ILLUSTRATIONS AND TABLES

SECTION 1

CALIBRATION

1.1 INTRODUCTION

1.1.1 General

The purpose of calibration is to take account of any long-term drifts in the components of the instrument and to restore the accuracy, traceable to a known standard.

The period between calibrations depends upon the accuracy performance required from the instrument and for guidance, guaranteed accuracies for 24 hours, 90 days and 1 year are quoted.

The calibration procedures presented in the following pages should cater for most calibration situations. If, however, a special problem arises, please contact our Customer Service Section.

1.1.2 The Essentials for Good Calibration

Temperature - So that the instrument can meet its specification over the quoted temperature range, the temperature environment should be stabilised at 23°C ± 1°C. In addition, temperature gradients around the instrument should be considered, therefore calibrate the instrument in its normal operating position and allow plenty of room for ventilation.

Warm up - It is essential that the instrument has fully temperature stabilised if the best results from calibration are to be achieved. Therefore, at least a 2 hour warm-up period is recommended during which time the line supply or the covers should not be removed even for a short period. In addition, if the covers have been removed, make certain that they are correctly fitted and that the leaf contacts to the Earth and Guard Shields are in good shape.

Calibration Source - To perform a useful calibration the accuracy of the source should always be at least four times that of the instrument being calibrated. In most cases, examples of likely sources are given for each calibration function.

With some calibration sources, the output may take several seconds to settle to a final value, therefore unless a shorter settling time is assured, a period of 10 seconds is recommended before each calibration operation.

Guarding - It is preferable to arrange for the DVM to be calibrated with 'Guard' connected to 'Lo' at the DVM. Furthermore to arrange for the 'Lo' terminal of the DVM to remain at 'earth' throughout and let the calibration source float. If the front panel input terminals are used then 'Guard' is permanently connected to 'Lo' internally. If 'Rear' panel input is selected then 'Guard' can either be connected locally or remotely. If a remote guard connection is desirable then examples are shown in the User's Handbook.

1.1.3 The 'AUTOCAL' Process

1.1.3.1 General

The Datron 'AUTOCAL' process means that complete calibration of AC, DC and Ohms on every range can be carried out from the instrument's own front panel. In the process, an internal non-volatile memory stores calibration constants for each function and range as determined when the instrument takes a series of 16 readings of the applied calibration source. Internally, each of the readings is deviated by one sixteenth of a digit and when an average is taken, the instrument is able to resolve to better than one least significant digit displayed.

Access to the non-volatile memory is gained using a key inserted into the rear panel. When calibration is complete, the key is removed, therefore preventing accidental or unauthorised use of the calibration routine.

1.1.3.2 Procedure Outline

- Select the 'FUNCTION' and 'RANGE' to be calibrated.

- If the instrument is to be manually calibrated, set the rear panel address switch to 31, i.e. all 1's.

- Insert the key into the 'CALIBRATE ENABLE' keyswitch on the rear panel and turn to the 'CAL' position. (The 'Cal' legend will be displayed on the front panel, the operation of the keys in the 'MODE' group changes to that indicated above the keys and the 'MODE' functions are automatically cancelled).

- Connect the calibration source to the input terminals and operate the keys shown in the tables in the following pages. When a calibration key in the 'MODE' group is operated, its associated L.E.D. indication will light and will go out when the calibration operation is executed.

- When all calibration is complete, turn the keyswitch to 'RUN' and remove the key.

1.1.3.3 The Five Calibration Keys

When the instrument is in the calibration mode of operation, as described in the procedure outlined above, the five keys in the front panel 'MODE' group operate as labelled above the keys.

'Zero' - This takes account of offsets in the instrument and in the calibration source.

'Gain' - This sets a scaling factor for each range and function.

'AcHf' - This flattens the response of the A.C. amplifier used for AC voltage measurement. It should only be used when a full calibration i.e. 'Zero', 'Gain' and 'AcHf' is carried out. The calibration action is iterative and requires several operations of the key to complete.

'Lin' - This is an important calibration operation as it optimises the basic linearity of the internal measurement circuitry used for all ranges and functions. It must be used before any DC voltage or Ohms calibration is carried out.

'Keyboard' - This is an extension of the 'AUTOCAL' process which is useful when using a calibration source set to a nominal value but with known errors. This means for example that calibration directly to a standard cell is possible. A full explanation of the procedure is covered in section 1.5.

1.1.3.5 'AUTOCAL' over the Bus

Each of the five calibration operations can be controlled using the IEEE bus. This means that the instrument can be entirely calibrated remotely or under program control. As mentioned in the 'Procedure Outline' for a manual calibration, the rear panel address switch should be set to 31, i.e. all 1's. When a bus calibration is required the address switch must be set to the address number assigned to the DVM in the system. More details of calibration with the bus are included in section 1.6.

1.1.3.6 'Err 4'

If during calibration 'Err 4' is displayed, this indicates that the Calibration Source deviates too far from the calibration span of the instrument. Under these circumstances, the calibration memory is not updated and the calibration key LED remains on.

In the case of 'Zero', 'Gain' or 'AcHf' the Calibration Source should be checked and the same Calibration key repressed. If 'Err 4' follows 'Lin' or persistently appears following 'Zero', 'Gain' or 'AcHf' then an instrument failure may have occurred. Therefore either consult our Customer Service Section or the Servicing Section of this Handbook.

1.2 DC VOLTAGE CALIBRATION

1.2.1 General

The procedure in the tables opposite is all that is necessary to completely 'AUTOCAL' the DC voltage function. Steps 1 and 2 affect the accuracy on all ranges and should therefore be carried out even if just one range is being calibrated.

On each range a 'Zero' and 'Gain' calibration is required for each polarity of input. The two 'Zero' calibrations are included to overcome a possible zero difference with the polarity setting of the DC calibration source.

If the 'DVM Reading After Calibration' is not in accordance with the table, repeat operations of the same Calibrate key are permissible. Where no tolerance is shown in this column, only the exact reading quoted with an occasional least significant digit showing is to be expected.

1.2.2 Equipment Required

- A copper shorting link.

- A DC Calibration Source. e.g. — Datron 4000 Autocal Standard.

1.2.3 Checking Accuracy after 'AUTOCAL'

To check the accuracy after 'AUTOCAL' the 'Specification Verification' section of the User's Handbook will be useful; it provides tables for quick reference of accuracy on all ranges and functions in displayed digits.

DC VOLTAGE CALIBRATION

5½ DIGIT

Step	Calibration Operation	Calibration Source Output	DVM Setting	Calibrate Key	DVM Reading After Calibration	Remarks
1	Linearity	Copper shorting link	DC,10 Filter	'Lin'	<10 digits	This calibration step may take around 30 seconds to complete
2	10V Range Zero	+0.0000V	DC,10	'Zero'	±0.0000V	
3	10V Positive Full Range	+10.0000V	DC,10	'Gain'	+10.0000V	
4	10V Range Zero	−0.0000V	DC,10	'Zero'	±0.0000V	
5	10V Negative Full Range	−10.0000V	DC,10	'Gain'	−10.0000V	
6	1V Range Zero	+0.00000V	DC,1	'Zero'	±.00000V	
7	1V Positive Full Range	+1.00000V	DC,1	'Gain'	+1.00000V	
8	1V Range Zero	−0.00000V	DC,1	'Zero'	±.00000V	
9	1V Negative Full Range	−1.00000V	DC,1	'Gain'	−1.00000V	
10	.1V Range Zero	+0.000mV	DC,.1	'Zero'	±0.000mV ±1 digit	Wait for the reading to stabilize before operating 'Zero'
11	.1V Positive Full Range	+100.000mV	DC,.1	'Gain'	+100.000V ±1 digit	
12	.1V Range Zero	−0.000mV	DC,.1	'Zero'	±0.000mV ±1 digit	Wait for the reading to stabilize before operating 'Zero'
13	.1V Negative Full Range	−100.000mV	DC,.1	'Gain'	−100.000V ±1 digit	
14	100V Range Zero	+0.000V	DC,100	'Zero'	±0.000V	
15	100V Positive Full Range	+100.000V	DC,100	'Gain'	+100.000V	
16	100V Range Zero	−0.000V	DC,100	'Zero'	±0.000V	
17	100V Negative Full Range	−100.000V	DC,100	'Gain'	−100.000V	
18	1000V Range Zero	+0.00V	DC,1000	'Zero'	±0.00V	
19	1000V Positive Full Range	+1000.00V	DC,1000	'Gain'	+1000.00V	⚡ Lethal voltages present - increase calibration source in 100V steps if possible
20	1000V Range Zero	−0.00V	DC,1000	'Zero'	±0.00V	
21	1000V Negative Full Range	−1000.00V	DC,1000	'Gain'	−1000.00V	⚡ Lethal voltages present - increase calibration source in 100V steps if possible

6½ DIGIT (1065A only -- "Filter" selected)

Step	Calibration Operation	Calibration Source Output	DVM Setting	Calibrate Key	DVM Reading After Calibration	Remarks
1	Linearity	Copper shorting link	DC,10 Filter	'Lin'	< 100 digits	This calibration step may take around 30 seconds to complete
2	10V Range Zero	+0.0000V	DC,10 Filter	'Zero'	±0.00000V ±4 digits	
3	10V Positive Full Range	+10.0000V	DC,10 Filter	'Gain'	+10.00000V ±4 digits	
4	10V Range Zero	−0.0000V	DC,10 Filter	'Zero'	±0.00000V ±4 digits	
5	10V Negative Full Range	−10.0000V	DC,10 Filter	'Gain'	−10.00000V ±4 digits	
6	1V Range Zero	+0.00000V	DC,1 Filter	'Zero'	±.000000V ±4 digits	
7	1V Positive Full Range	+1.00000V	DC,1 Filter	'Gain'	+1.000000 ±4 digits	
8	1V Range Zero	−0.00000V	DC,1 Filter	'Zero'	±.000000V ±4 digits	
9	1V Negative Full Range	−1.00000V	DC,1 Filter	'Gain'	−1.000000V ±4 digits	
10	.1V Range Zero	+0.000mV	DC,.1 Filter	'Zero'	±0.0000mV ±10 digits	Wait for the reading to stabilize before operating 'Zero'
11	.1V Positive Full Range	+100.000mV	DC,.1 Filter	'Gain'	+100.0000mV ±10 digits	
12	.1V Range Zero	−0.000mV	DC,.1 Filter	'Zero'	±0.0000mV ±10 digits	Wait for the reading to stabilize before operating 'Zero'
13	.1V Negative Full Range	−100.000mV	DC,.1 Filter	'Gain'	−100.0000mV ±10 digits	
14	100V Range Zero	+0.000V	DC,100 Filter	'Zero'	±0.0000V ±4 digits	
15	100V Positive Full Range	+100.000V	DC,100 Filter	'Gain'	+100.0000V ±10 digits	
16	100V Range Zero	−0.000V	DC,100 Filter	'Zero'	±0.0000V ±4 digits	
17	100V Negative Full Range	−100.000V	DC,100 Filter	'Gain'	−100.0000V ±10 digits	
18	1000V Range Zero	+0.00V	DC,1000 Filter	'Zero'	±0.000V ±4 digits	
19	1000V Positive Full Range	+1000.00V	DC,1000 Filter	'Gain'	+1000.000V ±10 digits	⚡ Lethal voltages present - increase calibration source in 100V steps if possible
20	1000V Range Zero	−0.00V	DC,1000 Filter	'Zero'	±0.000V ±4 digits	
21	1000V Negative Full Range	−1000.00V	DC,1000 Filter	'Gain'	−1000.000V ±10 digits	⚡ Lethal voltages present - increase calibration source in 100V steps if possible

1.3 OHMS CALIBRATION

1.3.1 General

The procedure in the tables opposite is all that is necessary to completely 'AUTOCAL' the Ohms function. If just the Ohms or just one range of the Ohms is to be calibrated, then step 1 in the DC Voltage Calibration table should be carried out first. Then on each Ohms range just a 'Zero' and 'Gain' calibration is required.

If the 'DVM Reading After Calibration' is not in accordance with the table, repeat operations of the same Calibration key are permissible to improve the reading. Where no tolerance is shown in this column, only the exact reading quoted with an occasional least significant digit showing is to be expected.

1.3.2 'Zero Resistance Source

For accurate 'Zero' calibration on Ohms it is ESSENTIAL that a correctly connected zero source is used.

Figures 1.1 and 1.2 show the connections for front and rear panel input respectively. It can be seen that two arrangements are necessary depending upon the value of the standard Resistor source being used.

It should be noted that a 4 wire connection is recommended throughout.

1.3.3 Equipment Required

Datron 4000 Autocal Standard or a set of resistance standards from 100Ω to 10MΩ in decades; it is essential that 100Ω to 100kΩ standards are 4 terminal devices.

1.3.4 Checking Accuracy after 'AUTOCAL'

To check the accuracy after 'AUTOCAL' the 'Specification Verification' section of the Operating Handbook will be useful. It provides tables for quick reference of accuracy on all ranges and functions in displayed digits.

