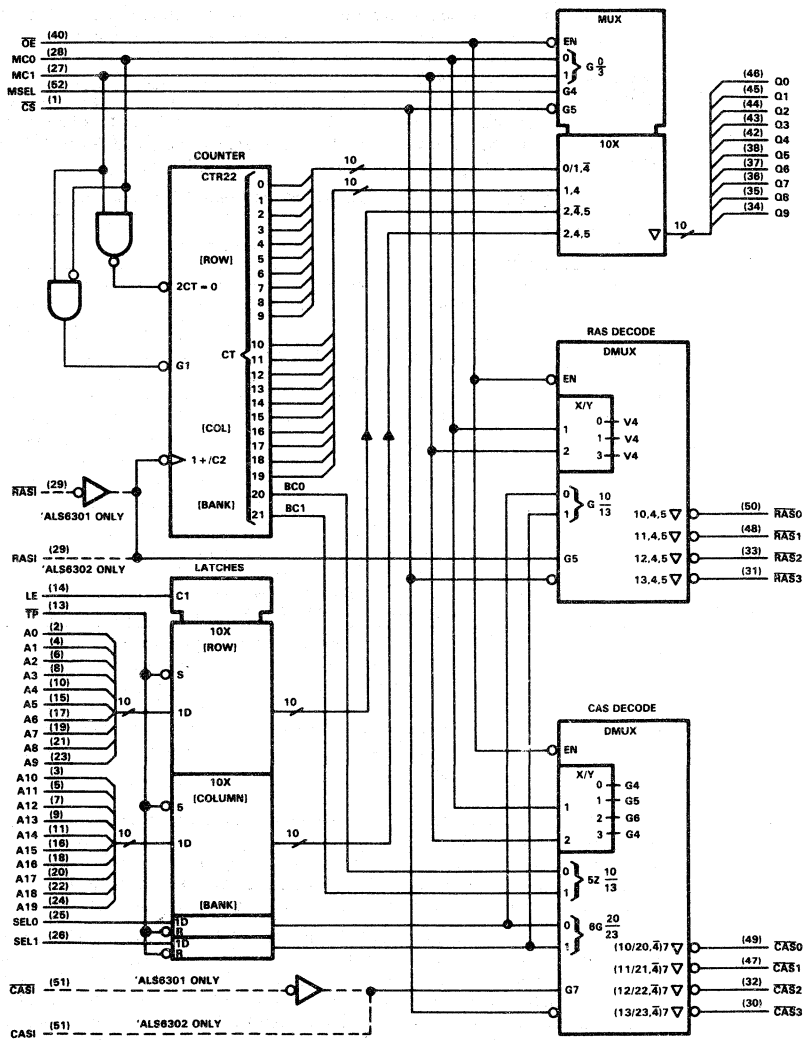

Figure 2-7. 'ALS6301, 'ALS6302 Functional Block Diagram

Table 2-2 describes the four operating modes of the 'ALS6301 and 'ALS6302 as controlled by inputs MC0 and MC1. During normal read/write operations, the row and column addresses are multiplexed to the DRAM. When MSEL is high, the column address is selected; when MSEL is low, the row address is selected. The corresponding $\overline{\text{RAS}}_n$ and $\overline{\text{CAS}}_n$ output signals strobe the addresses into the selected memory bank or banks. A single 'ALS6301 or 'ALS6302 can control as many as four banks of 1M memory. Additional banks of memory can be controlled by using additional 'ALS6301 or 'ALS6302 devices and decoding each chip select ($\overline{\text{CS}}$) input.

Table 2-2. 'ALS6301, 'ALS6302 Mode-Control Function Table

SIGNAL		MODE SELECTED
MC1	MC0	
L	L	Refresh without Scrubbing. Refresh cycles are performed using the row counter to generate the addresses. In this mode, all four $\overline{\text{RAS}}$ outputs are active while the four $\overline{\text{CAS}}$ outputs remain high.
L	H	Refresh with Scrubbing/Initialize. Refresh cycles are performed using both the row and column counters to generate the addresses. MSEL selects the row or the column counter. All four $\overline{\text{RAS}}$ outputs go low in response to $\overline{\text{RAS}}_i$ ('ALS6301) or $\overline{\text{RAS}}_i$ ('ALS6302), while only one $\overline{\text{CAS}}_n$ output goes low in response to $\overline{\text{CAS}}_i$ ('ALS6301) or $\overline{\text{CAS}}_i$ ('ALS6302). The bank counter keeps track of which $\overline{\text{CAS}}$ output goes active. This mode can also be used during system power-up so that the memory can be written with a known data pattern.
H	L	Read/Write. This mode is used to perform read/write cycles. Both the row and column addresses are multiplexed to the address output lines using MSEL. $\overline{\text{SELO}}$ and $\overline{\text{SEL1}}$ are decoded to determine which $\overline{\text{RAS}}_n$ and $\overline{\text{CAS}}_n$ outputs will be active.
H	H	Clear Refresh Counters. This mode clears the three refresh counters (row, column, and bank) on the inactive transition of $\overline{\text{RAS}}_i$ ('ALS6301) or $\overline{\text{RAS}}_i$ ('ALS6302), putting them at the beginning of the refresh sequence. In this mode, all four $\overline{\text{RAS}}$ outputs are driven low after the active edge of $\overline{\text{RAS}}_i$ ('ALS6301) or $\overline{\text{RAS}}_i$ ('ALS6302) so that DRAM wake-up cycles can also be performed.

In systems where addresses and data are both multiplexed onto a single bus, the 'ALS6301 and 'ALS6302 use latches (row, column and bank) to hold the address information. The 22 input latches are transparent when the latch enable input (LE) is high; the input data is latched whenever LE goes low. For systems in which the processor has separate address and data buses, LE may be tied high.

The two 10-bit counters in the 'ALS6301 and 'ALS6302 support 128, 256, and 512 line refresh operations. Transparent, burst, synchronous, or asynchronous refresh modes are all possible as determined by the memory timing controller. The refresh counters are advanced on the low-to-high transition of $\overline{\text{RAS}}_i$ on the 'ALS6301, and on the high-to-low transition of $\overline{\text{RAS}}_i$ on the 'ALS6302. This is true in either refresh mode. In the clear refresh counter mode, the refresh counters (row, column, and bank) can be reset to zero on the low-to-high transition of $\overline{\text{RAS}}_i$ on the 'ALS6301 or on the high-to-low transition of $\overline{\text{RAS}}_i$ on the 'ALS6302.

2.3.2 Typical Implementation

Figure 2-8 shows a system interface using the 'ALS6301 between a Motorola 68000L10 and four banks of 1M DRAMs. Addresses A21 and A22 are used to select one of the four memory banks. Since members of the 68000 processor family have separate address and data busses, the input latches on the 'ALS6301 are left transparent by tying the latch enable (LE) input high. The $\overline{CAS0}$ thru $\overline{CAS3}$ outputs of the 'ALS6301 are fed into the byte controller along with processor signals \overline{LDS} and \overline{UDS} . The byte controller made from programmable logic allows the processor to determine whether upper, lower or both bytes are accessed.

The \overline{RASi} , \overline{CASi} , MSEL and mode control (MC0, MC1) inputs on the 'ALS6301 must be generated by the memory timing controller. The memory timing controller functions as an arbitrator between refresh cycles and 68000L10 access cycles. It also guarantees that timing requirements of the DRAM will be met.

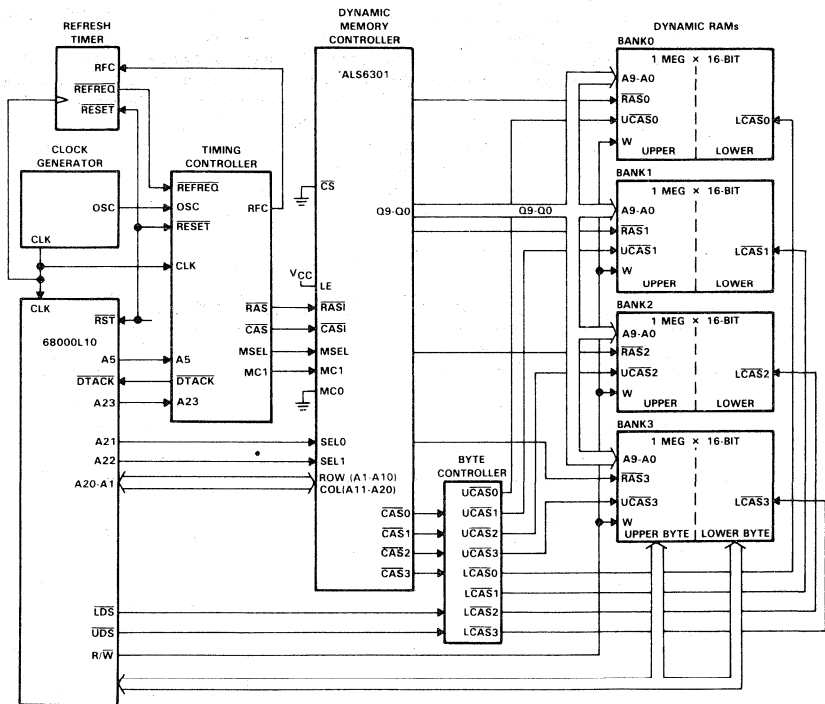

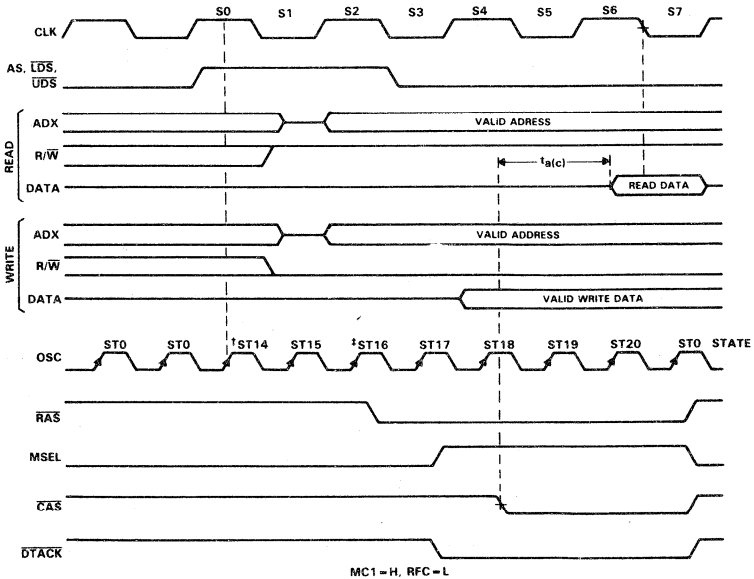

Figure 2-8. 'ALS6301, 'ALS6302 Timing Controller Interface

2.3.3 Timing Controller Details

Figure 2-9 is a timing diagram for a typical 68000L10 access cycle. The 'ALS6301 control signals required to execute the access cycle are also shown. Control signals for the 'ALS6301 are referenced from the OSC output of the 8284A clock generator. OSC runs at 2 times the speed of the system clock, that is $CLK = 10\text{ MHz}$ and $OSC = 20\text{ MHz}$. By running the timing controller at a higher speed than the system clock, the system performance is improved. A programmable logic sequencer, the TIB82S167B, was programmed for use as the timing controller.

In this example, refresh requests (\overline{REFREQ}) are generated every 155 clock cycles. The timing controller will perform the refresh cycle (\overline{RAS} only) immediately if the processor is not in the middle of an access cycle. If the controller is in the middle of an access cycle, the refresh cycle will be delayed until the access cycle is complete. If the controller is asked to perform an access cycle during a refresh, the access cycle will begin immediately after the refresh cycle is completed. Address bit A23 indicates whether the access requested is a memory access ($A23 = L$) or an I/O access ($A23 = H$). The timing controller will perform an access cycle only if Address bit A23 is low. Figure 2-10 is a timing diagram of the refresh/access cycle as explained above. To implement memory scrubbing, the controller must execute a read/write cycle during the refresh cycle and then place the 'ALS6301 in the memory scrubbing mode. (This example executes a \overline{RAS} only refresh.) The flowchart in Figure 2-11 outlines the required functionality of the timing controller. This flowchart was used along with the timing diagrams in Figures 2-9 and 2-10 to design the timing controller.

[†]Start sequence when $AS = H$, $CLK = H$, $\overline{REFREQ} = H$, $STATE = 0$

[‡]Return to ST0 if A23 is high

Figure 2-9. 68000 Access Cycle

† Start sequence when REFREQ=L, STATE=0
 ‡ Return to STATE 0 if REQ=H or A23=H
 § REQ is internal status register used to store an access request during a refresh cycle. (if AS=H during refresh cycle ST1-ST5)

Figure 2-10. Refresh/Access Cycle

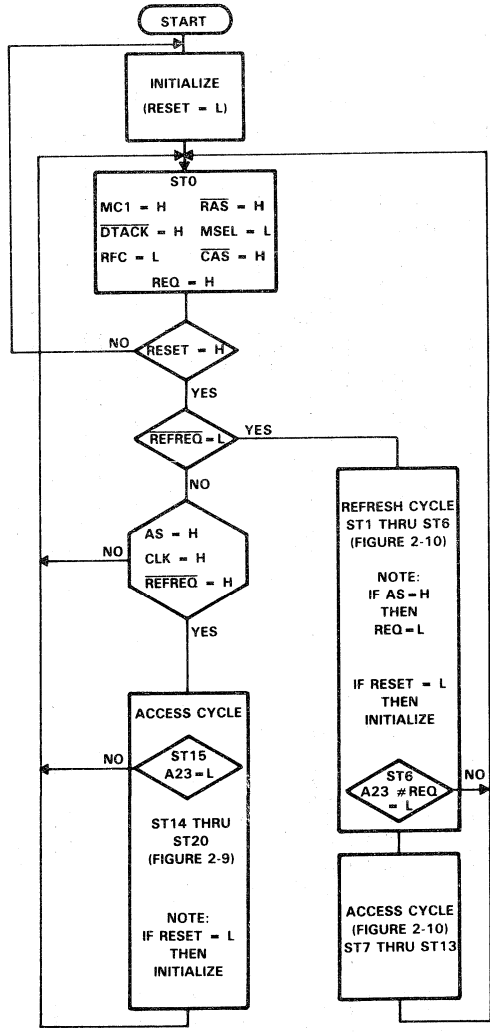

Figure 2-11. 'ALS6301, 'ALS6302 Memory Timing Controller Flow Chart

2.3.4 Refresh Timer Details

Figure 2-12 shows the actual circuit implementation of the refresh and memory timing controller. The refresh timer signals the controller whenever it is time to execute a refresh cycle. As required by memory, every row (512 on the TMS4C1025 DRAM) must be addressed every 8 ms. This implies that one row should be refreshed at least once every 15.6 ms. With a 10-MHz system clock, the refresh timer should use approximately a division factor of 155. This results in a refresh request every 15.3 ms. The refresh complete input (RFC) is used to signal the refresh timer that the refresh has been completed. It is important that the timer not stop so that the 8 ms memory requirement is maintained.

The TIBPAL22V10 circuit shown in Figure 2-12 is used to generate the refresh request signal every 155 clock cycles. The refresh request signal (active low) will remain active (low) until a refresh complete (RFC) signal is received from the timing controller. During a system reset, the refresh request output is set to a high logic level. When using different clock rates or memory sizes, the division circuit in the refresh timer should be adjusted accordingly.

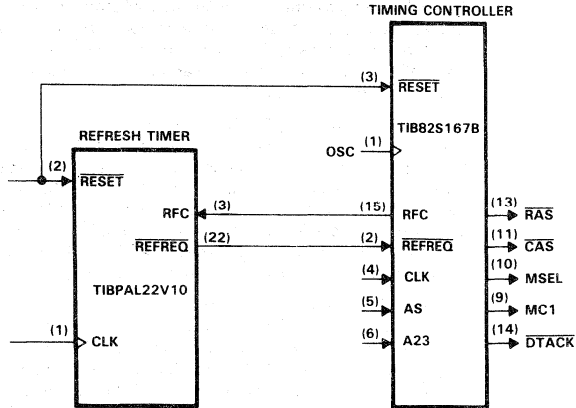

Figure 2-12. Refresh/Memory Timing Controller

2.3.5 Programmable Logic Designs

As mentioned previously, the timing controller, byte controller, and the refresh timer used in this example are created using programmable logic. ABEL™ and CUPL™ software packages have been used to reduce equations and generate the fuse maps needed to program these devices. The files used to generate the fuse maps have been included for reference at the end of this application report. Test vectors are included with the device files so software simulation can be performed on the computer. If the proper instruction is provided, the software will attach the test vectors to the end of the fuse map. This allows programming equipment to run a functional test on each device immediately after programming. To help familiarize the reader with these software tools, the timing controller design was done in both ABEL™ and CUPL™.

The TIB82S167B field programmable sequencer shown in Figure 2-12 is configured as a state machine to execute the flow chart shown in Figure 2-11. As shown in the flowchart, the timing controller is initialized by taking the reset input low. From the initialization state, state 0, the timing controller can perform either an access or a refresh cycle depending on the signals AS, CLK, and REFREQ. If an access is requested (AS = H) during a refresh cycle, an internal status register, REQ, will flag the request and as soon as the refresh cycle is completed, an access cycle will be started. At the start of an access cycle, the timing controller checks the state of the A23 address bit. If A23 is high, indicating an I/O access, the timing controller terminates the access cycle and returns to state 0.

As seen in Figures 2-9, 2-10, and 2-11, a state, ST0-ST30, has been assigned to each clock cycle. The appended ABEL™ and CUPL™ files can be easily understood by comparing the state equations to the states shown in these figures. Since the only difference between the 'ALS6301 and the 'ALS6302 is that the \overline{RAS} and the \overline{CAS} inputs are active-high instead of active-low, a slight modification to the timing controller software file will allow an 'ALS6302 to be used instead of an 'ALS6301. The TIBPAL22V10 refresh timer and the TIBPAL16L8 byte controller designs are straight forward and easily achieved as can be seen in the appended files.

In applications with different systems timings, the ABEL™ and CUPL™ files can be modified to fit the processor requirements. A preprogrammed sample of the timing controller, refresh timer and byte controller can be obtained by calling LSI/PAL/PROM Applications, 214/995-2980. If a basic understanding of programmable logic is needed, see the Texas Instruments Field Programmable Logic Applications note.

2.3.6 Summary

The 'ALS6301 and 'ALS6302, coupled with programmable logic, offer the system designer a solution to high speed dynamic memory requirements. Programmable logic allows the designer to tailor the timing controller to a selected processor and memory. In many cases, the generation of a high speed timing controller from programmable logic will allow the designer to use slower DRAMs without affecting system speed. This results in lower total system cost because of the large number of memory devices used.

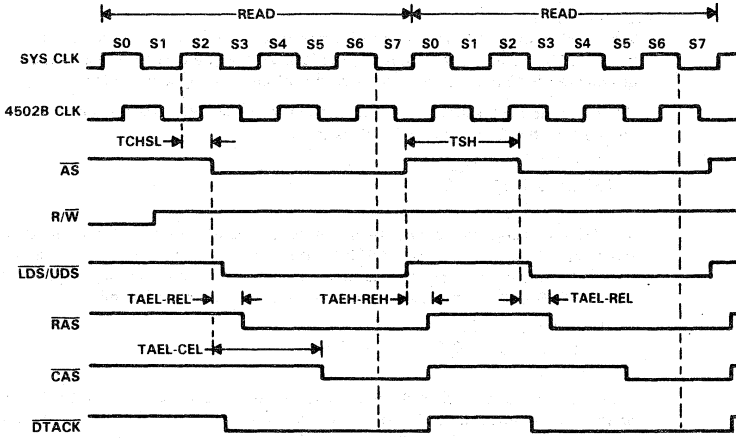

Figure 2-14. THCT4502B/MC68000L8 Read Cycle Timing Diagram

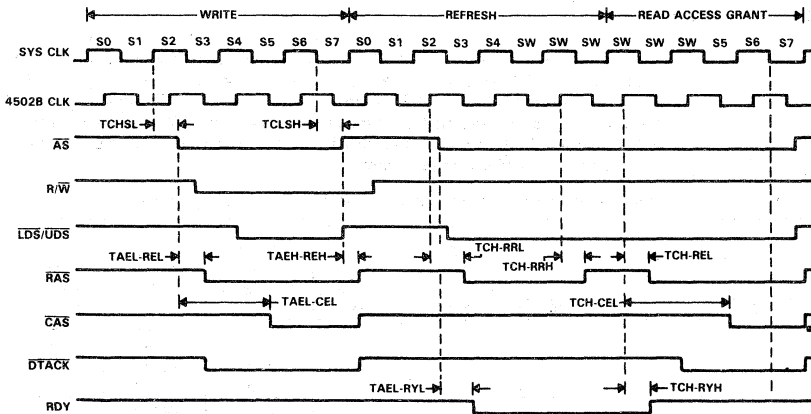

Figure 2-15. THCT4502B/MC68000L8 Write Access, Refresh, and Read Access Timing Diagram

2.4.2 ALE-to-Clock Relationship

When using the THCT4502B, the high-to-low transition of ALE should not occur between 15 ns before and 15 ns after the falling edge of the clock signal. This condition guarantees the proper selection between refresh and access cycles.

When connecting the Address Strobe (AS) of the MC68000 processor directly to ALE, ensure that the following condition is met.

$$\begin{aligned} 15 < 0.5T - t_{\text{CHSL}} \\ 15 < 0.5(125) - 60 \\ 15 < 2.5 \end{aligned}$$

At 8 MHz, this condition cannot be guaranteed. Therefore a circuit is required to shift the input phase of the THCT4502B clock signal by 90 degrees. As shown in Figure 2-13, this circuit can be built using standard 'AS74 D-type flip-flops. With the THCT4502B CLK shifted by 90 degrees, the new equation becomes:

$$\begin{aligned} 15 < 0.5T + 0.25T - t_{\text{CHSL}} \\ 15 < 0.5(125) + 0.25(125) - 60 \\ 15 < 33.75 \end{aligned}$$

It should be noted that all of the following equations take into account the 90 degree phase shift. At lower clock frequencies, such as 6 MHz, the AS signal can be directly connected to the THCT4502B and the phase shift circuits are not required.

2.4.3 DRAM Refresh Time

The refresh clock frequency is controlled by the strap input pins (TWST, FS1, and FSO) on the THCT4502B. Table 2-3 shows the strap configuration for the THCT4502B. At 8 MHz, with no wait states, setting TWST low, FS1 high, and FSO high yields a refresh rate of 11.375 $\mu\text{s}/\text{row}$. The TMS4256/4257 requires that each of the 256 rows be refreshed at least once every 4 ms. With a refresh rate of 11.375 $\mu\text{s}/\text{row}$, the time required to refresh all 256 rows will be 2.9 ms. This easily satisfies the 4-ms refresh requirement.

Table 2-3. Refresh Clock Frequency Input Pin Strap Configuration

STRAP INPUT MODES			WAIT STATES FOR MEMORY ACCESS	REFRESH RATE	MINIMUM CLOCK FREQUENCY (MHz)	REFRESH FREQUENCY (kHz)	CLOCK CYCLES FOR EACH REFRESH
TWST	FS1	FS0					
L	L	L [†]	0	EXTERNAL	—	REFREQ	4
L	L	H [‡]	0	EXTERNAL	—	REFREQ	3
L	H	L	0	CLK ÷ 61	3.904	64-95 [‡]	3
L	H	H	0	CLK ÷ 91	5.824	64-88 [§]	4
H	L	L	1	CLK ÷ 61	3.904	64-95 [‡]	3
H	L	H	1	CLK ÷ 91	5.824	64-75 [‡]	4
H	H	L	1	CLK ÷ 106	6.784	64-73 [‡]	4
H	H	H	1	CLK ÷ 121	7.744	64-83 [¶]	4

[†] This strap configuration resets the Refresh Timer Circuitry.

[‡] Upper figure in refresh frequency is the frequency that is produced if the minimum clock frequency of the next select state is used.

[§] Refresh frequency if clock frequency is 8 MHz.

[¶] Refresh frequency if clock frequency is 10 MHz.

2.4.4 DRAM Precharge Time

The precharge time is the time required between access cycles to allow internal nodes on the DRAM to charge to their correct reference levels. This is specified on the DRAM data sheet as $t_w(\text{RH})$ min. As with most DRAMs, there is a choice of performance ranges. For the TMS4256/4257, $t_w(\text{RH})$ ranges from 100 ns on the -12 device to 120 ns on the -20 device.

When using the THCT4502B, there are three precharge conditions which can occur during normal operation. Each condition must be checked to be sure the precharge condition is met. The following equations check these three conditions.

1. Access-to-Access cycle

$$\begin{aligned} t_w(\text{RH}) &< t_{\text{SH}} - t_{\text{AEH-REH}} - t_t(\text{REH}) + t_{\text{AEL-REL}} \\ t_w(\text{RH}) &< 150 - 35 - 30 + 35 \\ t_w(\text{RH}) &< 120 \end{aligned}$$

2. Access-to-Refresh cycle

$$\begin{aligned} t_w(\text{RH}) &< 1.5T + 0.25T + t_{\text{CH-RRL}} - t_{\text{CLSH}} - t_{\text{AEH-REH}} - t_t(\text{REH}) \\ t_w(\text{RH}) &< 1.5(125) + 0.25(125) + 50 - 70 - 35 - 30 \\ t_w(\text{RH}) &h 133.75 \end{aligned}$$

3. Refresh-to-Access cycle

$$\begin{aligned} t_w(\text{RH}) &< T - t_{\text{CH-RRH}} - t_t(\text{REH}) + t_{\text{CH-REL}} \\ t_w(\text{RH}) &< 125 - 30 - 30 + 45 \\ t_w(\text{RH}) &< 110 \end{aligned}$$

When the listed equations are correct, the THCT4502B guarantees the precharge condition for either the -12 or -15 TMS4256/4257 DRAMs.

2.4.5 Row Address Setup and Hold Time

To meet the row address setup-time requirement, the address must be present at the RAO-RA8 and CA0-CA8 inputs to the THCT4502B for at least 10 ns ($t_{\text{AV-AEL}}$) before ALE goes low. The row address setup time from the MC68000L8 is defined by the t_{AVSL} specification. At 8 MHz, t_{AVSL} is 30 ns minimum. This meets the THCT4502B specification. The row address setup time to the DRAM must also be satisfied. For the TMS4256/4257, $t_{\text{su}}(\text{RA})$ is specified as 0-ns minimum. The following equation applies:

$$\begin{aligned} 0 \text{ ns} &< t_{\text{AVSL}} + t_{\text{AEL-REL}} - t_{\text{RAV-MAV}} \\ 0 \text{ ns} &< 30 + 35 - 42 \\ 0 \text{ ns} &< 23 \end{aligned}$$

When the equation is correct, the THCT4502B guarantees the row address setup time to the DRAM. The row address hold time required by the TMS4256/4257 is 15 ns. This specification is guaranteed by the THCT4502B. From the data sheet, $t_{\text{REL-MAX}}$ is specified as 20 ns min.

