1.0 GENERAL INFORMATION

1.1 PROGRAM ABSTRACT

The aztec front-end host diagnostic is a diagnostic program to test the aztec disk drive subsystem. Tests are performed to verify that:

a. The processor can properly communicate with the aztec through the adapter card.

b. The aztec can seek and head select properly.

c. The aztec conforms to the specified seek and rotational times.

d. The aztec can perform certain basic functions in response to mscp commands.

The aztec front-end/host diagnostic consists of one program that runs in the host processor and programs that run in the aztec controller's buffer memory through an interpreter called the "diagnostic machine" which resides in the aztec. The host processor program will be responsible for testing the aztec adapter, testing some of the drive functions, downline loading the "diagnostic machine" programs into the aztec and starting their execution. When the "diagnostic machine" programs are running, they will control the testing by requesting the host processor to supply information and print error messages. The "diagnostic machine" programs will inform the processor when a test is complete.

Up to four (4) aztec controllers with one or two spindles each may be selected for test by this diagnostic.

One aztec "unit" is defined as a single platter. There are two platters on one spindle in an aztec drive. an aztec controller may have either one or two drives (two or four platters). the unit numbers for the aztec platters come in pairs. the removable media has an even number and the fixed media has the sequentially following odd number.

Software parameter questions include number of retries in case of an error, whether to continue execution after failures, select seek area in the disk, select manual intervention test and set trace mode.

This diagnostic is divided into 6 modules:

module 0 - documentation

module 1 - literals, format statements, ascii text, global data, hardware configuration questions and default tables, software parameter questions and default table, initialization code, cleanup code, summary report code

module 2 - global routines

module 3 - tests 1 - 12 **base level**

module 4 - tests 9 _ 12 (dm code)

module 5 - last address and setup section

AZTEC0.R16 is a file containing literals and field delaraiions used throughout the program.

This diagnostic has been written for use with the diagnostic runtime services software (supervisor). These services provide the interface to the operator and to the software environment. This program can be used with XXDP+, ACT, APT, slide and paper tape. For a complete description of the runtime services, refer to the XXDP+ user's manual. There is a brief description of the runtime services in section 2 of this document.

1.2 SYSTEM REQUIREMENTS

PDP-11 Processor
28K Words of memory (minimum)
XXDP+ Load media
One or more aztec disk drive subsystems
Line clock - either type L or P
Console terminal

1.3 RELATED DOCUMENTS AND STANDARDS

AZTEC - RC25 Functional specification Rev 5, 3/9/82
Mass storage control protocol (MSCP) (version 1.0)
Unibus/Q-bus storage systems port (version 1.3)
Diagnostics and utilities protocol (R. Lary, May 1981)
Aztec diagnostic project plan
Diagnostic engineering functional specification for aztec
Resident diagnostics
XXDP+ User's manual

1.4 DIAGNOSTIC HIERARCY PREREQUISITES

The bus, host processor, memory, system clocks and console terminal are all assumed to be functioning properly when this diagnostic is run. If they are not, the result of running this program is unpredictable.

1.5 ASSUMPTIONS

An aztec that meets the specifications for diagnostic machine timing will meet the specifications for MSCP timing.

2.0 OPERATING INSTRUCTIONS

This section contains a brief description of the rurtime services. for detailed information, refer to the XXDP+ user's manual (CHQUS).

2.1 COMMANDS

There are eleven legal commands for the diagnostic runtime services (supervisor). This section lists the commands and gives a very brief description of them. The XXDP+ user's manual has more details.

COMMAND	EFFECT
START	Start the diagnostic from an initial state
RESTART	Start the diagnostic without initializing
CONTINUE	Continue at test that was interrupted (after ^C)
PROCEED	Continue from an error halt
EXIT	Return to XXDP+ monitor (XXDP+ operation only!)
ADD	Activate a unit for testing (all units are considered to be active at start time
DROP	Deactivate a unit
PRINT	Print statistical information (if implemented by the diagnostic - section 4.0)
DISPLAY	Type a list of all device information
FLAGS	Type the state of all flags (see section 2.3)
ZFLAGS	Clear all flags (see section 2.3)

A command can be recognized by the first three characters. So you may, for example, type "STA" instead of "START".