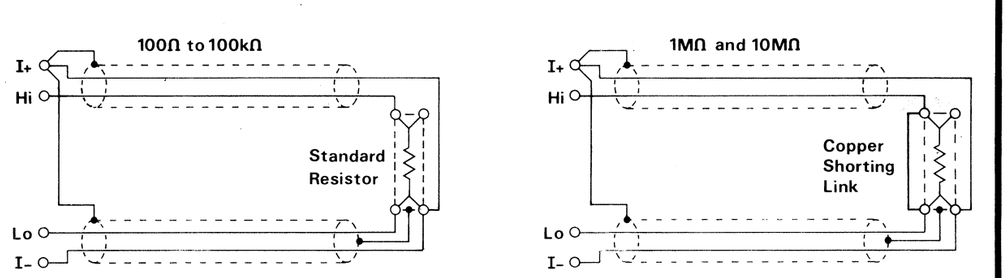

Fig.1.1 ZERO RESISTANCE SOURCE CONNECTIONS USING FRONT PANEL INPUT

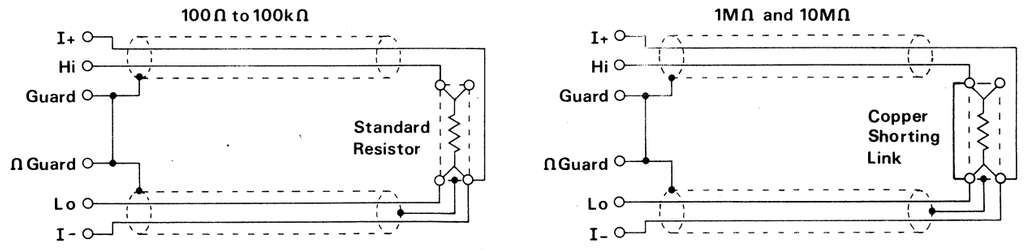

Fig.1.2 ZERO RESISTANCE SOURCE CONNECTIONS USING REAR PANEL INPUT

OHMS CALIBRATION TABLE

5½ DIGIT

Step	Calibration Operation	Calibration Source	DVM Setting	Calibrate Key	DVM Reading After Calibration	Remarks
1	.1kΩ Range Zero	4 wire zero	kΩ, .1	'Zero'	±0.000Ω	Wait for the reading to stabilize before operating 'Zero'
2	.1kΩ Full Range	100Ω [1] Standard Resistor	kΩ, .1	'Gain'	100.000Ω	Wait for the reading to stabilize before operating 'Gain'
3	1kΩ Range Zero	4 wire zero	kΩ, 1	'Zero'	±.00000kΩ	
4	1kΩ Full Range	1kΩ [1] Standard Resistor	kΩ, 1	'Gain'	1.00000kΩ	
5	10kΩ Range Zero	4 wire zero	kΩ, 10	'Zero'	±0.0000kΩ	
6	10kΩ Full Range	10kΩ [1] Standard Resistor	kΩ, 10	'Gain'	10.0000kΩ	
7	100kΩ Range Zero	4 wire zero	kΩ, 100	'Zero'	±0.000kΩ	
8	100kΩ Full Range	100kΩ [1] Standard Resistor	kΩ, 100	'Gain'	100.000kΩ	
9	1000kΩ Range Zero	4 wire zero	kΩ, 1000, Filter	'Zero'	±0.00kΩ	
10	1000kΩ Full Range	1000kΩ [1] Standard Resistor	kΩ, 1000, Filter	'Gain'	1000.00kΩ ±3 digits	
11	10MΩ Range Zero	4 wire zero	kΩ, 10MΩ, Filter	'Zero'	±0.0000MΩ	
12	10MΩ Full Range	10MΩ [1] Standard Resistor	kΩ, 10MΩ, Filter	'Gain'	10.0000MΩ ±5 digits	

[1] - With Standard Resistor sources it may be useful to use the 'Keyboard' method of calibration - see section 1.5

6½ DIGIT (1065A only – "Filter" selected)

Step	Calibration Operation	Calibration Source	DVM Setting	Calibrate Key	DVM Reading After Calibration	Remarks
1	.1kΩ Range Zero	4 wire zero	kΩ, .1 Filter	'Zero'	±0.0000Ω ±10 digits	Wait for the reading to stabilize before operating 'Zero'
2	.1kΩ Full Range	100Ω [1] Standard Resistor	kΩ, .1 Filter	'Gain'	100.0000Ω ±10 digits	Wait for the reading to stabilize before operating 'Gain'
3	1kΩ Range Zero	4 wire zero	kΩ, 1 Filter	'Zero'	±.000000kΩ ±4 digits	
4	1kΩ Full Range	1kΩ [1] Standard Resistor	kΩ, 1 Filter	'Gain'	1.000000kΩ ±4 digits	
5	10kΩ Range Zero	4 wire zero	kΩ, 10 Filter	'Zero'	±0.00000kΩ ±4 digits	
6	10kΩ Full Range	10kΩ [1] Standard Resistor	kΩ, 10 Filter	'Gain'	10.00000kΩ ±4 digits	
7	100kΩ Range Zero	4 wire zero	kΩ, 100 Filter	'Zero'	±0.0000kΩ ±4 digits	
8	100kΩ Full Range	100kΩ [1] Standard Resistor	kΩ, 100 Filter	'Gain'	100.0000kΩ ±10 digits	
9	1000kΩ Range Zero	4 wire zero	kΩ, 1000, Filter	'Zero'	±0.000kΩ ±4 digits	
10	1000kΩ Full Range	1000kΩ [1] Standard Resistor	kΩ, 1000, Filter	'Gain'	1000.000kΩ ±30 digits	
11	10MΩ Range Zero	4 wire zero	kΩ, 10MΩ, Filter	'Zero'	±0.00000MΩ ±4 digits	
12	10MΩ Full Range	10MΩ [1] Standard Resistor	kΩ, 10MΩ, Filter	'Gain'	10.00000MΩ ±50 digits	

[1] - With Standard Resistor sources it may be useful to use the 'Keyboard' method of calibration - see section 1.5

1.4 AC VOLTAGE CALIBRATION

1.4.1 General

The procedure in the table opposite is all that is necessary to completely 'AUTOCAL' the AC voltage function. On each range just a 'Zero', 'Gain' and 'AcHf' calibration is required.

If the 'DVM Reading After Calibration' is not in accordance with the table, repeat operation of the same Calibration key is permissible to improve the readings. This will be necessary with the AcHf key.

1.4.2 Equipment Required

A copper shorting link and an AC calibration source e.g. Fluke 5200A and 5215A.

1.4.3 Checking Accuracy after 'AUTOCAL'

To check the accuracy after 'AUTOCAL' the 'Specification Verification' section of the User's Handbook will be useful. It provides tables for quick reference of accuracy on all ranges and functions in displayed digits.

AC VOLTAGE CALIBRATION TABLE

Step	Calibration Operation	Calibration Source Output	DVM Setting	Calibrate Key	DVM Reading After Calibration	Remarks
1	1V Range Zero	Copper shorting link	AC,1	'Zero'	.00000V ±1 digit	Do not select 'Filter'. Wait for reading to stabilize before operating 'Zero'
2	10V Range Zero	Copper shorting link	AC,10	'Zero'	0.0000V ±1 digit	
3	100V Range Zero	Copper shorting link	AC,100	'Zero'	0.000V ±1 digit	
4	1000V Range Zero	Copper shorting link	AC,1000	'Zero'	0.00V ±1 digit	
5	10V Full Range LF	10V rms 500 Hz	AC,10, Filter	'Gain'	10.0000V ±1 digit	Select 'Filter for remaining steps
6	10V Full Range HF	10V rms 30 kHz	AC,10, Filter	'AcHf'	10.0000V ±10 digits	
7	1V Full Range LF	1V rms 500Hz	AC,1, Filter	'Gain'	1.00000V ±1 digit	
8	1V Full Range HF	1V rms 30 kHz	AC,1, Filter	'AcHf'	1.00000V ±10 digits	
9	100V Full Range LF	100V rms 500 Hz	AC,100, Filter	'Gain'	100.000V ±1 digit	
10	100V Full Range HF	100V rms 30 kHz	AC,100, Filter	'AcHf'	100.000V ±10 digits	
11	1000V Full Range LF	1000V rms 500 Hz	AC,1000, Filter	'Gain'	1000.00V ±1 digit	⚡ Lethal voltage present - increase calibration source in 100V steps if possible
12	1000V Full Range HF	1000V rms 10 kHz	AC,1000, Filter	'AcHf'	1000.00V ±20 digits	⚡ Lethal voltage present - increase calibration source in 100V steps if possible. DO NOT EXCEED 25 kHz

1.5 CALIBRATION USING 'Keyboard'

1.5.1 General

The 'Keyboard' method of calibration is useful when a calibration source although set to a nominal value has known errors. In this situation the known value of the calibration source can be entered into the DVM before the 'AUTOCAL' process is executed. The process is functional during any calibration with a source of magnitude between 20% and 200% of the range selected, but it should be noted that for equal magnitude source errors, calibrating at the lower percentage end of range produces a higher percentage calibration error. The 'Keyboard' method operates for both the 'Gain' and AcHf' calibration operations. An example using 'Keyboard' to calibrate directly against a Standard Cell is shown in the table below.

When 'Keyboard' is selected the operation of the 'RANGE', 'INPUT' and 'FUNCTION' keys changes to the numeric, decimal point, polarity and clear labels shown on the front of the instrument.

1.5.2 'Keyboard' with Negative Inputs

If the 'KEYBOARD' method is used on DC Voltage calibration with Negative polarity sources, it is important NOT to enter a negative sign with the keyed-in source value. The instrument itself can determine the polarity of the source and update the appropriate calibration memory location.

CALIBRATION EXAMPLE USING 'KEYBOARD'

Step	Calibration Operation	Calibration Source Setting	DVM Setting	Calibrate Key	DVM Reading After Calibration	Remarks
1	1V Range Zero	Short-circuit	DC,1	'Zero'	±.00000V	Short connecting leads at Standard Cell end
2	Connect Standard Cell	Standard Cell	'Keyboard'	–	0	
3	Enter Standard Cell Voltage	Standard Cell	1,·,0,1,8,1,6	–	+1.01816	
4	1V Range Calibration	Standard Cell	–	'Gain'	+1.01816	

1.6 'AUTOCAL' OVER THE BUS

All the calibration procedures covered in this handbook can be carried out remotely using the IEEE Bus.

Effectively, the five calibration keys are replaced by five Bus instructions and these are used instead of the Calibration keys listed in the Calibration tables on previous pages.

An example of calibration with the Bus is given in the table below. A complete program listing for the same calibration operation assuming an HP9825 controller is as follows:—

```
Ø: dim D$[15]          define 15 character string variable
1:  clr 728            send 'device clear' to DVM (interface 7, address 28)
2: wrt 728,"F3R3Q1W1="  program to DC 1V, SRQ Mode 1, Enable Cal.
3: Ø→S
4: wrt 728,"GØ="       program zero cal. trigger
5: oni 7,"srq"         jump to SRQ service routine on interrupt
6: eir 7,128           enable SRQ interrupts from interface 7
7: if bit ("Ø1XXXXXX",S) check status byte S
   =Ø;jmp -1           obtained by service routine
8: dsp "Apply 1V &     prompt operator to apply
   CONTINUE"           calibration source on completing zero cal
9: Ø→S;stp
10: wrt 728,"G1="      program gain cal. trigger
11: oni 7,"srq"
12: eir 7,128
13: if bit ("Ø1XXXXXX",S)
   =Ø;jmp -1
14: wrt 728,"TØWØ="    program to Internal Trigger, Disable Cal. on completion of gain cal.
15: lcl 728            program DVM to local state
16: stp
17: "srq":rds(728)→S   SRQ service routine to read status byte
18: red 728,D$
19: iret
*7717
```

CALIBRATION EXAMPLE USING THE BUS

Step	Calibration Operation	Calibration Source	DVM Setting	Bus Controller Instruction	DVM Reading After Calibration	Remarks
1	Set DVM to known state	—	In Remote State	'Device Clear'	—	Program DVM to predetermined state CØDXEØF3NØ OØQØRSØT1
2	Set DVM to DCV, 1V Range, and prepare for calibration	+0.00000V	Calibration key to 'CAL'	'F3R3Q1W1='	—	Program DVM to Function: DC V(F3) Range: 1V (R3) SRQ Mode 1 (Q1) Enable Cal. (W1)

SECTION 2

MECHANICAL DESCRIPTION

2.1 GENERAL

The 1065 has been designed to be either rack mounted in a standard 19" rack (3½" (2U) height required) or bench top/portable with integral tilt stand. An exploded view of the instrument is shown in Fig. 2.1.

2.2 FRONT PANEL

The front panel incorporates the signal input terminals, input, function, mode and power switches and a numeric/legend gas discharge display.

2.3 REAR PANEL

The rear panel incorporates the power cable input plug and fuse, the IEEE Bus connector and address selection switch, the rear signal input plug, the run/calibrate keyswitch and the calibration interval select switch.

2.4 EXTERNAL CONSTRUCTION

An overlay adheres to the front panel, it labels the keys and retains a polarising filter in front of the display. Both the front and rear panels are held together by two side extrusions running from front to rear. These provide slots for the rack mounting 'ears' and locating points for the structural foam covers. The bottom cover is fitted with a tilt-stand and rubber feet. Earth screening of the covers and guarding is provided by aluminium plates, heat-staked to the inside of the covers with electrical connections made by spring contacts.

2.5 INTERNAL CONSTRUCTION

An internal chassis is constructed from four printed circuit boards, held together by connectors at each corner and held rigid by two inner aluminium shields fixed horizontally on the instrument's centre line running from front to rear. Input terminals, switches and display are mounted on the front printed circuit board (pcb) and the power supply on the rear pcb. The side and centre pcb's are used for interconnections between the main circuit boards.

All the main circuit boards are mounted on the inner shields with hinges and quick release fasteners with flexible connections to allow operation in the 'hinged-up' position.

The chassis is mounted on to the side extrusions with nylon screws, spacers and an insulation sheet to ensure that the 'electrical spacings' of the BSI, UL and VDE specifications are achieved.

SECTION 3

TECHNICAL DESCRIPTION

3.1 INTRODUCTION

The internal circuits of the instrument are built onto eight printed circuit board assemblies shown in Fig. 3.1.

Each of these assemblies will be described in turn by subdividing the circuit into separate blocks with a detailed explanation. This should assist servicing to component level.

3.2 DC ANALOG ASSEMBLY (Circuit Drawing No. 430421)

The DC Analog assembly is split into three distinct sections: (i) the Analog Interface, (ii) the DC Isolator and (iii) the Analog to Digital (A - D) Converter.

The Analog Interface receives data from the Digital assembly to control the selection of function, range and other features of the analog circuitry. Messages between the Analog and Digital assemblies are passed via opto-isolators, electrically isolating one from the other.

The DC Isolator includes the preamplifier, range scaling circuits and bootstrapped supplies. The A - D section converts the scaled input signal to a time period proportional to the signal using a modified triple slope technique.

3.2.1 Analog Interface (430421 sheet 5)

3.2.1.1 Introduction

The Analog Interface provides electrical isolation between the Digital and Analog circuitry. Latched data from the microprocessor is passed through opto-isolators, decoded and latched again on an analog assembly to select function, range, test, average and the D - A converter set up conditions.

3.2.1.2 Power-On

At power-on the A - D converter is placed into the RESET condition (See Section 3.2.3.8). The analog circuitry is placed into the DC, 1000V range until another range or function is selected (See Fig. 3.3).

In the description which follows (ID) is used to describe an Analog Interface Data line signal which drives the opto-isolators from the digital assembly. (IA) describes an Analog Interface Address line signal.

For both ID and IA:

logic '1' ≡ + 5 volts
logic '0' ≡ 0 volts

Firstly, all assemblies are deselected by placing logic '1's on all the ID lines, then setting the IAØ and IA1 lines low (see Fig. 3.4), clocking the function select latches (M20 Analog assembly, M5 AC assembly, M9 Ohms assembly, M1 Rear assembly from M17-3). Both IA lines then return high. Secondly, the latches of the D - A converter (M13, M14) are reset. The ID lines are set to logic '0' and clocked on to M13 and M14 by a delayed low to high edge from M17-4, originating from IAØ going low. The delay makes sure that the signal from M17-10 has disabled the "F.E.T." latch M21. Once again, the IAØ line returns to the resting state of logic '1'. Thirdly, the DC analog circuits are enabled by setting all the ID lines except for ID0, then clocking M20 by a low to high edge from M16-6 caused by both IA lines going low. Once DC has been selected, the F.E.T. pattern latch is enabled from M12-1, and the penultimate step is to load this latch with 1000V range data from the ID lines (ID4 low, the rest high). This is executed by clocking the 'F.E.T.' latch from M17-4 once again, but this time being due to IA1 going low. The final step is to reselect DC as described above.