2.4.6 Data Valid to Write Enable Setup Time

Data can be written into DRAM by two different methods. Depending upon the mode of operation, the falling edge of $\overline{\text{CAS}}$ or the falling edge of $\overline{\text{W}}$ will strobe the data into memory. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$ going low, data out will remain in the high-impedance state for the entire cycle. This permits common input/output operation. This type of cycle is referred to as an early write cycle. When $\overline{\text{W}}$ goes low after $\overline{\text{CAS}}$ goes low, the type of cycle is referred to as delayed-write or read-modify-write cycle. To avoid bus contention, this operation requires a buffer between the Q outputs and the microprocessor.

The circuit shown in Figure 2-13 generates an early write cycle. Therefore, data valid to write enable needs to be referenced to the falling edge of $\overline{\text{CAS}}$. The TMS4256/4257 requirement for an early write cycle is $t_{\text{su}}(\text{WCL})$, which is 0 ns minimum. The following equation applies:

$$\begin{aligned} 0 \text{ ns} &< t_{\text{CHSL}} + t_{\text{AEL-CEL}} - 0.5T - t_{\text{CLDO}} \\ 0 \text{ ns} &< 60 + 115 - 0.5(125) - 70 \\ 0 \text{ ns} &< 42.5 \end{aligned}$$

When the equation is correct, the MC68000/THCT4502B combination guarantees that data will be valid before $\overline{\text{CAS}}$ goes low.

2.4.7 Read Access Time from CAS

When the microprocessor tries to read data from memory, the Read-Access-Time guarantees that data is available. When using the THCT4502B, there are two possible access situations. The most common is the normal access cycle. Another possible access situation is the access-grant cycle. The access-grant cycle occurs when an access cycle immediately follows a refresh cycle.

For the TMS4256/4257, access from $\overline{\text{CAS}}$ is specified as $t_{\text{a}}(\text{C})$. When using the TMS4256/4257, three speed types are available for selection. The three speed types are as follows:

$$\begin{aligned} \text{Speed type } -12 \quad t_{\text{a}}(\text{CA}) &= 60 \text{ ns} \\ \text{Speed type } -15 \quad t_{\text{a}}(\text{CA}) &= 75 \text{ ns} \\ \text{Speed type } -20 \quad t_{\text{a}}(\text{CA}) &= 100 \text{ ns} \end{aligned}$$

The following equations apply to the circuit shown in Figure 2-14.

1. Normal Access Cycles

$$\begin{aligned} t_{\text{a}}(\text{C}) &< 2.5T - t_{\text{CHSL}} - t_{\text{AEL-CEL}} - t_{\text{t}}(\text{CEL}) - t_{\text{p}}(\text{OR}) - t_{\text{D}}(\text{ICL}) \\ t_{\text{a}}(\text{C}) &< 2.5(125) - 60 - 115 - 20 - 15 - 15 \\ t_{\text{a}}(\text{C}) &< 87.5 \end{aligned}$$

2. Access Grant Cycles

$$\begin{aligned} t_{\text{a}}(\text{C}) &< 2.5T - 0.25T - t_{\text{CH-CEL}} - t_{\text{t}}(\text{CEL}) - t_{\text{p}}(\text{OR}) - t_{\text{D}}(\text{ICL}) \\ t_{\text{a}}(\text{C}) &< 2.5(125) - 0.25(125) - 140 - 20 - 15 - 15 \\ t_{\text{a}}(\text{C}) &< 91.25 \end{aligned}$$

As shown by the equations, the only speed type that does not meet the access time requirement is the -20 device. The -12 and -15 devices both meet $t_{\text{a}}(\text{C})$.

2.4.8 Other Considerations

The $\overline{\text{DTACK}}$ input on the MC68000L8 informs the microprocessor that data is available. Wait states are inserted by holding $\overline{\text{DTACK}}$ high. This process for the access-grant cycle is illustrated in Figure 2-15. If an access request occurs during a refresh cycle, the THCT4502B completes the refresh cycle, then finishes the access request. In this situation, the $\overline{\text{DTACK}}$ signal is held high until data is available. The AS74 flip-flop shown in Figure 2-13 is used to time the $\overline{\text{DTACK}}$ signal in relationship to the falling edge of S6.

On normal accesses, the RDY signal is high allowing either $\overline{\text{UDS}}$, $\overline{\text{LDS}}$ or $\text{R}/\overline{\text{W}}$ to force $\overline{\text{DTACK}}$ low. During write cycles, $\text{R}/\overline{\text{W}}$ will force $\overline{\text{DTACK}}$ low. During read cycles, $\overline{\text{UDS}}$ and/or $\overline{\text{LDS}}$ will force $\overline{\text{DTACK}}$ low. During access-grant cycles, the low RDY signal holds $\overline{\text{DTACK}}$ high until it is released.

2.4.9 Summary

This application report provides an example of how to interface the THCT4502B with the MC68000L8. The major design criteria has been calculated and checked against typical DRAM specifications. When using processor speeds lower than 8 MHz, the interface is simplified further because it is not necessary to shift the THCT4502B input clock frequencies. Additional design ideas can be obtained from an Applications Brief "TMS4500B/MC68000 INTERFACE", Texas Instruments publication SMCA008.

3 Cache Memory Systems

3.1 Introduction

As the typical operating speeds of processors have increased to provide for the ever increasing need for computing power, the necessity of developing a memory hierarchy (the incorporation of two or more memory technologies in the same system) has become apparent. One of these memory technologies is selected on the basis of fast access time (with associated high cost per bit) to allow minimum system cycle time. The other technologies are chosen with the lowest possible cost per bit relative to speed in order to achieve the maximum system memory capacity. In a system with a multiple level hierarchy, the speed-to-cost relationship depends upon the frequency of access and the total memory requirement at that level. By proper use of this hierarchy through coordination of hardware, system software, and in some cases user software, the overall memory system will reflect the characteristics that approximate the fast access time of the fast memory technology and the low cost per bit of the low cost memory technology. Large computer systems have made use of this memory optimization technique to maintain very large data bases and high throughput (see Figure 3-1). Many smaller processor systems use this technique to allow mass storage of data, where a tape or a disk is the low-cost memory and Random Access Memory (RAM) is the fast memory technology.

Because of the increase in processor speeds, memory hierarchy is now extending to the RAM memory used in microcomputer systems. Typically, Dynamic RAM (DRAM) is used as the bulk or main memory and High-Speed Static RAM (HSS) serves as the fast-access memory. This HSS RAM is usually 1K to 8K words deep and serves as a fast buffer memory between the processor and the main memory. This small fast buffer memory is called "cache" memory because it is the storage location for a carefully selected portion of the data from the main memory. The addresses for that portion of memory currently in the buffer memory is saved in the cache tag RAM (a small memory that is used to store the addresses of the data that has been mapped to cache).

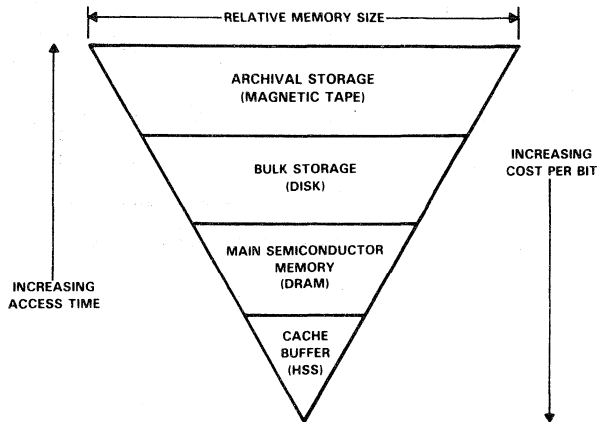

Figure 3-1. Memory Size vs Access Time and Cost Per Bit

3.2 Memory Systems with Cache

When the processor accesses main memory, the processor address is compared to the addresses currently present in the cache tag RAM. When a match occurs, the required data is resident in the cache and the access is called a "hit" and is completed in the cycle time of the fast memory. When a match does not occur (a "miss"), the main memory is accessed and the processor must be delayed to allow for the slower access cycle of the main memory. Whether a hit has occurred is determined by the cache-tag RAM. Figure 3-2 shows the relative placement of the processor, main memory, cache, and cache-tag RAM within a system.

Since there must be comparisons made between the current processor address and the addresses in the cache, the cache-tag RAM must have a very fast access time to prevent the degradation of processor accesses even when a match occurs. Previously, the memory used for the cache-tag RAM was the same as that used for the cache, which (because of added delays through comparison logic) meant that the full benefits of the cache were not realized.

The Cache Address Comparators were designed to reduce this cache access degradation to a minimum by incorporating the matching logic on-chip. This provides match-recognition times that are compatible to the access time of the cache-buffer memory.

Figure 3-2. Typical Memory System with Cache

3.3 Cache Memory Systems Using 'ACT2151 and 'ACT2152

3.3.1 Set-Associative Cache Address Matching

The 'ACT2151 and 'ACT2152 implement the set-associative type of cache address matching. This algorithm may be more clearly understood by considering main memory as an (m) by (n) array of blocks and the cache is an (n) by (k) array (see Figure 3-3). Each block is composed of (x) words, and transfers between main memory and cache memory always move all (x) words in that block. Corresponding to every block in the buffer RAM is a tag address specifying which block of main memory is currently resident in the buffer RAM at that location. The set-associative algorithm maps each modulo (n) group of (m) blocks into the corresponding (n) row of the cache. The low order address lines of the processor covering the sets (n) select a row of the cache buffer and the corresponding row in the tag RAM. The data is stored in the cache buffer and the high-order address specifying the block (m) is saved in the tag RAM. The high-order address then becomes the tag.

- K = Number of BUFFER/TAG groups for multiple cache systems
- X = Blocks moved to cache
- D = Valid data from main memory
- ? = Areas of cache that have not been loaded from main memory
- NV = Code to indicate non-valid label
- 0, 1, 2, m-1 = Labels from high order address specifying the block moved from main memory.

Figure 3-3. Set-Associative Cache Address Matching

3.3.2 Cycle Time Improvement

There are several algorithms used to determine which areas of main memory should be resident in cache and which should be replaced (first-in, first-out; least recently used; or random). Since programs typically have the property of locality (over short periods of time most accesses are to a small group of memory addresses), these replacement algorithms can make the cache have the majority of processor accesses resulting in hits. The hit ratio (number of hits \times 100%/number of memory accesses) runs 90% and higher in systems with well coordinated memory to cache mapping routines. As the block size (x) increases, the replacement mapping algorithm options have greater impact on the cache performance.

When running at maximum frequency, many microprocessors are operating with memory access times of 100 ns or less. After allowing for address buffering, decoding, and propagation delays through data buffers, the maximum access time that can be tolerated is 60 ns or less before processor throughput is affected. For large memory systems, DRAM can be used to achieve a cost effective memory.

However, these cannot meet a 60-ns access requirement. If the actual system throughput for a system with cache and one without cache are compared, the advantages of cache become obvious.

For comparison of the two architectures, assume that a processor is implemented in which 30% of the active cycle involve main memory (the other 70% used for instruction decoding and internal operations). Also assume that the processor cycles at 125 ns with a required memory access time of 60 ns. If the memory is not ready, the cycle time is extended by 125-ns increments till satisfied. This processor using 120-ns DRAMs would require one delay increment on main memory accesses and 200-ns DRAMs would require two delay increments. The average cycle time can be calculated for each memory speed as follows:

$$\text{Average Cycle Time} = [(INT) \times (CYC)] + [(MEM) \times (CYC + DEL)]$$

where INT = percent of time doing internal operations
 CYC = processor cycle time
 MEM = percent of time doing memory accesses
 DEL = number of delay increments \times 100 ns

For a processor using 120-ns DRAMs:

$$\begin{aligned} \text{Average Cycle Time} &= [(70\%) \times (125 \text{ ns})] + [(30\%) \times (125 + 125)] \\ \text{Average Cycle Time} &= 163 \text{ ns} \end{aligned}$$

For a processor using 200-ns DRAMs:

$$\begin{aligned} \text{Average Cycle Time} &= [(70\%) \times (125 \text{ ns})] + [(30\%) \times (125 + 250)] \\ \text{Average Cycle Time} &= 200 \text{ ns} \end{aligned}$$

For the same system with cache memory assume a 90% hit ratio with 60-ns cache and 120-ns DRAM:

$$\text{Average Cycle Time} = [(INT \times CYC) + [MEM \times [(HIT \times CAC) + (MIS \times (CYC + DEL))]]]$$

where INT = percent of time doing internal operations
 CYC = processor cycle time
 MEM = percent of time doing memory accesses
 DEL = number of delay increments \times 100 ns
 HIT = percent of memory accesses hit cache
 MIS = percent of memory accesses miss cache
 CAC = cache memory access cycle time

$$\begin{aligned} \text{Average Cycle Time} &= [70\% \times 125] + [30\% \times [(90\% \times 125) + (10\% \times \\ & \quad 125 + 125)]] \\ \text{Average Cycle Time} &= 129 \text{ ns} \end{aligned}$$

This value represents a 20% improvement with 120-ns devices over the non-cache implementation with 120-ns devices and 35% using 200-ns devices. This performance improvement can be further demonstrated for those systems using custom or bit-slice processors where the memory cycle time as well as access time is of concern. For this example, consider a processor with a cycle time of 50 ns and main memory cycle time of 100 ns (use the same access ratios as in the previous example):

Average Cycle Time = [(70%) × (50)] + [(30%) × (100)] = 65 ns
(Without Cache)

Average Cycle Time = [70% × 50] + [30% × [(90% × 50) + (10% × 100)]]
(With Cache) = 52 ns

This represents a 20% decrease in average cycle time for the processor using 50-ns cache memory. If the main memory was rated at a cycle time of 200 ns, either using slow main memory or due to allocation of alternate cycles for some other activity (multiprocessors, direct memory access, display refresh, etc.), the cache would still give an average cycle time of 55 ns. This is an improvement of 63% over the 95 ns average cycle time for a non-cache system.

3.3.3 Cache Memory Configurations

Figures 3-4, 3-5, and 3-6 illustrate applications for the 'ACT2151 and the 'ACT2152 in cache memory systems. Figure 3-4 shows a cache-memory configuration that has a 512M-byte main memory with a block size of 4 32-bit words. In this particular application, a cache containing 1024 four-word blocks was chosen thus defining the main (n) × (m) array as being 1024 sets of 32,728 four word blocks. The 128M-word memory requires an address bus of 27 lines. The least significant bits (A2-A3) are used as a word select for one of the four words in each block. The next least significant address lines (A4-A13) are used as the set select inputs to the cache buffer RAM and the cache tag RAM. The remaining high order address lines (A14-A28) form the label or tag which is stored and compared by the tag RAM.

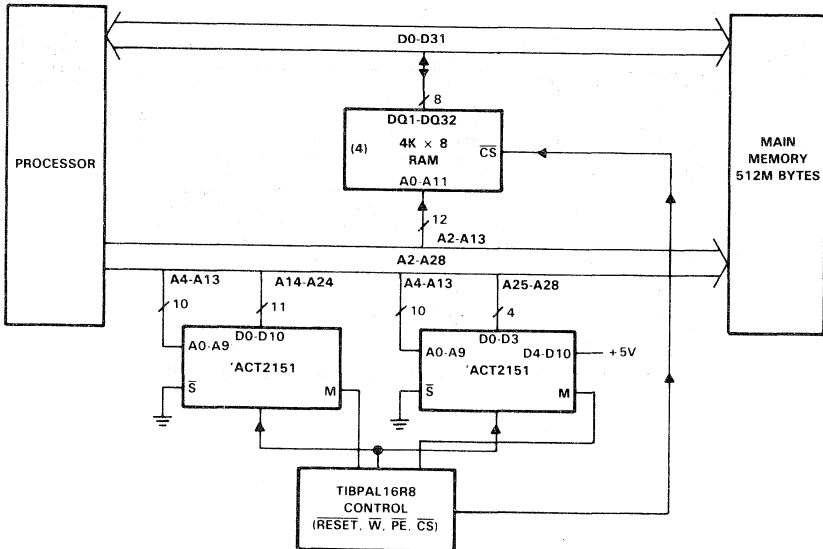

Figure 3-4. Cache Memory Configuration (Block Size = 4)

Since the label in this example is composed of 15 address lines, two 'ACT2151 devices are used to expand the tag. The 15 address lines are the data inputs to the tag RAM. The other data inputs are tied to 5 V so that, after Reset, invalid data cannot force a match. The match output of the two 'ACT2151 devices are combined to form the enable for the cache data buffer. If the contents of either 'ACT2151 do not contain a match, the cache is not enabled. These signals are also used by the control circuits to inform the system that the address is not present in the cache so that main memory might be accessed. The control circuit also resets the cache upon power-up. This is accomplished by taking the RESET input of the 'ACT2151 low. After reset, no matches will occur at any locations until that location has been written.

In the application shown in Figure 3-5, the expansion of the cache RAM is carried out in both depth (more sets) and width (wider tag). The block size was chosen as one such that the 4K cache now represents 4096 blocks of one word each. The high-order addresses are still used as the label to the tag RAM. A13 is used to select between two 'ACT2152 pairs. Each pair contains labels for 2048 of the cache-memory blocks. Address lines A2 thru A12 are used as the set-address inputs. If the chip select (CS) is at a logic high (deselected), the 'ACT2152 match output (M) is high. An AND function can be used to enable the cache data buffers and also notify the control circuit if access needs to be made into the main memory. The logic for this system illustrates that the upper pair are compared for the first 2048 blocks within cache and the lower pair are compared for the second depending on the state of address A13.

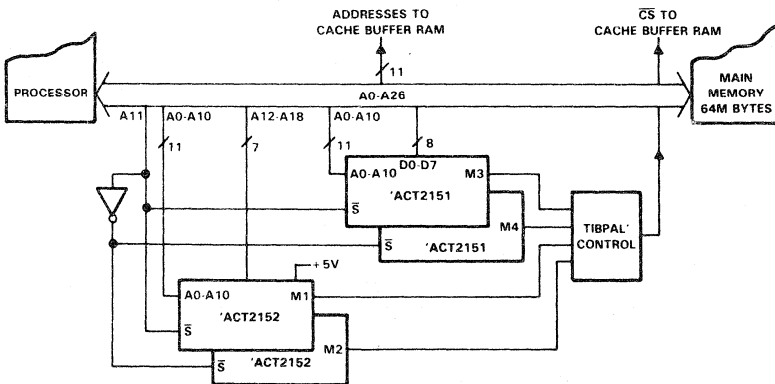

Figure 3-5. Cache Memory Configuration (Block Size = 1)

A dual cache structure ($K = 2$) is shown in Figure 3-6. The M-word memory is divided into 4096 sets of 256 four-word blocks. In this example, A0 and A1 are used to select which one of the four words within a block are accessed. A2-A12 select which of the 2048 block labels are to be compared. Addresses A14-A21 form the eight-bit label for the block. Address A13 is used by the cache control logic in conjunction with the possible processor status lines as chip select inputs. The match outputs from the two 'ACT2152 devices, A1 and A2, are NANDed to form an active-low enable to the cache data buffers and to serve as a request to the control logic. The match outputs from B1 and B2 also are NANDed to perform a similar function for cache RAM B. If no match is found in cache RAM A or B, the control logic will initiate an access from main memory. The purpose of the dual-cache architecture is to allow for rapid switching between multiple tasks or programs since the processor can have access to one cache while the controller moves data between main memory and the other cache. The dual or multiple cache approach also yields more replacement options than the single cache architecture. When an access results in a miss in the single cache system, the data in cache is replaced by the current data even though the old data may still be useful. By using independent caches, the control can determine which data is most expendable and replace that block while the other caches keep their potentially useful data.

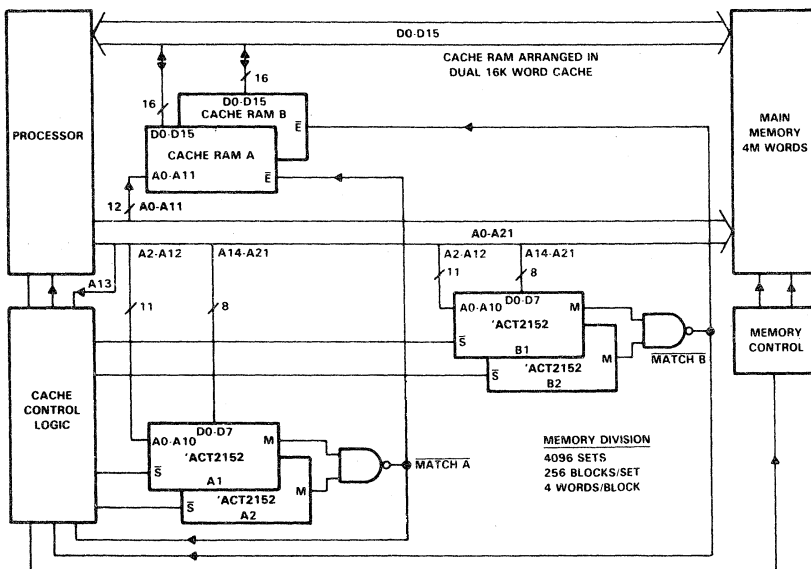

Figure 3-6. Cache Memory Configuration, Dual Cache ($K = 2$)

3.3.4 Summary

Cache-memory architecture can enhance the throughput of many microprocessor systems. This allows large low-cost memory to perform like a high-speed RAM. The 'ACT2151 and 'ACT2152 reduce the tag memory implementation cost and complexity and provides label comparison times comparable to the access times of high-speed memories. These additional benefits make high-performance microprocessor designs that can use the same techniques of optimizing cost, memory size, and throughput that had previously been available only in larger computer applications.

3.4 Article Reprints

The following three articles are being reprinted in this report for your convenience. The articles are "Caches Keep Main Memories From Slowing Down Fast CPUs", "Cache-Memory Functions Surface on VLSI Chip", and "Match Cache Architecture to Computer System".

Until main-memory speeds catch up to CPU processing speeds, cache memories can be called upon to keep overall throughput rates up—especially as main-memory sizes grow.

Caches keep main memories from slowing down fast CPUs

This article begins a series on cache-memory systems long employed in mainframes and high-end minicomputers, and just now ready to enter microcomputers as large, but slow dynamic RAMs become available. The strategy of Texas Instruments is sketched by Richard N. Gossen, manager of advanced development, in this issue (p. 32).

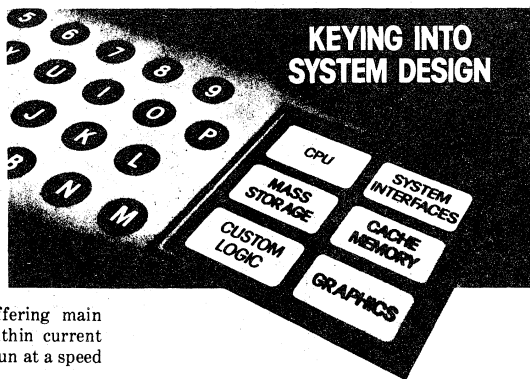

Whenever a speed mismatch occurs between main-memory bulk storage and a fast-processing CPU, a cache memory can provide the interface to take full advantage of the CPU's processing speed. From the main memory, the cache memory extracts and temporarily stores enough data to satisfy immediate CPU needs. Writing from the main memory is at the main-memory's slow speed, but reading to the CPU is at the CPU's high speed. As the word "cache" implies, the memory's operation is hidden from (or rather, transparent to) the user.

Figure 1a exemplifies an 8-Mbyte main-and-cache-memory system in a typical large computer (see "Caches Needed as Main Memories Grow"). The main memory alone can attain a cycle time of about 400 ns, but with error-detection-and-correction circuitry added to the system, a cycle time of about 500 ns is more likely. On the other hand, an ECL- or TTL-based CPU can be ten times faster with about a 50-ns cycle time. Buffering main memory with a 50-ns cache—well within current technology—enables the computer to run at a speed close to the CPU's maximum speed.

Figure 1b shows a more detailed block diagram of a typical cache memory. It represents a set-

associative cache system with 2-kbytes of data storage capacity in a single-set configuration and it serves a 16-bit microprocessor system with a 22-bit address bus. The basic storage elements are two RAM arrays: one, a 1024×16 -bit-word unit for data storage; and the other, a 1024×13 -bit-word unit for address, or tag, storage. Addresses that arrive via the CPU data bus (A_0 to A_{21}) are compared with those held in the tag RAM. If they match, the desired data are located in the cache's data RAM and the main memory can be bypassed.

When first turned on, or should the computer system malfunction or be shut down momentarily, the cache would then probably contain improper or erroneous data. Thus, a most important function not

Cache memories

specifically shown in the block diagram is a special control-logic section to perform initialization operations for loading the cache with valid initial data. Particularly important is the proper loading of the tag RAM to prevent false matches.

Traditionally, cache memories have been constructed with static-RAM bipolar-semiconductor technology, but recent improvements have given NMOS static RAMs an edge by requiring less power at the same speeds as bipolars. The CPUs, of course, are built from high-speed ECL or Schottky TTL, whereas main memories usually are composed of dynamic RAMs that are about an order of magnitude slower than the CPU.

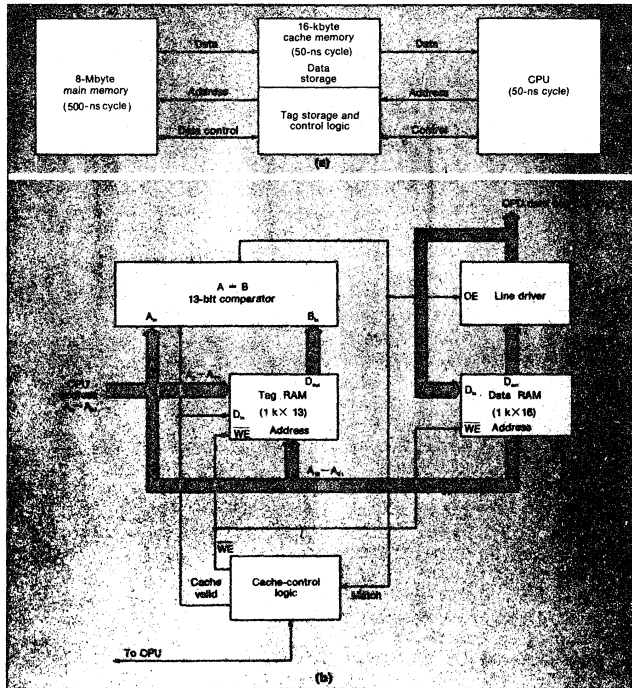

Cache concept based on probability

No matter what the cache is made of or how it is configured, its operation is based on "property-of-locality" probability principles, which experience

has shown to have the following characteristics: First, over short time periods, most CPU memory accesses are made to adjacent, small groups of locations; therefore, even a small cache, storing carefully selected data, will have data the CPU needs most of the time. Second, data stored in the cache and recently used will likely be reused shortly thereafter. Finally, data adjacent to data that have been recently used will most likely be used next.