2.2 SWITCHES

There are several switches which are used to modify supervisor operation. These switches are appended to the legal commands. All of the legal switches are tabulated below with a brief description of each. In the descriptions below, a decimal number is designated by "DDDDD".

SWITCH	EFFECT
/TESTS:LIST	Execute only those tests specified in the list. List is a string of test numbers, for example - /TESTS:1:5:7-10. This list will cause tests 1,5,7,8,9,10 to be run. All other tests will not be run.
/PASS:DDDDD	Execute DDDDD passes (DDDDD = 1 to 64000)
/FLAGS:FLGS	Set specified flags. flags are described in section 2.3.
/EOP:DDDDD	Report end of pass message after every DDDDD passes only. (DDDDD = 1 to 64000)
/UNITS:LIST	TEST/ADD/DROP only those units specified in the list. List example - /UNITS:0:5:10-12 use units 0,5,10,11,12 (unit numbers = 0-63)

Example of switch usage:

START/TESTS:1-5/PASS:1000/EOP:100

The effect of this command will be:

1. Tests 1 through 5 will be executed.

2. All units will tested 1000 times.

3. The end of pass messages will be printed after each 100 passes only.

A Switch can be reccgnized by the first three characters. You may, for example, type "/TES:1-5" instead of "/TESTS:1-5".

Below is a table that specifies which switches can be used by each command.

	TESTS	PASS	FLAGS	EOP	UNITS
START	X	X	X	X	X
RESTART	X	X	X	X	X
CONTINUE		X	X	X	
PROCEED			X		
DROP					X
ADD					X
PRINT					
DISPLAY					X
FLAGS					
ZFLAGS					
EXIT					

2.3 FLAGS

Flags are used to set up certain operational parameters such as looping on error. All flags are cleared at startup and remain cleared until explicitly set using the flags switch. Flags are also cleared after a start command unless set using the flag switch. The ZFLAGS command may also be used to clear all flags. with the exception of the START and ZFLAGS commands, No commands affect the state of the flags; they remain set or cleared as specified by the last flag switch.

FLAG	EFFECT
HOE	Halt on error - control is returned to runtime services command mode
LOE	Loop on error
IER*	Inhibit all error reports
IBR*	Inhibit all error reports except first level (first level contains error type, number, PC, test and unit)
IXR*	Inhibit extended error reports (those called by PRINTX macro's)
PRI	Direct messages to line printer
PNT	Print test number as test executes
BOE	"BELL" on error
UAM	Unattended mode (no manual intervention)
ISR	Inhibit statistical reports (does not apply to diagnostics which do not support statistical reporting)
IDR	Inhibit program dropping of units
ADR	Execute autodrop code
LOT	Loop on test
EVL	Execute evaluation (on diagnostics which have evaluation support)

*error messages are described in section 3.1

See the XXDP+ user's manual for more details on flags. You may specify more than one flag with the flag switch. For example, to cause the program to loop on error, inhibit error reports and type a "BELL" on error, you may use the following string:

```
/FLAGS:LOE:IER:BOE
```

2.4 HARDWARE QUESTIONS

When a diagnostic is started, the runtime services will prompt the user for hardware information by typing "CHANGE HW (L) ?" you must answer "Y" after a start command unless the hardware information has been "preloaded" using the setup utility (see chapter 6 of the XXDP+ user's manual). When you answer this question with a "Y", the runtime services will ask for the number of units (IN DECIMAL). You will then be asked the following questions for each unit.

UNITS (D) ?

Answer wiith the number of units to be tested (no default). This answer will determine how many times the following questions are asked. A unit is a logical disk (single platter) on an aztec. One to sixteen units may be specified (maximum configuration of four controllers with four platters per controller).

IP ADDRESS (O) 172150 ?

Answer with the address of the IP register of one aztec controller as addressed by the processor with memory management turned off (i.e., an even 16-bit address in the range of 160000 to 177774.)

VECTOR (O) 154 ?

Answer with the interrupt vector address of the aztec controller. A vector address in the range of 4 to 774 may be specified.

