# 1 ZODIAC DATA TYPES AND MESSAGE FORMATS

This document describes the formats of the two types of messages that can be communicated across the serial data interface for the Zodiac Global Positioning System (GPS) receiver engine. The structure and contents of each binary message is described in Section 2. The structure and contents of each National Marine Electronics Association (NMEA) message is described in Section 3.

## 1.1 Binary Message Format And Word Structure

**1.1.1 Binary Message Format.** The input/output binary data stream format is a low byte/high byte pattern. Each byte is output with its Least Significant Bit (LSB) first, followed by its higher order bits, ending with the Most Significant Bit (MSB) of the data byte.

The binary message format is nearly identical to that used by the previous NavCore/MicroTracker series of receivers, except that all floating point values are now represented as fixed-point integer numbers with explicit or implied scale factors.

Each binary message consists of a header portion and a data portion, each with its own checksum. Each message will have a header, but some messages may

not have data. Message acknowledgements are in the form of a header, and message requests are made using headers as well. Table I-1 shows the data types used to define the elements of the binary interface messages.

**1.1.2 Word Structure.** An integer is defined as 16 bits. While offsets are incorporated in the message description tables, the most convenient specification of memory layout in application implementation is likely to be a structure definition.

If the item is a fixed point quantity, the value of the LSB of the integer is given. To convert a fixed point item to a floating point variable, the integer representation is floated and multiplied by the

**Table I-1. Binary Message Data Types**

TYPE	ABBREVIATION	WORDS (Note 1)	BITS	MAXIMUM RANGE
Bit (Note 2)	Bit	N/A	0 to 15	0 to 1
Character (Note 3)	C	N/A	8	ASCII 0 to 255
Integer	I	1	16	-32768 to +32767
Double Integer	DI	2	32	-2147483648 to +2147483647
Triple Integer	TI	3	48	-140737488355328 to +140737488355327
Unsigned Integer	UI	1	16	0 to 65535
Unsigned Double Integer	UDI	2	32	0 to 4294967295
Unsigned Triple Integer	UTI	3	48	0 to 281474976710656
<p><b>Note 1:</b> The term "word" is used throughout this document to specify a quantity which occupies 16 bits of storage.</p> <p><b>Note 2:</b> Data items using bit storage are specified with a format of w.b, where w is the word number and b is the bit number (0-15, 0 LSB) within the word. Multiple-bit items (bit fields) are indicated by a range of 'word.bit' values (e.g., 8.4-8.7).</p> <p><b>Note 3:</b> Although the AAMP2 processor and C compiler use 16-bit character representations, this data interface will use the more common 8-bit representation. The Zodiac receiver software will pack/unpack the character data internally as needed.</p>				

High Byte		Low Byte		
1000	0001	1111	1111	Word 1
MSB	LSB	MSB	LSB	
Message ID				Word 2
Data Word Count				Word 3
DCLO QRAN 00XX XXXX				Word 4
Header Checksum				Word 5

**Figure 1-1. Binary Message Header Format**

resolution. When converting to float, consideration must be given to the range and resolution of the item to ensure that the type of float selected for the conversion has an adequate mantissa length to preserve the accuracy of the data item. Triple word items may require scaling portions of the variable separately and then adding them in floating point form.

Composite words may have independent definitions for each bit field in the word. Flag bits are either zero (false) or one (true). All bits that are designated as reserved within the bit descriptions of binary data have undefined values for outputs and must be set to zero for inputs.

## 1.2 Binary Message Header

The binary message header format has been modified slightly from the NavCore V format to accommodate message logging requests. The format of the new message header is shown in Figure 1-1.

**1.2.1 Message Header Word 1.** Each input/output message starts with a synchronization word of the form 0xFF81<sub>HEX</sub> with DEL (255 decimal) occupying the first eight bits followed by the Start Of Header (SOH) (129 decimal) occupying the second eight bits of the synchronization word.

**1.2.2 Message Header Word 2.** Word 2 contains the numeric message ID. For example, word 2 for Message ID 1000 would be:

High Byte		Low Byte	
0000	0011	1110	1000
MSB	LSB	MSB	LSB

Or 0x03E8<sub>HEX</sub>.

**1.2.3 Message Header Word 3.** Word 3 contains the word count for the data portion of the message. The word count does not include the data checksum word. A zero data word count indicates a “header-only” message.