Usually, then, several adjacent words are transferred from main memory into the cache: The immediate need may be for just one of the words, but eventually the subsequent words are likely to be required. This procedure reduces repeated accesses to main memory ("misses"), and increases the probability of finding the data in the cache, or "hits."

To demonstrate the effectiveness of a cache, consider a typical system, where 20% of all CPU operations are memory accesses (misses), the CPU cycle-

1. In a computer system with a main memory, whose cycle time is a relatively slow 500 ns, a fast 50-ns cache memory is interposed to match the CPU's 50-ns cycle time (a). In more detail, a set-associative cache system has address tag words stored in one RAM, while the data words are stored in a separate RAM (b).

time is 50 ns, and main-memory cycle-time is 500 ns. Accordingly, average machine-cycle time is

$$\frac{20 \times 500 + 80 \times 50}{100} = 140 \text{ ns.}$$

However, with a 90%-efficient, 50-ns cache, the average cycle time is

$$\frac{2 \times 500 + 18 \times 50 + 80 \times 50}{100} = 59 \text{ ns.}$$

Note that with an effective 90% hit ratio, the CPU is forced to access the main memory on just 2% of all machine cycles (10% of 20% of the cycles). Thus, most memory accesses are handled through the cache, and the average machine cycle-time is cut to almost a third. However, these calculations are

simplified, because only a monoprogram instruction stream is considered. Indeed, properly designed cache memories routinely achieve considerably better performance in mainframes and minicomputers with actual, more complex programs.

A cache memory's data-storage section can be implemented fairly simply with standard, high-speed static RAMs. However, the address, or tag-storage, section must do more than just store—it must also compare addresses on the CPU bus with those it stores. This is best done with an associative-addressing technique.

Data access by association

Data in an associative or content-addressable memory are not accessed merely by a location, or address, code as in conventional memories, but are found according to some property or "value" of the data. Instead of an address word, a so-called search key, or descriptor, is presented to the cache, which represents particular values of all or some of the bits of a stored word. When it is compared together with a "lock"—the so-called tag bits—with all the words stored in the cache, the search key ferrets out all associated words. If the key has few attributes—is therefore said to be "loose"—many words can match and be accessed.

Though simple in concept, the associative-search procedure is very complex in execution. The two most common mapping algorithms that associate a set of data in main memory—called a "block"—with a corresponding block in the cache are designated "fully associative mapping" and "minimal set-associative mapping."

In fully associative mapping (Fig. 2), any one of the $m \times n$ blocks in main memory can be placed in any one of the cache blocks, which then has a tag address associated with it that specifies from which main-memory block it came. (One of the tag bits—a control bit—checks the validity of the block, and

2. A fully associative mapping algorithm allows any one of the $m \times n$ main-memory blocks to be placed into any one of the cache-memory blocks.

3. The larger the cache, the smaller the number of misses (a). Splitting the cache into several independent sets further reduces the miss ratio (b); however, in both these cases the improvement rate tapers off sharply beyond some specific point. And when block-size and block-quantity are traded off against each other (c), miss rates are minimized sharply at some particular optimum size/number relationship.

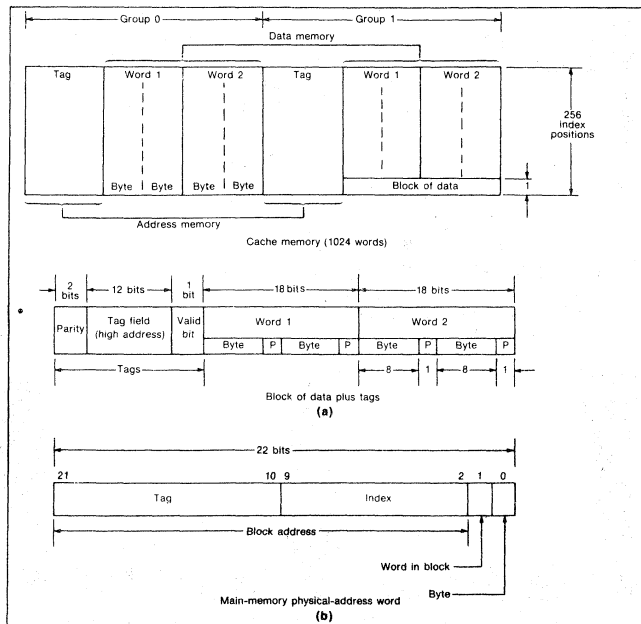

the low-order address bits can define bytes and data-transfer units, or words.) Each address generated by the CPU must be compared with all of the tags, and the field of address tags must span all main-memory $m \times n$ blocks, regardless of the cache's capacity. In this case, the cache acts as a linear array.

In set-associative mapping, a selection from an n row of m blocks is placed into the corresponding row of the cache. Then only those bits covering dimension m become the tag of the set n . Thus, for each CPU address only the tags in that row must be compared. However, for the minimum effective set—having a dimension of two—a linear array must swap blocks frequently because the cache cannot hold more than one block from a row at any time.

Whether fully associative or set-associative mapping, if data-block addresses in the cache tag-store match those on the CPU address-bus, the data are made available from the cache. And if no match, or a miss, occurs, the CPU is delayed while the needed data are fetched from main memory. In this process, the entire block containing the data sought is transferred into the cache.

Of course, the larger the cache, the smaller the number of misses on each CPU cycle. However, for a normalized miss-rate-vs-cache-size plot that assumes a fixed number of blocks in the cache and a main-memory size from 2 to 4 Mbytes, the rate of improvement in miss rate diminishes rapidly above 8 kbytes of cache size (Fig. 3a). Thus, the cost of a very large cache is not paid back in higher performance, when optimum size is exceeded.

However, further improvement can be obtained by breaking the cache capacity into a number of sets—defined as the number of parallel, independent caches in a system. For the same 2-to-4-Mbyte main memory and with the total cache size fixed at 8 kbytes, two separate caches of 4 kbytes each offer better performance than a single 8-kbyte implementation, because another quick data-replacement trial is available whenever a miss occurs the first time (Fig. 3b). With a single set, a miss forces accessing the slow main memory, which replaces all the data in the cache, even though the replaced data may soon be required again in the program. However, again performance increase slows significantly above an

4. The cache for the PDP 11/70 is organized into two 256 blocks of data totaling 1024 words (a). Every block has a tag field representative of the physical address of the word in the main memory (b).

optimum size—in this case, above between two and three independent sets for the 8-kbyte cache capacity.

Naturally, block size and the number of blocks also affect miss rate. However, in a constant-capacity cache, trading the number of blocks against their size seems to raise a conflict: Large blocks accommodate more adjacent data and thus would tend to reduce the miss rate. But a higher number of smaller blocks also would help reduce misses by providing more data choices. Figure 3c shows a minimum miss rate

at about 8 bytes per block, or 1000 blocks, for a total 8-kbyte cache capacity. For block sizes between 2 and 16 bytes, an 8-, 16-, or 32-kbyte cache offers the same normalized miss-rate performance, although larger the total capacity, the smaller the absolute miss-rate.

To complete this general overall description of cache operation, one additional important function must be examined—the data-replacement algorithm. Again, any time a cache memory records a miss, a new block containing the required data must

Caches needed as main memories grow

Although advanced microprocessor-based systems are beginning to see the dawn of the cache-memory era, large systems like the IBM 360 class and large minicomputers like the DEC PDP-11 series have been "caching-in" for years. On a cost-effective basis, a cache system offers higher system speed for the cost of just a small quantity of fast memory plus its associated logic.

The resulting speed depends on the size and organization of the cache, not the size of main memory, and no programming changes follow when a cache system is used. Nevertheless, it is the increased main-memory size that will fuel the growth of cache-type systems in the upcoming high-performance microcomputers and microprocessor systems.

The high-density RAM chips that will significantly

memories to enable CPUs to make full use of their improved capabilities. The accompanying table projects the expected speed performance in 1982 of several of the best known processors.

For example, TI's 99000, with a maximum clock-rate of 6 MHz, is expected to support memory access times of 90 ns. This meshes perfectly with the new generations of NMOS static RAMs, whose access times are now in the 30-to-50 ns range. A 99000 will almost certainly benefit from a cache-memory system when it supports main memories in the megabyte range. Indeed, the Zilog Z8001A, the Motorola M68000,

1982 projected 16-bit μ C performance		
Processor	Maximum clock rate	Fastest supportable memory access
99000	6 MHz	90 ns
8001A	6 MHz	215 ns
68000	8 MHz	225 ns
8086-?	8 MHz	280 ns

increase the main-memory sizes that microprocessors and microcomputers will be called upon to support are relatively slow dynamic units (see table). By 1983, as the 64-kbit dynamic RAM becomes a cost-effective chip, the average 16-bit processor will be operating with 128 kbytes of memory. And by 1985, with the expected maturity of the 256-kbit dynamic RAM, 1/2-Mbyte memories will be commonplace in 16-bit processor systems (see curve). Already, TI's 16-bit 99000 processors can address up to 16 Mbytes with the addition of a memory-management unit. Systems of this size, like mainframes and large minicomputers, will demand cache memories to enhance performance.

While physical memory size encourages the growth of cache systems, improved microprocessor performance also contributes to wider cache use. Processor speeds will certainly increase, necessitating fast cache

and the Intel 8086-2 are somewhat slower than the 99000 in memory-access times; therefore, they should most definitely benefit from a cache for high-performance applications.

In such microprocessor systems, dynamic RAM used as the main memory will always remain the limiting factor to improved system performance because it is slower than a microprocessor. Even a dynamic RAM with access time as fast as 150 ns slows considerably when operated in a 1-Mbyte memory system using error-detection-and-correction circuitry. The best performance of such a RAM is in the range of 400 to 500 ns, minimum. If a processor is forced to interface at this slow speed, severe performance penalties result in the system.

Cache memories

be fetched from main memory to replace the block already in the cache. But which block should be removed to make way for the new information?

Clearly, replacement should be based on some type of index of value for maximum effectiveness, not randomly performed. An index of value can be based on the chronology of the data, such as FIFO (first-in, first-out), or the frequency of use, LRU (least recently used), or a combination of the two. Of these, LRU is one of the most popular techniques. It is based on the theory that if information has been often and recently referenced, it is likely to be referenced again in the near future.

LRU offers some advantage over the FIFO algorithm. Even though FIFO eliminates the possibility of loading data and immediately removing it, FIFO has a serious disadvantage: Even when a block of data is frequently and continually used, eventually it becomes the oldest and is removed, although experience shows it likely will be needed again, soon. In addition, FIFO can introduce some unusual side effects.

The associative cache in the PDP-11

In an actual cache system, say the PDP-11/70, a 1024-word (2048-byte) memory is organized as an associative cache in two groups, or sets—each group containing 256 blocks of data and each block containing two words divided into two bytes (Fig. 4a). Every block also has a tag field to represent the physical address in main memory, where the original copy of the data-block resides.

Data from main memory can be stored in the cache in an index position determined by its main-memory physical address (Fig. 4b). An 8-bit index field (bits 2 to 9) of the main memory's 22-bit physical-address word determines which of the 256 cache-memory-array blocks will contain the data (either in group 0 or group 1 as determined by the hit or miss conditions). And the lowest two bits (bits 1 and 2) select word-1 or word-2 and byte locations in the block. But only the high-address field (bits 10 to 21)—the tag field—is stored in the cache.

Data are always sought in the cache first. If the information is not present—a miss—a two-word block of data is transferred (written) from main to cache memory. In a typical program, writes to the cache occur just 10% and reads from the cache, 90% of the time. Read hits average 80 to 95% of all memory operations in a typical program. □

Design

A cache-tag store and comparator on a single chip will reduce parts count, save space, and also greatly simplify cache systems in upcoming minicomputers and microcomputers having large memories.

Cache-memory functions surface on VLSI chip

This is the second article in a series on cache-memory systems. The first article, which covers the basic philosophy of cache systems, appeared in the Jan. 21 issue (p. 179). The overall approach was sketched by Richard N. Gossen, manager of advanced memory development at Texas Instruments, in the same issue (p. 32).

Given the growth now occurring, and in the offing, in the main-memory size of minicomputer and microcomputer systems, cache memories will be needed to take full advantage of their CPUs' speed. The TMS2150 cache-address and comparator IC represents a major step in simplifying the cache designer's task, as it handles most of the so-called tag functions—cache-address storage and comparison.

A cache memory is a small, fast buffer memory interposed between a fast CPU and a relatively slow main memory, like a dynamic RAM. In this way, with anticipated and frequently used information prestored in the cache, the CPU can obtain most of the data and addresses it needs at a speed comparable to its own. By proper design, the number of information accesses to the large but slow main memory can be reduced to a minimum. With a special memory-mapping technique, a small number of cache storage locations can represent large blocks of backing-memory information.

The cache, a fast static RAM, is divided into two sections—the tag store for the cache addresses; and the data store for numerical, program, or other types

of data. Cache memories, however, require more than mere storage. Just as important is high-speed data comparison to check a portion of the CPU address field against the tag addresses previously stored in the static RAM. This operation determines whether the data addressed by the CPU resides in the cache.

The 2150 (Fig. 1) stores the cache tags (or addresses) in a 512-word \times 9-bit static RAM, and also contains a 9-bit comparator. In addition, it generates and checks parity. The RAM's high speed, of course, matches or exceeds that of most available

Cache tag-comparator

microprocessors, and the 9-bit comparator circuit, which is integrated into the chip's memory-sensing amplifiers, is about 50% faster than bipolar comparators currently found in cache systems.

Housed in a 24-pin, 300-mil ceramic DIP, the 2150 works over an ambient temperature range of 0° to 70°C. Operation is from a single +5-V power supply, and the chip interfaces directly with both TTL and MOS logic circuits. Because of the ceramic package, power dissipation can go as high as 660 mW; typical dissipation, however, is 400 mW. To simplify cache-system design, the 2150 works fully statically—no clock or synchronizing signals needed—and it is easily expandable to fit any size processor bus or memory system (see "VLSI Built with Proven Techniques").

1. The TMS2150 cache-tag store and comparator, a single VLSI chip housed in a ceramic 24-pin DIP, occupies 24,600-mil² of silicon and is fabricated with proven 4.5- μ m design rules and NMOS technology.

The use of the 2150 makes for a minimum chip-count cache system, especially in conjunction with the companion TMS2149 1-k \times -4-bit static RAMs to store the data. The 2150 alone replaces 14 chips in conventional systems. Still, even the simplest cache-control circuit with the 2150 requires several TTL devices for buffering and control and some fast RAMs (like the 2149s) for storage.

In the block diagram of the 2150 (Fig. 2), the tag static-memory array of 64 rows by 72 columns is organized into the 512 words of 9 bits each, for a total of 4608 bits.

Initializing this memory is simple: Merely pulsing the Reset terminal low to clear all 512 memory locations forces the chip's Match output terminal high; and the reset pulse can be as short as 35 ns. Initializing a conventional cache memory, however, is much more complex. It requires a set of sequential operations that is time-consuming and demands far more hardware than the 2150's asynchronous single pulse.

A read cycle is enabled when the chip-select (\overline{CS}) input is driven low while the write-control input (\overline{W}) is held high (Fig. 3a). During this cycle, nine input-address bits (A_0 - A_8) select a 9-bit word in the memory array for comparison with eight input-data bits (D_0 - D_7) and an internally generated parity bit. Upon a valid match, the Match output terminal goes high. However, if the parity check indicates an error in the internal-memory data, the parity-error output (\overline{PE}) and the Match output go low. The \overline{PE} output is an open-collector type, allowing simple OR-tie connections to other devices.

For a write cycle, both \overline{CS} and \overline{W} must be driven low. Then, the data on the D_0 - D_7 terminals, plus an even parity bit from the internal parity generator are written into the memory-array location addressed (or rather tagged) by A_0 - A_8 . A parity error can be forced by holding the \overline{PE} terminal low, which is very useful for testing.

The 512 \times -9-bit tag memory-array structure permits the system to be expanded in building-block fashion for either wider or deeper tag stores. Patterned after bit-slice techniques, the 2150 can be considered an 8-bit-slice cache-address and comparator; accordingly, a 16-bit word could be divided into two 8-bit segments and operated on in parallel by two cache systems, speeding up performance in comparison with serial operation.

A key speed specification of a cache-address comparator is the delay time, $t_d(A)$, needed for the signal to go from the address input to the match outputs. Generally, this specification is a worst-case delay path in a cache-memory system. The 2150 is available with four delay versions—maximums of 45, 55, 70, and 90 ns—to meet a variety of cache-memory

VLSI built with proven techniques

Occupying just 24,600 mil² of silicon, the TMS2150 cache-address store and comparator is fabricated with conservative, 4.5- μm design rules and 2.5- μm NMOS polysilicon gate lengths. Many of the 2150's circuit techniques were first proven on the TMS2147H and TMS2149 4-k low-power, fast static RAMs. One such circuit, a distributed column-sensing amplifier (Fig. a), significantly improves the speed-power product over that of previous high-speed MOS designs.

During read cycles, tag data stored in the 2150's on-board memory are not directly accessible; instead, they are compared with the input data and checked for parity. Since this parity check must be performed at high speed, the sense amplifiers must reach valid

logic levels very quickly. That is beyond conventional differential amplifiers, but does not faze the distributed, column-sensing amplifier in the 2150. One method employed in the sense amplifier to help achieve the required speed is to isolate the bit lines (**BIT** and $\overline{\text{BIT}}$) fully from the data lines (D_{out} and $\overline{D_{\text{out}}}$) thus reducing the amplifier loading, which would hold speed down.

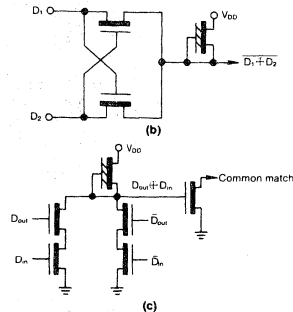

A cross-coupled pair of FETs driven by data-line source-followers acts as the main sense amplifier. This circuit provides fast level shifting, high gain, and excellent performance over the total expected range of semiconductor processing variations and operating temperatures.

Reading occurs when a column is selected by a high-

level signal to the circuit's column-select input. This input activates the column amplifier, which differentially drives the pair of common-data lines to the sensed state, which is then quickly transformed into sharp, clean logic levels by the sense amplifier.

To write data into the on-board memory, the pair of data-in signal lines (D_{in} and $\overline{D_{\text{in}}}$) must activate the gates of the bit-line pull-down transistors. With the desired column selected, forcing a data-in line to the V_{DD} voltage level pulls the associated bit line low to write the data in. At the same time, the complementary Data In line is held low, which permits the complementary bit line to rise to V_{DD} via the bit-line bias circuitry (not shown).

Because the bit lines are fully isolated from data-line loading, they can be driven efficiently by the

chip's small memory-cell transistors. Also, the sense-amplifier circuit has a precisely controlled differential-voltage gain. Moreover, the dynamic requirements for the column-decoding circuitry (also not shown) are light, because only one small transistor activates the column selection. And since the transistor's source terminal is at ground potential, a relatively low column-selection voltage is sufficient to activate the column.

In addition, the Exclusive-NOR gates were specially designed to minimize chip real estate. To simplify the layout, the parity circuit's Exclusive-NOR gate (Fig. b) requires just a single-polarity input signal, minimizing the needed interconnection area. Similarly, the comparator's Exclusive-NOR circuit (Fig. c) uses a common match line for the 9-bit comparator circuit to hold down the interconnection area.

Cache tag-comparator

system speeds (Fig. 3a shows a unit whose $t_d(A)$ is about 30 ns).

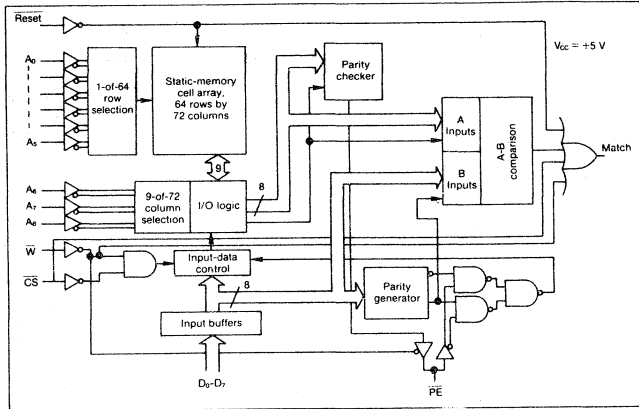

The fastest specified version (45 ns) is about 20% faster than the fastest conventional bipolar RAM and external TTL comparator circuit. In addition to being fast, the address-to-match signal time of the 2150 is relatively stable over the operating temperature range, increasing just 20% from its 25°C value with the Match output driving a 30-pF load (Fig. 4). In addition, $t_d(A)$ changes little with supply-voltage variations.

Other important timing parameters include the

chip-select-to-match delay time, $t_d(CS)$, which is about 25 ns maximum in the fastest 2150 version, and the input-address-to-PE delay time, $t_d(PE)$, which is specified at a maximum of 55 ns for the same version.

Applying the 2150

With the tag-store and comparator circuitry on a single chip, the 2150, of course, is a large saver of circuit-board space. One or more 2150s together with several 2149 static RAMs can be placed on a single board, rather than the 1½ to 2 boards usually

2. The 2150 contains a 64-row \times 72-column static-RAM memory array organized as 512 words of 9 bits each. The RAM stores tag-address data for the cache system, and the rest of the chip provides the logic for comparing the stored tag address with the address on the data-bus line for validity, and providing or checking the data's parity.

3. The timing cycles for 2150 start with a \overline{CS} -low signal. After comparison and matching, either a Match high or a parity error (PE) low is obtained (a). The worst-case time delay between the address input and match output, $t_d(A)$, is a key 2150 specification, and is available as one of four maximum values. A unit actually measured has a typical 30-ns $t_d(A)$ delay (b).

required. Moreover, a single-board cache memory virtually eliminates the delay times from the capacitances introduced by buffers, conductor traces, board connectors, and backplane wiring.

For example, the board can contain a single-set, 2-kbyte cache memory for 16-bit words (Fig. 5). Two 2150s serve for tag storage and comparison and four

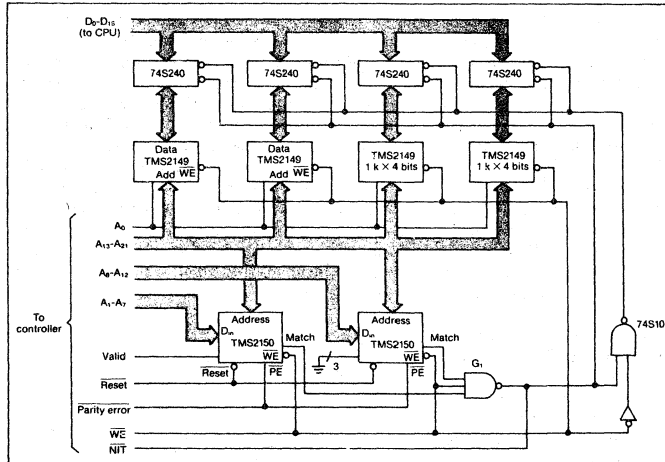

2149s hold the 16-bit data words. Taken together with some TTL packages—four 74S240 octal buffers and one 74S10—they make an 11-package tag and data-storage system that requires only a controller (not shown) to support a two-way interleaved backing dynamic memory. This cache board, which operates at a total delay from address input to valid-data output of less than 80 ns, can be applied to almost any 16-bit minicomputer or microprocessor system having a 22-bit address field.

Acting as 8-bit-slice devices, the two 2150s split the processor address bus into two sections when comparing and matching addresses. When an address match is verified by both chips, the Match outputs—gated through G_1 —supply an enable signal to the 74S240s configured as bidirectional buffers. In that way, address-input data can move from the 2149 static RAMs to the processor data bus.

When the write-enable (WE) line is pulled low, data are entered into the 2149 RAMs from the processor, while the tag addresses of the data are entered into the 2150's internal tag-store RAM. □

4. The delay between the address input and the match output, $t_d(A)$, of the 2150 is relatively insensitive to variations in temperature or V_{CC} .

5. The 2150 readily lends itself to building-block implementations of cache-memory systems, as in this 2-kbyte single-set cache that employs two 2150s for a 16-bit processor with a 22-bit address field. In addition, the cache system requires four TMS2149 static RAMs, four 74S240 bidirectionally connected buffers, and a 74S10 gate chip. Thus the cache circuit comprises 11 chips. Not shown is the hit/miss and controller circuit that a cache also requires.

Performance could be improved by fitting cache-memory hardware to the system software or fine-tuning the software to the cache hardware.

Match cache architecture to the computer system

The following article is the third in a series on cache-memory systems. The previous article covered the details of a particular cache tag-store and comparator IC (Feb. 18, 1982, p. 159). The first article covered the basic cache philosophy (Jan. 21, 1981, p. 179). Texas Instruments' overall approach was sketched by Richard N. Gossen, manager of Advanced Memory Development, in the Jan. 21 issue (p. 32).

Cache-system architecture can take many forms, each with its own performance advantages and disadvantages and differing degrees of economy. But for optimum performance, the architecture of a cache-memory system should be matched specifically to the architecture of the overall computer system. Moreover, the cache's hardware and operational logic should be fitted to both the statistical and structural properties of the computer system's software and be highly transparent to it.

Of course, existing software can also be tuned to fit a particular cache hardware and its functional properties. A properly configured and finely tuned cache software-hardware system can approach well over 80% of the throughput that a very expensive all-high-speed memory could deliver. What's more, a cache system can do it with a slow, low-cost bulk memory plus a small amount of additional high-speed hardware for the cache.

Very high speed memory is expensive; therefore, the typical computer system cannot afford too much. On the other hand, bulk memory offers a large amount of low-cost capacity, but it is slow. A cache-memory system can combine the advantages of the two types of memories economically: small, but fast memory in the cache with large but slow memory for bulk storage.

A well-designed cache-memory system can manage to keep the few most-likely-to-be-accessed data in the cache for quick reference, while the bulk memory serves as a backup on those occasions when the processor references data not contained in the cache. When successfully implemented, this approach yields an almost transparent, economical memory system with the capacity of the bulk storage, but with the quick response of the cache.