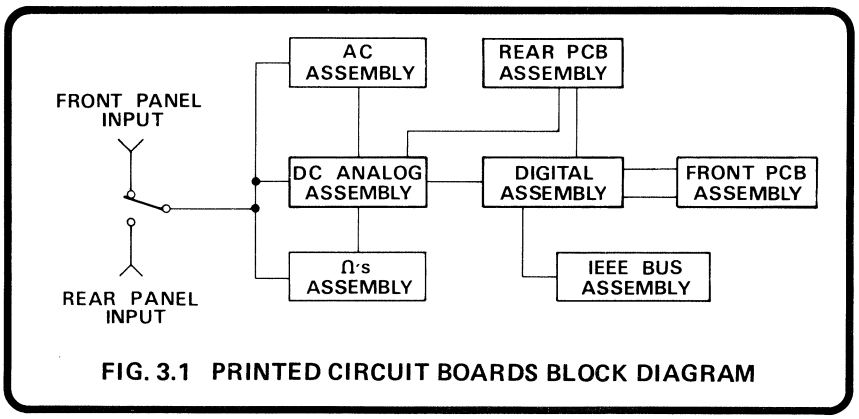

FIG. 3.1 PRINTED CIRCUIT BOARDS BLOCK DIAGRAM

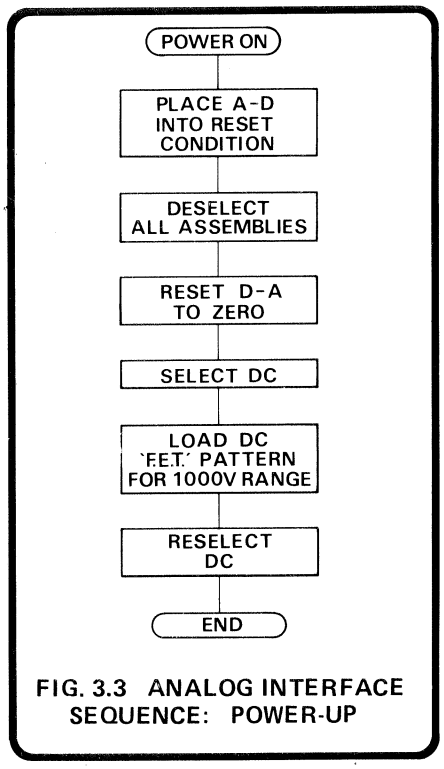

FIG. 3.3 ANALOG INTERFACE SEQUENCE: POWER-UP

3.2.1.3 General Interface Update Sequence

Before the start of each reading, the analog interface undergoes a complete update. The series of events is the same as the power-up sequence for selection of function and range, as can be seen by comparing the two flowcharts (Figs. 3.3 and 3.5). When Ohms is selected, the DC Isolator is also used in the measurement procedure as seen in the following table.

Type of Measurement	Circuits Selected	Use of D - A
DC Volts	Analog Assembly	Not used
AC Volts	AC Assembly	Frequency Compensation
AC + DC Volts	AC Assembly	Frequency Compensation
Resistance	Ohms Assembly and Analog Assembly	Not used

The update sequence order is (i) Deselect all assemblies, (ii) Load D - A latches, (iii) Select AC assembly or DC Isolator, (iv) Load range pattern into DC or AC range latches, (v) Deselect DC or AC and select the Ohms assembly, (vi) Load range pattern into Ω's latch, (vii) Reselect circuits selected in (iii) and (iv).

Note: Steps (v) and (vi) are used only when Ω's is selected.

Flowchart 3.5 gives the above sequence for an ohms update. The general form of the timing diagram for the above sequence is given in Fig. 3.6, the analog 'F.E.T.' patterns for each range of each function being given in Appendix 1.

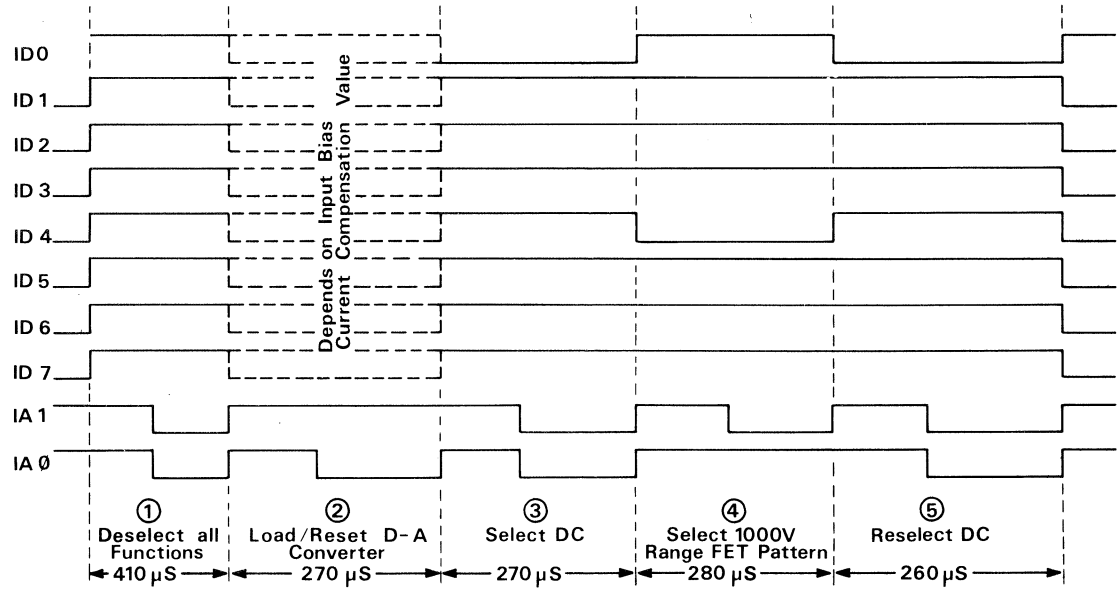

FIG. 3.4 ANALOG INTERFACE DATA LINE TIMING DIAGRAM (POWER-UP)

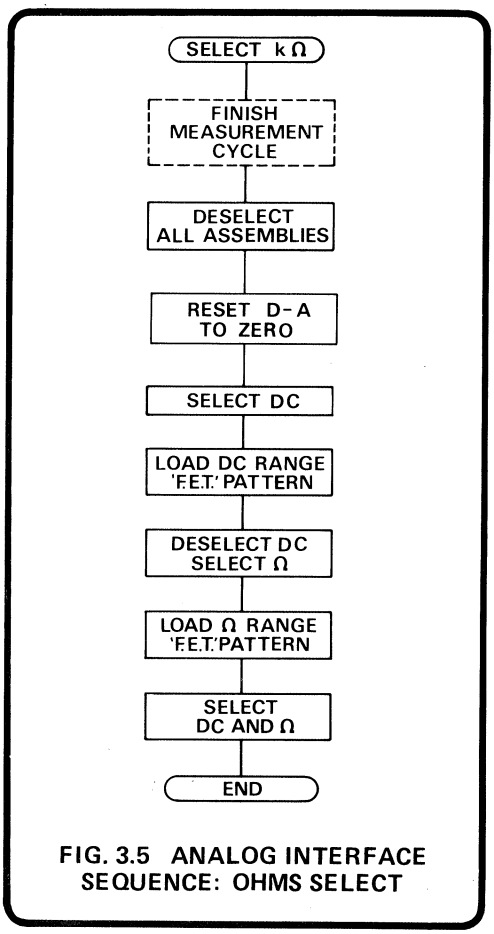

FIG. 3.5 ANALOG INTERFACE SEQUENCE: OHMS SELECT

3.2.1.4 Test

When TEST is selected, a logic '0' is placed on ID7 at stages (iii), (v) and (vii) in Fig. 3.6, i.e. each time a function measurement circuit is selected. Appendix I lists the 'F.E.T.' patterns of each assembly for each test measurement cycle.

3.2.2 DC Isolator Section

3.2.2.1 Preamplifier Scaling (430421 sheet 1)

Figure 3.8 shows the essential features of the isolator scaling circuit. For the purpose of explanation the same symbols are used, regardless of whether the switching is accomplished electronically (F.E.T.) or by means of relay contacts. In Fig. 3.8 all switches are shown in the 1V RANGE position.

The various switching combinations for the different ranges are as follows:—

Range	Gain	Q6	Q7	Q8	Q9	Q10	RL1
100mV	x31.6	ON	OFF	ON	OFF	OFF	ON
1V	x3.16	OFF	OFF	ON	OFF	ON	ON
10V	÷3.16	OFF	ON	OFF	ON	OFF	ON
100V	÷31.6	OFF	OFF	ON	OFF	ON	OFF
1000V	÷316	OFF	ON	OFF	ON	OFF	OFF
$\overline{DC}$		OFF	OFF	OFF	ON	OFF	OFF

The configuration of the circuit for each range is shown in Fig. 3.9.

Reference should be made to circuit diagram number 430421, sheet 1, for the complete circuit. Sheet 2 gives tables of the coding on the input control lines (from the Analog Interface).

When the 100V or 1kV range is selected, a ÷100, 10MΩ input attenuator (R143, R156, R149, R148) is incorporated into the circuit. This is a matched set of resistors for low temperature coefficient. The selection of a lower range energizes relay RL1 (via Q33), causing resistor chain R119-R122 to be in series with the Hi input. Should an overload signal then be applied, the resistor chain limits the current and the power dissipation is such that 1000V can be applied continuously.

The amplifier end of the resistors is clamped by zener diodes D22, D23 and Q18, Q19 to low, thus the amplifier input can never exceed approximately ± 24 volts.

The output from the DC Isolator, test point (TP13) is approximately 3.16 volts ($\approx\sqrt{10}$) for a full range (100,000) input by the following methods (See Fig. 3.9):—

100mV Range — Q6 and Q8 are turned on; all other F.E.T.'s are turned off and RL1 energised. Thus the output of the amplifier is connected to its inverting input via R108, R109, R110, R111 and Q6, an attenuator chain of ÷31.6, giving the amplifier an overall gain of X 31.6 Q8 connects the preamplifier directly to the output.

1V Range — Q10 and Q8 are turned on, all other F.E.T.'s are turned off and RL1 energised. The output of the amplifier is connected to its inverting input via R108, R109, R110, R111 and Q10, an attenuator chain of ÷3.16, giving the amplifier an overall gain of X 3.16. Q8 connects the preamplifier directly to the output.

10 V Range — Q9 and Q7 are turned on; all other F.E.T.'s are turned off and RL1 energised. Q9 causes the amplifier output to be directly connected to its inverting input, giving a gain of unity. The output of the amplifier is attenuated by 3.16 (R114, R115) before being passed to the output via Q7 instead of Q8.

100V and 1000V Ranges — These two ranges select the 1V and 10V ranges respectively but a ÷100 attenuator (R149, R156, R143, R148) is inserted between Hi and the preamplifier input when RL1 is de-energised.