**1.2.4 Message Header Word 4.** The fourth word of the message header is a 16-bit field allocated to protocol and message related flags. These flag bits extend control over ACK/NAK requests and implement message logging requests. The zeroes represented in the word 4 field shown in Figure 1-1 are reserved bits and should be set to zero within this word.

The ACK/NAK control mechanism gives the user the ability to request either ACK or NAK, or both, independently for each message request. The user sets the request (R) bit and either the acknowledge (A) bit or negative acknowledge (N) bit, or both, to select the proper acknowledge behavior. With this approach, the user can configure requests only to be NAKed, alerting the user when a problem arises without incurring the overhead necessary to continuously process ACKs.

The lower six bits of the flags word can be used as an additional input identifier. This identifier is not explicitly processed by the receiver; it is echoed back, in the same location, as part of the header in ACK/NAK responses. This feature allows the user to uniquely distinguish which input message an acknowledgement corresponds to when multiple

Trigger (on time, on update)	Word 6
Interval (sec)	Word 7
Offset (sec)	Word 8
Data Checksum	Word 9

**Figure 1-2. Standard Log Request Message Format (Data Portion)**

input messages with the same message ID were processed during a particular period of time.

The flags word now supports message logging requests. The connect (C) and disconnect (D) bits are used to enable and disable, respectively, message outputs, and can be used either independently or in conjunction with the log request bits. A header-only message, with a Message ID and the connect bit set, enables the specified message with existing timing characteristics. Likewise, a header-only message, with Message ID and the disconnect bit set, disables the specified message. A message with both connect and disconnect bits is ignored. Note that enabling and disabling a message does not modify its timing characteristics (trigger, interval, or offset). A log request with the connect bit set will set up the message's timing characteristics and then enable the message. Similarly, for a combined log and disable request, the message will be disabled after the timing characteristics are set. To disable all messages, set the message ID to FFFF<sub>HEX</sub> (all bits set) and set the disconnect (D) bit.

Setting the query (Q) request bit will output the message specified by the message ID one time during the next output interval. Standard log requests will be accepted if the log (L) bit is set and if the required data parameters are present in the data portion of the request message.

**1.2.5 Message Header Word 5.** Word 5 of the message header is the data checksum, used to validate the header portion of the message. It is computed by summing (modulo  $2^{16}$ ) all words (including the word containing DEL and SOH) contained in the header and then performing a two's complement on the sum.

The computation of the header checksum may be expressed mathematically as:

$$SUM = Mod 2^{16} \sum_{i=1}^4 Word(i)$$

If sum = - 32768, Header Checksum = SUM; else Header Checksum = - SUM

where:

- Unary negation is computed as the two's complement of a 16-bit data word.
- Mod  $2^{16}$  indicates the least 16 bits of an arithmetic process. That is, carry bits from bit position 16 are ignored.
- The summation is the algebraic binary sum of the words indicated by the subscript *i*.
- The -32768 sum value must be treated as a special case since it cannot be negated.

**1.2.6 Log Request Messages.** Figure 1-2 shows the format of the data portion of standard log request messages. The ranges for words 6, 7, and 8 of these messages are as follows:

Trigger	0 = on time, 1 = on update
Interval	0 to 65535 seconds (an interval of zero produces a query as if the query bit [Q] in word 4 of the message header has been set).
Offset	0 to 60 seconds (an offset of zero specifies an initial output relative to the current time. An offset of 60 specifies an initial output relative to the next even minute [zero seconds into the next minute]).

When the Trigger field is set to “on time” (integer value 0), the first output will occur at the next Offset seconds into the minute, and will repeat every Interval seconds thereafter. When the trigger field is

set to “on update,” the specified message will be output only when the data is updated (e.g., when satellite almanac is collected).

### 1.3 Binary Message Data

The data portion of a binary message, if it exists, can be variable in length, as specified by the data word count found in the header. The Data Checksum follows the data and is not included in the data word count.

The Data Checksum is a 16-bit word used to validate the data portion of the message. It is transmitted as the last word of any message containing data (Figure 1-2 or Figure 1-3).

When the Word Count field is zero, the Data Checksum does not exist. It is computed by summing (modulo  $2^{16}$ ) all words in the data portion of the message and then complementing that sum. The mathematical expression for the Data Checksum is:

$$SUM = \text{Mod } 2^{16} \sum_{i=6}^{5+N} \text{Word}(i)$$

If sum = - 32768, Data Checksum = SUM; else Data Checksum = - SUM

where:

- Unary negation is computed as the two's complement of a 16-bit data word.
- Mod  $2^{16}$  indicates the least 16 bits of an arithmetic process. That is, carry bits from bit position 16 are ignored.
- The summation is the algebraic binary sum of the words indicated by the subscript (i).
- The -32768 sum value must be treated as a special case since it cannot be negated.