The memory system of an inexpensive microcomputer system today is likely to be made up of a relatively low-cost disk and dynamic RAMs. Such a two-level memory hierarchy is well-suited to the needs of the less expensive popular microprocessor, whose minimum memory cycle times are on the order of 500 ns. Some of the newer high-performance microprocessors, however, have much shorter cycle times. An example is the 24-MHz 16-bit TMS99000, whose minimum memory cycle is 167 ns. For such a processor to access a block of relatively slow dynamic RAM, it must be slowed down by adding wait states to each memory cycle. This can be avoided by adding a third level to the memory hierarchy in the form of a high-speed cache of relatively simple design. The performance of such a processor can be improved dramatically, and the cache itself will represent only an incremental cost to the total

1. Even a simple single-microprocessor system can benefit from a cache system. With it, the number of accesses that must be made to disks and slow main memories like dynamic RAMs can be reduced substantially.

Jerry VanAken, Computer Systems Engineer
Texas Instruments Inc.
8600 Commerce Park, Houston, TX 77036

system—especially with the help of support chips such as the TMS2150 cache address comparator to keep the chip count low.

Although the per-bit cost of disk and semiconductor memory has decreased dramatically in recent years, microcomputers remain expensive largely because each decrease in the per-bit cost of memory devices is countered by a proportionate increase in the size of the average memory system. However, adding a cache to a memory system can produce a more than proportionate yield on the user's investment in his memory system—in the form of more memory-access cycles per second per dollar.

But even though the addition of a cache to a conventional, centralized high-performance microcomputer can greatly increase memory effectiveness, even greater improvements are possible with a distributed-intelligence architecture. The centralized-processor arrangement shown in Fig. 1 is based on the economics of past years, when the processor part of the system represented a much larger part of the overall system cost than it does today. Now, the situation is different: to have a single \$20 microprocessor control \$1000 worth of memory no longer makes economic sense. Low-cost independent microprocessors with local I/O arrangements in a distributed-intelligence system not only makes more economic sense, but can provide substantially better overall performance by using more of the available memory bandwidth (Figs. 2 through 5).

Moreover, the amount of memory bandwidth available can be effectively improved through the addition of caches; hence, the distributed-intelligence processing system can benefit from properly applied caching even more than the centralized-processor system of Fig. 1. In the simplest distributed system (Fig. 2), a central, global, bulk-storage memory can serve many independent microprocessors along a common bus. As the number of processors on the bus increases, the system throughput at first increases proportionately. But the bus gradually saturates—its bandwidth capability can handle no more data (Fig. 3). Adding more processors soon does not improve overall throughput: Since access to the memory for all data and instructions, as well as messages between the processors, is via the bus, the bus quickly becomes very busy. As more processors are added, contention for the bus mounts, and delays become longer.

Distribute memory too

Moving some of the memory to the local sites of execution (Fig. 4)—in a so-called function-to-function architecture (FFA)—will help alleviate bus-contention problems by locally storing most of the instructions and data needed for the special func-

tions performed at that site. In this way, the global memory need contain just the shared data and those instructions needed for overall coordination, which together with interprocessor messages now have more “room” on the bus. This arrangement then allows still more processors to be handled with a given bus bandwidth.

Depending on the effort expended in organizing the software and the amount of local memory, the traffic on the bus can be cut way down—perhaps to as little as 10% of that of a nondistributed memory architecture. But to allow a high-performance microprocessor to operate at full speed, this local memory should be the fast, static-RAM type, which unfortunately is expensive and, in practice, limited to small capacities. However, configuring this small memory into a cache system would help matters since its capacity, though small, will be filled continually with current data (in a properly designed system). The small cache capacity would be as effective as a much larger static-RAM block mapped into a fixed set of memory addresses.

Moreover, with more of the bus bandwidth made available, entire blocks of data can be moved with each global-memory access. Block transfers from the global memory can have much the same advantage as moving blocks from a disk: Following the initial access time, the overhead time for each additional data word in the block is merely incremental.

For example, the global memory is likely to be made up of several dynamic RAMs, which support paged-mode operation. In this mode, only one row address is needed for a subsequent series of column addresses, which decreases the amount of overhead time per access. Or, the global-memory circuit may access not one, but several words in parallel, and then feed these to the system one-by-one at the maximum transfer rate of the bus. (Recent bus interfaces, such as the proposed IEEE-P896 standard, have been designed to support such efficient block transfers.)

Block transfers are particularly beneficial to

2. A distributed-intelligence, or function-to-function, system, having several local microprocessors instead of one centralized CPU, not only makes more economic sense, but can provide substantially better overall throughput.

caches because of their locality property, which characterizes the memory-access patterns of all programs. Basically, if a program accesses one word in a data or instruction block, it is likely to access other words in the same block subsequently. By reading the entire block into the cache at once, there's a good chance that the cache will be able to satisfy a greater number of additional access requests from the local processor without requiring more trips to the global memory for data.

Where to locate the cache

After the decision has been made to go with block transfers of data to the cache in the distributed-intelligence system, the next thing to determine is the location of the cache. In Fig. 2, the cache is located on the global-memory board. This cache location can decrease the time on the bus for memory accesses; accordingly, the bus is available for more data transfers. While this cache location decreases the overhead time per memory-data bus transfer, the number of such bus transfers remains the same as without the cache.

However, if the cache memory is located as in Fig. 4, the number of transfers over the bus is reduced. A block of data is accessed from main memory just once, but locally the same data can be used many times over without having to go back to the main memory via the bus. The bus bandwidth, thus freed up, now allows an increase in the amount of data transferred in each block. In addition, the cache block can be made large enough to achieve a desired hit ratio.

But if the processors run very long, uninterrupted programs and need just a few global-memory accesses, a simple FFA configuration (Fig. 4 without a cache, but with ordinary local memory) could be the most economical approach. With such programs, each processor executes the same on-board routines and accesses the same data locations repeatedly. Then the global memory need handle just messages between processors and system-wide instructions and data.

With the traffic on the bus reduced substantially, more processors can be added to the bus. And global-to-local-memory transfers could proceed via a direct-memory-access (DMA) system, which of course would be initialized under software control. Transfers via a local cache system (Fig. 4 with cache systems), however, would carry out the transfers automatically, transparent to the software.

Almost transparent

When a distributed system is implemented with local caches, the software is virtually unaware of the split between the local and global memories:

3. When a multiprocessor system shares a single bus, throughput rises proportionately at first with the number of processors, but tapers off as the bus's data-handling capacity saturates.

Hardware—the cache's control logic—maps the contents of each local cache into the global memory, and the cache is largely transparent to the software. (By comparison, in a DMA arrangement, the software would have to be totally involved in the local-global memory split.) Accordingly, with distributed cache systems, existing software (such as Pascal) for centralized-CPU systems can be used, with but minor modifications, for a higher-performance distributed-intelligence system.

Clearly, the distributed cache-system approach is general-purpose: All data and instructions can be mapped into the global memory as in the centralized system, and the local caches will then (almost) transparently remap the information for local use. In other words, the distributed system with local cache can best serve a general-purpose processing environment, where the specific functions of the individual processors cannot be predicted in advance, and thus where the contents of the local memories cannot be fixed at the time the system hardware is configured.

On the other hand, with a fairly fixed and predictable installation, perhaps with Fortran software, or in a plant-process-control application, where the data and software needed on each processor (board) are firmly established, the FFA approach could be used in place of local caches. But to achieve even greater performance, a distributed memory system can combine two or more of the approaches described. For example, cache memories can be employed for both the local and global memories—a combination of Figs. 2 and 4. The local cache decreases the number of references to the global memory, and the global cache decreases the average length of the bus cycles when global accesses do become necessary. Or, in a variation of the distributed-processor system of Fig. 2c, local memory and local cache can be used on the same processor. In Fig. 2d, the addition of a cache improves the performance of a large but slow local memory composed of 64-kbyte (or larger) dynamic RAMs.

Cache-memory architectures

Although, in general, employing local caches in a distributed system (like the one in Fig. 2c) will remove local instruction and data traffic from the bus and speed throughput substantially, trying to make the caches appear totally transparent can introduce interference problems with messages between processors. In the distributed system of Fig. 2c, for example, messages between processors should not be accessed through the local caches because this class of data is not held there: The caches contain only local current instructions and data from the global memory. As a result, in Fig. 3, when microprocessor 1 writes a message to microprocessor 2, the data should pass via a particular location in the global memory that acts as a message buffer. In the process, the local cache on the microprocessor-1 board must be prevented from intercepting the message. And when microprocessor 2 tries to read the message, its cache also must be removed from the message path. Otherwise, microprocessor 2 will encounter stale data in cache memory, and not the new message from microprocessor 1, which had just been deposited into the global-memory.

A write-through (as opposed to nonwrite through or write-back) caching policy can ensure microprocessor 1 writes its message to global memory, but additional steps are needed to ensure that microprocessor 2 reads the message from global memory without interference from its cache. Software recognition of the special status of interprocessor messages can easily solve this potential problem. But this approach constitutes a lack of total transparency for the caches.

One approach passes all interprocessor messages through the microprocessor's I/O space. Since I/O data are not cached, this strategy automatically

avoids the interference problem. Interprocessor messages pass through the I/O space, bypassing the caches altogether. So if the software is initially written to handle the interprocessor messages via the I/O space, then when caches are introduced, they will automatically be transparent to the caches.

Alternately, a particular set of addresses in the global-memory space can be dedicated to message passing. The control logic in each processor-board's cache could incorporate a comparison circuit that recognized the message-space addresses and allows access to the message area in global memory to bypass the cache.

System data should also bypass the caches and be taken by a processor directly from the master copy in the main memory: Such data are constantly being updated by the other processors. If passed via the local caches, such data would invariably be perceived as stale because of the constant updating. If allocated to specific and exclusive global-memory addresses, these system data can be handled like the interprocessor messages to bypass the caches.

Similarly, each processor should have exclusive access to its own private instruction and data segments in the global memory. In this way, the data are "protected," with some support from bus hardware, from a processor that may go "berserk" and corrupt the instruction and data segments of the other processors in the system.

Clearly, with caches in distributed-intelligence systems, the memory accesses must be organized rationally to optimize throughput, avoid inefficient data thrashing and, most important of all, avoid using data belonging to other processors. Of course, with a single cache (as in Figs. 1 and 2), it is rather difficult to mix up the data, since the cache should always contain updated master versions of the corresponding blocks of memory (which is never changed without knowledge of the cache). In a multiprocessor system like Fig. 4, however, each local cache is supposed to keep a separate, accurate copy of some portion of the global memory—as it pertains to its own processor. But a mixup is possible because of the multiplicity of processors.

The point of all this is that it is exceedingly difficult to make the cache memories in a distributed system totally transparent to software, while simultaneously ensuring that each processor is provided with a coherent, updated version of the contents of global memory. Methods have been proposed for accomplishing just this, but they tend to be expensive in terms of the hardware required, and are therefore beyond the reach of the typical microprocessor-based system.

In some systems, the entire contents of the cache may have to be "flushed," if for any reason its

4. A cache, located at the slow global memory as in Fig. 2, can reduce the number of required slow accesses to main memory, thus leaving the bus more time for other activities. But locating part of the memory at each processor—in a distributed architecture—is even better.

contents have become invalid. For example, a DMA device may alter the contents of main memory, invalidating the contents of the cache. Also, consider the case of a processor attached to a memory mapper (like a 74LS610), which translates the logical addresses output from the processor into the physical addresses used to access the memory. A cache will usually be attached directly to the processor to avoid lengthening the cache access time with the propagation delay through the mapper circuitry. However, this means that the cache contents are mapped into the logical rather than the physical address space. Consequently, when the map file is altered, this makes the cache contents invalid since the mapping of the logical into the physical address space is no longer the same.

For applications where the cache contents must frequently be flushed, a cache-reset function is essential. Without the ability to flush the cache instantaneously, the system would be forced to clear each cache block, one by one.

But flushing the entire cache when just a small portion of its contents needs updating is wasteful. Naturally, a more complex reloading arrangement can be designed to provide higher caching efficiency where only part of the cache data must be replaced frequently, but only at the expense of increased overhead in logic and software. Selectively dumping

only the affected areas of the cache capacity—such as when a DMA operation partially alters the contents of the global memory—instead of a total reset, would be more efficient, but also much more expensive. It would also occupy more board space.

Complexity requires board space. With the trend to smallness in electronic packaging, sometimes compromises must be made. CPU speed is generally compromised when going from a multiboard minicomputer design to a design that just barely crams a CPU onto a single board. To put substantial memory onto the board as well usually requires going to a slower microcomputer design, which puts the CPU into a chip, and leaves board room for the memory. However, the speed lost because of these compromises can be partially recovered by incorporating a cache on the board (or even on the microprocessor chip). The cache effectively raises the individual processor's memory access speed when it is used with a slow on-board dynamic RAM (Fig. 5).

The TMS9995 microprocessor is a precache step in this direction: It contains a modest chunk (256 bytes) of high-speed random-access memory, which is mapped into a fixed area of the processor's address space. Thus, it does not qualify strictly as a cache. However, it can be used to the same effect by loading the RAM—under explicit software control—with currently needed data and instructions.

The next step would be to put a cache on the processor board (or chip) with as much memory as the board space allows, all of which would be almost transparent to the system software. Equally important, a cache could make the most of the limited amount of memory that now can be put onto a board with the microprocessor and I/O.

Despite the transparency, a programmer who is aware of the cache's capability can fine-tune the software to maximize its efficiency. On the other hand, overly refined software for one hardware system can produce poor efficiency on another, while remaining transportable in the sense that it executes without error. But as software can be adapted to maximize the efficiency of cache configuration and minimize its limitations, so can cache-system hardware be designed to best fit very extensive existing software. It is a two-way street.□

5. The local memory can be in "ordinary" RAM form (as in function-to-function architecture) or in cache form. Or, both a cache and a local dynamic RAM can be used.

6. Interprocessor messages should bypass caches to avoid interference. This can be accomplished with the software or special overhead hardware, or by employing the microprocessor's I/O space to carry the messages.

4 Error Detection and Correction (EDAC)

4.1 Use of an Error Detection and Correction (EDAC) Device

4.1.1 Introduction

The DRAM technology of today (i.e., 256K/M) has enabled system designers to use much larger memory sizes than ever before. However, as with most advances in technology, this has brought a new problem. For system memory sizes larger than 1/2 million bits, it is generally considered that error detection and correction is required to guarantee system reliability without a tradeoff in performance. Although present methods of parity checking will identify errors, they are not able to correct them. And not correcting these errors can be costly. For example, in personal computers when parity errors are encountered, the system has to be reset to eliminate the problem. This system reset destroys any data stored in RAM and it must be reentered. Obviously this is unacceptable to your customers. To eliminate this problem, TI has produced a cost effective Error Detection and Correction (EDAC) device.

4.1.2 Error Types and Sources in Dynamic Memories

Two kinds of errors occur in memory devices; soft and/or hard errors. A hard error is a physical failure of the memory device (e.g., an internal short or an open lead). This type of error causes the memory location to always be either a high or a low. A soft error is a random occurrence of a memory location change from a high level to low level. These errors may be caused by system noise, alpha particle radiation, or power surges.

In spite of design techniques used by memory chip manufactures to reduce these errors, they are still a source of major concern in your system. Table 4-1 indicates that as the density of memory chips increase their probability of errors also increase. Therefore, your data integrity decreases in larger memory arrays.

Table 4-1. Chip Densities vs Soft-Error Rates

CHIP DENSITY BITS/CHIP	TYPICAL SOFT-ERROR RATE (% PER 1000 HOURS)
64K	0.10 - 0.20
256K	0.15 - 0.30
1M	0.20 - 0.35

4.1.3 Solutions to Boost System Reliability

There are several alternatives available that will either decrease or eliminate these errors in your system. One method used to determine data integrity is the incorporation of parity checking. This can be accomplished by using an SN74ALS29833 Parity Bus Transceiver. To identify an error, the data word and the generated parity are compared by performing an exclusive-OR operation. If several bits in the data word are in error or the parity has changed, the exclusive-OR output would be low. While data integrity can be determined using this method, it is unable to correct errors.

To obtain the desired level of quality, some type of error-correction scheme must be incorporated. An EDAC chip provides the simple solution to the problem, while dramatically extending the system Mean Time Between Failures (MTBF). This is accomplished by detecting and correcting single bit errors and detecting double bit errors. See Table 4-2.

Table 4-2. System MTBF Increases with an EDAC

	MTBF [†]	
	Without EDAC	With EDAC
CORRECTABLE SOFT ERROR (SINGLE BIT)	7 Months	>200 Years

[†]Based on 16M-Bit memory system using 256K DRAMs with a 0.30% per 1000 hour soft error rate.

When you include the other system variables causing errors (power surges, noisy systems, etc.), your memory system MTBF, without an EDAC could be reduced to several days. These types of memory-cell errors can be corrected using an EDAC.

4.1.4 EDAC Operation

When data is written to memory, the TI SN74AS632 (32-Bit EDAC) generates parity check bits. Each check bit is generated by performing a specific parity check on the 32-bit data word. For example, CB0 is obtained by comparing specific bits of the 32-bit word with those corresponding to an "X" in the Hamming Code Parity Algorithm (see Table 4-3). CB0 will be at a high level if the total number of highs corresponding to these locations is an odd number. CB0 will be at a low level if this number is even. This procedure is repeated 7 times to obtain the 7 check bits, CB0-CB6 of the Hamming Code. Check bits CB0-CB2 are used to determine odd parity. Check bits CB3-CB6 are used for even parity.

Table 4-3. Hamming Code Parity Algorithm

CHECK WORD BIT	32-BIT DATA WORD																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CB0	X	X	X	X						X		X	X	X		X		X	X	X	X		X	X	X	X		X		X		X
CB1				X	X	X	X		X	X	X	X	X						X	X	X	X		X	X	X	X		X	X	X	X
CB2	X	X		X	X	X	X		X	X	X	X	X		X	X	X	X		X	X	X	X		X	X	X	X		X	X	X
CB3		X	X	X	X				X	X	X	X	X		X	X	X	X						X	X	X	X		X	X	X	X
CB4	X	X							X	X	X	X	X		X	X				X	X					X	X	X	X	X	X	
CB5	X	X	X	X	X	X	X								X	X	X	X	X	X	X	X										
CB6	X	X	X	X	X	X	X	X																	X	X	X	X	X	X	X	X

The seven check bits are parity bits derived from the matrix of data bits as indicated by "X" for each bit.

These check bits are stored along with the data in your systems main memory. This additional memory requirement is the only overhead involved with the use of an EDAC. Figure 4-1 shows a typical system using an EDAC and illustrates this overhead.

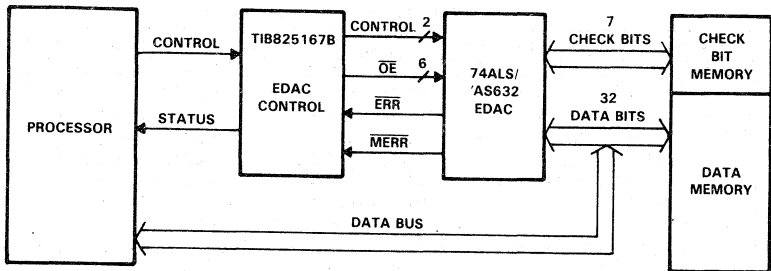

Figure 4-1. Typical 'AS632 System

During a read cycle, the data and check bits are read from memory, any of which may be invalid. New check bits are computed from the stored data bits. To determine the validity of the data, the new and old check bits are exclusive-ORed producing a 7-bit syndrome code. When decoded, these syndrome bits describe the condition of the data word: free of errors, having a single bit error, or having multiple errors. See Table 4-4. Any single error in the 32-bit word can be corrected. Both single and double bit errors are indicated to the processor via single and double bit error flags.

There are two additional options for implementing EDAC into your system; detect only and correct always. Of these two, correct always is the easiest to implement. The EDAC always corrects single-bit errors and writes this corrected word onto the system data bus or into memory.

Because days can elapse between errors, correction can be done only when needed. The detect-only option increases your system performance during a read cycle by allowing data to be written directly to the system processor. If a single or double bit error occurs, the EDAC will flag the processor. This enables the processor to enter a wait cycle until the word is corrected. This method of implementation does not use the error correction portion of the EDAC until the processor determines what action to take in the event of an error.

Another method of ensuring data integrity in your system is to use an EDAC unit during memory refresh. The EDAC will "clean" every memory location of errors during the mandatory refresh cycles. This process is known as memory scrubbing. The data can then be checked again during a memory-access cycle. By checking the data twice, the time between corrections is reduced. Therefore, the probability of multibit errors in your system declines.

Table 4-4. 'AS632 Syndrome Decoding

SYNDROME BITS		ERROR	SYNDROME BITS		ERROR	SYNDROME BITS		ERROR	SYNDROME BITS		ERROR

CB X = error in check bit X
 DB Y = error in data bit Y
 2-bit = double-bit error
 unc = uncorrectable multibit error

The circuit illustrated in Figure 4-2 is an example of a memory system that used scrubbing. This circuit consists of the TI SN74ALS6302, a 1M-DRAM Controller, the TMS4C1024, 1M DRAMs, the SN74AS632, a 32-bit EDAC, and control circuits.

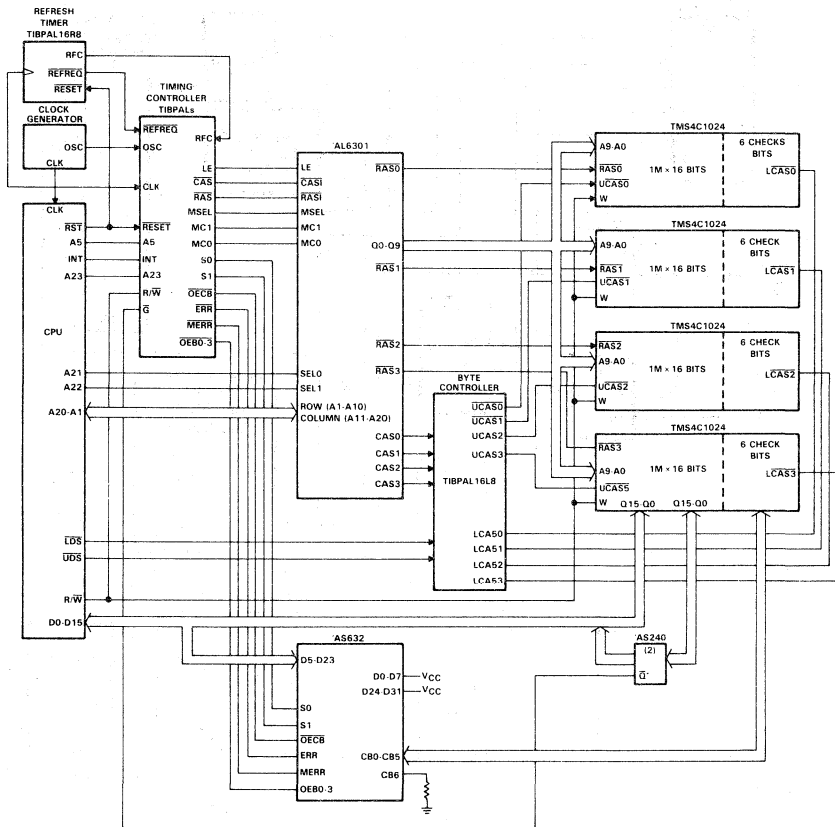

Figure 4-2. Memory Management Systems Using Scrubbing

4.1.5 Texas Instruments EDAC Family

Because of the increase in MTBF, the SN74AS632 can increase system reliability typically by well over 500-fold. The 'AS632 provides built-in diagnostics to assure reliable device operation. Byte-write capability is included to allow operation on 8-bit, 16-bit, or 32-bit word widths in 3-state bus applications. The 'AS632 provides the fastest correction time, 32 ns, and error-detection time, 25 ns, available today. The architecture of the 'AS632 is illustrated in Figure 4-3.

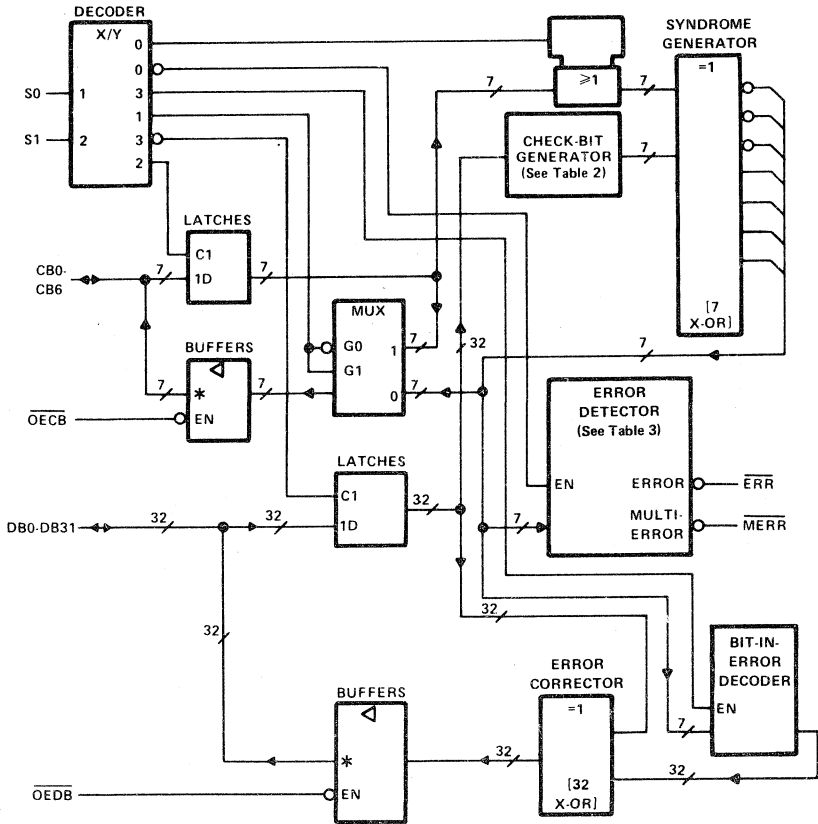

Figure 4-3. 'AS632 Logic Diagram

Along with the 'AS632 32-bit EDAC, TI has a complete family of high-performance EDAC products to fit your particular application. See Table 4-5.

Table 4-5. Texas Instruments Error Detection and Correction Devices

DIP PINS	DEVICE TYPE	DETECTION† TIME (MAX)	CORRECTION TIME (MAX)	FEATURES	AVAILABLE
40	ALS616	40	65	16-BIT, 3-STATE	NOW

‡Design Goals

All of the products listed in Table 4-5 offer the following:

1. Built-in Diagnostic Capabilities
2. Modified Hamming Code Operation
3. Dependable Texas Instruments Quality and Reliability

4.1.6 Summary

Memory errors are becoming a very important concern to the system designer. To effectively ensure data integrity, a method of correcting data errors is necessary. An EDAC unit provides you with this essential function along with increasing system MTBF from days to years. The TI EDAC family offers you ease of implementation, high performance, and a device that is compatible with any microprocessor you might be using.