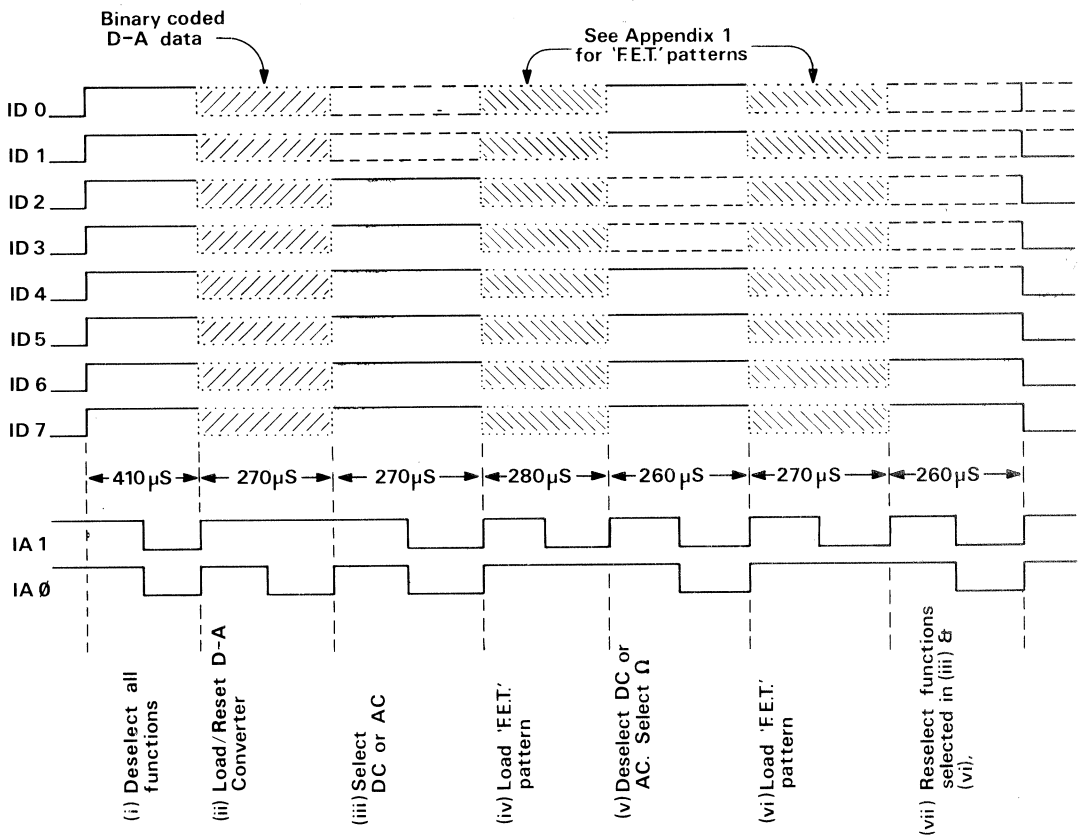

FIG. 3.6 GENERAL FORM OF ANALOG INTERFACE UPDATE TIMING DIAGRAM

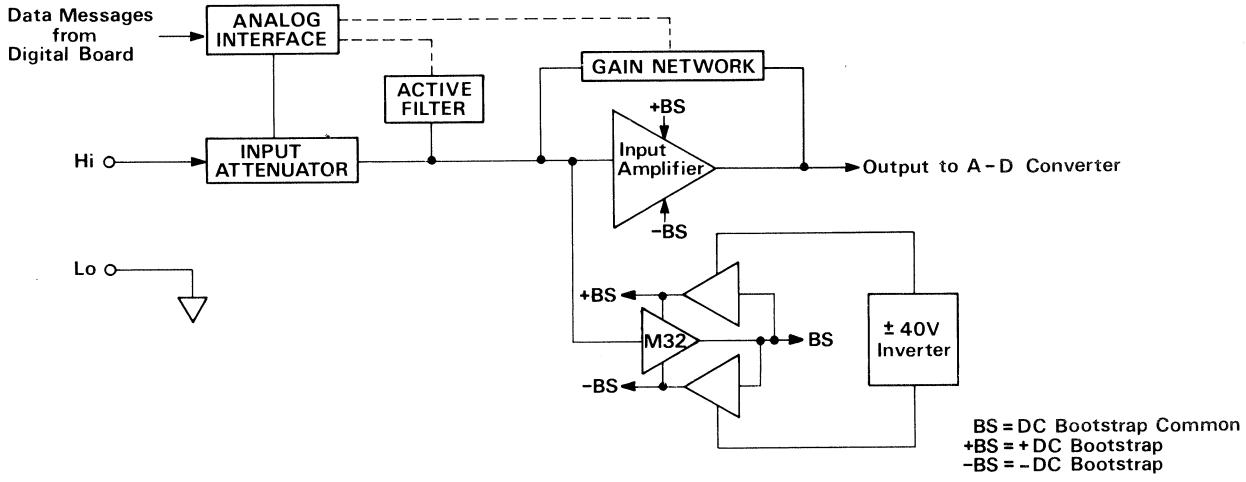

FIG. 3.7 SIMPLIFIED DIAGRAM OF DC ISOLATOR

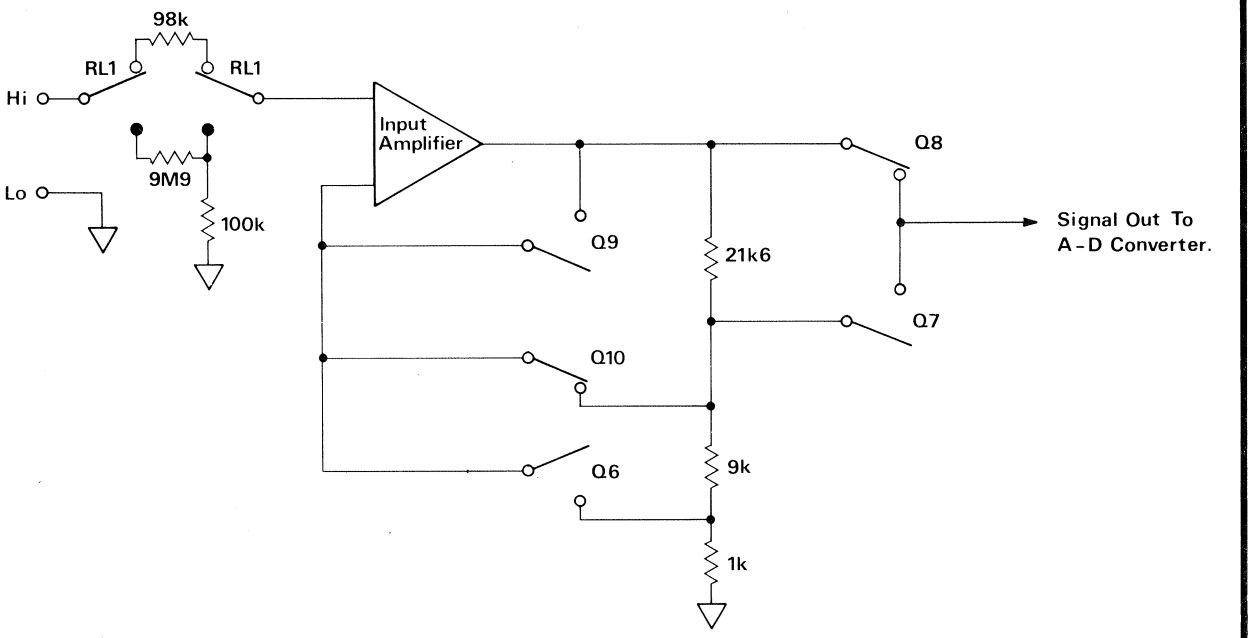

FIG. 3.8 SIMPLIFIED DIAGRAM OF ISOLATOR SWITCHING

3.2.2.2 Preamplifier (430421 sheet 1)

The preamplifier is designed to present an input impedance of greater than 10,000MΩ for signals up to ±20 volts. It is also bootstrapped (tracking of both ground lines and supply voltages with input signal) being essential for correct operation of input bias compensation, temperature compensation and common mode rejection.

Q12 is a well matched monolithic NPN transistor pair exhibiting minimal voltage drift and low noise characteristics, the output being buffered by M31. The input bias current is compensated as described in 3.2.2.5.

3.2.2.3 D.C. Bootstrap (430421 sheet 2)

Bootstrapped supplies are generated which track the input signal directly (BS), track the input signal with a positive offset of +12V(+BS) and track the input signal with a negative offset of −12(−BS).

M32 is the high impedance buffer which tracks the inverting input of the preamplifier. The offset of M32 is adjusted so that its input is within 100μV of the input of the preamplifier. M32 thus functions as the low impedance rail (BS) following the input signal.

Selection of DC(M20-3) enables the capacitive inverter driven from M33 to provide an unregulated +42V(TL4) and −42V(TL5) supply from the ±15V supply.

The positive bootstrap supply (+BS) is generated as a current source comprising Q26 and the shunt regulator, Q27, referenced to D50. When the output voltage of the regulator is approximately 1.2 volts above D50 cathode, Q27 conducts current into R175. Since the current in R175 is controlled to be constant by Q30, referenced to D50, the current flowing through R174 is reduced. Hence the supply current, "mirrored" in R173, is reduced and the output voltage controlled.

The negative bootstrap supply (−BS) is generated in a similar manner. Thus bootstrapped supplies of approximately ±12 volts are produced, tracking the input signal exactly.

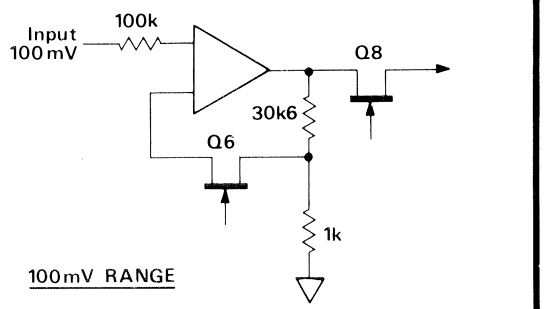
3.2.2.4 Filtering (430421 sheet 1)

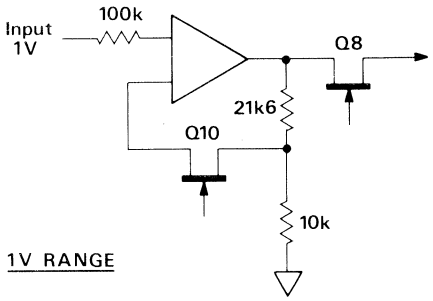
Selection of filter causes an active filter to be switched in by relay, R12, (via Q32). The filter gives an attenuation of −34 dB at 50Hz. The essential components of the filter are shown in Fig. 3.10.

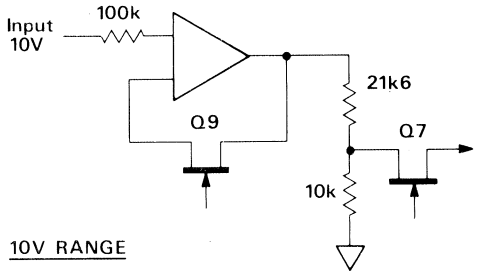
3.2.2.5 Input Bias Current Compensation (430421 sheets 1 and 5)

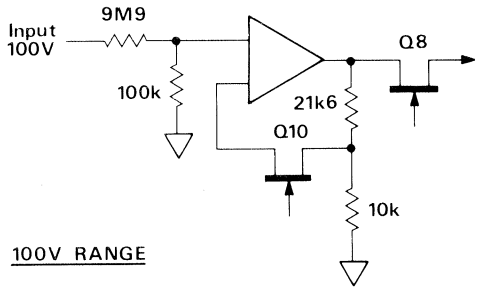
To avoid taking current for the input bias of Q12 through the input attenuator and therefore from the source being measured, network R152, R153, R159 and R128 provides this current from the internal bootstrap supplies. R159 is adjusted to reduce the current in R144 to less than 10pA.

Since the gain of Q12 varies with temperature, without any further form of compensation, the bias current of Q12 will change and pass current through R144. To avoid this and maintain the input bias current of Q12 constant with temperature, the emitter current is made to vary with temperature using network R123, R126 and R135 in conjunction with the base-emitter temperature sensitivity of Q12, see Fig. 3.11.









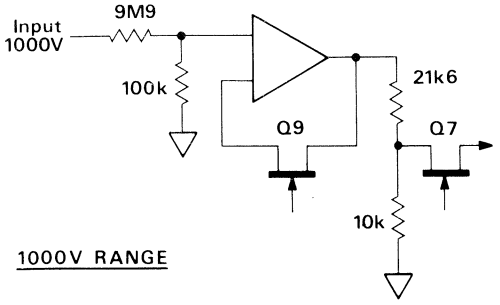


FIG. 3.9 PREAMPLIFIER GAIN CIRCUITS

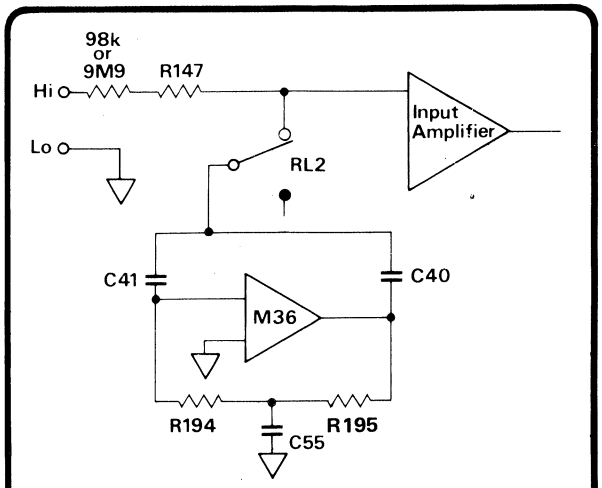

FIG. 3.10 SIMPLIFIED DC ISOLATOR FILTERING CIRCUIT

3.2.2.6 Test (430421 sheets 1 and 5)

During the self-test routine, (actuated from the front panel or remotely programmed) the DC isolator is checked for correct operation. The circuitry is placed into the 0.1V range, as described in 3.2.1.3, except that relay RL1 is not energized, (i.e. the ÷ 100 attenuator is across the input amplifier). Filter is selected and F.E.T. Q5 'closed' via M20-5 causing a small signal to be injected into the feedback path of the input amplifier. Thus a signal of −3.125 volts is output from the DC Isolator (TP13). This signal is then measured and compared with a stored value. If the measured signal is within ±6% of the stored value, the test continues with a 1V range check and a 10V range check.

Range	Output signal from DC Isolator (TP13)
0.1V	− 3.125 volts
1V	− 0.2193 volts
10V	− 0.06932 volts

DC Isolator Output Test Voltages

3.2.3 Analog to Digital Conversion (Analog Section) (430421 sheets 3 and 4)

3.2.3.1 General Principles

Section 1 and Fig. 1.2 of the User's Handbook gives a very basic description of the principles of the integration involved. The technique used in the Autocal Voltmeter is a quadruple slope, the two extra slopes being towards the end of the signal and reference integration periods respectively.

Fig. 3.12 is a simplified diagram showing the essentials of the analog section of the A - D conversion and should be used with timing diagram Fig. 3.13 for full appreciation of the circuit operation.