Data elements identified as “Reserved” must be set to zero for input messages and are undefined for output messages. All data storage which is not explicitly defined should be handled as if it were marked “Reserved.”

Unless otherwise stated, the resolution of each numeric data item is one integer unit, as specified by that item in the “Units” field.

### 1.4 NMEA Messages, Format, And Sentence Structure

NMEA messages are output in response to standard Q (Query) or proprietary ILOG (Log Control) messages as described in Section 3. The timing of output messages is synchronized with the Time Mark output event.

**1.4.1 NMEA Output Messages.** The following supported NMEA output messages comply with the NMEA-0183 version 2.01 standard:

- GGA: GPS Fix Data
- GSA: GPS DOP and Active Satellites
- GSV: GPS Satellites in View
- RMC: Recommended Minimum Specific GPS Data

The Zodiac receiver also supports the following Rockwell proprietary output messages:

- BIT: Rockwell Proprietary Built-In Test Results
- RID: Rockwell Proprietary Receiver ID
- ZCH: Rockwell Proprietary Zodiac Channel Status

These proprietary messages conform to the message format described below.

**1.4.2 NMEA Input Messages.** The Zodiac receiver supports the following proprietary input messages:

- IBIT: Rockwell Proprietary Built-In Test Command
- ILOG: Rockwell Proprietary Log Control
- INIT: Rockwell Proprietary Receiver Initialization
- IPRO: Rockwell Proprietary Protocol

The INIT message is used to command initialization of the receiver and the IPRO message is used to change the message protocol. The first character of the message sentence is “P,” followed by a three-character mnemonic code for Rockwell International (RWI) according to Appendix III of the NMEA-0183 standard.

**1.4.3 NMEA Message Format.** All NMEA-0183 data messages are in ASCII form. Each message begins with ASCII \$ (24<sub>HEX</sub>) and ends with ASCII <CR><LF> (0D<sub>HEX</sub> and 0A<sub>HEX</sub>). The valid character set consists of all printable ASCII characters, 20<sub>HEX</sub> to 7E<sub>HEX</sub>, except for the reserved characters listed in Table I-2.

Each NMEA message, or sentence, consists of a set of fields separated by a comma delimiter character. Each field can contain either a string of valid characters or no characters (null field). Valid characters must conform with the formats described in Table I-3.

The maximum number of characters in a sentence is 82, consisting of a maximum of 79 characters between the starting delimiter “\$” and the terminating <CR> and <LF>.

Since the number of data fields can vary from sentence to sentence, it is important that the “listener” (or application software) locate fields by counting delimiters rather than counting the total number of characters received from the start of the sentence.

**1.4.4 NMEA-0183 Approved Sentences.** An approved NMEA-0183 sentence contains the following elements, in the order shown:

“ \$ ”	Start of the sentence (24 <sub>HEX</sub> )
<address field>	Talker identifier and sentence formatter.
[“,”<data field>]	Zero or more data fields.
.	.
.	.
.	.
[“,”<data field>]	
[“*”<checksum field>]	Optional checksum field.
<CR><LF>	End of sentence delimiter (0D 0A <sub>HEX</sub> ).

**NOTE:** Since the Zodiac receiver is a GPS device, the “talker” identifier is always “GP.”

**Table I-2. NMEA Reserved Characters**

CHARACTER	HEX VALUE	DECIMAL VALUE	DESCRIPTION
<CR>	0D	13	Carriage return (end of sentence delimiter)
<LF>	0A	10	Line feed (end of sentence delimiter)
\$	24	36	Start of sentence delimiter
*	2A	42	Checksum field delimiter
,	2C	44	Field delimiter
!	21	33	Reserved
\	5C	92	Reserved
^	5E	94	Reserved
-	7E	126	Reserved