BR LEVEL (D) 5?

Answer with the interrupt priority used by the aztec. levels 4 to 7 are accepted.

UNIT NUMBER(S) (D) 0 ?

answer with the physical platter number(s) for the platter(s) you wish to test (NO DEFAULT). The removable platter is an even number and the fixed platter is the sequentially followng odd number.

2.5 SOFTWARE QUESTIONS

After you have answered the hardware questions or after a restart or continue command, the runtime services will ask for software parameters. These parameters will govern some diagnostic specific operation modes. You will be prompted by "CHANGE SW (L) ?" if you wish to change any parameters, answer by typing "Y". The software questions and the default values are described in the next paragraph(s).

Use top surface for all single surface tests (L) Y ?
Answer yes to use top surface for all single surface testing.
answer no to use bottom surface for all single surface testing.

Do you wish to limit the area tested in tests #13 through #15 (L) N ?
Answer yes if you wish to specify a starting and ending track for the test area. this limitation applies only to seek verification testing, tests #13 through #15. The following two questions will be asked only if this one is answered yes.

Starting track (D) 0 ?

Answer with the beginning track number of the area you wish to select for testing. This applies to tests #13 through #15 only.

Ending track (d) 799 ?

Answer with the last track number in the area you wish to select for testing. This applies to tests #13 through #15 only.

Do you want to do the manual intervention test (L) Y ?

Answer yes to do the test of the write protect switches. Answer no to omit this test.

Do you need trace mode (L) Y ?

Answer no if you do not like the test names to be printed out.
Default is yes.

2.6 EXTENDED P-TABLE DIALOGUE

When you answer the hardware questions, you are building entries in a table that describes the devices under test. The simplest way to build this table is to answer all questions for each unit to be tested. If you have a multiplexed device such as a mass storage controller with several drives or a communication device with several lines, this becomes tedious since most of the answers are repetitious.

To illustrate a more efficient method, suppose you are testing a fictional device, the XY11. Suppose this device consists of a control module with eight units (sub-devices) attached to it. These units are described by the octal numbers 0 through 7. There is one hardware parameter that can vary among units called the Q-FACTOR. This Q-FACTOR may be 0 or 1. Below is a simple way to build a table for one xy11 with eight units.

```
# UNITS (D) ?  8<CR>

UNIT 1
CSR ADDRESS (O)  ?  160000<CR>
SUB-DEVICE # (O) ?  0<CR>
Q-FACTOR (O) 0   ?  1<CR>

UNIT 2
CSR ADDRESS (O)  ?  160000<CR>
SUB-DEVICE # (O) ?  1<CR>
Q-FACTOR (O) 1   ?  0<CR>
```

```
UNIT 3
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  2<CR>
Q-FACTOR (0) 0   ?  <CR>

UNIT 4
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  3<CR>
Q-FACTOR (0) 0   ?  <CR>

UNIT 5
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  4<CR>
Q-FACTOR (0) 0   ?  <CR>

UNIT 6
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  5<CR>
Q-FACTOR (0) 0   ?  <CR>

UNIT 7
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  6<CR>
Q-FACTOR (0) 0   ?  1<CR>

UNIT 8
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  7<CR>
Q-FACTOR (0) 1   ?  <CR>
```

Notice that the default value for the Q-FACTOR changes when a non-default response is given. Be careful when specifying multiple units!

As you can see from the above example, the hardware parameters do not vary significantly from unit to unit. The procedure shown is not very efficient.

The runtime services can take multiple unit specifications however. Let's build the same table using the multiple specification feature.

```
# UNITS (D) ?  8<CR>

UNIT 1
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  0,1<CR>
Q-FACTOR (0) 0   ?  1,0<CR>

UNIT 3
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  2-5<CR>
Q-FACTOR (0) 0   ?  0<CR>

UNIT 7
CSR ADDRESS (0)  ?  160000<CR>
SUB-DEVICE # (0) ?  6,7<CR>
Q-FACTOR (0) 0   ?  1<CR>
```

As you can see in the above dialogue, the runtime services will build as many entries as it can with the information given in any one pass through the questions. In the first pass, two entries are built since two sub-devices and Q-FACTORS were specified. The services assume that the CSR address is 160000 for both since it was specified only once. In the second pass, four entries were built. This is because four sub-devices were specified. The "-" construct tells the runtime services to increment the data from the first number to the second. In this case, sub-devices 2, 3, 4 and 5 were specified. (If the sub-device were specified by addresses, the increment would be by 2 since addresses must be on an even boundary.) The CSR addresses and Q-FACTORS for the four entries are assumed to be 160000 and 0 respectively since they were only specified once. The last two units are specified in the third pass.