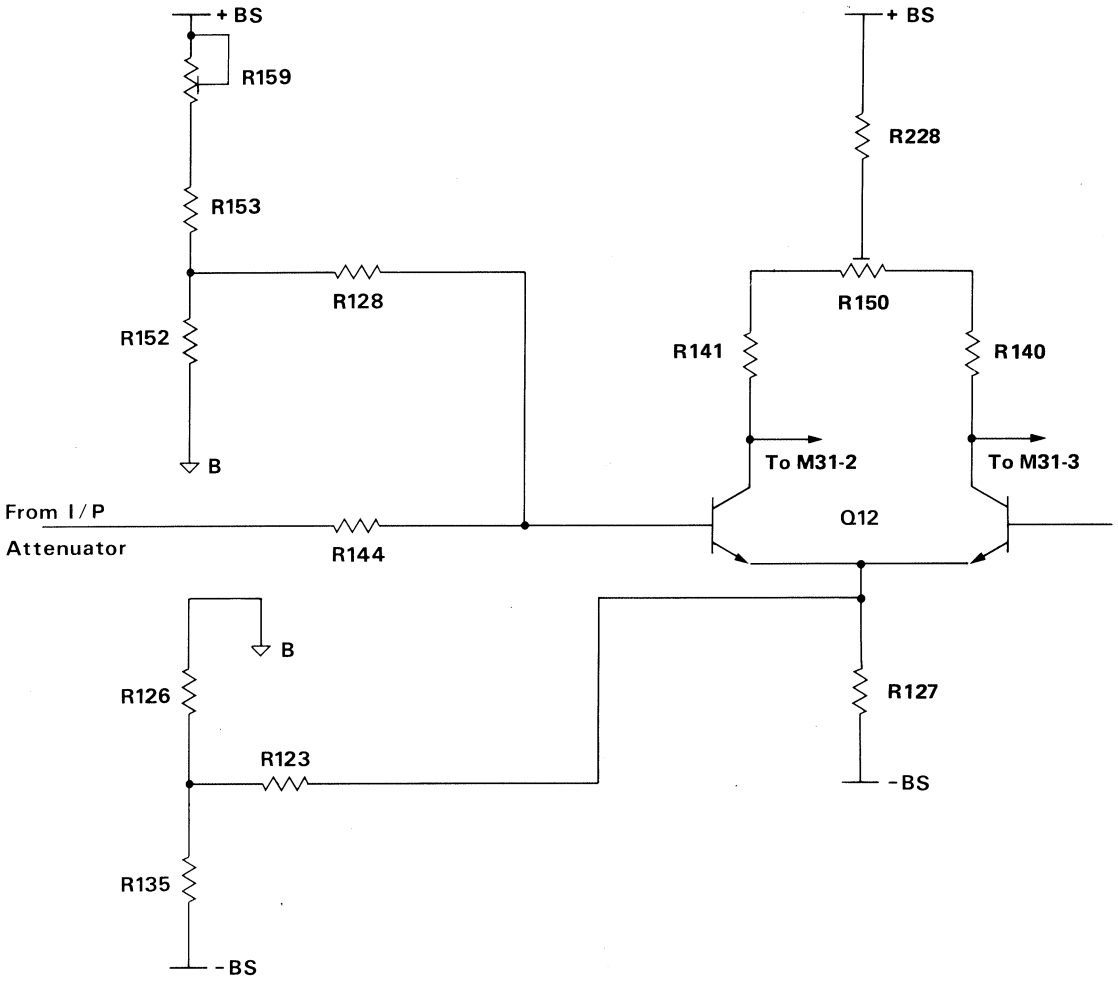

Fig. 3.11 PREAMPLIFIER INPUT BIAS CURRENT COMPENSATION

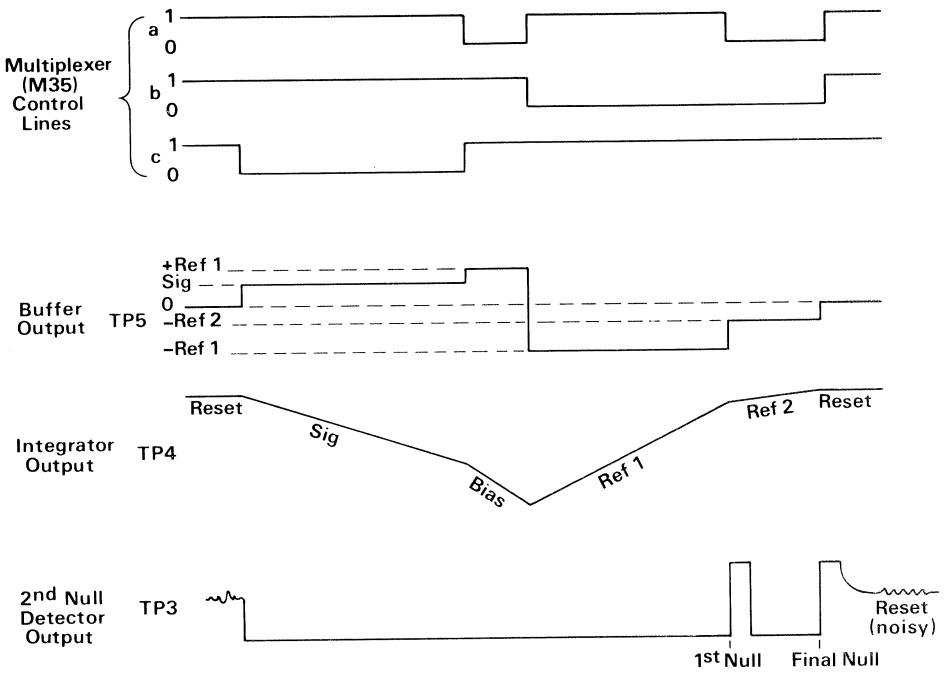

FIG. 3.13 TIMING DIAGRAM FOR ANALOG SECTION OF A – D CONVERTER (Positive Signal)

Timing is not to scale, Bias & Ref. 2 periods being very short compared with Sig & Ref.1

3.2.3.2 A - D Input Control

The analog signal from the DC Isolator is applied to the analog multiplexer (M35) and fed to the input of the buffer (Q36/M34). This in turn feeds the signal to the integrator comprising of Q35, M25 and C9.

Control of the multiplexer is derived from the Digital assembly via opto-isolators M4, M5 and M6. These signals control the sequence of events, allowing first the signal, then a bias voltage of the same polarity as the signal, followed by opposite polarity reference and reference ÷16 signals to the buffer and integrator. The multiplexer is then placed in a reset condition ready for the next measurement cycle. Fig. 3.14 gives the multiplexer control line sequence for both positive and negative signals.

STATE	a	b	c	STATE	a	b	c
RESET	1	1	1	RESET	1	1	1
SIG	1	1	0	SIG	1	1	0
+ BIAS	0	1	1	–BIAS	0	1	0
–REF 1	1	0	1	+REF 1	1	0	0
–REF 2	0	0	1	+REF 2	0	0	0
RESET	1	1	1	RESET	1	1	1

Positive signal — Negative signal

Logic levels : (0 ≡ –8V, 1 ≡ +8V)

Fig 3.14 MULTIPLEXER CONTROL LINE SIGNALS

3.2.3.3 Reference Voltages and Control Logic Power Supply

REF 1 : The two halves of M39 in conjunction with zener diodes D60 and D59 form the positive and negative reference voltages respectively, D65 and D64 being 'start-up' diodes (see Fig. 3.15). The outputs of M39 (+11 and –11 volts) supply the defined current for the reference zeners via R212 and R38 respectively. R19 and R18 are selected by Datron so that each zener has very low voltage temperature coefficient.

The resistor chains R41-R43 and R88-R90 are binary weighted values allowing the set up of the exact nominal REF 1 voltages, of ±6.42V, by cutting the appropriate links.

REF 2 : The second reference is 1/16th of REF 1. The positive and negative REF 1 voltages are divided by R71, R68 and R214, R70 respectively.

The power supplies for the logic circuits M35, M29, M27, M28 and opto-isolators M1, M4, M5 and M6 are also derived from M39 via zener diodes D61 and D62, giving supply voltages of ±8 volts.

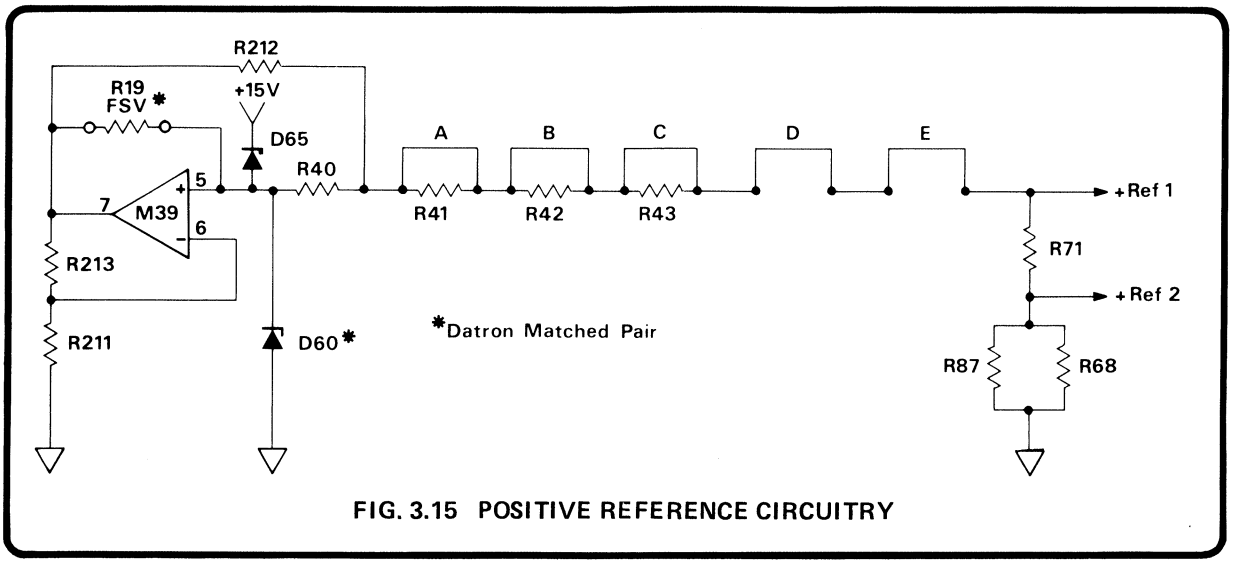

FIG. 3.15 POSITIVE REFERENCE CIRCUITRY

3.2.3.4 High Speed Buffer

C22 slows the switching edges from the multiplexer M35 so that the buffer cannot slew-limit and thus lose the charge. The signals are fed to Q36, M34 which comprise a high speed buffer with high common mode rejection ratio (See Fig. 3.16). The common mode rejection is dependent on the power supplies of Q36 (from R66 and R11-R15) being bootstrapped to the output of the buffer, via D2 and D4. Thus the difference between input signal and power supply around the input stage is maintained constant whatever the input signal.

Q2 and Q3 boosts the gain of Q36 by allowing the drains to see a high load resistance.

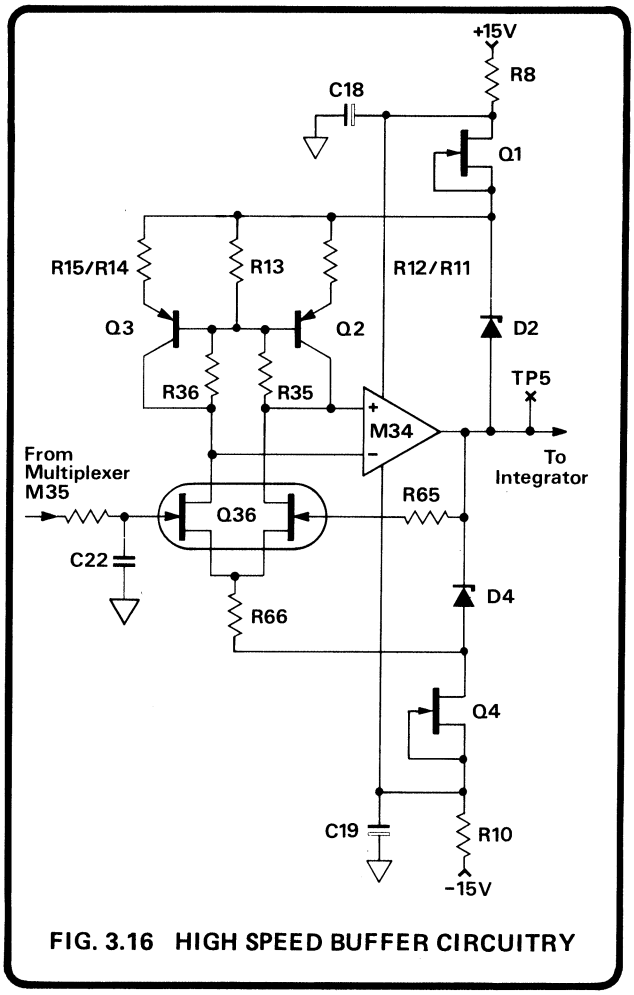

FIG. 3.16 HIGH SPEED BUFFER CIRCUITRY

3.2.3.5 Integrator

The Integrator basically comprises an amplifier made up from Q35 and M25 with a charge storing capacitor C9 (See Fig. 3.17). The low gate leakage F.E.T. pair, Q35, boosts the gain of the integrator such that it is great enough to guarantee no non-linearity errors due to finite gain.

R4, C10 driven by an attenuated and inverted version of the integrator-output waveform, via R26 and R5, form a circuit to compensate for the small amount of dielectric absorption present in C9.

C11, R23 and R27 provide similar compensation but in this case the time constant is such that it effects the linearity, with R23 set to correct linearity at 1/10th of full range.

3.2.3.6 1st Null Detector

The 1st null detector comprises a low noise amplifier, M22, an inverting configuration, where the dc gain is controlled by the ratio of R59 to R28 for small inputs. For larger inputs from the integrator the clamp diodes, D1 and D3, prevent the amplifier from saturating.

During REF 1 the non-inverting input is offset by approximately 10mV to determine the point at which REF 2 is applied (after counting is synchronised). In REF 2 the offset reduces by a factor of 16 giving the null reference point.

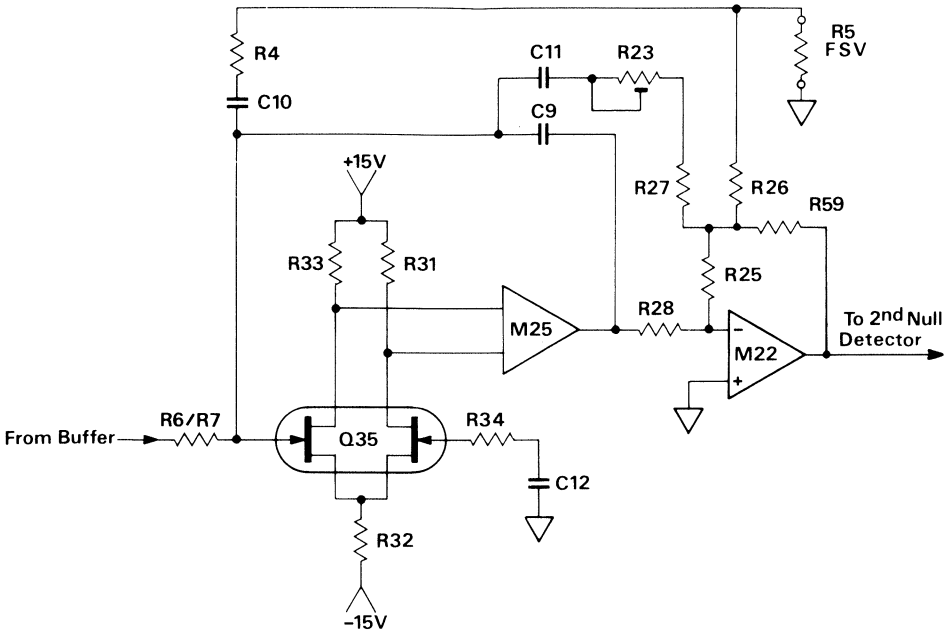

FIG. 3.17 INTEGRATOR CIRCUIT

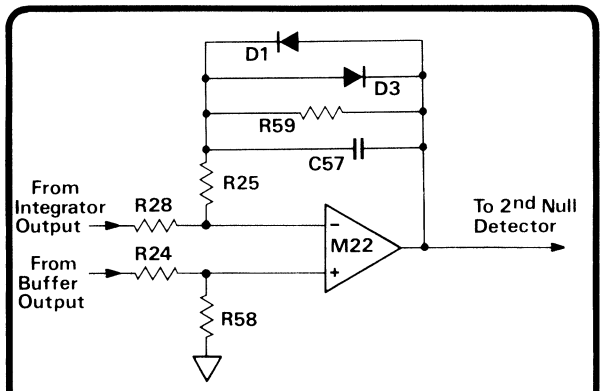

FIG. 3.18 1st NULL DETECTOR CIRCUITRY

3.2.3.7 2nd Null Detector

The signal from the 1st null detector is applied to M15 which boosts the voltage gain. The output provides a logic drive signal via opto-isolator M1, signalling the digital circuitry whenever a null condition changes, Fig. 3.19.