**Table I-3. NMEA Field Type Summary**

Field Type	Symbol	Definition
<b>Special Format Fields</b>		
Status	A	Single character field: A = Yes, Data Valid, Warning Flag Clear V = No, Data Invalid, Warning Flag Set
Latitude	III.II	Fixed/variable length field: Degrees/minutes.decimal -- two fixed digits of degrees, two fixed digits of minutes and a variable number of digits for decimal-fraction of minutes. Leading zeros always included for degrees and minutes to maintain fixed length. The decimal point and associated decimal-fraction are optional if full resolution is not required.
Longitude	yyyy.yy	Fixed/variable length field: Degrees/minutes.decimal -- three fixed digits of degrees, two fixed digits of minutes and a variable number of digits for decimal-fraction of minutes. Leading zeros always included for degrees and minutes to maintain fixed length. The decimal point and associated decimal-fraction are optional if full resolution is not required.
Time	hhmmss.ss	Fixed/variable length field: Hours/minutes/seconds.decimal -- two fixed digits of hours, two fixed digits of minutes, two fixed digits of seconds and a variable number of digits for decimal-fraction of seconds. Leading zeros always included for hours, minutes, and seconds to maintain fixed length. The decimal point and associated decimal-fraction are optional if full resolution is not required.
Defined field		Some fields are specified to contain pre-defined constants, most often alpha characters. Such a field is indicated in the NMEA-0183 standard by the presence of one or more valid characters. The following characters and character strings used to indicate field types are excluded from the list of allowable characters: "A," "a," "c," "hh," "hhmmss.ss," "III.II," "x," and "yyyy.yy."
<b>Numeric Value Fields</b>		
Variable numbers	x.x	Variable length integer or floating point numeric field: Optional leading and trailing zeros. The decimal point and associated decimal-fraction are optional if full resolution is not required (e.g., 73.10 = 73.1 = 073.1 = 73).
Fixed HEX field	hh__	Fixed length HEX numbers only, most significant bit on the left.
<b>Information Fields</b>		
Variable text	c- - c	Variable length valid character field.
Fixed alpha field	aa__	Fixed length field of uppercase or lowercase alpha characters.
Fixed number field	xx__	Fixed length field of numeric characters.
Fixed text field	cc__	Fixed length field of valid characters.
<b>NOTES:</b>		
<ol style="list-style-type: none"> <li>1. Spaces may only be used in variable text fields.</li> <li>2. A negative sign ("- or 2D<sub>HEX</sub>) is the first character in a field if the value is negative. The sign is omitted if the value is positive.</li> <li>3. All data fields are delimited by a comma (",").</li> <li>4. Null fields are indicated by no data between two delimiters.</li> </ol>		

**1.4.5 Proprietary Sentences.** Proprietary sentences allow OEMs to transfer data that does not fall within the scope of approved NMEA sentences.

A proprietary sentence contains the following elements, in the order shown:

“ \$ ”	Start of the sentence (24 <sub>HEX</sub> )
“ P ”	Proprietary sentence ID (50 <sub>HEX</sub> ).
<aaa>	OEM’s mnemonic code. [<valid characters, OEM’s data>]

[“*”<checksum field>]	Optional checksum field.
<CR><LF>	End of sentence delimiter (0D 0A <sub>HEX</sub> ).

**1.4.6 Checksum.** The checksum is the 8-bit exclusive OR (no start or stop bits) of all characters in the sentence, including delimiters (except for the \$ and the optional \* delimiters). The hexadecimal value of the most significant and least significant four bits of the result are converted to two ASCII characters (0-9, A-F) for transmission. The most significant character is transmitted first.

***THIS PAGE INTENTIONALLY LEFT BLANK***

## 2 ZODIAC BINARY DATA MESSAGES

This section describes the binary data messages of the Zodiac GPS receiver. All of the output and input binary messages are listed in Table II-1 together with their corresponding message IDs. Power-up default messages are also identified.

Binary mode is selected according to the logic described in the hardware interface section of the *Zodiac GPS Receiver Family Designer's Guide*. Binary messages are transmitted and received across the host port serial I/O interface (RS-232) with the following default communications parameters:

- 9600 bps
- 8 data bits
- no parity
- 1 stop bit

All of the output binary messages are described in detail in section 2.1. All of the input binary messages are described in detail in section 2.2.

**Table II-1. Zodiac Binary Data Messages**

Output Message Name	Message ID	Input Message Name	Message ID
Geodetic Position Status Output (*)	1000	Geodetic Position and Velocity Initialization	1200
ECEF Position Status Output	1001	User-Defined Datum Definition	1210
Channel Summary (*)	1002	Map Datum Select	1211
Visible Satellites (*)	1003	Satellite Elevation Mask Control	1212

## 2.1 Output Message Descriptions

**2.1.1 Geodetic Position Status Output (Message 1000).** This message outputs the receiver's estimate of position, ground speed, course over ground, climb rate, and map datum. A solution status indicates whether or not the solution is valid (based on the solution validity criteria) and also the type of solution. The number of measurements used to compute the solution is also included.