For more information on the TI family of EDAC devices, please contact your local TI Sales Representative or the Customer Response Center at 1-800-232-3200.

For your convenience, the TI documentation is listed below.

4.2 Error Detection and Correction Using 'ALS632B, 'ALS633, 'ALS634A, and 'ALS635

4.2.1 Introduction

With memory systems continuing to expand and the expectation of 256K-byte DRAMs in the near future, error detection and correction has become increasingly important. Generally, the larger the chip density, the greater the probability for device errors. It is easy to recognize this probability when one considers that a 32-bit \times 64K-byte memory, using 64K-byte DRAMs, equals approximately 2.1 million bits of information. This expands to 8.4 million bits of information when using 256K-byte DRAMs. For memory sizes larger than 0.5 million bits, error detection and correction is required to guarantee high reliability.

The SN54/74ALS632B, SN54/74ALS633, SN54/74ALS634A, and SN54/74ALS635 provide a solution to these requirements in 32-bit machines. In addition, the 'ALS632B and 'ALS633 provide the necessary hardware to perform byte-write operations which are typically used in the more advanced systems. To ensure the integrity of the error detection and correction circuit, diagnostic capabilities have been provided in all four devices.

The 'ALS632B series devices are not limited to 32-bit systems. They can be implemented in 16- or 24-bit systems. In the case of 16-bit systems, the additional memory needed for holding the check bits can be reduced when compared to conventional 16-bit EDACs.

The pin functions are listed in Table 4-6. Mechanical data for the 'ALS632B, 'ALS633, 'ALS634A, and 'ALS635 is shown in Figure 4-4.

Table 4-6. Pin Function for 'ALS632B, 'ALS633, 'ALS634A, and 'ALS635

PIN NAME	DESCRIPTION																				
S1, S0	<p>Selects the operating mode of the EDAC</p> <table border="1"> <thead> <tr> <th>S1</th> <th>S0</th> <th>MODE</th> <th>OPERATION</th> </tr> </thead> <tbody> <tr> <td>L</td> <td>L</td> <td>WRITE</td> <td>Input dataword and output checkword</td> </tr> <tr> <td>H</td> <td>L</td> <td>READ & FLAG</td> <td>Input dataword and output error flags</td> </tr> <tr> <td>H</td> <td>H</td> <td>CORRECT</td> <td>Latched input data and checkword/output corrected Data and error syndrome code</td> </tr> <tr> <td>L</td> <td>H</td> <td>DIAGNOSTIC</td> <td>Input various datawords against latched checkword/output valid error flags</td> </tr> </tbody> </table>	S1	S0	MODE	OPERATION	L	L	WRITE	Input dataword and output checkword	H	L	READ & FLAG	Input dataword and output error flags	H	H	CORRECT	Latched input data and checkword/output corrected Data and error syndrome code	L	H	DIAGNOSTIC	Input various datawords against latched checkword/output valid error flags
S1	S0	MODE	OPERATION																		
L	L	WRITE	Input dataword and output checkword																		
H	L	READ & FLAG	Input dataword and output error flags																		
H	H	CORRECT	Latched input data and checkword/output corrected Data and error syndrome code																		
L	H	DIAGNOSTIC	Input various datawords against latched checkword/output valid error flags																		
DB0 through DB31	I/O port for entering or outputting data																				
$\overline{OE}B0$ through $\overline{OE}B3$ ('ALS632B, 'ALS633)	Three state control for the data I/O port. A high allows data to be entered, and low outputs the data. Each pin controls 8 data I/O ports (or one byte). $\overline{OE}B0$ controls DB0 through DB7, $\overline{OE}B1$ controls DB8 through DB15, $\overline{OE}B2$ controls DB16 through DB23, and $\overline{OE}B3$ controls DB24 through DB31.																				
$\overline{OE}D$ (ALS634, ALS635)	Three state control for the data I/O port. When low allows data to be entered and a high allows data to be outputted.																				
LED80	Controls the dataword output latch. When low, the data output latch is transparent. When high, the latch stores whatever data was setup at its inputs when the last low to high transition occurred on the pin.																				
CS0 through CS6	I/O Port for entering or outputting the checkword. It is also used to output the syndrome error code during the error correction mode.																				
OECS	Three state control for the checkword I/O port. A high allows data to be entered and a low allows either the checkword or syndrome code (depending on EDAC mode) to be outputted.																				
ERR	Single error output flag, a low indicates at least a single bit error.																				
MERR	Multiple error output flag, when low indicates two or more errors present

Figure 4-4. Mechanical Data

4.2.2 Operational Description

4.2.2.1 Write Mode

During a memory write cycle, the EDAC is required to generate a 7-bit check word to accompany the 32-bit data word before being written into memory. To place the 'ALS632B, 'ALS633, 'ALS634A and 'ALS635 in the write mode, take S1 and S0 low. Output-enable controls $\overline{OE}B0$ through $\overline{OE}B3$ for the 'ALS632B, 'ALS633 or $\overline{OE}DB$ for the 'ALS634A, 'ALS635 must be taken high before the data word can be applied. Output-enable control $\overline{OE}CS$ must be taken low to pass the check word to the external bus.

The check word will be generated in not more than 30 ns after the data word has been applied. During the write mode, the 'ALS632B series EDACs can be made to appear transparent to memory, because typical write times of most DRAMs are much larger than the propagation delay of data to check word.

4.2.2.2 Read-Flag-Correct Operation

During a memory read cycle, the function of the 'ALS632B series EDACs is to compare the 32-bit data word against the 7-bit check word previously stored in memory. It will then flag and correct any single-bit error which may have occurred. Single-bit errors will be detected through the ERR flag and double-bit errors will be detected through the MERR flag. Figure 4-5 shows a typical timing diagram of the read-flag-correct operation.

When S0 is taken high, the EDAC will begin the internal correction process, although the error flags are enabled while in the read mode. For many applications, the simplest operation can be obtained by always executing the correction cycle, regardless if a single-bit error has occurred.

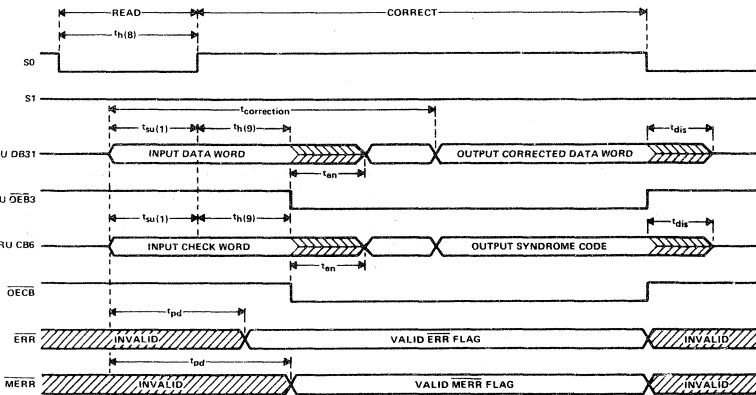

Figure 4-5. Read-Flag-Correct Timing Diagram

4.2.2.3 Important Timing Considerations for Read-Flag-Correct Mode

The most frequently asked question for an EDAC is how fast can a correction cycle be executed. Before $S0$ can be taken high, the data and check word must be set up for at least 5 ns. In addition, the data and check word must be held for at least 10 ns after $S0$ goes high. This ensures that the data and check word are saved in the EDAC input latches. After the hold time has been satisfied, the source which is driving the data bus can be placed in high impedance and the EDAC's output drivers can be enabled. This is accomplished by taking $\overline{OE}B0$ through $\overline{OE}B3$ ('ALS632B, 'ALS633) or $\overline{OE}D\overline{B}$ ('ALS634A, 'ALS635) low.

If the minimum data setup time is used as a reference and the output drivers are enabled after the minimum data hold time, then correction will be accomplished in 37 ns or less.

4.2.2.4 Read-Modify-Write Operations

The 'ALS632B and 'ALS633 contain the necessary hardware to perform byte-write operations. The 'ALS634A and 'ALS635 are not capable of byte-write operations because they do not contain an output data latch or individual byte controls. When performing a read-modify-write function, perform the read-flag-correct cycle as previously discussed and shown in Figure 4-5. This ensures that corrected data is used at the start of the modify-write operation.

The corrected data is then latched into the output data latch by taking $\overline{LE}D\overline{B}0$ from low to high. Upon completing this, modifying any byte or bytes is accomplished by taking the appropriate byte control $\overline{OE}B0$ through $\overline{OE}B3$ high. This allows the user to place the modified byte or bytes back onto the data bus while retaining the other byte or bytes. An example of a read-modify-write for byte 0 is shown in Figure 4-6.

Since the check word is no longer valid for the modified data word, a new one is generated by taking $S0$ and $S1$ low. After the appropriate propagation delay, the new check word will be available.

4.2.2.5 Important Timing Considerations for Read-Modify Write Operations

$\overline{LE}D\overline{B}0$ should not be transitioned from low to high for 30 ns after $S0$ goes high. This ensures that corrected data is latched into the data output latches. However, $\overline{LE}D\overline{B}0$ should be taken high before either $S0$ or $S1$ go low. Again, this is to ensure that the corrected data is stored into the data output latches. It is important that the new check word be available no later than 32 ns after $S0$ and $S1$ go low.

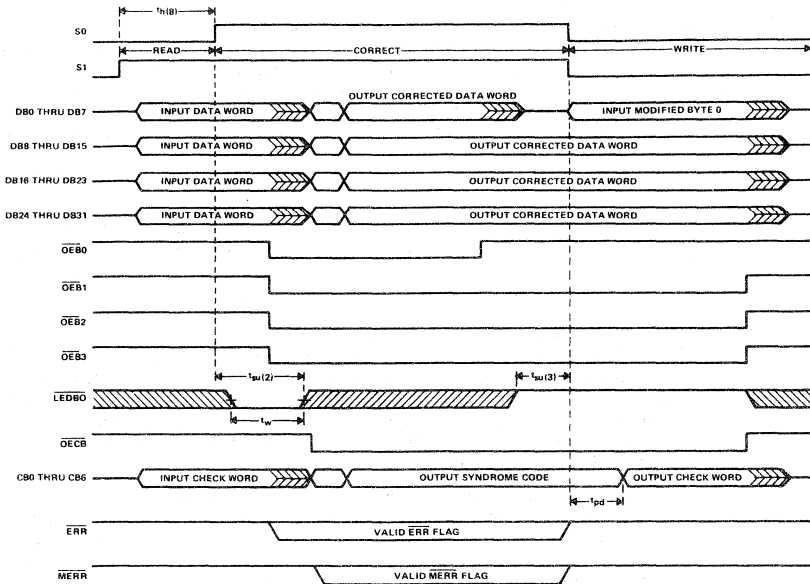

Figure 4-6. Read-Modify-Write Operation

4.2.2.6 Diagnostic Mode Operation

The purpose of the diagnostic mode is to provide the capability of detecting when the EDAC or memory is failing. There are several possible methods of using this feature. Figure 4-7 shows a typical timing diagram of some diagnostics which can be performed with these devices. Generally, the EDAC is first placed in the read mode ($S0 = L$, $S1 = H$) and a valid check word and data word are applied. A valid check word is one in which the associated data word is known. The EDAC is next placed into the diagnostic mode by taking $S0$ high and $S1$ low. This latches the valid check word into the input latches but leaves the data input latches transparent. To verify that the valid check word was properly latched, \overline{OECS} can be taken low causing the valid check word to be placed back onto the bus. Since the data input latches remain transparent, this allows various diagnostic data words to be applied against the valid check word. A diagnostic data word is one in which either a single- or double-bit error exists. In either case, the error flags respond. The output data latch can be verified by taking $\overline{LEDB0}$ high and confirming the stored diagnostic data word is the same. This is possible because error correction is disabled while in the diagnostic mode ($S0 = H$, $S1 = L$). Taking $S1$ high and $\overline{LEDB0}$ low will verify that the EDAC will correct the data word. In addition, the error-synndrome code can be verified by taking \overline{OECS} low. It should be noted that only the 'ALS632B and 'ALS633 are capable of this pass through verification of the diagnostic data word. The 'ALS634A and 'ALS635 do not have the output data latch required to perform this function.

Figure 4-7. Diagnostic Mode Timing Diagram

4.2.2.7 16-Bit Systems Using the 'ALS632B Series EDACs

The 'ALS632B series EDACs can reduce the memory size required in 16-bit systems where conventional 16-bit EDACs (6 check bits, 16 data bits) are presently used. Figure 4-8 shows the typical system architecture for the 16-bit EDAC. In this system, 88 devices would be required for the 22-bit × 256K-byte memory array, assuming 64K-byte DRAMs are used. It is easy to see that 27.3%, or 24 devices, are required for storing the check bits. When using the 'ALS632B series EDACs, the memory required for the check bits can be reduced to 17.9%, or only 14 devices. This reduces the total number of DRAMs required by 10 devices. Figure 4-9 shows the architecture using the 32-bit EDAC. The four 'LS646s are used to group two 16-bit data words into one 32-bit data word. In addition, this type of system can be used in byte-write operations where the other system cannot.

Figure 4-9. 16-Bit System Using 32-Bit EDAC

5 First-In First-Out Memories (FIFO)

5.1 High-Speed Bus Coupling Considerations - FIFO Memory Buffers

5.1.1 Introduction

High-speed First-In-First-Out (FIFO) memory buffers are becoming very important tools for those system design engineers looking for innovative ways to increase system performance. Texas Instruments (TI) brought you the first monolithic FIFO (SN74S225). But many of present day systems require more than the SN74S225 can provide. To meet the needs of those systems, TI has designed an enhanced family of IMPACT™ Bipolar and EPIC™ CMOS FIFO products. Table 5-1 lists some typical applications, key requirements, and the TI FIFO available to meet those needs.

Table 5-1. FIFO Applications

APPLICATION	KEY REQUIREMENTS	FIFO PRODUCTS
CPU Buffering	Data rate of processor Word width/depth Zero fall-through	'LS222/224/227/228 'ALS229A/232A/233A 'ALS2232/2233/2234
Peripheral I/O	Deep/fast Data-path synchronization Status flags	'ALS234/235/236 'ALS2232/2233/2234 TACT7202 TACT2202
Data Acquisition	High data rate	'ALS229A/232A/233A 'ALS234/235/236 'ALS2232/2233/2234
Data/Telecom	Low power/large depth Status flags	TACT7202 TACT2202

This report explains how a TI FIFO can help boost your system performance by maximizing data transfer rates, handling large data streams, or matching different transfer rates. It will also define FIFO architectures and the details of the design considerations needed.

A FIFO is a dual-port buffer memory that is organized in a manner that the first data entered into the memory is the first removed. One port is the input, where the data "producer" enters words into the buffer. The other port is the output, where the data "consumer" removes words. Data in the buffer cannot be randomly addressed like a RAM. A FIFO operates much like a line of people at a checkout counter.

There are two major architectures used in single-chip FIFO; toggle fall-through and zero fall-through.

5.1.2 Toggle Fall-Through Architecture

The toggle fall-through type of FIFO consists of an array of registers. Figure 5-1 illustrates this architecture for an M-word by N-bit FIFO. The output of each register is connected to the input of the following register in a chain-like fashion. Data is input to the first register and is removed from the last register. As each word is input into the FIFO, internal control logic toggles the word through the series of registers to the last one available. As each word is output from the FIFO, all the words are shifted down one register.

EPIC is a trademark of Texas Instruments Incorporated

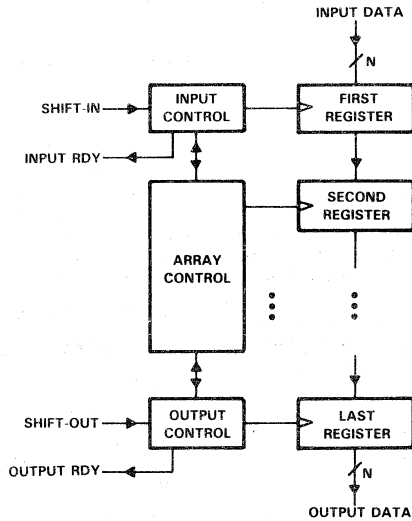

Figure 5-1. Toggle Fall-Through FIFO (M words by N bits)

A toggle fall-through FIFO is described by the number of words in depth, number of bits in width, maximum input and output clocking rates, and fall-through time. The fall-through time is the maximum delay required for a word to travel from the input to the output in an empty FIFO. The complement to this specification is the bubble-through time or the delay it takes for all words to ripple down one register after a word has been read from a full FIFO. However, these two specifications are roughly equivalent so only the greater value is included in the data sheet.

TI offers several toggle fall-through FIFO products. The SN74S225 is a 16×5 , 10 MHz FIFO. It has 3-state outputs and is cascadable in depth. The SN74ALS234 is a 16×4 , 30 MHz, cascadable FIFO with 3-state outputs. The SN74ALS235 is a 16×5 , 25 MHz, cascadable FIFO. It has 3-state outputs and includes half-full and almost full/empty flags. The SN74ALS236 is a bi-state version of the SN74ALS234.

5.1.3 Zero Fall-Through Architecture

The zero fall-through type of FIFO consists of a dual-port RAM with read and write address pointers. Figure 5-2 illustrates this architecture for an M-word by N-bit FIFO. Data is input to the word addressed by the write pointer and data is output from the word addressed by the read pointer. Upon reset, both pointers are cleared to a value of zero. After each word is read or written, the respective pointer is incremented by one. Internal comparison logic is used to generate condition flags such as full and to prevent overrun and under-run (too much writing and too much reading of data).

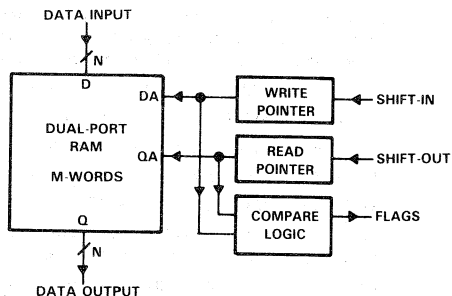

Figure 5-2. Zero Fall-Through FIFO (M words by N bits)

A zero fall-through FIFO is described in terms similar to the toggle products. However, the fall-through time now consists of the delay for incrementing the pointer and comparing the new pointer values. This time is roughly equivalent to the time between shift clocks for the input and the output, or "zero". In many applications zero fall-through FIFOs are preferred to toggle FIFOs for this reason.

TI offers several zero fall-through FIFO products. The SN74LS222 and SN74LS224 are 16×4 , 10-MHz FIFOs with 3-state outputs. The SN74LS227 and SN74LS228 are open-collector versions of the SN74LS222 and SN74LS224. The SN74ALS229A is a 16×5 , 30-MHz, 3-state FIFO. It has 4 flags: full, empty, full - 2, and empty + 2. The SN74ALS232A is a 16×4 , 30-MHz, 3-state FIFO with full and empty flags. The SN74ALS233A is a version of the SN74ALS229A with full - 1 and empty + 1 flags instead of the full - 2 and empty + 2.

The SN74ALS2232 is a 64×8 , 40-MHz FIFO with 3-state outputs and both full and empty flags. The SN74ALS2233 is a 64×9 , 40-MHz FIFO with 3-state outputs and four flags: full, empty, almost full/empty, and half full. The SN74ALS22XX is a 64×9 , 40-MHz, cascadable FIFO with 3-state outputs and both full and empty flags. The TACT7202 is a $1K \times 9$, 16-MHz cascadable FIFO with full and empty flags. The TACT2202 is a $1K \times 8$, 16-MHz FIFO with full and empty flags.

5.1.4 Buffering Design Considerations

A FIFO can be used as a buffer between two communication devices. In buffering applications where the delay from input to output is not critical (e.g., CPU to printer) either a toggle or zero fall-through FIFO can be used. In this instance, only the input and output clocking rates and the depth of the FIFO are critical. In buffering applications where the fall-through delay is important (e.g., bus interface) then the zero fall-through architecture should be used.

The rare case for FIFO operation is when the consumer is faster than the producer. A FIFO depth of one word would suffice. The other situation (see Figure 5-3) requires more words.

Figure 5-3. Buffering Application

The following equations can be used, to determine the depth needed. If the data producer writes a frame of (L) words at a rate of (X) MHz and the data consumer reads words at a rate of (Y) MHz, the resulting equations are:

1. $L \cdot 1/X + (\text{BUFFER DELAY}) = L \cdot 1/Y$
2. $\text{MAX (BUFFER DELAY)} = \text{DEPTH} \cdot 1/X$
3. $\text{MAX (L)} \cdot 1/X + \text{DEPTH} \cdot 1/X = \text{MAX (L)} \cdot 1/Y$
4. $\text{DEPTH} \cdot 1/X = \text{MAX (L)} \cdot (1/Y - 1/X)$
5. $\text{DEPTH} = \text{MAX (L)} \cdot (X/Y - 1)$

For example, with L = 100 words maximum, X = 8 MHz, and Y = 5 MHz, the necessary depth = 60 words. In this case, a 64-word FIFO would suffice.

The reverse of equation 5 gives the maximum length of a frame for a given FIFO depth:

$$6. \text{MAX (L)} = \text{DEPTH} \cdot \frac{1}{(X/Y - 1)}$$

For example, with depth = 64, X = 1 MHz, and Y = 0.8 MHz, the maximum length of a frame = 256 words.

5.1.5 Synchronization Design Considerations

In synchronizing applications, the data producer and consumer can operate continuously but asynchronously. The maximum throughput of the FIFO depends on both the clock rate at each port (F_{in} and F_{out}) and the fall-through time (T_F). (f_{max}) is derived from the maximum one-word time delay through the FIFO. The equations are:

$$7. \text{MAXIMUM DELAY} = \frac{1}{F_{in}} + T_F$$

$$8. \frac{1}{f_{max}} = \frac{1}{F_{in}} + T_F$$

$$9. f_{max} = \frac{1}{1/F_{in} + T_F}$$

For a toggle fall-through FIFO in these conditions f_{max} is considerably less than F_{in} . For example, if $F_{in} = 30$ MHz and $T_F = 1000$ ns, then $f_{max} = 967$ KHz. For a zero fall-through FIFO, f_{max} approaches F_{in} . For example, if $F_{in} = 35$ MHz and $T_F = 40$ ns, then $f_{max} = 14.6$ MHz. To ensure only a single-clock delay from the input and to output ports, the FIFO must be clocked at a rate less than f_{max} .

The FIFO may be operated at higher rates by working near the half-full condition. The number of words that can be written into an empty FIFO in the fall-through time (or read from a full FIFO) determines the margins from the empty condition for operating the FIFO at its maximum rate (F_{in}). The numbers correspond to:

$$10. \text{MARGIN} = \frac{F_{in}}{1/T_F}$$

For example, if $F_{in} = 30$ MHz and $T_F = 1000$ ns, then the margin = 30 words. For a 64-word FIFO this would mean that the FIFO could be operated at its maximum throughput rate (F_{in}) when it is between 30 words and 64 words full. Figure 5-4 shows the throughput curve for this type FIFO.

Figure 5-4. Throughput Curve for 64-Word, 30-MHz FIFO

In general, cascading N FIFOs in depth causes equations 9 and 10 to change to:

$$11. f_{max} = \frac{1}{1/(F_{in} + N \cdot T_F)}$$

$$12. MARGIN = \frac{F_{in}}{1/(N \cdot T_F)}$$

5.1.6 Summary

FIFOs are versatile building blocks for the design of data communication products. The need for buffering and/or synchronization of data can be met by selecting the appropriately-sized toggle or zero fall-through FIFO using the methods presented in this report. TI produces many different single-chip FIFO products for a wide range of applications. Contact your local TI representative to obtain individual FIFO data sheets for further information about a particular product.

6 BiCMOS

6.1 BiCMOS Memory Drivers Boost Performance

In current memory management systems, the replacement of discrete logic with single-chip solutions for DRAM control, Error Detection and Correction, and Cache Tag control has greatly improved memory access times. However, in large MOS memory applications the use of external drivers in conjunction with the memory management products can provide added drive to maintain maximum performance. These drivers must meet the requirements of high drive for high capacitive loads, high speed for maximum system throughput, and low power for system power constraints. The designer can now meet these needs with the TI 2000 series Bus Interface devices with improved performance and reliability. The devices offered in new BiCMOS, 'AS, and 'ALS technologies provide designers with the characteristics needed to drive the high capacitive loads in MOS memory and bus-intensive systems while reducing undershoot for reliable system performance.

6.1.1 Reducing Undershoot Problems

In order to maintain maximum system throughput, memory drivers require high-speed operation with very fast switching speeds. As a result, these switching speeds together with the high inductance and capacitance in bus intensive environments can create problems with output signal undershoot and overshoot. This undershoot and overshoot can cause system reliability problems such as false reads at the input to DRAMs. Commonly, these problems with undershoot and overshoot are controlled with an external series resistor, which increases package count and board space. The 2000 series devices provide on-chip $25\text{-}\Omega$ series damping resistors on all outputs to reduce undershoot and overshoot without adding to board real estate. Figure 6-1 compares the initial undershoot of the 'AS640 and the 'AS2640 with on-chip series damping resistors. The 'AS2640 can reduce initial undershoot by 58% thus supplying a more reliable input to systems susceptible to undershoot problems.

Figure 6-1. Effect of On-Chip Series Output Resistors

6.1.2 BiCMOS Drivers Match MOS Memory Needs

The 2000 series devices offered in the new TI BiCMOS technology provide the advantages of both bipolar and CMOS. BiCMOS combines 2- μ M IMPACT™ bipolar with 1.5- μ M CMOS to provide the high drive and speeds of bipolar and the low power of CMOS. These interface devices have TTL input and output transistors with CMOS internal circuits. The output transistors supply 48/64 mA of drive current necessary for bus structures such as VME and MULTIBUS II, while the CMOS internal circuits provide low power during disabled or 3-state operation. As with all 2000 series devices, the BiCMOS parts have series damping resistors to reduce undershoot and overshoot.

The BiCMOS drivers can provide the drive and speed necessary in MOS memory applications with a power savings over bipolar devices. Figure 6-2 shows a 4-M word \times 32-bit memory configuration consisting of a SN74ALS6301 Dynamic Memory Controller (DMC), a SN74BCT2828 Memory Driver and 4-M words of memory comprised of four banks of TMS4C1024 DRAMs. Each SN74ALS6301 can control up to 4M words of memory. The memory driver provides extra drive to maintain maximum performance in a 32-bit system.