The whole process could have been accomplished in one pass as shown below.

```
# UNITS (D) ?  8<CR>

UNIT 1
CSR ADDRESS (O)  ?  160000<CR>
SUB-DEVICE # (O) ?  0-7<CR>
Q-FACTOR (O) 0   ?  0,1,0,,,,1,1<CR>
```

As you can see from this example, null replies (commas enclosing a null field) tell the runtime services to repeat the last reply.

2.7 QUICK START-UP PROCEDURE (XXDP+)

To start-up this program:

1. Boot XXDP+
2. Give the date
3. Type "R Name", where name is the name of the bin or bic file for this program
4. Type "START"
5. Answer the "CHANGE HW" question with "Y"
6. Answer all the hardware questions
7. Answer the "CHANGE SW" question with "N"

When you follow this procedure you will be using only the defaults for flags and software parameters. These defaults are described in sections 2.3 and 2.5.

3.0 ERROR INFORMATION

3.1 TYPES OF ERROR MESSAGES

There are three levels of error messages that may be issued by a diagnostic: general, basic and extended. General error messages are always printed unless the "IER" flag is set (section 2.3). The general error message is of the form:

```
        Name  type  number  on unit number  tst number PC:XXXXXX
        error message

,where; NAME = Diagnostic name
        TYPE = Error type (SYS FATAL, DEV FATAL, HARD or SOFT)
        NUMBER = Error number
        UNIT NUMBER = 0 - N (N is last unit in ptable)
        TST NUMBER = Test and subtest where error occurred
        PC:XXXXXX = Address of error message call
```

Basic error messages are messages that contain some additional information about the error. These are always printed unless the "IER" or "IBR" flags are set (section 2.3). These messages are printed after the associated general message.

Extended error messages contain supplementary error information such as register contents or good/bad data. These are always printed unless the "IER", "IBR" or "IXR" flags are set (section 2.3). These messages are printed after the associated general error message and any associated basic error messages.

3.2 SPECIFIC ERROR MESSAGES

The following are device fatal error messages:

1) RCSA FAILED TO RESPOND
2) RCIP FAILED TO RESPOND
3) INIT STEP READ ERROR
   STEP MASK = XX FAILING REGISTER = DATA =
   XX = 1 - STEP 1 READ FAILURE
   XX = 2 - STEP 2 READ FAILURE
   XX = 4 - STEP 3 READ FAILURE
   XX = 10 - STEP 4 READ FAILURE

4) STEP READ DATA DOES NOT MATCH
   ADDRESS: EXPECTED: READ:

5) VECTOR AND BR LEVEL TEST FAILURE
6) INTERRUPT AT VEC= BR LEVEL=
7) NO INTERRUPT FROM PORT / CONTROLLER
8) BR LEVEL RECEIVED/TYPED IS INCORRECT !
9) HOST DETECTED TIME OUT ERROR
10) RING BUFFERS NOT CLEARED BY THE PORT
11) DATA ECHOED FROM RCSA DOES NOT MATCH
12) MEMORY BUFFER DOES NOT CONTAIN EXPECTED DATA
13) DM CODE RETURNED FAILURE CODE
14) RC25 UNIT DOES NOT COME ONLINE
15) EX_SUP_PROG DUP COMMAND FAILURE
16) SEND_DATA DUP COMMAND FAILURE
17) REC_DATA DUP COMMAND FAILURE

The following are self-detected fatal port/controller errors.
These will be reported as extended error messages when RCSA
data contains fatal error codes:

$FTLERR- UNRECOGNIZABLE ERROR CODE
$FTLERR- ENVELOPE/PACKET READ (PARITY OR TIMEOUT)
$FTLERR- ENVELOPE/PACKET WRITE (PARITY OR TIMEOUT)
$FTLERR- CONTROLLER ROM AND RAM PARITY
$FTLERR- CONTROLLER RAM PARITY
$FTLERR- CONTROLLER ROM PARITY

WRITE PROTECTED
COMPARE ERROR
DATA ERROR
HOST BUFFER ACCESS ERROR
CONTROLLER ERROR
DRIVE ERROR
MESSAGE FROM AN INTERNAL DIAGNOSTIC
```

4.0 PERFORMANCE AND PROGRESS REPORTS

At the end of each pass, the pass count is given along with the total number of errors reported since the diagnostic was started. The "EOP" switch can be used to control how often the end of pass message is printed. Section 2.2 describes switches.

5.0 DEVICE INFORMATION TABLES

The Supervisor builds one Hardware P_Table for every logical unit tested while answering Hardware P_table questions. This diagnostic gets one table at a time in sequence and runs diagnostic tests as selected. The P_table looks like this:

HWP_TABLE:

0	HWP_IP_ADDRESS
2	HWP_VECTOR
4	HWP_BR_LEVEL
6	HWP_UNIT_NUMBER

6.0 TEST SUMMARIES

A brief description of the tests done are described below:

TEST #1 REGISTER EXISTENCE TEST

This test will first check for the existence of the address of the IP and SA registers for the device under test. If these memory addresses are non-existent, the error will be reported.
If the operator has specified loop on error, looping will be from the beginning of each sub test.

TEST #2 INITALZATION TEST (POWER UP DIAGNOSTICS)

This test init's the aztec and runs the power up diagnostics by writing with step 1 data. Then it will check for errors and report if aztec does not come upto step 2 read.

TEST #3 DIAGNOSTIC WRAP TEST

The aztec will be initialized in diagnostic wrap mode and a one bit and also zero bit floated through the SA register to see that it echoes properly.

A failure to echo what was written will result in a callout to the adapter card fru.

If the operator has specified loop on error, the program will loop on the failing write and read.

TEST #4 - VECTOR AND BR LEVEL TEST

The init sequence will be started with the interrupt enable bit set to verify the aztec's vector and BR level.

This test assumes the vector given by the operator is correct.

The priority level of the interrupt request will be verified.

Failure of the aztec to vector properly will necessitate that this program be restarted. A completed interrupt at the wrong BR level will be reported.

Loop on error will restart this test if the error is recoverable.

TEST #5 STEP 1 -3 INITIALZATION TEST

This test will check for information echoed from the port at each step read coming upto that step from scratch. If there was an error reported or echoed information was incorrect the error will be reported. Loop on error will be from the beginning of sub test.

Port gives some information about the Port at every step read in RCSA Register. This information will be printed out to the operator as follows:

1) At step 1 read the following will be given:
PORT SPECIFIC INFO: /NV/QB/DI/OD/MP/ = xx (O)

NV = 1 means that the port does not support a host settable interrupt vector address
QB = 1 means that the Port supports a 22-bit host bus. This bit will be a 0 for unibus.
DI = 1 means that the Port implements enhanced diagnostics, i.e. wraparound, purge and poll tests.
OD = 1 means that the Port allows odd host address to be specified in the buffer descriptor.
MP = 1 means that the Port supports address mapping. The host supplies a virtual data address in the buffer descriptor which is mapped to a resultant address using mapping registers maintained in host memory.
xx Two digit octal value of the above right justified.

2) At step 2 read the following will be given:
PORT TYPE NUMBER = xx (O)

xx 0 means UNIBUS/QBUS storage systems port.

3) At step 4 read the following will be given:
MICRO CODE: MODEL = xx (O) VERSION = yy (O)

xx = 0 UDA50
1 RC25 Integrated Controller
5 TU81 Integrated Controller
6 UDA50A
7 QDRX01
yy = Mod 16 value of the actual controller microcode version.