The Polar Navigation flag is used to indicate that the solution estimate is too close to the North or South Pole to estimate longitude. When this flag is true, the longitude and true course outputs are invalid and are not updated. Users operating near the poles should use the ECEF Position Status Output message.

The contents of the Geodetic Position Status Output Message are described in Table II-2.

**Table II-2. Message 1000: Geodetic Position Status Output Message (1 of 3)**

<b>Message ID:</b> 1000					
<b>Rate:</b> Variable; defaults to 1 Hz					
<b>Message Length:</b> 55 words					
<b>Word No.:</b>	<b>Name:</b>	<b>Type:</b>	<b>Units:</b>	<b>Range:</b>	<b>Resolution:</b>

53-54	Clock Drift Standard Deviation (Note 7)	DI	m/sec	±0 to 1000	10 <sup>-2</sup>
55	Data Checksum				

**Note 1:**

Set time is an internal 10 millisecond (T10) count since power-on initialization enabled the processor interrupts. It is not used to derive GPS time, but only serves to provide a sequence of events knowledge. The set time or T10 count references the receiver's internal time at which the message was created for output. The T10 range is approximately 71 weeks.

**Note 2:**

The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.

**Note 3:**

The satellite measurement sequence number relates the position solution data to a particular set of satellite measurements found in binary messages 1002 and 1007 (Channel Summary Message and Channel Measurement Message, respectively).

**Note 4:**

The value of this data item was initially set using the Solution Validity Criteria Message (Message 1217).

**Note 5:**

Bit zero of word 11 does *not* refer to a solution propagated by the navigation software. This bit is used to indicate if the solution was propagated by the serial I/O manager to generate a 1 Hz output message when no new navigation state data was available. This is an error condition potentially caused by a shortage of throughput in one cycle. It is unlikely to occur and is self-correcting. Normal state propagation which occurs within the navigation software with or without measurements available for processing does not cause this bit to be set.

**Note 6:**

The table in Appendix A contains map datum codes from 0 to 188. Codes 300 to 304 are user-defined.

**Note 7:**

The data displayed by this field is not valid until the receiver is in navigation mode.

**2.1.2 ECEF Position Status Output (Message 1001).** This message outputs the receiver's estimate of ECEF position and velocity, and map datum. A solution status indicates whether or not the solution is valid (based on the solution validity criteria) and also

the type of solution. The number of measurements used to compute the solution is also included.

The contents of the ECEF Position Status Output Message are described in Table II-3.

**Table II-3. Message 1001: ECEF Position Status Output Message (1 of 2)**

22	Data Checksum				
<p><b>Note 1:</b> Set time is an internal 10 millisecond (T10) count since power-on initialization enabled the processor interrupts. It is not used to derive GPS time, but only serves to provide a sequence of events knowledge. The set time or T10 count references the receiver's internal time at which the message was created for output. The T10 range is approximately 71 weeks.</p> <p><b>Note 2:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.</p> <p><b>Note 3:</b> The selected candidate list is a 32-bit flag, each bit representing candidate selection status for one satellite (i.e., bit 0 = SV1 status, bit 1 = SV2 status...bit 31 = SV32 status).</p>					

**2.1.9 Built-In Test (BIT) Results (Message 1100).**

This message provides detailed test results of the last BIT is commanded since power-up. It is output automatically after the completion of a commanded BIT, but may also be queried manually as needed.

Non-zero device failure status indicates failure. The contents of the Built-In Test (BIT) Results Message are described in Table II-10.

**Table II-10. Message 1100: Built-In Test Results Message**

<p><b>Note 1:</b> Set time is an internal 10 millisecond (T10) count since power-on initialization enabled the processor interrupts. It is not used to derive GPS time, but only serves to provide a sequence of events knowledge. The set time or T10 count references the receiver's internal time at which the message was created for output. The T10 range is approximately 71 weeks.</p> <p><b>Note 2:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.</p> <p><b>Note 3:</b> The GPS time associated with the valid satellite measurement data. The integer portion is the GPS second count from the start of week.</p>					

**Table II-11. Message 1102: Measurement Time Mark Message (3 of 3)****Note 4:**

The fractional portion of the solution measurement time is the offset from the GPS second count.

**Note 5:**

The Measurement Engine has decoded and applied at least one Hand-Over Word.