When 'Zero' is selected or the instrument is in the 'Cal' mode, an averaging process is performed over a series of 16 readings to provide greater resolution. (See Fig.3.20). This is achieved by sequentially introducing a small offset into the second null detector from the digital to analog converter, M28, which is clocked by M6 and enabled by the level shifted $\overline{AVE}$ signal.

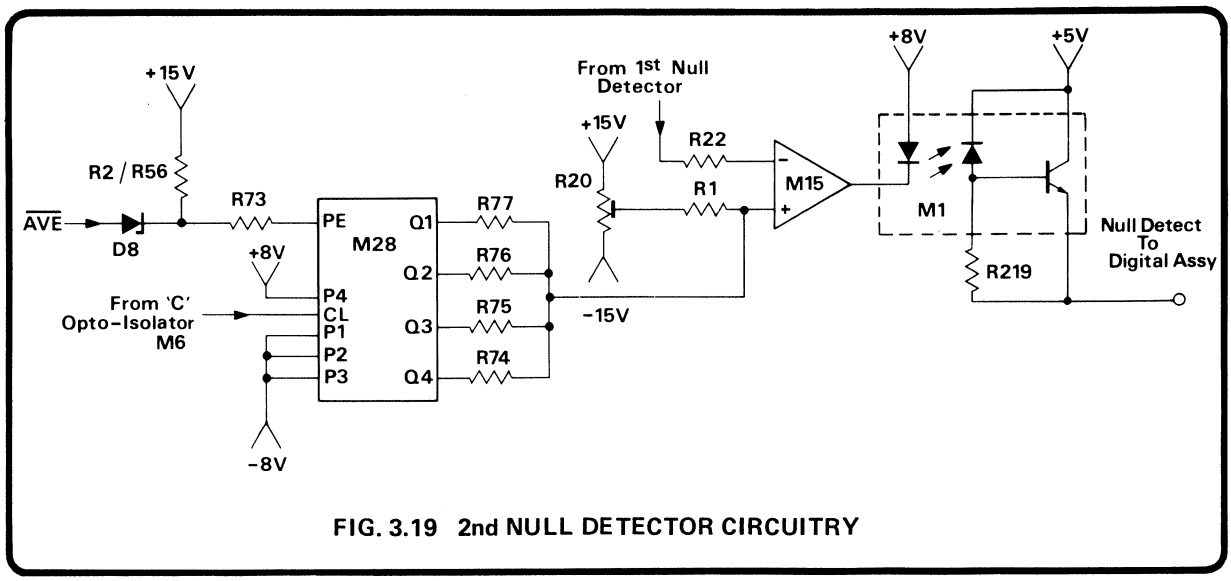

FIG. 3.19 2nd NULL DETECTOR CIRCUITRY

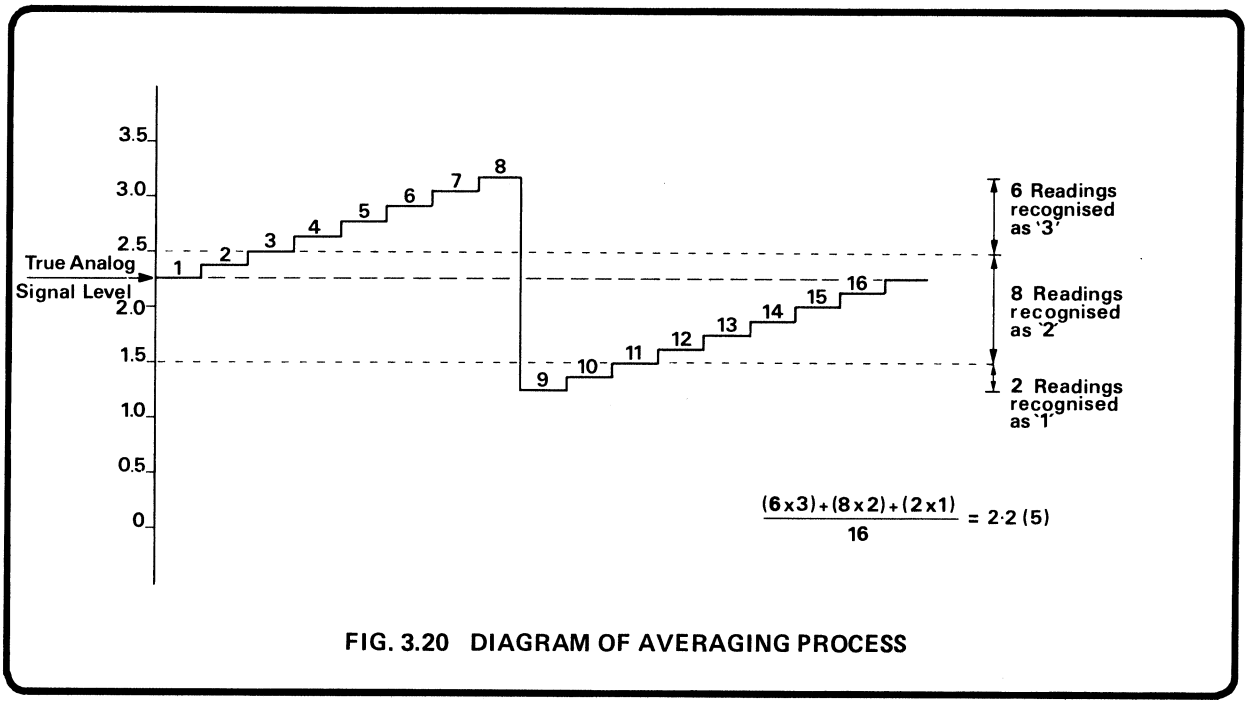

FIG. 3.20 DIAGRAM OF AVERAGING PROCESS

3.2.3.8 Reset Period

At the end of a measurement cycle or when 'Reset' is selected on the front panel, the circuitry is placed into a reset condition. The control lines of the multiplexer M35 allows the 0 volts reference input, at pin 4, to be connected to its output. (See Fig. 3.21). At the same time the reset line (M27-3) is taken high, turning on M26. This reset signal, applied to pins 5 and 12 of M26, allows the output of the 1st null detector to be fed back via R60 to a sample and hold capacitor C12 on the integrator.

Thus, with the input to the A - D converter at zero volts, the charge stored on C12 is the sum of all the offsets from the multiplexer, buffer, integrator and 1st null detector, allowing the 1st null detector to indicate the true zero crossing (null) point.

The reset signal applied to M26 pins 6 and 13 merely allows a lower impedance path between the buffer and the integrator to speed up the settling time as C9 is discharged to zero.

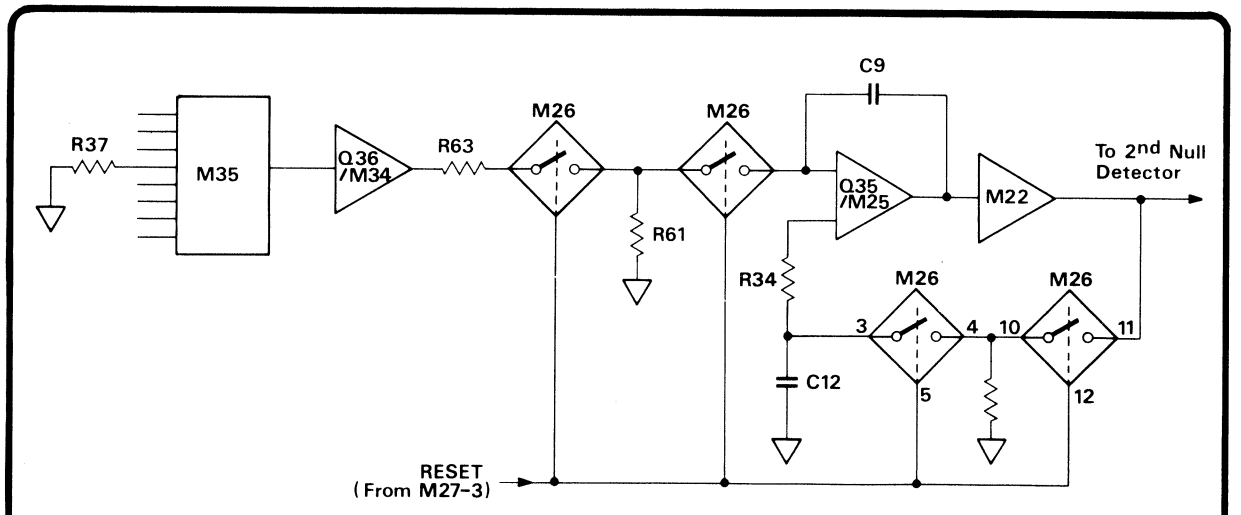

FIG. 3.21 SIMPLIFIED DIAGRAM OF A – D DURING RESET PERIOD

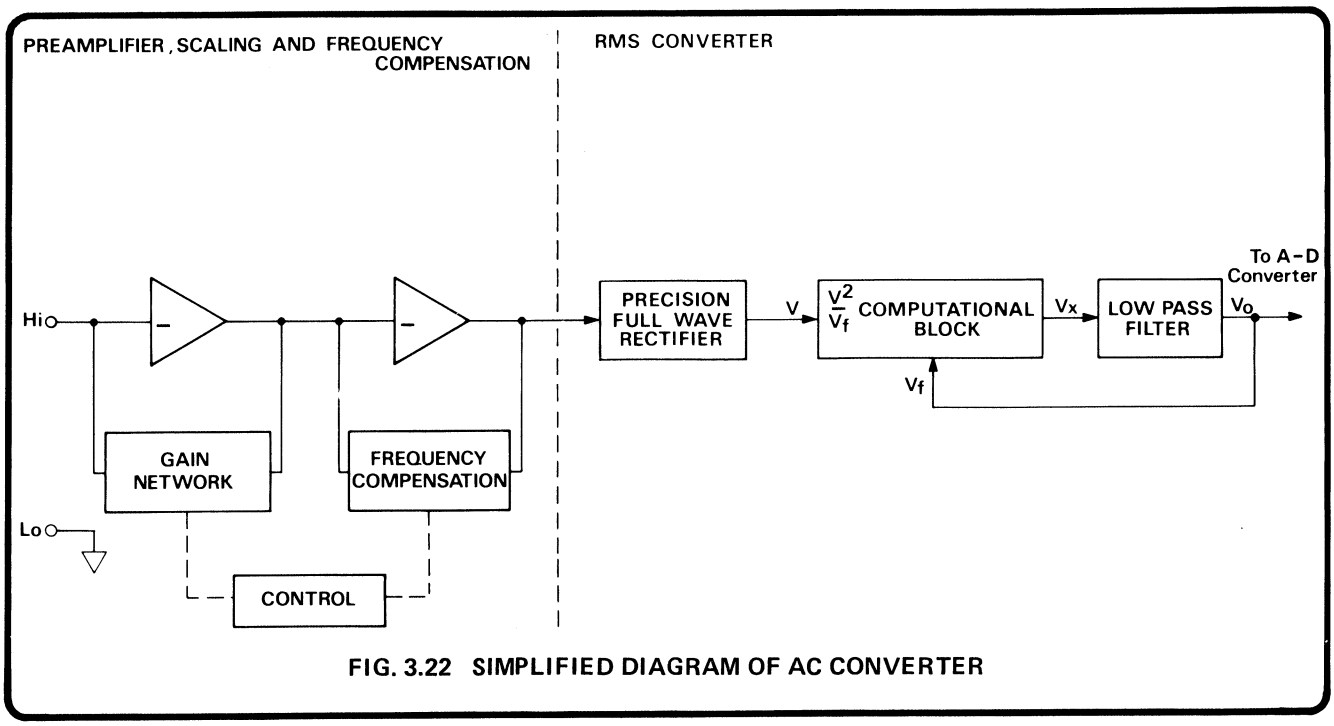

FIG. 3.22 SIMPLIFIED DIAGRAM OF AC CONVERTER

3.3 AC ASSEMBLY (Circuit Drawing No. 430425)

3.3.1 General Principles

The preamplifier buffers and ranges the signal in order to present 0.9 volts full range to the RMS converter section.

Once converted to an equivalent DC signal, it is applied to the analog to digital converter on the main analog assembly.

The conversion technique is electronic true RMS sensing as shown in the simplified block diagram Fig. 3.22. The Datron RMS module can be best considered as a functional block consisting of circuitry which accepts two inputs, V and V_f, computes V^2/V_f and has an output of V_x which is then filtered so that all the AC components are removed. The output of the block is fed back to V_f, thus closing the loop around the whole circuitry.

Mathematically: $\overline{V_x} = V_o$

but $V_x = V^2/V_f$

$\overline{V^2}/V_f = V_o$, but $V_o = V_f$

$\overline{V^2} = V_o^2$

i.e. $\underline{V_o = \sqrt{\overline{V^2}}}$

3.3.2 Preamplifier and Scaling (430425 sheet 1)

Relay RL2 is energised on selection of AC, directly connecting the Hi terminal to the input of the AC assembly. If DC and AC are selected together, the AC assembly becomes DC coupled by energising RL3, causing C57, the AC coupling capacitor, to be by-passed.

The signal is then fed to the switched gain inverting preamplifier whose full range output is 0.9 volts r.m.s. A simplified diagram of this arrangement is shown in Fig. 3.23. The frequency response is held flat, to within ±1%, by controlling the gain defining component time constants, to a similar order of accuracy. Residual errors are removed by the frequency compensation stage. (See section 3.3.4).

The preamplifier has a stable DC path provided by a dual transistor pair Q33 and a fast AC path by dual F.E.T.'s Q32 and Q34. Further gain is provided by the following long-tail pair cascade of Q20, Q21, Q22 and Q23, which is loaded by a current mirror, Q24. Q15 and Q16 with bias components Q17 and Q18 form a conventional class AB output stage. R121 compensates for the bias current of Q33, whileR112 trims the offset voltage to zero.

The unity gain frequency compensation amplifier consists of M11. The bootstrap circuit of Q19 presents the varicap diode, D11, with a high impedance, thus ensuring that the varicap is not shunted to ground.