TEST #6 PURGE AND POLL TEST

This test will perform the first three steps of the init sequence. When the host responds to the step 3 transition it will write a one bit to bit 15 of the SA register, therby requesting the execution of purge and poll testing. The host then waits for the SA register to transition to a zero value. The host then writes zeroes to the SA register simulating a "purge completed" host action. the host then reads the IP register to simulate a "start polling" command from the host to the port. The test is complete when the controller announces the transition to step 4 in the SA register.

Failure to properly complete this test will be reported.

Loop on error will restart the test.

TEST #7 - SMALL RING BUFFER INIT TEST

The aztec will be initialized without interrupts and using the smallest ring buffer. This will be the first time that the initialization sequence is carried out to completion. Initializing with the smallest ring buffer minimizes the host memory area with which the aztec controller must be able to communicate.

Failure to properly initialize the aztec and com_area will be reported.

If the operator has specified loop on error, looping will be from the start of this test.

TEST #8 - LARGE RING BUFFER INIT TEST

The init sequence is executed without interrupts with a ring buffer large enough to cover the normal host communciations area packet and buffer space (a 5 in message length and a 5 in command length).

A failure to complete the initialization sequence without error will be reported.

If the operator has specified loop on error, looping will be from the beginning of this test.

TEST #9 - "DIAGNOSTIC MACHINE" CODE DOWN LINE LOAD TEST

This "Diagnostic Machine" program will attempt to transfer a block of data from host memory to an area in the controller and then examine the transfered data.

If the transfered data does not compare correctly, then an error will be reported. This test also reports errors if any of the routines used returned failure code.

If the operator has specified loop on error, looping will be from the start of this test.

TEST #10 - NONEXISTENT MEMORY TEST

This 'Diagnostic Machine" program will attempt to read the first address of the I/O page of the host CPU. This location is reserved for diagnostics and a nxm should occur.

If the controller does not see the nxm, there will be a fru callout of the adapter card.

If the operator has specified loop on error, looping will be from the start of this test.

TEST #11 - BUS ADDRESSING/DATA TEST A

This 'Diagnostic Machine" program asks the PDP-11 program to fill free memory (that memory available to the PDP-11 program that is not being used by the program or the PDP-11 supervisor) with an addressing pattern (write address with address) and report the location and size of the free memory. Every location of free memory will be read and the data checked.

If the data does not compare correctly, the address, data expected and data received are reported.

TEST #12 - BUS ADDRESSING/DATA TEST B

This test first brings aztec drive Ready and Online and then loads DM_12 program vector to port controller memory, then does the following:

a. Give free memory address and buffer size to DM code and ask DM code write a pattern of one's complement of address at the address and expects to receive success or failure code from DM program. Then checks memory buffer for the expected pattern and reports error if encountered.

b. If success, asks DM code to write to memory a pattern of all ones and checks for the pattern in memory.

c. If success, asks DM code to write to memory a pattern of all zeroes and checks for the pattern in memory.

d. If failure, retries will be done as controlled by a software question. Loop on error flag will loop from beginning of test to the point of failure.

7.0 MAINTENANCE HISTORY

Modified By: Date: Version:

****
This is a base level release with tests 1 thru 12. A complete diagnostic with all 29 tests will be released in the following release cycle.