**Note 6:**

Indication of the position of subframe data word one within the GPS satellite's 50 bps telemetry data stream. For example, a value of 0 indicates that subframe data word one represents the first word of a particular telemetry data subframe. The data word subframe index is repeated once for each channel.

$$n = 25 + (j * 19), \text{ where } j = 0 \text{ to } 11$$

**Note 7:**

1 = the signal strength fell below a threshold.

**Note 8:**

1 = a carrier phase change exceeded a threshold.

**Note 9:**

1 = carrier cycle slips may have affected this measurement or the previous measurement.

**Note 10:**

PRN equal to 0 is used to indicate an unused channel.

**Note 11:**

C/No observed for this measurement interval.

**Note 12:**

Code phase (pseudorange) at the measurement epoch. The physical range value in meters is obtained by scaling by  $c(2^{-45}/50)$ , where  $c$  is the WGS-84 value of the speed of light. The factor of 50 results from the 50 Hz accumulation of code phase.

**Note 13:**

Continuously integrated carrier phase at the measurement epoch.

**Note 14:**

If channel data word one is unused, so is channel data word two. Channel data word one is indexed into the telemetry subframe by the Data Word Frame Index.

**Note 15:**

30-bit subframe data word from the 50 bps satellite telemetry data stream.

**Note 16:**

Parity is computed based on the six parity bits found at the end of each 30-bit subframe data word. Parity is computed based on the parity algorithm given in the *Global Positioning System Standard Positioning Service Signal Specification* (November 5, 1993).

**2.1.11 UTC Time Mark Pulse Output (Message 1108).** This message provides the UTC seconds into week associated with the UTC synchronized Time Mark pulse. This message is output approximately

400 milliseconds before the Time Mark pulse strobe signal. The contents of the UTC Time Mark Pulse Output Message are described below.

**Table II-12. Message 1108: UTC Time Mark Pulse Output Message**

<b>Message ID:</b>		1108			
<b>Rate:</b>		1 Hz

## 2.2 Input Message Descriptions

**2.2.1 Geodetic Position and Velocity Initialization (Message 1200).** This message allows the user to initialize the receiver with the specified geodetic position, ground speed, course over ground, and climb rate. The course may be either true or magnetic, as indicated by the Magnetic Course field.

The GPS/UTC time represents the time at which the solution was computed and, if present, will be used to propagate the solution to the current time. The contents of the Geodetic Position and Velocity Initialization Message are described in Table II-16.

**Table II-16. Message 1200: Geodetic Position and Velocity Initialization Message (1 of 2)**

<p><b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.</p>					

**2.2.2 User-Defined Datum Definition (Message 1210).** This message allows the user to define a datum to be used by the receiver to transform its position solution. Up to five user-defined datums may be stored. Storage of these parameters requires EEPROM. The contents of the User-Defined Datum Definition Message are described in Table II-17.

Note that datum definition does not imply datum use. Message 1211 is used to specify the “Datum In Use” for the navigation function. Also, any Message 1210 that contains an undefined datum code is ignored.

**Table II-17. Message 1210: User-Defined Datum Definition Message**

<b>Message ID:</b> 1210					
<b>Rate:</b> As required - maximum rate is 1 Hz					
<b>Message Length:</b> 20 words					
Word No.:	Name:	Type:	Units:	Range:	Resolution:
1-4	Message Header

10	Semi-Major Axis - Fractional Part	UI	meters	0 to 9999	10 <sup>-4</sup>
11	Inverse Flattening - Integer Part	UI		280 to 320	
12-13	Inverse Flattening - Fractional Part	UDI		0 to 999999999	10 <sup>-9</sup>
14-15	WGS-84 Datum Offset - dX	DI	meters	0 to ±9000000	10 <sup>-2</sup>
16-17	WGS-84 Datum Offset - dY	DI	meters	0 to ±9000000	10 <sup>-2</sup>
18-19	WGS-84 Datum Offset - dZ	DI	meters	0 to ±9000000	10 <sup>-2</sup>
20	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.3 Map Datum Select (Message 1211).** This message allows the user to select a datum to be used by the receiver to transform its position solution. The

contents of the Map Datum Select Message are described in Table II-18.