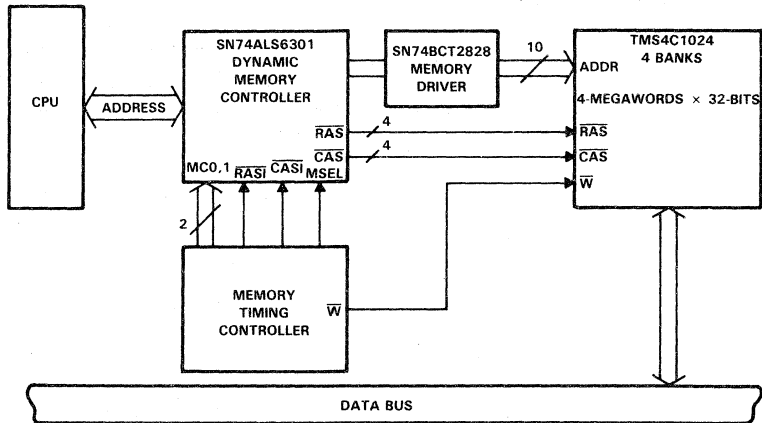

Figure 6-2. 4M Word \times 32-Bit Memory System

6.1.3 BiCMOS Lowers Power by 50% or More

When comparing the performance of the SN74BCT2828 to the functionally equivalent AM29828, there is a considerable power reduction. As shown below, there is a 50% reduction in supply current while enabled. However, the real savings comes from the disabled operation. There is more than a 95% supply current reduction while disabled. Since the amount of time a driver is enabled varies with each system, power reduction will vary with the minimum being 50% improvement.

	AM29828	BCT2828
ICC enabled	80 mA	40 mA
ICC disabled	80 mA	3 mA

In applications that involve multiple drivers the power savings is even more apparent. For example, if a system requires five drivers with only one enabled at any given time, the AM29828 would use almost 8 times more current than the SN74BCT2828.

	AM29828	BCT2828
ICC enabled	1 × 80 mA	1 × 40 mA
ICC disabled	4 × 80 mA	4 × 3 mA
Total	400 mA	52 mA
Result =	87% power savings	

6.1.4 Less Undershoot Means Higher Reliability

The use of the 2000 series BiCMOS drivers also provides the reduced undershoot to prevent false reads at the inputs to the DRAMs without the addition of external resistors. Figure 6-3 shows the improvement of initial undershoot of the SN74BCT2828 compared with the AM29828. The SN74BCT2828 undershoot is 40% less than the AM29828 providing a more reliable signal with the same package count.

Figure 6-3. Initial Undershoot Comparison of 74BCT2828 vs AM2928

6.1.5 How Do I Get More Information

Each of the 2000 Bus Interface series devices provide the designer with reliable signals without increasing package count and board real estate. The high drive and speed complement Memory Management products for use in large memory and bus applications. The onset of BiCMOS also brings a tremendous power savings which can be appreciated in all designs. Below is a listing of the 2000 series offered. For more information on these Bus Interface and Memory Management products, contact your local Texas Instruments field sales representative or authorized distributor.

6.2 BiCMOS Bus Interface

6.2.1 Abstract

Bipolar and CMOS processes have their individual advantages. The advantages of bipolar are speed and output drive current capability. The advantage of CMOS is significantly lower power consumption with continually improving speed performance. The merge of the two processes in order to use their individual advantages for optimal product development was therefore a predictable technology transition.

This portion of this report concerns the use of such a process, BiCMOS, and the advantages provided in bus-interface logic. Ultimately, the system advantage gained from the use of BiCMOS bus interface logic results in a 25% reduction of total system power.

6.2.2 Introduction

Bus-interface logic requires very high output-drive currents of 48/64 mA. These currents are required to drive high-capacitive loads and backplanes and to meet the required specifications of established standards. Advanced speed performance is also a necessity to allow the rapid transfer of information and to complement the performance of other system components.

Excessive power consumption was the tradeoff that system designers were forced to accept to achieve the desired output-drive current and speed performance. In an average system, 30% of the total device supply current is required to support the bus interface logic. The use of BiCMOS bus-interface logic can reduce the required device supply current by more than 90%. This results in an overall system power savings of more than 25%.

6.2.3 Reduction of Supply Current Demand Without Sacrificing Performance

The combination of bipolar and CMOS components makes the power savings a reality without sacrificing required output drive current or speed performance. An examination of bus-interface logic in system operation reveals that the device is either enabled

(active) or disabled. Since in bus configurations only one device is active at any given time, the remaining devices tied to the bus are disabled. Therefore, for the majority of the time, devices tied to the bus are in a disabled mode. Further evaluation reveals that the currently available bipolar devices that are capable of meeting the specifications required for bus-interface logic require supply currents ranging from 75 mA to 160 mA per device depending upon the function.

BiCMOS requires approximately 10 mA maximum (I_{CCZ}) when disabled and further reduces the active supply current demand by approximately 50% compared to equivalent bipolar devices. Table 6-1 is a comparison of the SN74BCT29861 and AM29861 supply currents. Figure 6-4 illustrates typical switching performance and disabled supply current demand between the two devices.

Table 6-1. SN74BCT29861/AM29861 I_{CC} Comparison

SN74BCT29861			
I_{CC}	Supply current	Enable	30 mA (Max)
	($V_{CC} = 5.5 \text{ V @ } 70^\circ\text{C}$)	Disable	7 mA (Max)
AM29861			
I_{CC}	Supply current		150 mA (Max)
	($V_{CC} = 5.5 \text{ V @ } 70^\circ\text{C}$)		

†Advanced Micro Devices Bipolar Microprocessor Logic and Interface 1985 Data Book. No breakout given for enable or disable I_{CC} .

Figure 6-4. SN74BCT29861 and AM29861 Required Off-State Current vs Average Propagation Delay

To highlight the system power savings advantage exhibited by BiCMOS bus-interface products, see the conditions in Figure 6-5. Assuming a bus network contains a fanout of ten bus interface devices, Figure 6-5 illustrates that only one device is enabled, while the other nine are disabled.

Figure 6-5. Bus Network

Assumption:

		Advanced Bipolar	BICMOS
ICC	(Enable)	150 mA	30 mA
ICCZ	(Disable)	150 mA	10 mA
Advanced Bipolar			
ICC	(Enable)	1 × 150 mA = 150 mA	
ICCZ	(Disable)	9 × 150 mA = 1350 mA	
ICC	(Total)	1500 mA	
BICMOS			
ICC	(Enable)	1 × 30 mA = 30 mA	
ICCZ	(Disable)	9 × 7 mA = 63 mA	
ICC	(Total)	93 mA	
Result: 94% power savings.			

6.2.4 Combinational Bipolar and CMOS Optimal Process Solution

BiCMOS bus-interface logic is a TTL-to-TTL interface product that provides the optimal combination of speed performance, output drive, and low power. To achieve these characteristics, TI combines 2- μ m bipolar IMPACT™ (Implanted Advanced Composed Technology) process with 1.5- μ m CMOS process is shown in Figure 6-6.

The bipolar process provides output transistors capable of supplying the required 48/64 mA. The transistors also use the smaller TTL voltage swings of -0.5 V- to -3.5 V as compared to their rail-to-rail GND-to-V_{CC} voltage swings that are associated with CMOS transistors. The smaller voltage swings associated with TTL outputs reduce the overall effect of transient voltage noise on the ground pins. Excessive noise spikes can be detrimental to reliable system performance due to output glitching, loss of stored data, increase of system noise, etc.

Figure 6-6. BiCMOS Process

The following equation is a simple method of calculating the induced voltage on the ground and V_{CC} pins due to transient currents caused by switching capacitive loads.

$$V_L(t) = -L_P C_L \frac{d^2V_O(t)}{dt^2}$$

Where:

- $V_L(t)$ = Voltage transient
- L_P = Package inductance
- C_L = Load capacitance
- $d^2V_O(t)$ = Change in the slope of the transition edge
- dt = Transition edge time

Since L_P , C_L , and dt are the same, the amount of voltage level transition swing is the only difference between the bipolar and CMOS transistors. Since CMOS transistors require a wider voltage swing, it becomes apparent that a CMOS output transistor will produce a larger amount of voltage noise that, if excessive, could cause system reliability problems.

The CMOS process provides a disable circuit that consumes considerably less current than a pure bipolar circuit. Figure 6-7 illustrates how the CMOS components combine with the bipolar components to interrupt the flow of supply current during the disable mode or three state. The remaining internal components are also fabricated from CMOS which further reduces the required amount of supply current.

Both the bipolar and CMOS processes provide the capability to adequately meet the advanced speed performance required for bus interface.

- DURING OPERATION: A SHORTED, B OPEN
- DURING THREE-STATE: A OPEN, B SHORTED

Figure 6-7. BiCMOS Three-State Gate Schematic

6.2.5 Variety of Functional Options in Two-Package Configurations

Additional design support for bus-interface logic is the availability of popular functions in multiple variation such as true or inverting outputs and synchronous or asynchronous operation. BiCMOS will be offered with two pinout options; 1) The traditional pinout for pin-to-pin compatibility with existing bipolar devices. 2) Flow through architecture with center power pins to further reduce the voltage noise associated with multiple output switching.

As indicated by the $V_L(t)$ equation, the amount of switching noise can be reduced through a decrease in the package inductance.

The functional options that will be available in BiCMOS are as follows:

FUNCTION	DESCRIPTION
'240 Series	Octal Buffers/Drivers
'245 Series	Octal Transceivers
'373 Series	Octal Latches
'543 Series	Octal Registered Transceivers
'646 Series	Octal Registered Transceivers
'2000 Series	Memory Drivers
'29818/819	Pipeline Registers
'29820 Series	8-10 Bit Buffers and Registers
'29830 Series	Bidirectional Parity Transceivers
'29840 Series	8-10 Bit Latches and D-Latches
'29850 Series	Bidirectional Parity Transceivers with Latches
'29860 Series	9-10 Bit Transceivers

6.2.6 Summary

BiCMOS bus-interface logic is a TTL-to-TTL product that provides a 95% reduction in standby current demand. This results in a 25% total system power savings without sacrificing high output drive or speed performance.

INTRODUCTION

The new 32-bit microprocessors are capable of addressing 4G bytes of physical memory and typically feature clock frequencies greater than 16 Mhz. However, clock speed alone does not guarantee increased system performance; if the processor must wait for data, then memory bandwidth will be the limiting factor.

This situation exists between today's microprocessors and the access times of affordable DRAMs. One solution to optimizing system performance is to mix and match memory, using lower cost dynamic RAM in conjunction with fast, more expensive static RAM caches. However, this approach is only attractive to high end systems where cost and board space is a less significant factor.

Another approach to improving system performance is to utilize the new accessing modes available on certain 1 meg DRAMs, such as static column decode. This method does not improve system performance as much as caches, but it does involve less hardware, resulting in lower system cost. This approach can also be used in systems already using caches, further improving system performance.

This application note describes the theory of using static column decode and also describes how it might be implemented in a typical system. In addition, it highlights three new products from Texas Instruments. The

SN74ALS6300 "Selectable Refresh Timer", the SN74ALS6310 "Static Column Access Detector", and the TIBPSG507 "Programmable Sequence Generator".

STATIC COLUMN DECODE

The TMS4C1027 is a 1,048,576-bit \times 1 dynamic RAM featuring static column decode. Static column decode allows high-speed read and write operations by reducing the number of required signal setup, hold, and transition timings. This is achieved by first strobing the row and column addresses in the normal manner by taking $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ low. If $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ are kept low, new data can be accessed by simply changing the column addresses, assuming the new address is in the same row. If the new address is not in the same row, then a normal access cycle must be performed.

Figure 1 is a timing diagram taken from the TMS4C1027 datasheet showing static column decode mode read cycle timing.

If the assumption is made that the majority of memory references tend to be sequential, which is a similar assumption made when using caches, then it is logical to assume that a large percentage of memory accesses will be within the same row. The trick is how to implement a timing controller which will take full advantage of the static column mode of operation.

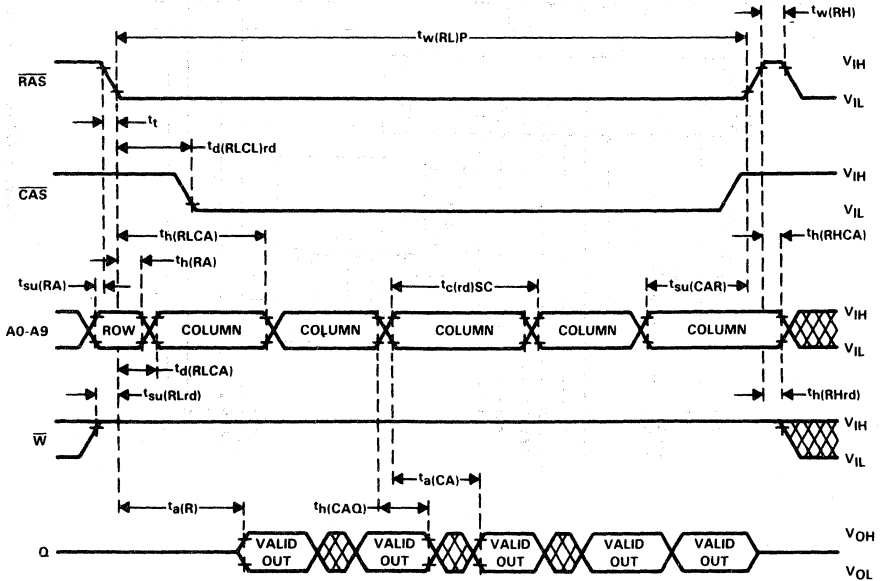

Figure 1. Static Column Decode Mode Read Cycle Timing

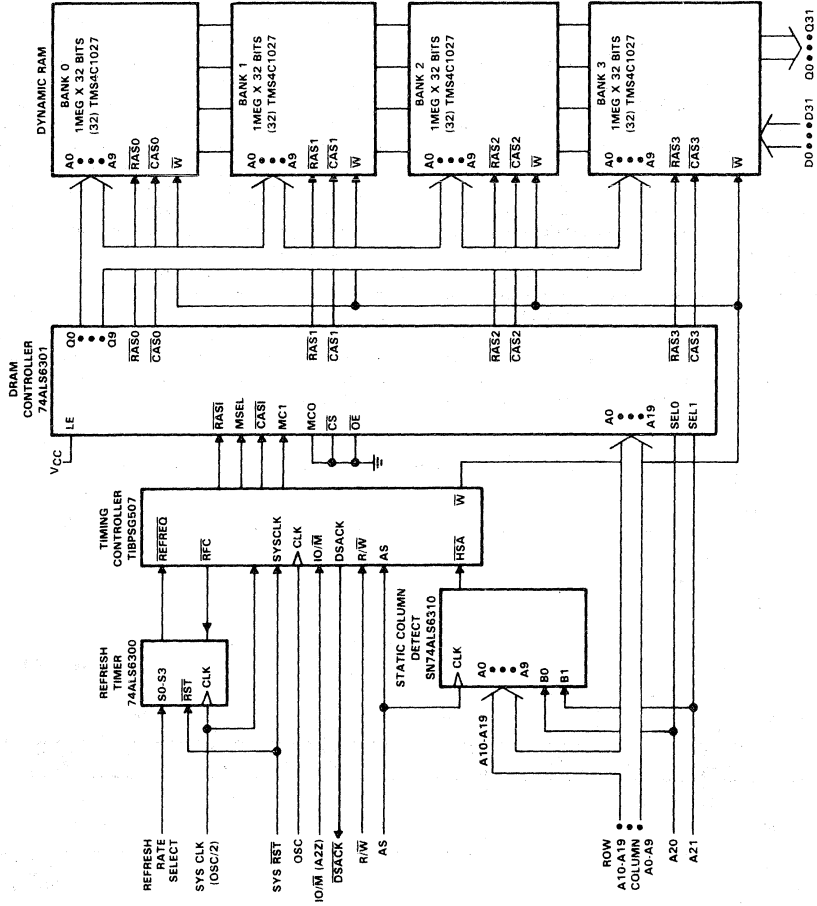

Figure 2. 68020 Static Column Memory Controller

TYPICAL MEMORY CONTROLLER

Figure 2 shows a block diagram of a memory system utilizing static column decode. The ALS6310 is a new circuit offered by Texas Instruments which detects if the present row being accessed is the same as last row accessed. This is the fundamental requirement for implementing static column decode. Note that the row addresses from the 68020 are used as the most significant bits (A10-A19) and the column addresses are used as the least significant bits (A0-A9). Figure 3 shows a block diagram of the ALS6310.

In circuit operation, when address strobe (AS) from the 68020 is taken low, the present row (A10-A19) and bank address (B0, B1) is clocked into the first register of the ALS6310. The previous bank and row address, stored in the first register, is clocked into the second register at the same time. The two addresses are then compared to see if they are equal. If they are equal, the high speed access output (HSA) will be logically low. If not, HSA will be high.

The function of the PSG507 is to generate the required memory timing control signals (RAS, CAS, etc.) for the ALS6301 dynamic memory controller. The ALS6301 is responsible for multiplexing row and column addresses into DRAM. The ALS6301 is also capable of driving 4 banks of 1M-byte memory.

Supporting the PSG507 is the ALS6300 refresh timer. This device is responsible for generating a refresh request signal (REFREQ) every 15.5 μ s. The input select lines are hardwired to match the microprocessor clock frequency. The refresh complete input (RFC), resets the REFREQ signal after the timing controller completes the refresh cycle.

TIMING CONTROLLER DETAILS

Figure 4 shows a typical flow chart for implementing static column decode. As stated before, the PSG507 is responsible for implementing the flow chart shown in Figure 4. A breakdown of this flow chart reveals 9 states (ST0-ST8), associated with 5 different sequences. States ST0, ST1, ST3, and ST4 are holding and transition states, leading into the various sequences. The five possible sequences are listed below.

- ST2 Normal Access Sequence
- ST5 Extended Access Sequence
- ST6 High-Speed Access Sequence
- ST7 Normal Refresh Sequence
- ST8 Extended Refresh Sequence

Notice that the HSA signal from the ALS6310 decides if the timing controller will execute ST5, the Extended Access Sequence, or ST6, the High-Speed Access Sequence. A brief description of each sequence follows.

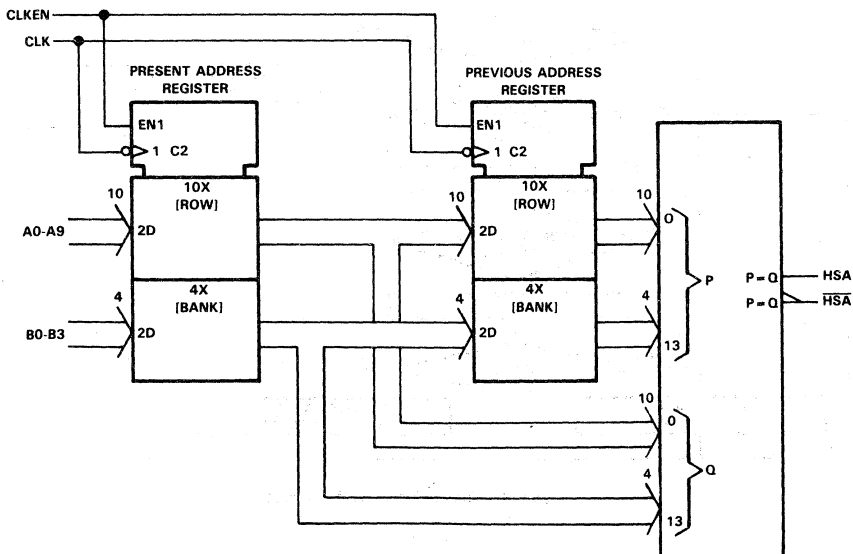

Figure 3. ALS6310 Static Column Page Mode Access Detector

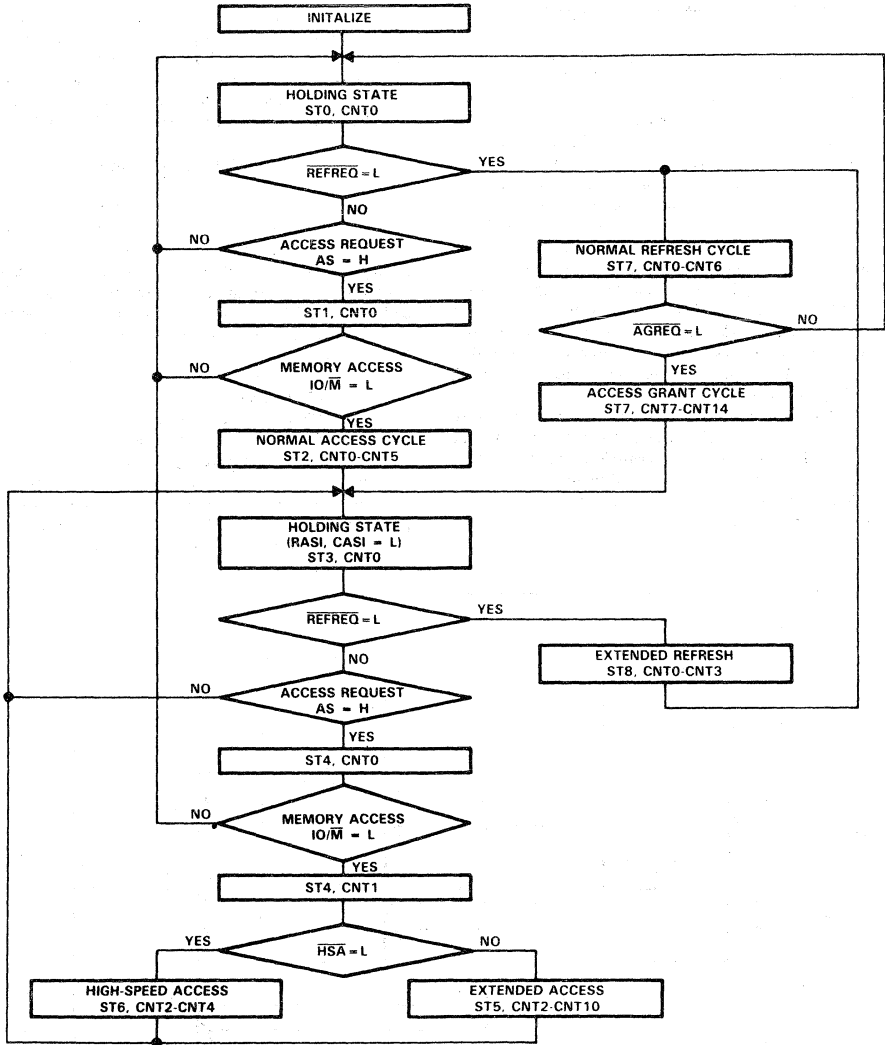

Figure 4. Timing Controller Flowchart

NORMAL ACCESS SEQUENCE

The normal access sequence is shown in Figure 5. This sequence begins by executing a normal RAS/CAS cycle. Notice that a wait state of one clock cycle is needed to guarantee that data is valid for the 68020. This is the problem mentioned in the introduction; if all access cycles had to be performed in this manner, then the processor would face a wait state every access cycle. As will be shown later, this wait state can be eliminated if the next address is from the same row.

Notice also, at the end of this sequence, the RAS and CAS output signals are left active low. Here we are making the assumption that the next access cycle will be a high-speed access. We will not know if this assumption is true until the next address is presented by the 68020. At that time, the ALS6310 will signal the timing controller if it can execute a high-speed access.

HIGH-SPEED ACCESS SEQUENCE

For a high-speed access sequence to be executed, two conditions must be met. The RAS and CAS inputs must already be low, and secondly, the static column access detector must be indicating the present row is the same as the last row ($HSA = L$). The bank addresses must also be unchanged as detected by the ALS6310.

Figure 6 shows the timing diagram for the high-speed access sequence. Notice that no wait states are required. If the assumption is made that the majority of memory references are sequential, then this sequence will be the one typically used. In other words, this sequence is similar to accessing data from a static RAM, or just like taking data from cache.

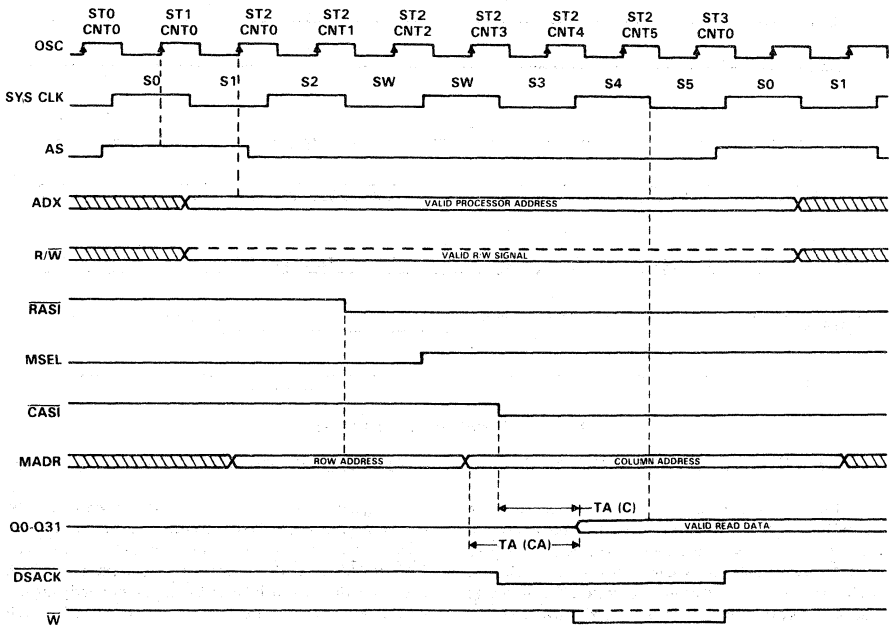

Figure 5. Normal Access Cycle

Figure 6. High-Speed Access Cycle

EXTENDED ACCESS SEQUENCE

The extended access sequence is executed if the ALS6310 detects a difference between the present, and last row addresses. This cycle is called extended because RAS and CAS are presently low and both must be brought high to strobe in the new row and column addresses. The precharge time of the DRAM has to be met before taking RAS and CAS low. From the timing diagram in Figure 7, it can be seen that wait states of three clock cycles are generated when executing this timing sequence.

In systems where sequential data is not the general rule, it would be more efficient to execute only normal access sequences, since this generates fewer wait states. The system designer must understand what type of memory accesses will be used. For example, the designer may want only to enter the high-speed access portion of the flow chart when the system is performing DMA access cycles.

NORMAL/EXTENDED REFRESH SEQUENCES

Figures 8 and 9 show the timing diagrams for the normal and extended refresh sequences. The refresh sequence selected is a function of the present condition of RAS and CAS. If RAS and CAS are presently low, an extended refresh cycle is performed. If RAS and CAS are presently high, a normal refresh cycle is executed. At the end of each refresh sequence, the controller checks to see if an access request has been generated. If there has been an access request, the controller will perform an access grant sequence at the end of the refresh cycle before returning to normal process flow.

Referring back to Figure 1, there is a maximum time that RAS and CAS can be held low, $t_w(\text{RL})P$. For the TMS4C1027, $t_w(\text{RL})P$ must not exceed 100 μs . Since our refresh timer forces a refresh cycle every 15.5 μs , $t_w(\text{RL})P$ cannot be violated. If the designer chooses to use a different refresh scheme, then $t_w(\text{RL})P$ must be considered.