;        3762      global routine DECODE : novalue =          !Decodes failing SA reg data
;        3763
;        3764  !++
;        3765  ! Functional Description :
;        3766  !       Due  to the implimentation of the DUP  and UQ Port protocol there
;        3767  !       are  two levels  at which an issued command to  a port/controller
;        3768  !       can fail and they are:
;        3769  !
;        3770  !         1. The issued command can time out.
;        3771  !
;        3772  !         2. An  error  can be posted in SA register bit 15 by the port  to
;        3773  !            report an error.
;        3774  !
;        3775  !         3. The  issued  command  to  the port/controller can  be executed
;        3776  !            correctly without  any  errors but the response  packet status
;        3777  !            field could have an error or  status other than success posted.
;        3778  !
;        3779  !       This  routine  will  then be called when the return from a queued
;        3780  !       command  comes  back with an error code or non successfull status
;        3781  !       code.  This is  by  definition  when bit 0 in the returned status
;        3782  !       is equal to 1.
;        3783  !
;        3784  !

2272  ! TEST #6 - PURGE AND POLL TEST
2273  !
2274  ! DESCRIPTION:
2275  !
2276  !       THIS TEST WILL PERFORM THE FIRST THREE STEPS OF THE INIT SEQUENCE.
2277  !       WHEN THE HOST RESPONDS TO THE STEP 3 TRANSITION IT WILL WRITE A ONE
2278  !       BIT TO BIT 15 OF THE SA REGISTER, THERBY REQUESTING THE EXECUTION OF
2279  !       PURGE AND POLL TESTING.  THE HOST THEN WAITS FOR THE SA REGISTER TO
2280  !       TRANSITION TO A ZERO VALUE.  THE HOST THEN WRITES ZEROS TO THE SA
2281  !       REGISTER SIMULATING A "PURGE COMPLETED" HOST ACTION.  THE HOST THEN
2282  !       READS THE IP REGISTER  TO SMULATF A "START POLLING" COMMAND FROM THE
2283  !       HOST TO THE PORT.  THE TEST IS COMPLETE WHEN THE CONTROLLER ANNOUNCES
2284  !       THE TRANSITION TO STEP 4 IN THE SA REGISTER.
2285  !
2286  !       FAILURE TO PROPERLY COMPLETE THIS TEST WILL BE REPORTED.
2287  !
2288  !       LOOP ON ERROR WILL RESTART THE TEST.

2736  ! TEST #11 - BUS ADDRESSING/DATA TEST A
2737  !
2738  ! DESCRIPTION:
2739  !
2740  !       THIS "DIAGNOSTIC MACHINE" PROGRAM ASKS THE PDP-11 PROGRAM TO FILL FREE
2741  !       MEMORY (THAT MEMORY AVAILABLE TO THE PDP-11 PROGRAM THAT IS NOT BEING
2742  !       USED BY THE PROGRAM OR THE PDP-11 SUPERVISOR) WITH AN ADDRESSING
2743  !       PATTERN (WRITE ADDRESS WITH ADDRESS) AND REPORT THE LOCATION AND SIZE
2744  !       OF THE FREE MEMORY.  EVERY LOCATION OF FREE MEMORY WILL BE READ AND
2745  !       THE DATA CHECKED.
2746  !
2747  !       IF THE DATA DOES NOT COMPARE CORRECTLY, THE ADDRESS AND DATA
2748  !       EXPECTED ARE REPORTED.
2749  !

2861  ! TEST #12 - BUS ADDRESSING/DATA TEST B
2862  !
2863  ! DESCRIPTION:
2864  !
2865  !       THIS TEST FIRST BRINGS AZTEC DRIVE READY AND ONLINE AND THEN
2866  !       LOADS DM_12 PROGRAM VECTOR TO PORT CONTROLLER MEMORY. THEN
2867  !       DOES THE FOLLOWING:
2868  !
2869  !               A.  GIVE FREE MEMORY ADDRESS AND BUFFER SIZE TO DM CODE
2870  !                   AND ASK DM CODE WRITE A PATTERN OF ONE'S COMPLEMENT
2871  !                   OF ADDRESS AT THE ADDRESS AND EXPECTS TO RECEIVE
2872  !                   SUCCESS OR FAILURE CODE FROM DM PROGRAM. THEN CHECKS
2873  !                   MEMORY BUFFER FOR THE EXPECTED PATTERN AND REPORTS
2874  !                   ERROR IF ENCOUNTERED.
2875  !
2876  !               B.  IF SUCCESS, ASKS DM CODE TO WRITE TO MEMORY A PATTERN
2877  !                   OF ALL ONES AND CHECKS FOR THE PATTERN IN MEMORY.
2878  !
2879  !               C.  IF SUCCESS, ASKS DM CODE TO WRITE TO MEMORY A PATTERN
2880  !                   OF ALL ZEROES AND CHECKS FOR THE PATTERN IN MEMORY.
2881  !
2882  !               IF OPERATOR ASKS FOR RETRIES THE WHOLE TEST WILL BE RETRIED
2883  !               ONLY IF FAILURE ENCOUNTERED.