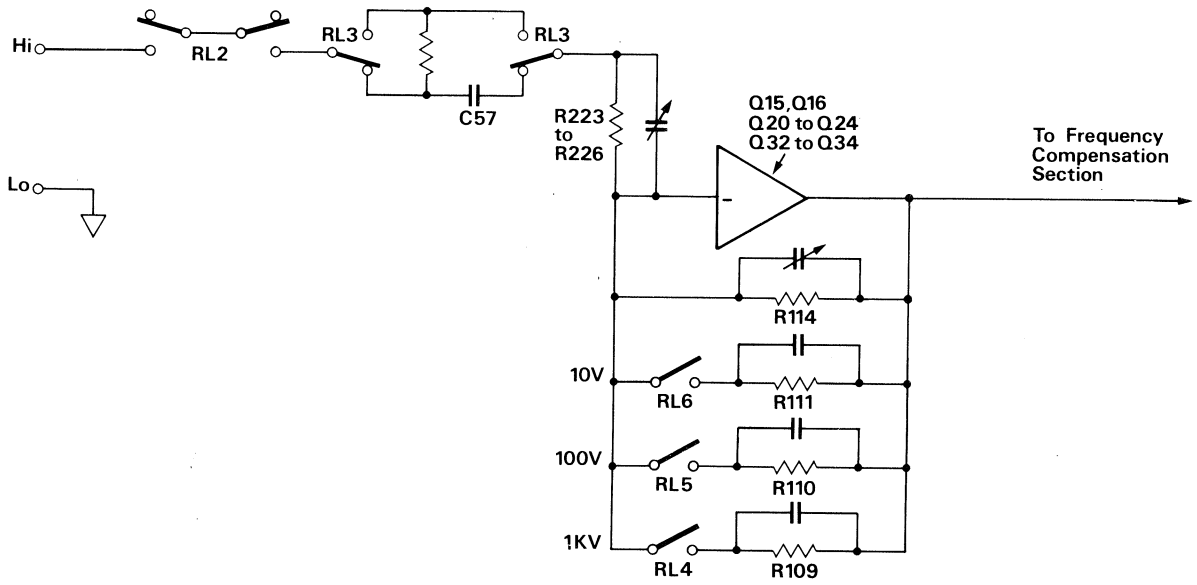

FIG. 3.23 SIMPLIFIED DIAGRAM OF THE AC PREAMPLIFIER SCALING

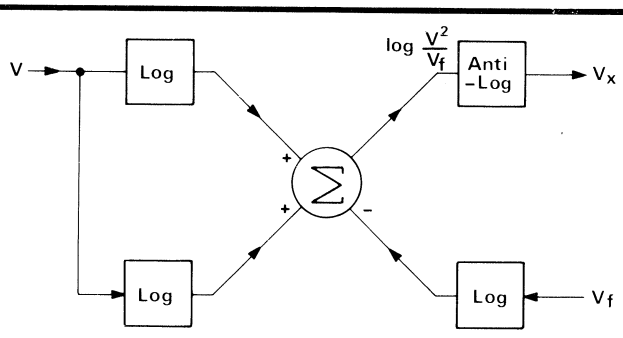

FIG. 3.25 BLOCK DIAGRAM OF RMS
CONVERSION TECHNIQUE

3.3.3 RMS Converter (430425 sheet 2)

The RMS converter takes the scaled AC signal from the preamplifier and converts it to an equivalent DC signal suitable for Analog-to-Digital conversion. The conversion technique is electronic true RMS sensing as shown in the simplified block diagram Fig. 3.25.

M8 and M9 form a summing type, full wave rectifier. The output of M8, a precision half-wave rectifier inverter, is summed with the non-inverted signal with a weighting of 2 : 1 at the input of M9. This forces a full-wave rectified current to flow in RMS module M6. Potentiometer R50 balances the rectifier to provide the same output for non-inverted or inverted asymmetric waveforms.

The output current from the RMS module passes into filter-buffer M1 and is converted to a nominal 5 volt for a full range signal. Q1 and Q2 switch in additional capacitors when FILTER is selected, to operate down to 45Hz. M2 is a voltage to current converter providing a feedback current to the RMS module proportional to the output voltage. R90 is the zero adjustment for the half wave rectifier M8 and R35 is the high crest factor gain adjustment. R75 is adjusted for optimum linearity.

The output of M1 (TP2) is fed to a resistor chain R1 - R7, to provide an output of 3.14 volts by the selection of resistors R2 - R5. Q3 is turned on when AC is selected and switches the output of the AC converter into the Analog-to-Digital Converter (Drawing No. 430425 sheets 3 and 4).

3.3.4 High Frequency Compensation

During the calibration cycle, the microprocessor notes and stores the high frequency (HF) error of each range. When AC volts is selected the compensation information for a particular range is recalled by the microprocessor, transferred across the isolation barrier and latched on to M13, M14 (Drawing No. 430425 sheet 5), see Fig. 3.26. The output from the latches is applied to a digital-to-analog converter via connector J1 pin 11 and applied to varicap D11. The varicap is thus adjusted to give the amplifier chain a flat frequency response.

The calibration is carried out at one H.F. frequency but since it flattens the AC amplifier response, the correction is valid for all specified frequencies. It should be noted that the calibration routine is iterative since the varicap is non-linear.

3.3.6 Test

During the self-test routine (actuated from the front panel or remotely programmed) the AC assembly is checked for correct operation. The circuitry is placed into the 1V range as described in Section 3.2.1.3. Filter is selected and F.E.T. Q31 is 'closed' from M5 - 13 causing a signal of 0.08 volts DC to be injected into the preamplifier. Thus a signal of approximately 0.314 volts is output from the RMS section and applied to the A - D converter situated on the Analog assembly. This signal is then measured and compared to within ±6% of the stored value.

Range	Output from RMS section
1	+0.314 volts

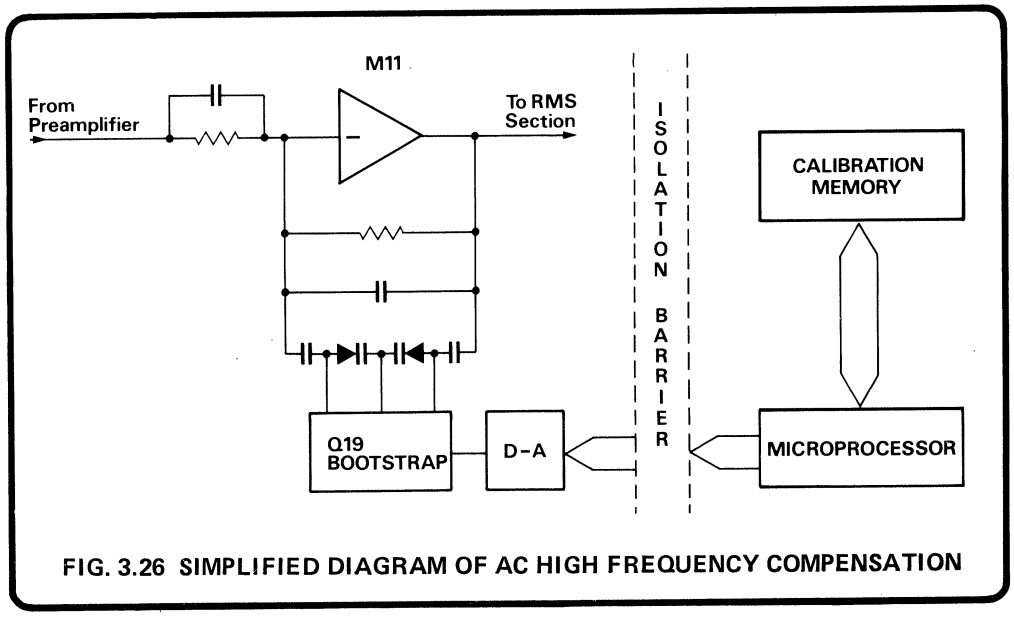

FIG. 3.26 SIMPLIFIED DIAGRAM OF AC HIGH FREQUENCY COMPENSATION

3.4 OHMS ASSEMBLY (Circuit Drawing No. 430426)

The instrument functions by measuring the voltage across an unknown resistance with a known constant current flowing in it. The converter can be split into two parts a low drift voltage follower and a constant current source covering 5 decades from 100nA to 1mA (see Fig. 3.27).

It should be noted that when the Ohms function is selected the DC Isolator Lo is no longer directly connected to the front/rear panel Lo terminal, but goes via RL1 on the Ohms assembly. Lo becomes an active terminal in resistance measurements.

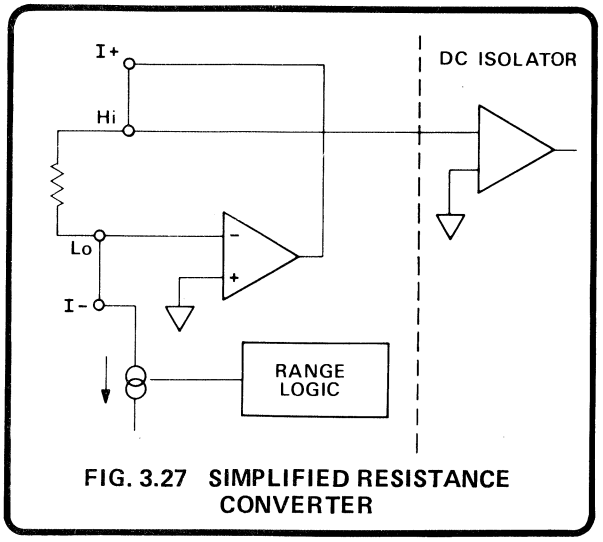

FIG. 3.27 SIMPLIFIED RESISTANCE CONVERTER

3.4.1 Low Drift Voltage Follower

When OHMS is selected, the front panel Lo terminal is connected to the –ve input of amplifier Q10/M3, the +ve input being referred to DC isolator Lo (this remains reference common). Q10/M3 will thus apply a voltage at the I+ terminal via RL1 such that the voltage at front panel Lo is at reference common plus any offset due to Q10/M3. This voltage offset drift is kept small for changes of temperature by compensating the input bias current of Q10 with the current in R67, which changes with temperature due to the voltage drift at Q10 emitters. Q10 input bias current is initially nulled by R26.

Thus if we consider 2-wire measurement, I+ is linked to Hi, I– is linked to Lo and the unknown resistance linked between Hi and Lo, with a constant current flowing from I+/Hi, through the unknown resistance (R_X) to Lo/I–. The Lo terminal is maintained at 0V. Therefore the Hi terminal (DC Isolator Input) is at $I_{constant} \times R_X$ volts above Lo. As long as the error is small referred to reference 0, the DVM will read the correct resistance.

Input protection is provided as follows:–

Voltage/Current applied to input terminals:

I+	R9, D10
I–	R2, D2, R23
Lo	R12, R13, Q8, Q9

Open circuit voltage limit protection:

I+	D10
I–	D2

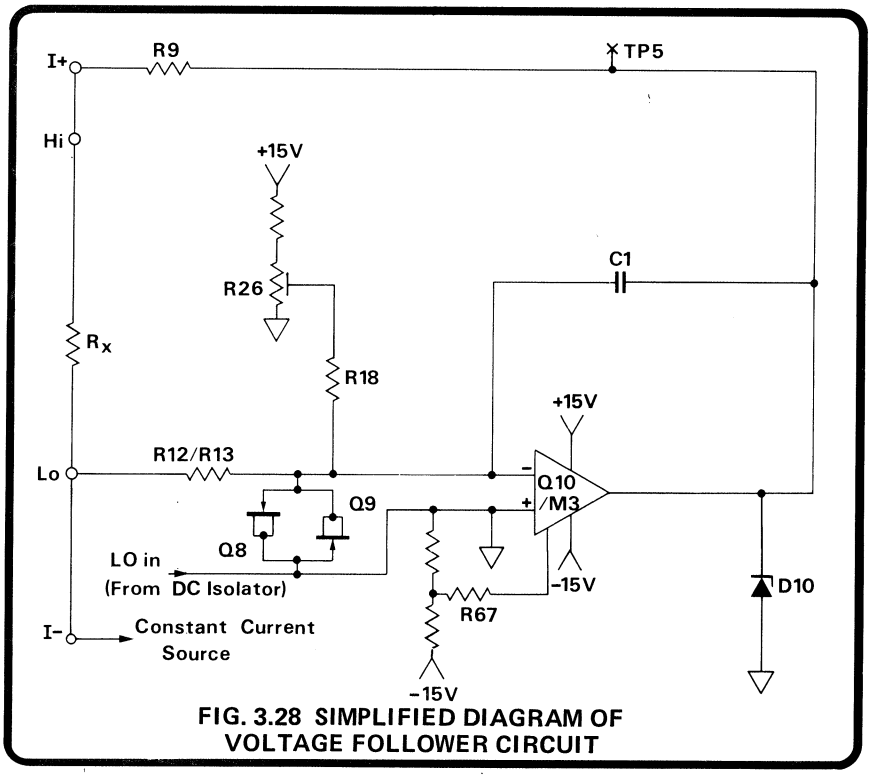

FIG. 3.28 SIMPLIFIED DIAGRAM OF VOLTAGE FOLLOWER CIRCUIT

3.4.2 Constant Current Source

Six decades of ohms ranges are provided by 5 ranges of current and 2 ranges of DC Isolator voltage gain (100mV range for 100Ω, 1V range otherwise). See Fig. 3.29.

Range	Current	F.E.T.'s/Switches turned on	
		Current Selector	Leakage path
100Ω	1mA	M1(A)	
1kΩ	1mA	M1(A)	
10kΩ	100μA	M1(B)	
100kΩ	10μA	M2(A)	M2(B)
1MΩ	1μA	M1(D)	M2(B), M2(C)
10MΩ	100nA	M1(C)	M2(B), M2(C)

FIG. 3.29 OHMS CURRENT RANGE SWITCHING

When kΩ's is selected, Q17 (430426 sheet 2) is turned on enabling astable M6 to produce a 200Hz signal to switch M5. Thus when gates B and C of M5 are open, C9 is charged up from the negative reference (originating from the analog section of the A - D converter). These gates then close and A and B open, sharing the charge with C8, the voltage across C8 equals the reference voltage (sheet 1). The voltage developed across C8 causes M4 to sink current through resistor chain R24, R25, R29, until the voltage developed across the chain balances that across C8. Thus the current required for a particular range is selected by the value of the resistor chain switched by M1 and M2. Simplified diagram Fig. 3.30 shows the resistor chain and switching for each range. On the high resistance ranges leakage paths are provided by M2(B) and M2(C).

To produce good common mode rejection, the negative supply of M4 is bootstrapped. The filtered bootstrap supply (−ΩBS) powers the astable (M6) and bilateral switch.

The use of ohms guard permits in-circuit measurement of resistors, provided shunt paths are greater than 500Ω and a suitable tapping point is available. Consider Fig. 3.31. Guard is reference 0, Lo is actively maintained within microvolts of reference 0 (as previously explained). Thus there is no voltage across Rz and consequently no current in Rz. Voltage follower Q10/M3 will simply pass more current into Ry from the I+ terminal until the selected current for the particular range flows through Rx.