Figure 9. Extended Refresh Cycle

SOFTWARE SUPPORT

The PSG507 is supported by two software packages. CUPL which was created by and is supported by Assisted Technologies, a division of Personal CAD Systems Inc. and ABEL which was created by and is supported by FutureNet a division of Data I/O Corp. Both of these software packages have been used to reduce equations and to generate the fusemap necessary to program the PSG507. Appendices A and B show the ABEL™ and CUPL™ source files for the described static column memory timing controller are attached to assist the designer in programming the PSG507.

Since only 54% (43 out of 80) of the PG507's product terms were used in this design, it will be easy to modify or add to the sequences used to meet specific system requirements. For detailed information on designing with the PSG507 see "A Designer's Guide to the PSG507" application report.

SUMMARY

Static column decode offers the system designer a method for improving system performance in applications where the microprocessor can outperform conventional DRAM access times. By utilizing the ALS6310 "Static Column Access Detector", the ALS6300 "Refresh Timer", and the TIBPSG507 "Programmable Sequence Generator" a high performance memory timing controller can be easily developed to take full advantage of static column decode.

Quality and Reliability

MOS Memory Quality and Reliability Strategy

Texas Instruments is committed to providing its customers with reliable, high quality memory products. MOS Memory management has applied a four point quality and reliability strategy to:

- Provide customers with the lowest cost of product ownership through quality, reliability, and service by:
 - On-time delivery to minimize customer inventory.
 - Quality performance that justifies ship-to-stock certification and eliminates the cost of component testing.
 - No system manufacturing fallout.
 - No warranty and service costs.
- Develop partnership relationships to service and solve customer problems and anticipate upcoming needs.
- Living quality improvement process from product creation and manufacture through product sales via our total quality control approach of:
 - Design-in and build-in quality and reliability.
 - In-control manufacturing.
 - Leadership customer service.
- TI's performance measurement shall be by the customer's measurement and perception. The performance standard is continuous customer satisfaction.

Total Quality Control (TQC)

Total Quality Control at TI is a business management process encompassing all company functions. The goal of Total Quality Control (TQC) is continuous customer satisfaction. Utilizing a process of improvement through a positive feedback cycle, TQC is deployed in the MOS Memory Division from the initial design-in Q&R stage through in-control manufacturing and customer service (see Figure 1).

Proper application of the concept of "PLAN-DO-CHECK-ACT" allows a positive feedback loop that creates continuous improvement and breakthrough, as opposed to the "FIX-FIX-FIX-FIX" results of a negative loop (see Figure 2).

A. Design-In Quality and Reliability

Quality and reliability improvements at TI start with the chip and package design. The objective of MOS Memory's Design-In Quality and Reliability (DIR) thrust is: First pass qualification of new products, internally and at the customer. The TI approach to DIR has been to understand customer requirements of a product, and to formalize this knowledge into a database which incorporates both reliability modeling knowledge and "lessons learned" from historical problems and data evaluations. Before any new design is approved, the design is verified against a DIR "checklist". Design verification is planned to evolve to computer verification utilizing artificial intelligence.

B. In-Control Manufacturing

Documentation/Audit System

To assure in-control manufacturing, TI employs a hierarchical specification system. General specifications on all aspects of quality, reliability, and customer service are written and controlled by the central Quality and Reliability group. More detailed specifications control the operating practices of Product Customer Centers (PCC), Fabrication Customer Centers (FCC), and other support organizations. These specifications follow guidelines set by the higher level specifications but concentrate on the type of semiconductor product built by the PCC and FCC.

Regularly scheduled audits are performed within TI to ensure compliance with all specifications. The five types of audits performed are:

1. Self-audit: An internal audit within each PCC, FCC, or functional operation. This type of audit is conducted by persons within the operation and an additional person from outside of the operation.
2. Cross-audit: An audit by persons independent of the operation being audited.
3. Group audit: An audit of an operation conducted by the semiconductor group audits and procedures function, which is a part of the central Quality and Reliability organization.
4. Procedures audit: An audit of lower level specifications with respect to higher level specifications.
5. Compliance audit: An audit of operating practices with respect to specifications.

Statistical Process Control (SPC)

Quality improvement is achieved through Statistical Process Control (SPC). SPC is applied throughout the manufacturing operations of the MOS Memory division. The objectives of SPC are:

- Control processes on a realtime basis.
- Improve process capability (CP).
- Reduce variability to target value (CPK).
- Eliminate "out-of-spec" lots.
- Achieve dependable delivery.
- Lower cost-of-quality.

Computer hardware and artificial intelligence software have been coupled to establish interactive control allowing the computer to generate realtime control charts and prompt adjustments to equipment and processes (see Figure 3).

Die Fabrication Control

In addition to extensive SPC applications in our MOS fabrication centers, TI implements wafer level quality and reliability controls.

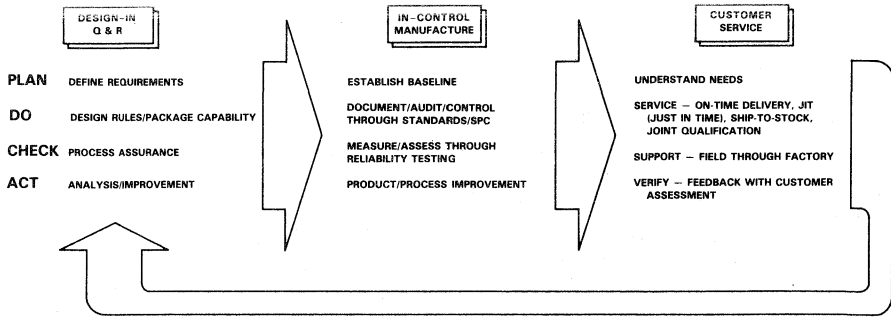

Figure 1. Total Quality Control

Figure 2. TQC Philosophy

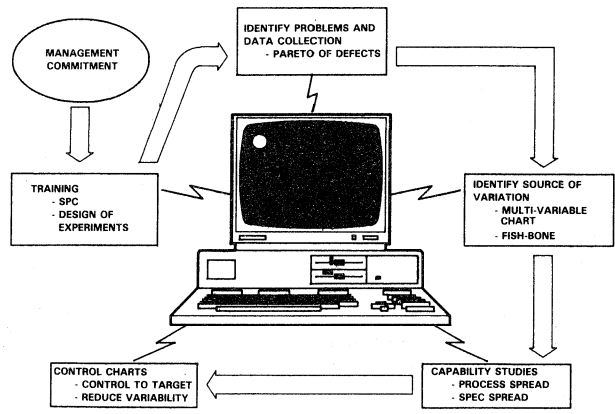

Figure 3. Computer Aided Statistical Process Control

Wafer (slice) level quality control focuses on reduction of variability around target values (CPK) for key functionality parameters and controls the processes that affect parameters. For example: Column access time (t_{CAC}) is a key DRAM parameter. One of the die manufacturing processes that affects t_{CAC} is the photo etch. To reduce variability of the target value of t_{CAC} , we control polysilicon width dimension at the photo etch process.

Wafer level reliability controls address process control of known reliability hazards. For example: Excessive phosphorus use in die processing can lead to corrosion defects in the finished device. Wafer level reliability controls require that phosphorus level control is built into the manufacturing process and that action is prescribed for out of control material. Other wafer level reliability controls are shown.

Table 1. Wafer Reliability Controls

PARAMETER	CONTROL
METAL	ELECTROMIGRATION TESTING GRAIN SIZE, SILICON NODULE MONITOR STEP COVERAGE/METAL NECKING MONITOR STRESS INDUCED METAL VOID TESTING
PROTECTIVE OVERCOAT	P.O. INTEGRITY STRESS TESTING THICKNESS MONITOR REFRACTION
CORROSION	% PHOSPHORUS IN MULTI-LEVEL OXIDE MONITOR
GATE OXIDE INTEGRITY	BREAKDOWN VOLTAGE

Device Assembly Control

TI has also implemented assembly level reliability controls and SPC at critical assembly points (see Table 2) to ensure highly reliable device packaging. Each parameter has certain controls performed at appropriate frequencies to ensure that assembly processing is progressing at qualified levels. Controls may be added or reduced after extensive testing has been performed and results studied carefully to preclude reliability problem introduction into the assembly process. The parameters and controls are shown in Table 3.

C. Product Assessment/Improvement

Reliability Control System

The MOS Memory reliability control system (Figure 4) provides closed loop system feedback resulting in corrective actions and ongoing product improvements. Each new product, process, or major change to an existing product is internally qualified to industry leadership standards prior to production. This is followed by eight weeks of monitoring during production ramp-up and routine monitoring of more than 20,000 units a month once product achieves final production release. In 1986, almost one million memory devices were tested in all phases of the reliability control system.

Reliability Development Issues

Soft Error. TI has been doing much work in all phases of device development to minimize the effects of soft error. Soft errors are caused by alpha particles emitted by the decay of small amounts of thorium and uranium located in device packaging materials. TI maintains an aggressive program of evaluating new mold compounds to ensure low alpha emissivity. Certain device design and processing techniques are also applied to ensure a low soft error rate. The goal of device design and processing is to maximize the cell capacitance by employing an oxide-nitride dielectric, as opposed to an oxide dielectric. Also, the cell capacitance increases as the dielectric thickness decreases. Testing has shown that the trench capacitor used in dynamic RAMs has competitive soft error rates.

Channel Hot Electron. Channel hot electrons are caused by impact ionization in the drain pinch-off region. Electrons are accelerated toward the drain, collide with positive ions and can be trapped in the gate oxide. This trapped charge can change the characteristics of the transistor by raising the V_T (threshold voltage). One method employed to reduce the effects of hot electrons is to add a lightly doped drain to reduce the electric field at the gate. Testing for channel hot electrons is performed at a low temperature (-10°C) and a high drain voltage.

Latch-up. A CMOS device can latch up when the gain of the parasitic PNP+NPN transistors is greater than 1. These PNP+NPN transistors act as a silicon controlled rectifier (SCR). If enough current flows through the resistors, the transistors will turn on and the device will latch up.

To control latch-up, the SCR gain must be controlled to less than or equal to one. Methods for improving latch-up immunity include using an epitaxial substrate, incorporating guard rings between P+ and N+ diffusions, and isolating P+ and N+ diffusions.

Latch-up testing is performed to ensure our CMOS devices meet the minimum holding current for industry standards.

D. Customer Service

Quality, Reliability, Service, and the Cost of Ownership

The goal of Texas Instruments is to offer the best quality, reliability, and service in the semiconductor industry. The foundation for this approach is to ship consistent quality. Consistent quality allows ship-to-stock programs that foster the elimination of the customer's incoming inspection. Ship-to-stock quality, coupled with 100% on-time delivery to narrow shipping windows mean support of the customer's just-in-time manufacturing program. This combination of quality, reliability, and service can be measured by a single index called "the cost of ownership." The "cost of ownership" is defined as being composed of the purchase price, quality adders (for incoming inspection and board rework), inventory adders (for maintenance of a buffer inventory for suppliers who cannot meet just-in-time delivery), in-house reliability adders (for system burn-in and rework), and field reliability adders (for warranty and post warranty field repairs).

For more information about the cost of ownership concept, contact your local TI sales office and request the brochure "Texas Instruments Lowers Semiconductor Cost of Ownership," SSYB057.

Quality Improvement

Significant improvement in product quality has been achieved through:

- Better definition of customer requirements.
- Greater emphasis on quality as a design criterion.
- Improved control of incoming materials.
- Intensive training of supervisors and operators.
- Extensive use of statistical process control.
- More automation of operations to minimize operator related defects.

Figure 4. Reliability Control System

As is demonstrated in Figure 5, MOS Memory EPROM and DRAM outgoing quality has dramatically improved during the last few years. This significant improvement has occurred for all TI product lines and has been recognized publicly by many of our customers, who have given TI more than 70 major quality awards in the last three years. Included among these awards are Ford's Q-1 award, the Naval Quality award, and the Deming Prize, which is Japan's most prestigious quality award.

Reliability Improvement

Low IC failure rates are achieved through design-in reliability, computer aided design, stringent qualification testing prior to product release, routine monitoring of released products, and an extensive failure mode tracking and feedback system for IC failures.

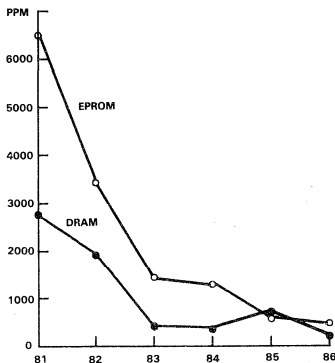

Figure 5. MOS Memory Quality Improvement

Since the early '80's, MOS Memory products have exhibited a device failure rate improvement trend which has resulted in highly reliable memory devices (see Figure 6). Since the memory device complexity also increases in an ongoing manner, the failure rate by function has improved at an even faster pace. TI continues to emphasize reliability improvement as a major factor in reducing the total cost of ownership for our customers. Reliability improvement is reflected as a reduction in the expected field failures during system lifetime.

Up-to-date quality and reliability data for MOS Memory products is available. Please contact your local TI sales office for information.

EXPLANATION OF IEEE/IEC LOGIC SYMBOLS FOR MEMORIES

1. INTRODUCTION

The International Electrotechnical Commission (IEC) has been developing a very powerful symbolic language that can show the relationship of each input of a digital logic circuit to each output without showing explicitly the internal logic. At the heart of the system is dependency notation, which will be partially explained below.

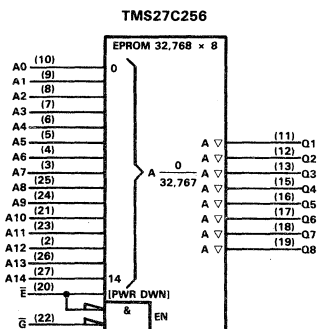

The system was introduced in the USA in a rudimentary form in IEEE/ANSI Standard Y32. 14-1973. Lacking at that time a complete development of dependency notation, it offered little more than a substitution of rectangular shapes for the familiar distinctive shapes for representing the basic functions of AND, OR, negation, etc. This is no longer the case.

The current standards are IEC Publication 617-12, 1983, and ANSI/IEEE Standard 91-1984. Most of the data sheets in this data book include symbols prepared in accordance with these standards. The explanation that follows is necessarily brief and greatly condensed from the explanation given in the standards. This is not intended to be sufficient for people who will be developing symbols for new devices. It is primarily intended to make possible the understanding of the symbols used in this book.

2. EXPLANATION OF A TYPICAL SYMBOL FOR A STATIC MEMORY

The TMS27C256 symbol will be explained in detail. This symbol includes almost all the features found in the PROMs and EPROMs.

The address inputs are arranged in the order of their assigned binary weights and the range of addresses are shown as A_m^n where m is the decimal equivalent of the lowest address and n is the highest. The outputs affected by these addresses are designated by the letter A, as data inputs would also be if the device were a RAM.

The polarity indicator \triangleleft indicates that the external low level causes the internal 1-state (the active or asserted state) at an input or that the internal 1-state causes the external low level at an output. The effect is similar to specifying positive logic and using the negation symbol \circ .

The ∇ symbols indicate three-state outputs. Three-state outputs will always be controlled by an EN function. When EN stands at its internal 1-state, the outputs are enabled; when EN stands at its internal 0-state, the outputs stand at their high-impedance states. Sometimes the EN is a single input but in the illustrated case, it is the output of a two-input AND gate. Both inputs (pins 20 and 22) are active low so if either one of them goes high, the outputs will be disabled. The upper one of these two inputs (pin 20) has another function. When nonstandard labels and explanatory labels are used within symbols, they are enclosed within square brackets. Here we find the label "[PWR DWN]". This is intended to indicate that if pin 20 is high, the memory will go to a low-power standby state.

3. THE BASICS

Section 3.1 illustrates the most common building blocks that are used in constructing symbols for memories. On the left are shown the symbols that specify the active levels for level-operated inputs, and the direction of active transition for dynamic inputs.

It is preferred to show all input lines on the left and all output lines on the right. When an exception is made to this left-to-right signal flow, an arrowhead is used to show the reverse signal flow.

Three symbols are shown that indicate three-state, open-drain, and open-source outputs. If none of these are used, the output should be assumed to be totem-pole. The common control block is a point of placement for inputs that affect an array of elements.

The drawings on the right define the three forms of *dependency notation* used in this book. At an input (or output) that affects other inputs or outputs, a letter (G, C, or Z) is placed followed by a number. That same number is placed at the affected inputs and outputs. The letter G indicates that an AND relationship exists; if the affecting input stands at the 0-state, it imposes that 0-state on the affected input or output. The letter C indicates a control relationship, usually between a clock and a D (data) input. If the C input stands at its 0-state, the affected input is disabled. A D input is always an input to a storage element, which it either sets to the 1-state or resets to the 0-state, unless the D input is disabled to have no effect. Z dependency is used to transfer a signal from one place in a symbol to another, for example from the output at Z4 across to a terminal labeled "4", or from the output at Z5 back to the "5" where it serves as an input with no terminal attached.

3.1 DIAGRAMATIC SUMMARY

INPUTS

G (AND) DEPENDENCY

INPUT/OUTPUT

C (CONTROL) DEPENDENCY

OUTPUTS

Z (INTERCONNECTION) DEPENDENCY

COMMON CONTROL BLOCK

*The active-low indicator may be used in combination with the 3-state and open-circuit indicators.

†L-types include N-channel open-drain and P-channel open-source outputs.

‡H-types include P-channel open-drain and N-channel open-source outputs.

4. EXPLANATION OF A TYPICAL SYMBOL FOR A DYNAMIC MEMORY

4.1 THE TMS4C1024 SYMBOL

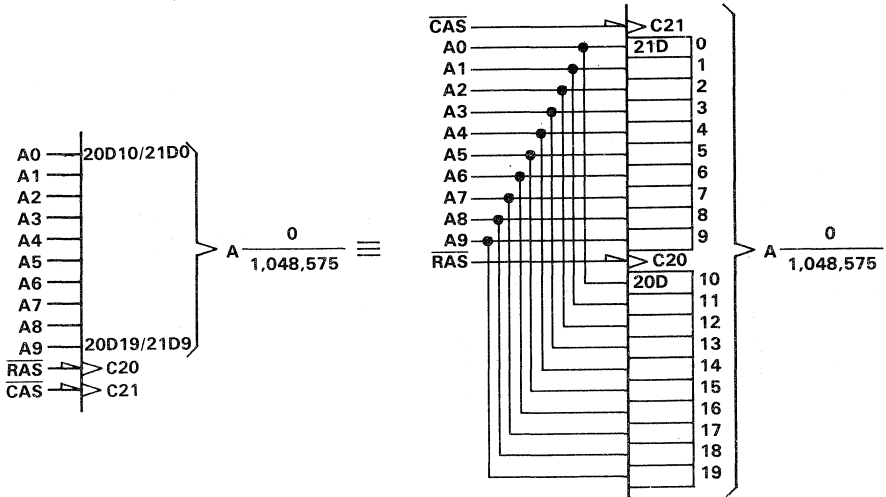

The TMS4C1024 symbol will be explained in detail for each operating function. The assumption is made that Sections 2 and 3 have been read and understood. While this symbol is complex, so is the device it represents and the symbol shows how the part will perform depending on the sequence in which signals are applied.

4.2 ADDRESSING

The symbol above makes use of an abbreviated form to show the multiplexed, latched addresses. The blocks representing the address latches are implied but not shown.

Logic Symbols

11

When $\overline{\text{RAS}}$ goes low, it momentarily enables (through C20, \blacktriangleright indicates a dynamic input) the D inputs of the ten address registers 10 through 19. When $\overline{\text{CAS}}$ goes low, it momentarily enables (through C21) the D inputs of the ten address registers 0 through 9. The outputs of the address registers are in 20 internal address lines that select 1 of 1,048,576 cells.

4.3 REFRESH

When $\overline{\text{RAS}}$ goes low, row refresh starts. It ends when $\overline{\text{RAS}}$ goes high. The other input signals required for refreshing are not indicated by the symbol.

4.4 POWER DOWN

$\overline{\text{CAS}}$ is ANDed with $\overline{\text{RAS}}$ (through G24) so when $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ are both high, the device is powered down.

4.5 WRITE

By virtue of the AND relationship between $\overline{\text{CAS}}$ and $\overline{\text{W}}$ (explicitly shown), when either one of these inputs goes low with the other one and $\overline{\text{RAS}}$ already low ($\overline{\text{RAS}}$ is ANDed by G23), the D input is momentarily enabled (through C22). In an "early-write" cycle it is $\overline{\text{W}}$ that goes low first; this causes the output to remain off as explained below.

4.6 READ

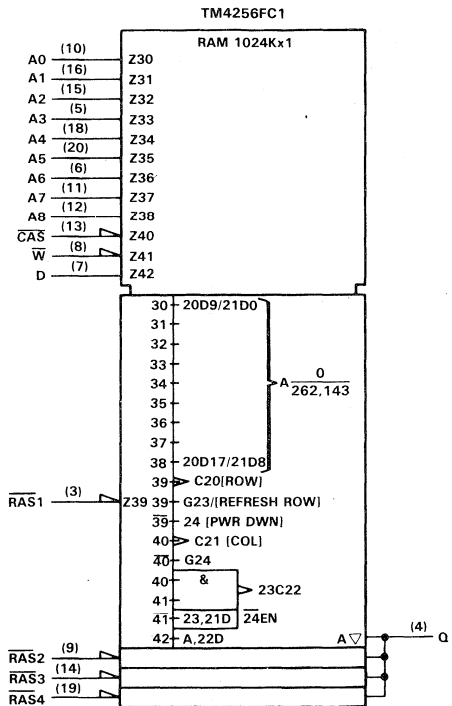

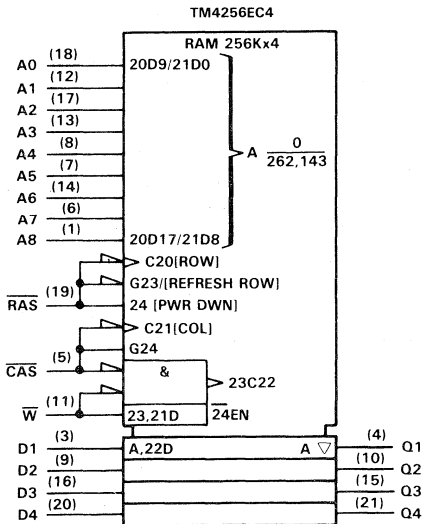

The ANDed result of $\overline{\text{RAS}}$ and $\overline{\text{W}}$ (produced by G23) is clocked into a latch (through C21) at the instant $\overline{\text{CAS}}$ goes low. This result will be a "1" if $\overline{\text{RAS}}$ is low and $\overline{\text{W}}$ is high. The complement of $\overline{\text{CAS}}$ is shown to be ANDed with the output of the latch (by G24 and 24). Therefore, as long as $\overline{\text{CAS}}$ stays low, the output is enabled. In the "early-write" cycle referred to above, a "0" was stored in the latch by $\overline{\text{W}}$ being low when $\overline{\text{CAS}}$ went low, so the output remained disabled.

5. SYMBOLS FOR DYNAMIC RAM MODULES

A dynamic RAM module is created by attaching separate DRAMs in chip-carrier packages to a common substrate. The symbols for the composite memory thus created starts with the symbol for the original DRAM and is used with as little change as possible.

So far, two types of organizations have evolved. In the first, all like address and control inputs are connected in parallel between the separate packages. Taking the TM4256EC4 as typical of this group, the symbol starts with that of the TMS4256 with the qualifying symbol changed from "RAM 256K x 1" to "RAM 256 x 4", and this becomes a common control block for an array of four input-output elements shown below it.

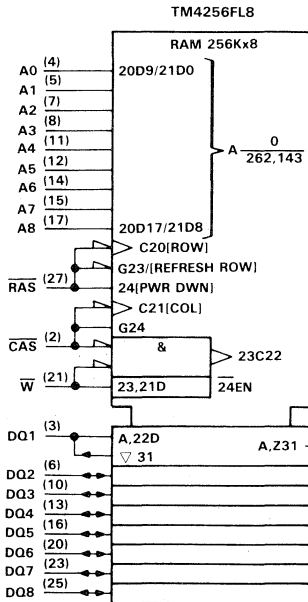

In the second type of organization, of which the TM4256FC1 is typical, most of the address and control lines are parallel connected, but some are brought out separately for each of the DRAM packages. To maintain the recognizability of the original TMS4256 symbol, it has now been placed in the first element of the array. The empty rectangles located below the first element represents three other identical elements. Now interconnection (Z) dependency has been used (see 2 and 2.1) to show how CAS, W, D, and the address inputs connect to the first element, and since these inputs are located in the common control block, the connections apply equally to all the elements. The connections for RAS1, RAS2, RAS3, and RAS4 apply only to the individual elements.

The drawings below illustrate the handling of control lines that in the original symbol were broken up into active-high and active-low functions. To make the combined symbol, the one of the two levels that seemed most appropriate was chosen, and then bars were used over the dependency numbers if necessary. For example, PWR DWN is an active-high function of pin 3, but it was decided that pin 3, $\overline{\text{RAS}}$, should be considered active low. The bar over the number 39 indicates that PWR DWN is a function of the complement of Z39 (ANDed with the complement of Z40 through G24), and the complement of active low is active high.

Another modification of the basic symbols that can occur in either organization is illustrated by the TM4256FL8. The TMS4256 has separate input and output pins. In the module, these have been connected together to form a single I/O port. In the module symbol, this is indicated using Z dependency to transfer the output signal from the right side to the left side.

Military Packages

The packages offered by the Military Products Division of Texas Instruments Semiconductor Group are designed to provide the most efficient and cost-effective method of meeting Military system requirements. Products are offered in hermetic ceramic dual-in-line, ceramic flatpack, leadless ceramic chip carrier, leaded ceramic chip carrier, and ceramic pin grid array packages. All packages conform to the mechanical outlines contained in Appendix C of MIL-M-38510 except for package types that are not included in that specification. In the event of a conflict between dimensions contained in MIL-M-38510 Appendix C and other TI published mechanical outlines, MIL-M-38510 will take precedence.

Physical dimensions of the packages not contained in MIL-M-38510 Appendix C are contained in this document. This document also includes packages that are not completely defined in MIL-M-38510.