**Table II-18. Message 1211: Map Datum Select Message**

<b>Message ID:</b> 1211					
<b>Rate:</b> As required - maximum rate 1 Hz					
<b>Message Length:</b> 8 words					
<b>Word No.:</b>	<b>Name:</b>	<b>Type:</b>	<b>Units:</b>	<b>Range:</b>	<b>Resolution:</b>
1-4	Message Header				
5	Header Checksum				
6	Sequence Number (Note 1)	I		0 to 32767	
7	Datum ID (Note 2)	UI		0 to 188 and 300 to 304	
8	Data Checksum				
<p><b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.</p> <p><b>Note 2:</b> The table in Appendix C contains map datum codes from 0 to 188. Codes 300 to 304 are user-defined.</p>					

**2.2.4 Satellite Elevation Mask Control (Message 1212).** This message allows the user to set the elevation mask angle used by the receiver to select visible satellites. Storage of the Elevation Mask

Angle parameter requires EEPROM. The contents of the Satellite Elevation Mask Control Message are described in Table II-19.

**Table II-19. Message 1212: Satellite Elevation Mask Control Message**

<b>Message ID:</b> 1212

8	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.5 Satellite Candidate Select (Message 1213).**  
 This message allows the user to construct the list of satellites which will be considered for selection by

the receiver. The contents of the Satellite Candidate Select Message are described in Table II-20.

**Table II-20. Message 1213: Satellite Candidate Select Message**

<b>Message ID:</b> 1213					
<b>Rate:</b> As required - maximum rate 1 Hz

9.1-9.15	Reserved				
10	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.6 Differential GPS Control (Message 1214).**  
 This message allows the user to control the behavior of the receiver's differential capability. Storage of

this message's parameters requires EEPROM. The contents of the Differential GPS Control Message are described in Table II-21.

**Table II-21. Message 1214: Differential GPS Control Message**

<b>Message ID:</b> 1214					
<b>Rate:</b> As required - maximum rate 1 Hz					
<b>Message Length:</b> 9 words					
<b>Word No.:</b>	<b>Name:</b>	<b>Type:</b>	<b>Units:</b>	<b>Range:</b>	<b>Resolution:</b>

8	Correction Time-Out	UI		0 to 32767	
9	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.7 Cold Start Control (Message 1216).** This message allows the user to disable the Cold Start acquisition mode of the receiver. Normal operation is to leave cold start enabled. However, in certain enclosed situations (e.g., parking garages, houses,

office buildings, etc.), faster acquisitions may be achieved with cold start disabled. Storage of the Cold Start Disable parameter requires EEPROM. The contents of the Cold Start Control Message are described in Table II-22.

**Table II-22. Message 1216: Cold Start Control Message**

<b>Message ID:</b> 1216

9	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.8 Solution Validity Criteria (Message 1217).**  
 The receiver will always output the best position solution it can attain, depending on the number and quality of available measurements. The Solution Validity Criteria Message allows the user to define the criteria for setting the position validity status

specified in the position output messages. The status will be set to 'invalid' if any of the specified requirements are not met. Storage of this message's parameters requires EEPROM. The contents of the Solution Validity Criteria Message are described in Table II-23.

**Table II-23. Message 1217: Solution Validity Criteria Message**

<b>Message ID:</b> 1217					
<b>Rate:</b> As required - maximum rate is 1 Hz					
<b>Message Length:</b> 13 words

7.0	Altitude Not Used	Bit		1 = required	
7.1	Differential GPS	Bit		1 = required	
7.2-7.15	Reserved				
8	Minimum Number of Satellites Used	UI		0 to 12	
9-10	Maximum Expected Horizontal Position Error	UDI	meters	0 to 1000	10 <sup>-2</sup>
11-12	Maximum Expected Vertical Position Error	UDI	meters	0 to 1000	10 <sup>-2</sup>
13	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.9 Antenna Type Select (Message 1218).** This message allows the user to specify the type of antenna which is being used with the receiver. Selecting 'Active Antenna Present' will raise the floor on the receiver's expected signal level to reduce sideband correlations. Deselecting it indicates use of

a passive antenna, allowing the receiver to be more sensitive to low signal levels and preventing it from searching "hot" signals. Storage for the Active Antenna Present parameter requires EEPROM. The contents of the Antenna Type Select Message are described in Table II-24.

