

# SL6440

## HIGH LEVEL MIXER

The SL6440 is a double balanced mixer intended for use in radio systems up to 150MHz. A special feature of the circuit allows external selection of the DC operating conditions by means of a resistor connected between pin 11 (bias) and Vcc. When biased for a supply current of 50mA the SL6440 offers a 3rd order intermodulation intercept point of typically +30dBm, a value previously unobtainable with integrated circuits. This makes the device suitable for many applications where diode ring mixers had previously been used and offers the advantages of a voltage gain, low local oscillator drive requirement and superior isolation.

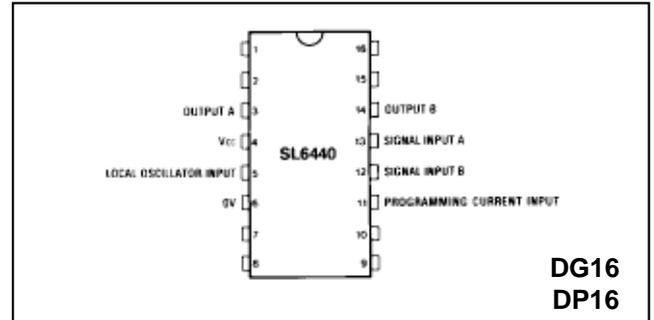

Fig.1 Pin connections - top view

### FEATURES

- +30dBm Input Intercept Point
- +15dBm Compression Point (1dB)
- Programmable Performance
- Full Military Temperature Range (SL644A)

### APPLICATIONS

- Mixers in Radio Transceivers
- Phase Comparators
- Modulators

### ORDERING INFORMATION

SL6440 A DG  
SL6440 C DP

### ABSOLUTE MAXIMUM RATINGS

Supply voltage and output pins	15V
Maximum power dissipation (Derate above 25°C: 8mW/°C)	1200mW
Storage temperature range	-65°C to +150°C
Programming current into pin 11	50mA

### THERMAL CHARACTERISTICS

Thermal resistance: $\theta_{JA}$	125°C/W
$\theta_{JC}$	
Time constant: Junction-Ambient	1.9 mins
Maximum chip temperature	150°C

### ELECTRICAL CHARACTERISTICS

Test conditions (unless otherwise stated):

V<sub>cc1</sub> = 12V; V<sub>cc2</sub> = 10V; I<sub>P</sub> = 25mA; T<sub>amb</sub> = -55°C to +125°C (SL6440A), -30°C to +85°C (SL6440C)  
Local oscillator input level = 0dBm; Test circuit Fig.2.

Characteristic	Value			Units	Conditions
	Min.	Typ.	Max.		
Signal frequency 3dB point	100	150		MHz	Two 0dBm input Signals V <sub>cc1</sub> = 15V V <sub>cc2</sub> = 12V V <sub>cc1</sub> = 12V V <sub>cc2</sub> = 10V Fig.8 test circuit 50Ω load Fig.2 Test circuit Fig.8 See applications information I <sub>P</sub> = 0  I <sub>P</sub> = 35mA  Single ended Differential

## CIRCUIT DESCRIPTION

The SL6440 is a high level mixer designed to have a linear RF performance. The linearity can be programmed using the IP pin (11).

The output pins are open collector outputs so that the conversion gain and output loads can be chosen for the specific application.

Since the outputs are open collectors they should be returned to a supply Vcc1 through a load.

The choice of Vcc1 is important since it must be ensured that the voltage on pins 3 and 14 is not low enough to saturate the output transistors and so limit the signal swing unnecessarily. If the voltage on pins 3 and 14 is always greater than Vcc2 the outputs will not saturate. The output frequency response will reduce as the output transistors near saturation.

$$\begin{aligned} \text{Minimum } V_{cc1} &= (I_P \times R_L) + V_S + V_{CC2} \\ \text{where } I_P &= \text{programmed current} \\ R_L &= \text{DC load resistance} \\ V_S &= \text{max signal swing at output} \end{aligned}$$

if the signal swing is not known:  
 $\text{minimum } V_{cc1} = 2 (I_P \times R_L) + V_{CC2}$

In this case the signal will be limiting at the input before the output saturates.

The device has a separate supply (Vcc2) for the oscillator buffer (pin 4).

The current ( $I_P$ ) programmed into pin 11 can be supplied via a resistor from Vcc1 or from a current source.

The conversion gain is equal to

$$\text{GdB} = 20 \text{ Log} \frac{R_L I_P}{56.61 I_P + 0.0785} \quad \text{for single-ended output}$$

$$\text{GdB} = 20 \text{ Log} \frac{2R_L I_P}{56.61 I_P + 0.0785} \quad \text{for differential output}$$

Device dissipation is calculated using the formula

$$\text{mW diss} = 2 I_P V_O + V_P I_P + V_{CC2} \text{ Diss}$$

where  $V_O$  = voltage on pin 3 or pin 14

$V_P$  = voltage on pin 11

$I_P$  = programmed current (mA)

$V_{CC2} \text{ Diss}$  = dissipation obtained from graph (Fig.6)

As an example Fig.7 shows typical dissipations assuming Vcc1 and  $V_O$  are equal. This may not be the case in practice and the device dissipation will have to be calculated for any particular application.

Fig.5 shows the intermodulation performance against  $I_P$ . The curves are independent of Vcc1 and Vcc2 but if Vcc1 becomes too low the output signal swing cannot be accommodated, and if Vcc2 becomes too low the circuit will not provide enough drive to sink the programmed current. Examples are shown of performance at various supply voltages.

The current in pin 14 is equal to the current in pin 3 which is equal to the current in pin 11.

**APPLICATIONS**

The SL6440 can be used with differential or single-ended inputs and outputs. A balanced input will give better carrier leak. The high input impedance allows step-up transformers to be used if desired, whilst high output impedance allows a choice of output impedance and conversion gain.

Fig. 2 shows the simplest application circuit. The input and output are single-ended and  $I_p$  is supplied from  $V_{cc1}$  via a resistor. Increasing  $R_L$  will increase the conversion gain, care being taken to choose a suitable value for  $V_{cc1}$ .

Fig. 8 shows an application with balanced input, for improved carrier leak, and balanced output for increased conversion gain. A lower  $V_{cc1}$  giving lower device dissipation can be used with this arrangement.

**DESIGN PROCEDURE**

1. Decide on input configuration using local oscillator data. If using transformer on input, decide on ratio from noise considerations.
2. Decide on output configuration and value of conversion gain required.
3. Decide on value of  $I_p$  and  $V_{cc2}$  using intermodulation and compression point graphs.
4. Using values of conversion gain,  $V_{cc2}$ , load and  $I_p$  already chosen, decide on value of  $V_{cc1}$ .
5. Calculate device dissipation and decide whether heatsink is required from maximum operating temperature considerations.