CERAMIC PACKAGES AVAILABLE

Package Designator	Description
GB	PGA
FD	Three-Layer Square LLCC — Non-JEDEC Pinouts
FG, FV	Three-Layer Rectangular LLCC — JEDEC Pinouts
FJ	Three-Layer Square "J" Formed LDCC
FK	Three Square LLCC — JEDEC Pinouts
J, JG, JT	Glass-Sealed CDIP
JD	Side-Brazed CDIP
HJ	"J" Formed Small Outline LDCC
HQ	Glass-Sealed Square LDCC
W, WA, WC, U	CPAK

MECHANICAL DATA

MOS MEMORY PRODUCTS—MILITARY

The TI published mechanical outlines for a given package type may vary slightly from product to product. To identify the detailed outline drawing for a particular product, refer to the specific data sheet for that product. There will be detail outline subsets within a generic package category that will be identified as follows:

For example, there are two "FV" package outlines identified in this book:

Mechanical Outline	Description
FV018	18-Pad Leadless Ceramic Chip Carrier used for SMJ4256-XXFV
FV018A	18-Pad Leadless Ceramic Chip Carrier used for SMJ4464-XXFV

INTRODUCTION

Texas Instruments has developed solutions for today's high density packaging needs. The TI facility at Attleboro, Massachusetts (one of the world's largest suppliers of multimetal systems) provides leading-edge technology which, combined with reliable, high-volume, off-the-shelf interconnection products, allows TI to quickly meet volume commercial applications.

During the last decade, TI has produced one of the largest IC socket families. TI's sockets include every type and size socket in common use today and are available in a wide choice of contact materials and designs.

Our sockets are designed for:

- easy and efficient hand assembly
- compatibility with automatic assembly equipment
- maximum performance and board density

This section provides information on the following types of IC socket products.

Flat Pack

Specially formulated alloys give the TI contact springs:

- Low Contact Resistance
- High Contact Strength (to stand up to repetitive insertions and withdrawals)
- High normal forces assure gas-tight reliability

A full line of reliable, readily available, low-cost interconnection systems means premium performance at an economical price.

Additional information on these and other TI products, including pricing and delivery quotations, may be obtained from your nearest authorized TI Distributor, TI Sales Representative or:

PLASTIC LEADED CHIP CARRIER

PERFORMANCE SPECIFICATIONS

Mechanical

Recommended PCB thickness range: 0.062 in to 0.092 in
 Recommended PCB hole size range: 0.032 in to 0.042 in
 Vibration: 15 G max
 Shock: 100 G max
 Insertion force: 0.59 lbs per position typ
 Withdrawal force: 0.25 lbs per position typ
 Normal force: 200 g min, 450 g typ
 Wipe: 0.075 in min
 Durability: 5 cycles min
 Contact retention: 1.5 lbs min

Electrical

Current carrying capacity: 1 A per contact
 Insulation resistance: 5000 MΩ min
 Dielectric withstanding voltage: 1000 V ac rms min
 Capacitance: 1 pF max

Environmental

Operating temperature:
 Operating: - 40°C to 85°C
 Storage: - 40°C to 95°C
 Temperature cycling with humidity: will conform to final EIA specifications

MATERIALS

Body - Ryton R-4 (40% glass) UL 94 V-0 rating
 Contacts - CDA 510 spring temper
 Contact finish - 90/10 tin/lead (200 μin - 400 μin) over 40 μin copper

Extraction tool available, consult factory
 Contact factory for detailed information

PRODUCT FEATURES

Can be loaded by top actuated insertion or press-in insertion, either manually or automatically
High reliability due to high pressure contact point
Open body and high stand-off design provide high efficiency in heat dissipation
High durability up to 10,000 cycles
Compact design

PERFORMANCE SPECIFICATIONS

Mechanical

Accommodates IC leads per specific IC device
Recommended PCB thickness range: 0.062 in to 0.092 in
Recommended PCB hole size range: 0.032 in to 0.042 in
Durability: 10,000 cycles 10 mΩ max contact resistance change

Insertion force: Zero g
Withdrawal force: Zero g[†]

Electrical

Contact rating: 1 A per contact
Contact resistance: 20 mΩ max initial
Insulation resistance: 1000 MΩ per MIL-STD 202, Method 302, Condition B
Dielectric withstanding voltage: 500 V ac rms per MIL-STD 202, Method 301

Environmental

Thermal shock: 100 cycles, -25°C to +150°C
Temperature soak: 150°C for 48 hours
Operating temperature: -40°C to +150°C

MATERIALS

Body — ULTEM glass filled (UL 94 V-0)
Contact — copper alloy
Plating[‡] — overall gold plate 4 μin over min 70 μin nickel plating

Mechanical

Accommodates IC leads 0.015 in to 0.021 in diameter
Recommended PCB thickness range: 0.062 in to 0.092 in
Recommended PCB hole size range: 0.032 in to 0.042 in
Recommended hole grid pattern: 0.100 in \pm 0.002 in each direction

Vibration: 15 G, 10-2000 Hz per MIL-STD 1344A, Method 2005.1 Test Condition III
Shock: 100 G, sawtooth waveform, 2 shocks each direction per MIL-STD 202, Method 213, Test Condition I
Durability: 5 cycles, 10 m Ω max contact resistance change per MIL-STD 1344, Method 2016
Insertion force: 3.6 oz (102 g) per pin typ using 0.018 in diameter test pin
Withdrawal force: 0.5 oz (14 g) per pin min using 0.018 in diameter test pin

Electrical

Contact rating: 1 A per contact
Contact resistance: 20 m Ω max initial
Insulation resistance: 1000 M Ω at 500 V dc per MIL-STD 1344, Method 3003.1
Dielectric withstanding voltage: 1000 V ac rms per MIL-STD 1344, Method 3001.1
Capacitance: 1 pF max per MIL-STD 202, Method 305

Environmental

Operating temperature: -65°C to 125°C, gold; -40°C to 100°C, tin/lead
Corrosive atmosphere: 10 m Ω max contact resistance change when exposed to 22% ammonium sulfide for 4 hours
Gas tight: 10 m Ω max contact resistance change when exposed to nitric acid vapor for 1 hour
Temperature soak: 10 m Ω max contact resistance change when exposed to 105°C temperature for 48 hours

MATERIALS

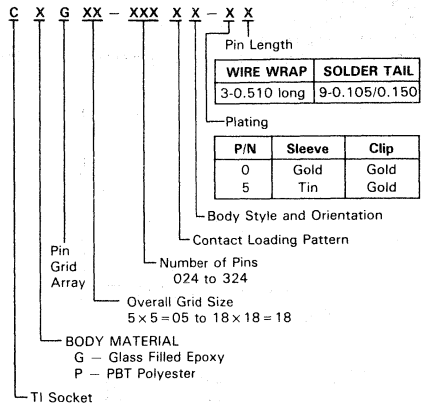

Body — PBT polyester UL 94 V-0
On request, G10/FR4 or Mylar film
Outer sleeve — Machined Brass (QQ-B-626)
Inner contact — Beryllium copper (QQ-C-530) heat treated
Plating: (specify by part number)

PIN GRID ARRAY

Inner contact — 30 μ m gold over 50 μ m nickel or 100 μ m tin/lead over 50 μ m nickel
Outer sleeve — 10 μ m gold over 50 μ m nickel or 50 μ m tin/lead over 50 μ m nickel

MECHANICAL DATA IC SOCKETS BURN-IN/TEST DIP

PERFORMANCE SPECIFICATIONS

Mechanical

Accommodates IC leads 0.011 in by 0.018 in
Recommended PCB thickness range: 0.062 in to 0.092 in
Recommended PCB hold size range: 0.032 in to 0.042 in
Durability: 10K cycles — CM Series, 5K cycles — CP/CQ

Electrical

Contact rating: 1 A per contact
Contact resistance: 20 mΩ max initial
Insulation resistance: 1000 MΩ at 500 V dc
Dielectric withstanding voltage: 1000 V ac rms
Capacitance: 1 pF max per MIL-STD 202, Method 305

Environmental

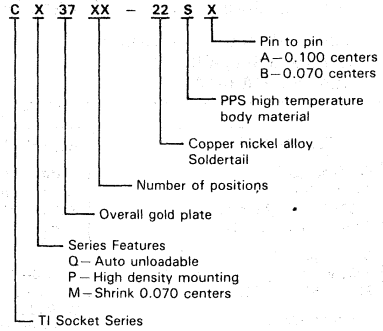

Operating temperature: -65°C to 170°C — CP/CM Series,
-65°C to 150°C — CQ Series
Humidity: 10 mΩ max contact resistance
Temperature Soak: 10 mΩ max contact resistance change

MATERIALS

Body — PPS (polyphenylene sulfide) UL 94 V-0
Contacts — Higher performance copper nickel alloy
Plating: 1 4 μin of gold min over 100 μin of nickel min

†For additional plating options consult the factory

Guidelines for Handling Electrostatic-Discharge Sensitive (ESDS) Devices and Assemblies

SCOPE

This specification establishes the requirements for methods and materials used to protect electronic parts, devices, and assemblies (items) susceptible to damage or degradation from electrostatic discharge (ESD). The electrostatic charges referred to in this specification are generated and stored on surfaces of ordinary plastics, most common textile garments, ungrounded people's bodies, and many other commonly unnoticed static generators. The passage of these charges through an electrostatic-sensitive part may result in catastrophic failure or performance degradation of the part.

The part types for which these requirements are applicable include, but are not limited to, those listed:

- 1) All metal-oxide semiconductor (MOS) devices, e.g., CMOS, PMOS, etc.
- 2) Junction field-effect transistors (JFET)
- 3) Bipolar digital and linear circuits
- 4) Op Amps, monolithic microcircuits with MOS compensating networks, on-board MOS capacitors, or other MOS elements
- 5) Hybrid microcircuits and assemblies containing any of the types of devices listed
- 6) Printed circuit boards and any other type of assembly containing static-sensitive devices.

Definitions

1. Antistatic material: ESD protective material having a surface resistivity between 10^9 and 10^{14} Ω /square.
2. Static dissipative material: ESD protective material having surface resistivity between 10^5 and 10^9 Ω /square.
3. Conductive material: ESD protective material having a surface resistivity of 10^5 Ω /square maximum.
4. Electrostatic discharge (ESD): A transfer of electrostatic charge between bodies at different electrostatic potentials caused by direct contact or induced by an electrostatic field.
5. Surface resistivity: An inverse measure of the conductivity of a material and is the resistance of unit length and unit width of a surface. Note: Surface resistivity of a material is numerically equal to the surface resistance between two electrodes forming opposite sides of a square. The size of the square is immaterial. Surface resistivity applies to both surface and volume conductive materials and has the dimension of Ω /square.
6. Volume resistivity: Also referred to as bulk resistivity. It is normally determined by measuring the resistance (R) of a square of material (surface resistivity) and multiplying this value by the thickness (T).
7. Ionizer: A blower that generates positive and negative ions, either by electrostatic means or by means of a radioactive energy source, in an airstream, and distributes a layer of low velocity ionized air over a work area to neutralize static charges.
8. Close proximity: For the purpose of this specification, is 6 inches or less.

Device Sensitivity per Test Circuit of Method 3015, MIL-STD-883

Devices are categorized according to their susceptibility to damage resulting from electrostatic discharge (ESD), and the type packaging required to adequately protect them.

- 1) Device electrostatic sensitivity:

Category	ESD Sensitivity (V)	Minimum Protective Packaging
A	20-2000	Antistatic Magazine & Conductive Bag/Box
B	> 2000	Antistatic Magazine & Antistatic Bag

- 2) Devices are to be categorized by their sensitivity
- 3) Devices are to be protected from ESD damage from receipt at incoming inspection through assembly, test and shipment of completed equipment.

FACILITIES FOR STATIC-FREE WORK STATION

The minimum acceptable static-free work station shall consist of the work surface covered with an ESD protective material attached to ground through a $1\text{ M}\Omega \pm 10\%$ resistor, an attached grounding wrist strap with integral $1\text{ M}\Omega \pm 10\%$ resistor for each operator, and air ionizer(s) of sufficient capacity for each operator. The wrist strap shall be connected to the ESD protective material. Ground shall utilize the standard building earth ground, refer to Figure 1. Conductive floor tile along with conductive shoes may be used in lieu of the conductive wrist straps. The Site Safety Engineer must review and approve all electrical connections at the static-free work station prior to its implementation.

Air ionizers shall be positioned so that the devices at the static-free work stations are within a 4-foot arc measured by a vertical line from the face of the ionizer and 45 degrees on each side of this line.

General grounding requirements are to be in accordance with Table 1.

All electrical equipment sitting on the conductive table top must be hard grounded but must be isolated from the conductive table top.

NOTE: Earth ground is not computer ground or RF ground or any other limited type ground.

Figure 1. Static-Free Work Station

*With 1 MΩ ± 10% resistor

Usage of Antistatic Solution in Areas to Control the Generation of Static Charges

The use of antistatic chemicals (antistats) should be a supplemental part of an overall organized ESD program. Any antistatic chemical application shall be considered as a means to reduce or eliminate static charge generation on nonconductive materials in the manufacturing or storage areas.

The application of any antistatic chemical in a clean room of class 10,000 or less shall not be permitted. Accordingly, any user of antistatic solutions must consider the following precautions:

1. Do not apply antistatic spray or solutions in any form to energized electrical parts, assemblies, panels, or equipment.
2. Do not perform antistatic chemical applications in any area when bare chips, raw parts, packages, and/or personnel are exposed to spray mists and evaporation vapors.

The need for initial application and frequency of reapplication can only be established through routine electrostatic voltage measurements using an electrostatic voltmeter. The following durability schedule is a reasonable expectation.

- 1) Soft surfaces (carpet, fabric seats, foam padding, etc.): each 6 months or after cleaning, by spraying.
- 2) Hard abused surfaces (floors, table tops, tools, etc.): each week (or day for heavy use) and after cleaning, by wiping or mopping.
- 3) Hard unabused surfaces (cabinets, walls, fixtures, etc.): each 6 months or annually and after cleaning, by wiping or spraying.
- 4) Company-furnished and maintained clothing and smocks: after each cleaning, by spraying or adding antistatic concentrate to final rinse water when cleaned.

The use of antistatic chemicals, their application, and compliance with all appropriate specifications, precautions, and requirements shall be the responsibility of the Area Supervisor where antistatic chemicals are used.

ESD Labels and Signs in Work Areas

ESD caution signs at work stations and labels on static-sensitive parts and containers shall be consistent in color, symbols, class, and voltage sensitivity identification, and appropriate instructions. Signs shall be posted at all work stations performing any handling operations with static-sensitive items. These signs shall contain the following information.

Labels shall be affixed to all containers containing static-sensitive items at a place readily visible and proper for the intended purpose. Additionally, labels must be consistently placed on containers and packages at a standard location to eliminate mishandling. Use only QC accepted and approved signs and labels to identify static-sensitive products and work areas. The use of ESD signs and labels, and their information content shall be the responsibility of the Area Supervisor to assure consistency and compatibility throughout the static-sensitive routing.

Relative Humidity Control

Since relative humidity has a significant impact on the generation of static electricity, when possible, the work area should be maintained within the following relative humidity ranges: incoming/assembly/test/storage 50%-65% (ref. Ashrae, 55-74), within $\pm 5\%$ to avoid static voltage monitor variations.

PREPARATION FOR WORKING AT STATIC-FREE WORK STATION

A work station with a conductive work surface connected to ground through a $1\text{ M}\Omega \pm 10\%$ resistor, a grounding wrist strap with the ground wire connected to the conductive work surface, and an ionizer constitute a static-free work station (Figure 42). An operator is properly grounded when the wrist strap is in snug (no slack) contact with the bare skin, usually positioned on the left wrist for a right-handed operator. The wrist strap must be worn the entire time an operator is at a static-free work station. The operator should first touch the grounded bench top before handling static-sensitive items. This precaution should be observed in addition to wearing the grounding wrist strap. If possible, operators should avoid touching leads or contacts even though grounded.

CAUTION

Personnel shall never be attached to ground without the presence of the $1\text{ M}\Omega \pm 10\%$ series resistor in the ground wire.

An operator's clothing should never make contact or come in close proximity with static sensitive items. They must be especially careful to prevent any static-sensitive items (being handled) from touching their clothing. Long sleeves must be rolled up or covered with antistatic sleeve protector banded to the bare wrist which shall "cage" the sleeve at least as far up as the elbow. Only antistatic finger cots may be used when handling static-sensitive items.

Any person not properly prepared, while at or near the work station, shall not touch or come in close proximity with any static-sensitive items. It is the responsibility of the operator and the Area Supervisor to ensure that the static-free work area is clear of unnecessary static hazards, including such personal items as plastic coated cups or wrappers, plastic cosmetic bottles or boxes, combs, tissue boxes, cigarette packages, and vinyl or plastic purses. All work-related items, including information sheets, fluid containers, tools, and parts carriers must be those approved for use at the static-free work station.

GENERAL HANDLING PROCEDURES AND REQUIREMENTS

1. All static-sensitive items must be received in an antistatic/conductive container and must not be removed from the container except at static-free work station. All protective folders or envelopes holding documentation (lot travelers, etc.) shall be made of nonstatic-generating material.
2. Each packing (outermost) container and package (internal or intermediate) shall have a bright yellow warning label attached, stating the following information or equivalent:

The warning label shall be legible and easily readable to normal vision at a distance of 3 feet.

3. Static-sensitive items are to remain in their protective containers except when actually in work at the static-free station.
4. Before removing the items from their protective container, the operator should place the container on the conductive grounded bench top and make sure the wrist strap fits snugly around the wrist and is properly plugged into the ground receptacle, then touch hands to the conductive bench top.
5. All operations on the items should be performed with the items in contact with the grounded bench top as much as possible. Do not allow conductive magazine to touch hard grounded test gear on bench top.

6. Ordinary plastic solder-suckers and other plastic assembly aids shall not be used.
7. In cases where it is impossible or impractical to ground the operator with a wrist strap, a conductive shoe strap may be used along with conductive tile/mats.
8. When the operator moves from any other place to the static-free station, the start-up procedure shall be the same as in PREPARATION FOR WORKING AT STATIC-FREE WORK STATION.
9. The ionizer shall be in operation prior to presenting any static-sensitive items to the static-free station, and shall be in operation during the entire time period the items are at the station.
10. "Plastic snow" polystyrene foam, "peanuts," or other high-dielectric materials shall never come in contact with or be used around electrostatic sensitive items, unless they have been treated with an antistat (as evidenced by pink color and generation of less than ± 100 volts).
11. Static-sensitive items shall not be transported or stored in trays, tote boxes, vials, or similar containers made of untreated plastic material unless items are protectively packaged in conductive material.

PACKAGING REQUIREMENTS

Packaging of static-sensitive items is to be in accordance with Device Sensitivity, item 1). The use of tape and plain plastic bags is prohibited. All outer and inner containers are to be marked as outlined in GENERAL HANDLING PROCEDURES AND REQUIREMENTS, item 2, and conductive magazines/boxes may be used in lieu of conductive bags.

SPECIFIC HANDLING PROCEDURES FOR STATIC-SENSITIVE ITEMS

Stockroom Operations

1. Containers of static-sensitive items are not to be accepted into stock unless adequately identified as containing static-sensitive items.
2. Items may be removed from the protective container (magazine/bag, etc.) for the purpose of subdividing for order issue only by a properly grounded operator at an approved static-free station as defined in FACILITIES FOR and PREPARATION FOR WORKING AT STATIC-FREE WORK STATION.
3. All subdivided lots must be carefully repackaged in protective containers (magazine/bag, etc.) prior to removal from the static-free work station and labeled to indicate that the package(s) contain static-sensitive items. If it is suspected that a static-sensitive item is not adequately protected, do not transfer it to another container, return it to the originator for disposition unless the originator is a Customer. In that case, the QC Engineer should contact the Customer and negotiate an appropriate disposition.
4. It is the responsibility of the Stockroom Supervisor to ensure that all personnel assigned to this operation are familiar with handling procedures as outlined in this specification. A copy of this specification is to be posted in the vicinity so that it is accessible to the operators. Stock handlers and all others who might have occasion to move stock are to be instructed to avoid direct contact with unprotected static-sensitive items.

Module and Subassembly Operations

1. Static-sensitive items are not to be received from a stockroom, kitting, or machine insertion area unless received in approved static-protective packaging, and properly labeled to indicate that its contents are static sensitive.
2. All single station, progressive line manual assembly operators, and visual inspectors prior to wave soldering operations are to be properly grounded with a grounding wrist strap when handling static-sensitive items.
3. Progressive lines used as single stations where operators will be working on a mix of boards, both static-sensitive and nonstatic-sensitive, will require that all operators working on the line be properly grounded. This is necessary to accommodate the sliding of static-sensitive boards along the assembly bench or across positions not engaged in the assembly of this type board.
4. It is the responsibility of the Area Supervisor to ensure that all personnel handling static-sensitive items are familiar with this procedure and fully aware of the damage or degradation of these units in the event of noncompliance. A periodic inspection should be made using an electrostatic voltmeter to assure that the static-free stations are in proper working order and to ensure that operators are wearing grounding wrist straps properly (snugly in contact with bare skin).

Soldering and Lead-Forming Operations

1. All soldering machines, conveyors, cleaning machines, and equipment shall be electrically grounded to ensure that they are at the same ground potential as the grounded operators working on their stations. No machine surfaces exposed to static-sensitive items are to be above the ground potential.
2. All processing equipment shall be grounded, including all loading and unloading stations, that is, the stations before and after each piece of processing equipment.
3. All nonmetallic, static-generating components in the handling systems shall be treated to ensure protection from static.
4. All stations shall be identified by posting signs as outlined in **ESD Labels and Signs in Work Areas**.
5. Operators are to be properly grounded with a grounding wrist strap during any handling, loading, unloading, inspection, rework, or proximity to static-sensitive items.
6. Unloading operators working at a grounded station shall place static-sensitive items into approved static-protective bags or containers.
7. All manual soldering, repair, and touch-up work stations on the solder line are to be static protected. Operators are to wear grounding wrist straps when working on static-sensitive items. Only grounded-tip soldering/desoldering irons are allowed when working on static-sensitive items.
8. It is the responsibility of the Area Supervisor to ensure that all personnel handling static-sensitive items are familiar with this procedure and fully aware of the damage or degradation of these units in the event of noncompliance. A periodic inspection should be made using an electrostatic voltmeter to assure that the static-free stations are in proper working order and to ensure that operators are wearing grounding wrist straps properly (comfortably snug in contact with bare skin).

Electrical Testing Operations

1. All electrical test stations shall be static protected. Operators shall be properly grounded when working on these items.
2. Reused antistatic magazines must be monitored for maintenance of antistatic characteristics.
3. Devices should be in an antistatic/conductive environment except at the moment when actually under test.
4. Devices should not be inserted into or removed from circuits or tester with the power on or with signals applied to inputs to prevent transient voltages from causing permanent damage.
5. All unused input leads should be biased if possible.
6. Device or module repairs must be performed at static-free stations with the operator attached to a grounding wrist strap. Grounded-tip soldering irons shall be used when working on static-sensitive items.
7. Static-sensitive items shall be handled through all electrical inspections in static protective containers. Removal of the items from the protective containers shall be done at a static-free work station as discussed in **PREPARATION FOR WORKING AT A STATIC-FREE WORK STATION**. The units must be returned to the containers before leaving the station.
8. All such items shall be shipped with an ESD warning label affixed as listed.
9. It is the responsibility of the Area Supervisor to ensure that all personnel handling static-sensitive items are familiar with this procedure and fully aware of the damage or possible degradation of these units in the event of noncompliance. A periodic inspection should be made using an electrostatic voltmeter to assure that the static-free stations are in proper working order and to ensure that operators are wearing grounding straps properly (snugly in contact with bare skin).

Packing Operations

1. Static-sensitive items are not to be accepted into the packing area unless they are contained in a static-protected bag or conductive container.
2. A static-sensitive item delivered to the packer within an approved container or bag and found to be in order regarding identification shall be packed in the standard shipping carton or other regular packaging material. Containers are to be labeled in accordance with **GENERAL HANDLING PROCEDURES AND REQUIREMENTS**, item 2.
3. Any void-fillers shall be made of an approved antistatic material.

Burn-In Operations

1. Burn-in board loading and unloading of static-sensitive items shall be done at a static-free station.
2. Shorting clips/shorted connectors shall be installed on the board plug-in tab prior to loading any units into the board sockets. The clip/connector shall be taken off just prior to plugging the board into the oven connector. The clip/connector shall be installed immediately upon removal of the board from the oven connector. Installation and removal of the clip/connector shall be done by a properly grounded operator.
3. All automatic or semiautomatic loading and unloading equipment shall be properly electrically grounded.
4. It is the responsibility of the Area Supervisor to ensure that all personnel handling static-sensitive items are familiar with this procedure and fully aware of the damage or possible degradation of these units in the event of noncompliance. A periodic inspection should be made using an electrostatic voltmeter to assure that the static-free stations are in proper working order and to ensure that operators are wearing grounding straps properly (snugly in contact with bare skin).

CUSTOMER RETURNED ITEM HANDLING PROCEDURE

Receipt of ESDS-labeled items is to be done at a static-free work station and handled in accordance with applicable sections within this guideline.

QUALITY CONTROL PROVISIONS

Sampling

Each manufacturing, stockroom, and testing operation handling ESDS devices will be audited a minimum of once each quarter for compliance with all terms of this specification by the responsible process control or QRA organization. Ground continuity and the presence of uncontrolled static voltages are considered critical and shall be checked more frequently as specified below.

Ground Continuity (minimum of once a week).

Ground connections (grounding wrist strap, ground wires on cords, etc.) shall be checked for electrical continuity. The presence of a $1\text{ M}\Omega \pm 10\%$ resistor in the ground connections between both the operator wrist straps to the work surface and the work surface to ground connector must be verified.

Grounded Conditions (minimum of once a week).

A visual inspection shall be made to determine full compliance with this specification at static-free work stations during handling of static-sensitive items, including operator being grounded as required, static-sensitive items not being handled in unprotected or unauthorized areas, and no static-generating materials at the grounded work station.

Sleeve Protectors (minimum of once a week).

A visual check shall be made to determine that each operator wearing loose-fitting or long-sleeved clothing either has sleeves properly rolled or covered with sleeve protectors properly grounded to the bare skin at the wrist.

Static Voltage Levels (minimum of once a week).

In addition to the visual inspections, a sample inspection using an electrostatic voltmeter will be used to check for uncontrolled electrostatic voltages at or near electrostatic-controlled work stations.

Conductive Floor Tiles (minimum of once a month).

Conductive floors must have a resistance of not less than $25\text{ k}\Omega$ from any point on the tile to earth ground. Also, resistance from any point-to-point on the tile floor 3 feet apart shall be not less than $25\text{ k}\Omega$. The test methods to be used are ASTM-F-150-72 and NFPA 56.

Records

Written records must be kept of all these QC audits.

TRAINING

Training is applicable for all areas where individuals come in contact with ESDS (category A) devices. It is the responsibility of each Area Supervisor to make sure that his/her people receive ESD training initially and every 12 months thereafter to maintain proficiency. Training should include static fundamentals, a review of applicable parts of this specification, and actual applications in the work area.