**Table II-24. Message 1218: Antenna Type Select Message**

<b>Message ID:</b> 1218					
<b>Rate:</b> As required - maximum rate 1 Hz					
<b>Message Length:</b> 8 words

5	Header Checksum				
6	Sequence Number (Note 1)	I		0 to 32767	
7.0	Antenna Type	Bit		0 = passive 1 = active	
7.1-7.15	Reserved				
8	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.10 User-Entered Altitude Input (Message 1219).** This message allows the user to enter an altitude to be used for altitude hold during 2-D navigation. If the Force Use field is not set, the receiver may ignore the altitude input if it thinks it has a better estimate. Setting the Clear field will clear out the last estimate of altitude which the receiver uses for altitude hold. Setting the MSL Select field

allows entry of mean-sea-level altitude. A standard deviation can be specified to indicate the uncertainty associated with the entered altitude. The receiver will weight the altitude measurement according to this uncertainty. As a special case, a zero standard deviation indicates that the quality of the altitude is not known. The contents of the User-Entered Altitude Input Message are described in Table II-25.

**Table II-25. Message 1219: User-Entered Altitude Input Message**

<p><b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.</p> <p><b>Note 2:</b> For an altitude sensor that is supplying data in real-time, the OEM must ensure that bits 7.2 and 7.3 are set to zero so the altitude value will not be stored continuously in memory (RAM or EEPROM).</p>					

**2.2.11 Application Platform Control (Message 1220).** This message allows the user to adjust the receiver’s dynamics based on the type of application in which the receiver is being used. Storage for the

Platform parameter requires EEPROM. The contents of the Application Platform Control Message are described in Table II-26.

**Table II-26. Message 1220: Application Platform Control Message**

<b>Message ID:</b> 1220					
<b>Rate:</b> As required - maximum rate is 1 Hz					
<b>Message Length:</b> 8 words

8	Data Checksum				
<b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.					

**2.2.12 Nav Configuration (Message 1221).** This message allows the user to control various features in the navigation processing. The held altitude disable bit controls the use of stored GPS-based altitude to aid the receiver when the vertical geometry deteriorates. The ground track smoothing bit controls the use of satellite range bias estimates to minimize the position shifts resulting from SA and constellation changes. The position pinning bit

controls the use of a horizontal speed test to pin the position reported by the receiver and eliminate the wander associated with SA when static. Ground track smoothing and position pinning are not used when DGPS corrections are in use.. The contents of the Nav Configuration Message are described in Table II-27.

**Table II-27. Message 1221: Nav Configuration Message**

<p><b>Note 1:</b> The sequence number is a count that indicates whether the data in a particular binary message has been updated or changed since the last message output.</p> <p><b>Note 2:</b> Pre-scale and post-scale parameters are used to establish custom bps rates. The bps rate is equal to:  <math display="block">\text{CPU clock} / (16 \times \text{pre-scale} \times 2^{\text{post-scale}})</math></p>					

**2.2.16 Message Protocol Control (Message 1331).**

This message allows the user to set the message format protocol which will be used to communicate information to and from the receiver through the host serial I/O port. Currently, the available protocols are

binary (with fixed-point numbers) and NMEA-0183. Storage for the Protocol Type parameter requires EEPROM. The contents of the Message Protocol Control Message are described in Table II-31.

**Table II-31. Message 1331: Message Protocol Control Message**

### 3 ZODIAC NMEA DATA MESSAGES

This section describes the National Marine Electronics Association (NMEA) data messages of the Zodiac GPS receiver. All of the output and input NMEA messages are listed in Table III-1 together with their corresponding message IDs. Power-up default messages are also identified.

NMEA mode is selected according to the logic described in the hardware interface section of the *Zodiac GPS Receiver Family Designer's Guide*. NMEA messages are transmitted and received across the host port serial I/O interface (RS-232) with the following default communications parameters:

- 4800 bps
- 8 data bits
- no parity
- 1 stop bit

This interface conforms with the NMEA-0183, version 2.01, specification. All of the output NMEA messages are described in detail in section 3.1. All of the input NMEA messages are described in detail in section 3.2.

**Table III-1. Zodiac NMEA Data Messages**

<b>Output Message Name</b>	<b>Message ID</b>

**3.1.2 GPS Fix Data (GGA).** This message contains time, position, and fix related data for the Zodiac receiver. When a navigation solution passes all of the validity criteria (set using the binary Solution Validity Criteria message), a GGA message is generated automatically. Otherwise, if any of the

validity criteria are invalid for the solution, a GGA message is not generated.

The contents of the GGA Message are described in Table III-3.

**Table III-3. GGA Message: GPS Fix Data Message (1 of 2)**

<b>Message ID:</b>		GGA (while receiver is in Navigation Mode -- Note 1)		
<b>Rate:</b>		Variable; defaults to 1 Hz