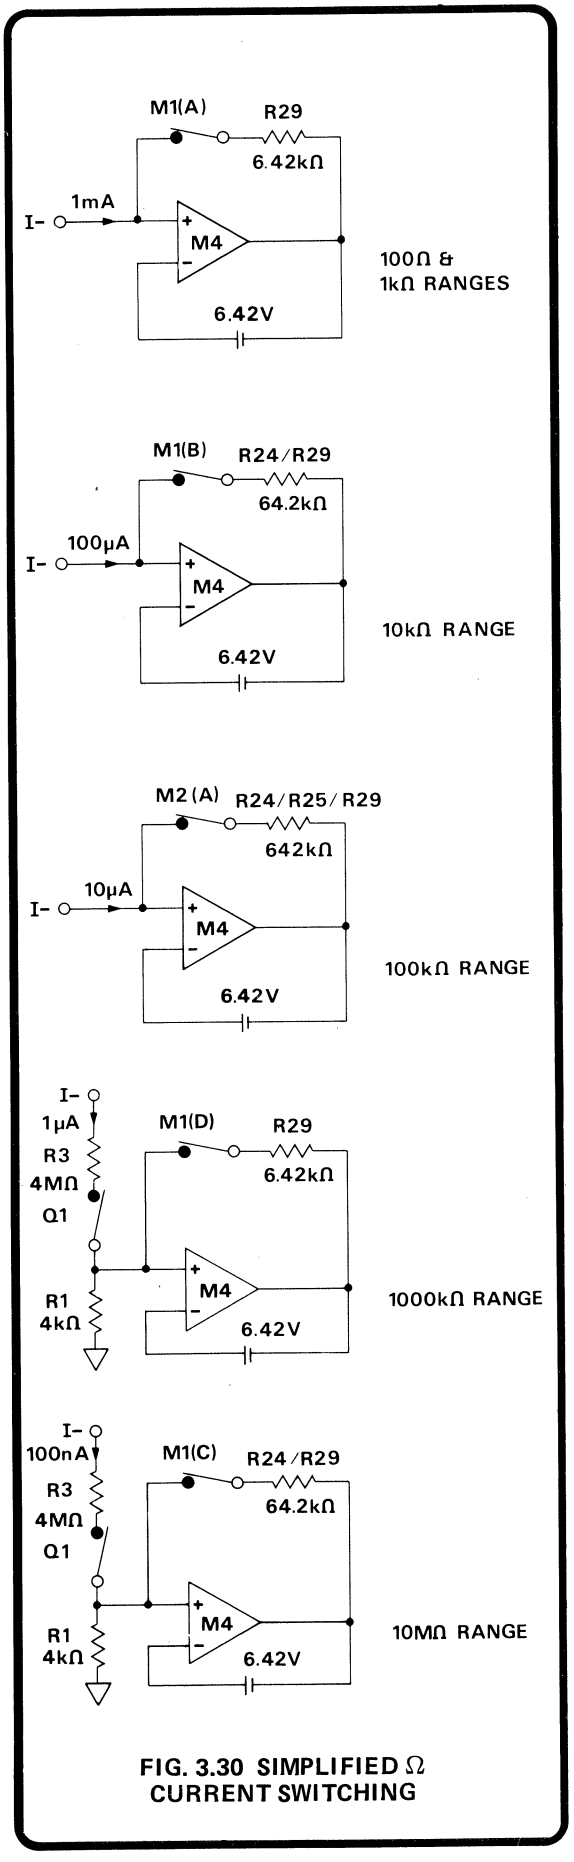

FIG. 3.30 SIMPLIFIED Ω CURRENT SWITCHING

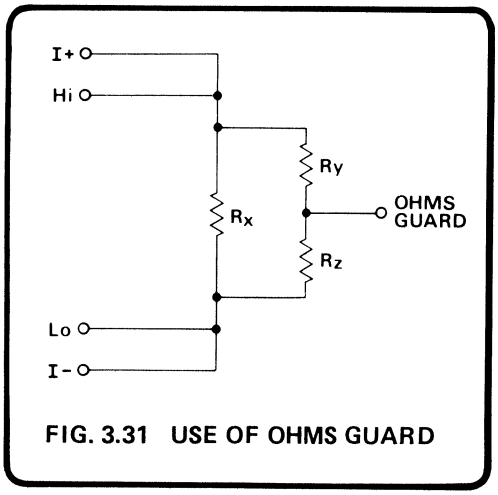

FIG. 3.31 USE OF OHMS GUARD

3.4.3 Test

During the self-test routine (actuated from the front panel or remotely programmed), the Ohms Converter is checked for correct operation. The circuitry is placed into the 10kΩ range as described in Section 3.2.1.3. Filter is selected and F.E.T. Q5 'closed' from M9-1 causing R8 (9.76kΩ) to be placed between I+ and I–. Thus with I+ and Hi, I– and Lo connected (2-wire if front panel input selected), the DC Isolator (which is also in the TEST mode) measures the voltage developed across the resistor (approx 1 volt). The resulting voltage output from the DC Isolator is applied to the A-D converter, measured and compared to the stored value. If the measured signal is within ± 6% of the stored value, the test is complete.

3.8 DIGITAL ASSEMBLY (Circuit Drawing No. 430422)

The Digital assembly contains the circuitry providing the general management of the instrument and the digital section of the A-D converter. Fig. 3.33 outlines the main portions and signal highways of this board.

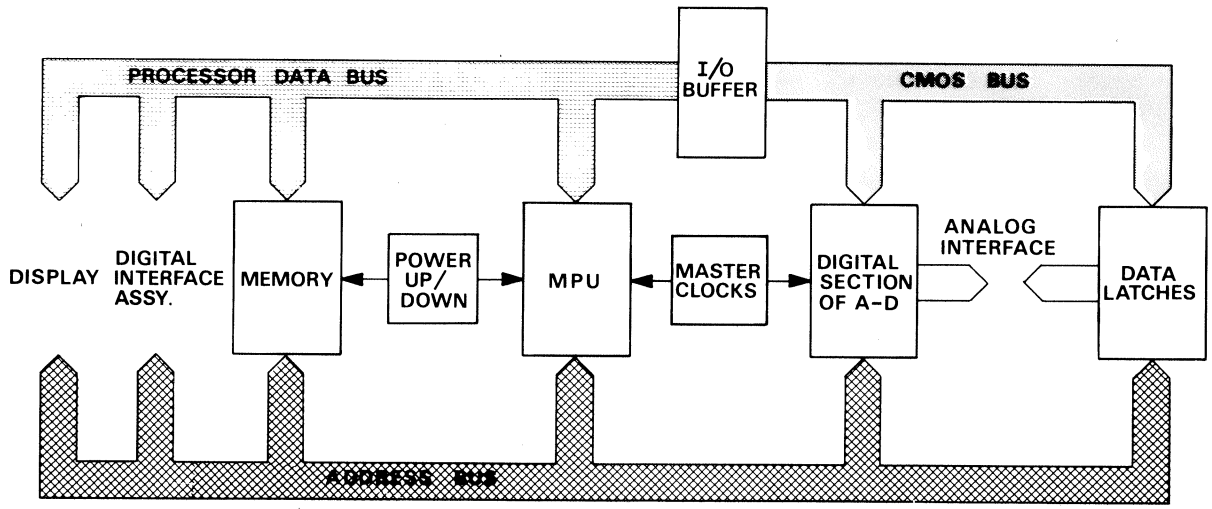

FIG. 3.33 SIMPLIFIED BLOCK DIAGRAM OF DIGITAL ASSEMBLY

3.8.1 Processor and Memory (430422 sheet 1)

A 6800 microprocessor (MPU) together with 8k bytes of memory controls the communication between the front panel, digital interface, display drivers, Digital and analog assemblies. The memory can be split into five main areas:—

(1) Program Memory - needed to operate the whole instrument system.

(2) Constant Data Memory - e.g. Self Test limits, Error read-out specifications and other fixed factors.

(3) Non-volatile Calibration Memory - used to store all the calibration errors used for each reading and determined during the 'Auto-cal' cycle.

(4) Operating Memory - used for scratch pad operations and storing.

(5) Volatile Display Memory - volatile data such as Max-Min stores, Limit stores and computation stores.

3.8.1.1 Software Overview

The system uses the technique of a looping prioritised job scheduler (see Fig. 3.34). Each job driven from the scheduler is controlled by a flag in the system workspace which is set when the job is required to be run and cleared when completed. Priority of activation is ensured by making each job exit on completion, to the top of the scheduler.

Program Modules: The program memory is split into a series of functional modules, each module corresponding fairly closely to a major functional area and hence to one of the jobs activated by the job scheduler, the larger jobs being sub-divided, see Drawing No. 890028.

Data Flow: Two streams of data are handled by the system. The first is the measurement data on which calibration and computation operations are carried out. The second, asynchronous with the first, consists of commands derived from the front panel or IEEE 488 I/F and controls the measurement circuits and the computation programs. Operations on the measurement stream basically consist of acquiring the raw data from the A-D converter, calibrating this data and carrying out any other computations, and converting and formatting the data for output. Note that a job consuming data is given higher priority than the one producing data for it, allowing a producer to place data into an empty buffer. The consumer is activated by a flag, set by the producer to indicate data ready in the buffer.

Processing Control: Control of the instrument by the processor, initiated from the front panel or digital interface, is arranged by using a 'pipeline control' of the major system state and a 'first in/first out' buffer between the interrupt level routine receiving the control command and the main program implementing it. The major system state consists of the range, function, resolution, filter, ratio, autorange, etc., flags and the computation mode (reading, A-B, ÷C, etc.). The pipeline comprises three levels. The top, level 1, reflects the state being programmed, the second, level 2, the state of the measurement circuits and the third, level 3, the measurement being processed. When a command is input, level 1 is updated (e.g. a new range is selected) and as soon as the measuring circuits are not converting an input signal, the state in level 1 is moved to level 2 causing the measurement circuits to update to the new state. When an A-D conversion is complete, data is read from the A-D and the state transferred from level 2 to 3, providing information for the processing routines. Additionally, at this time, the level 1 to level 2 transfer is repeated and the measurement circuits again updated to allow for commands received while the conversion is in progress.

A second control mechanism used is to input all the commands via a 'first in/first out' buffer between the interrupt level routine receiving the command and the main program implementing it. Thus the processor under remote control is able to 'simultaneously' set up the requirements for the next reading, convert the current reading and process the last one.

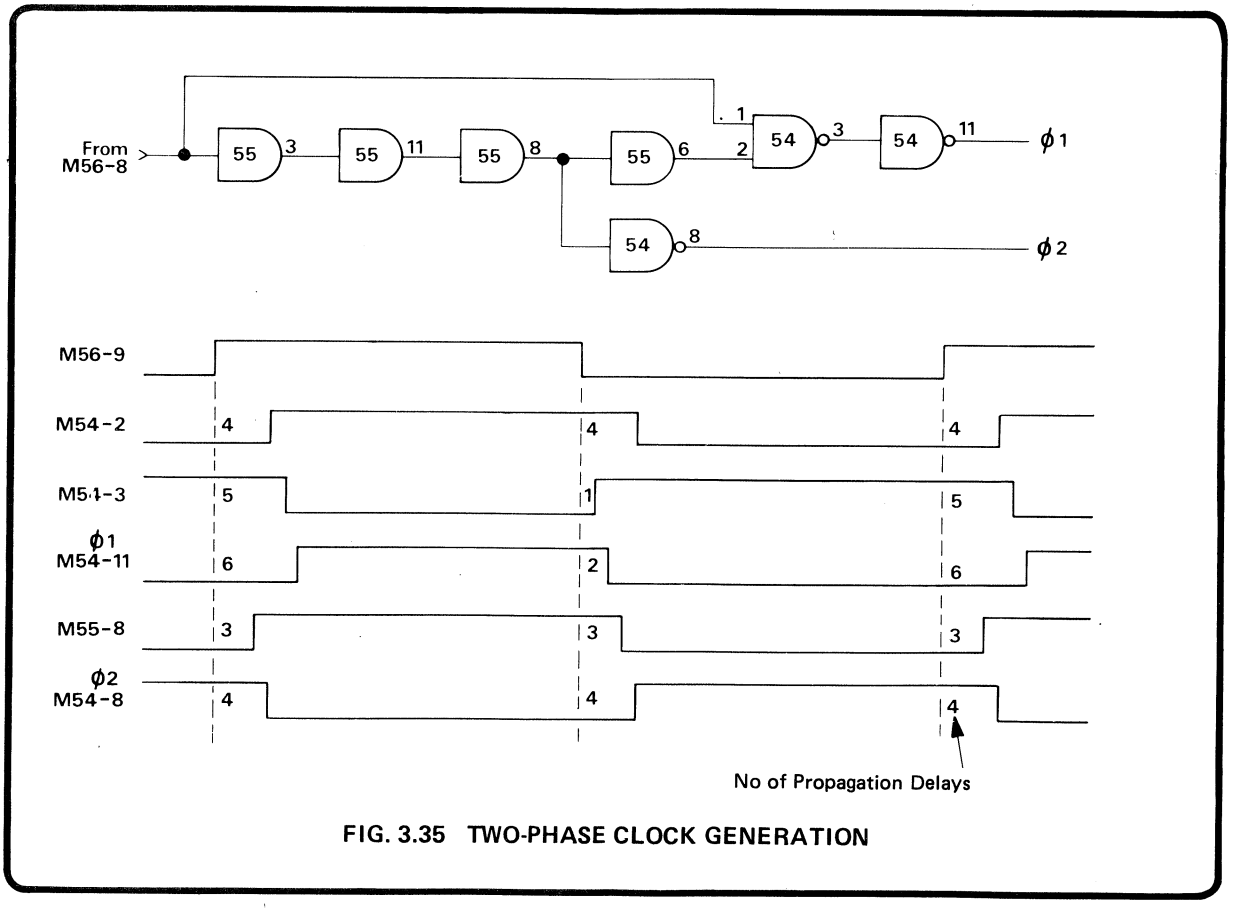

FIG. 3.35 TWO-PHASE CLOCK GENERATION

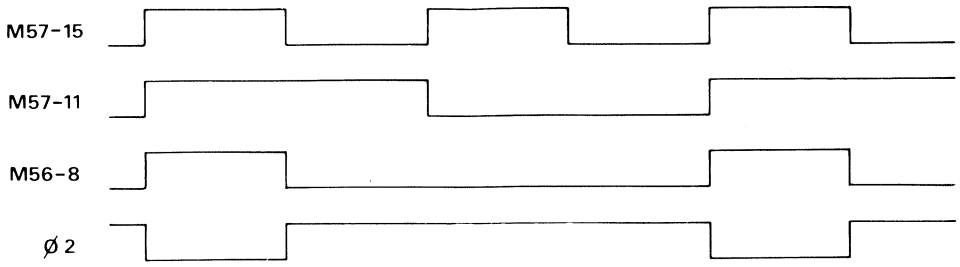

FIG. 3.36 TIMING DIAGRAM OF STRETCHED TWO-PHASE CLOCK

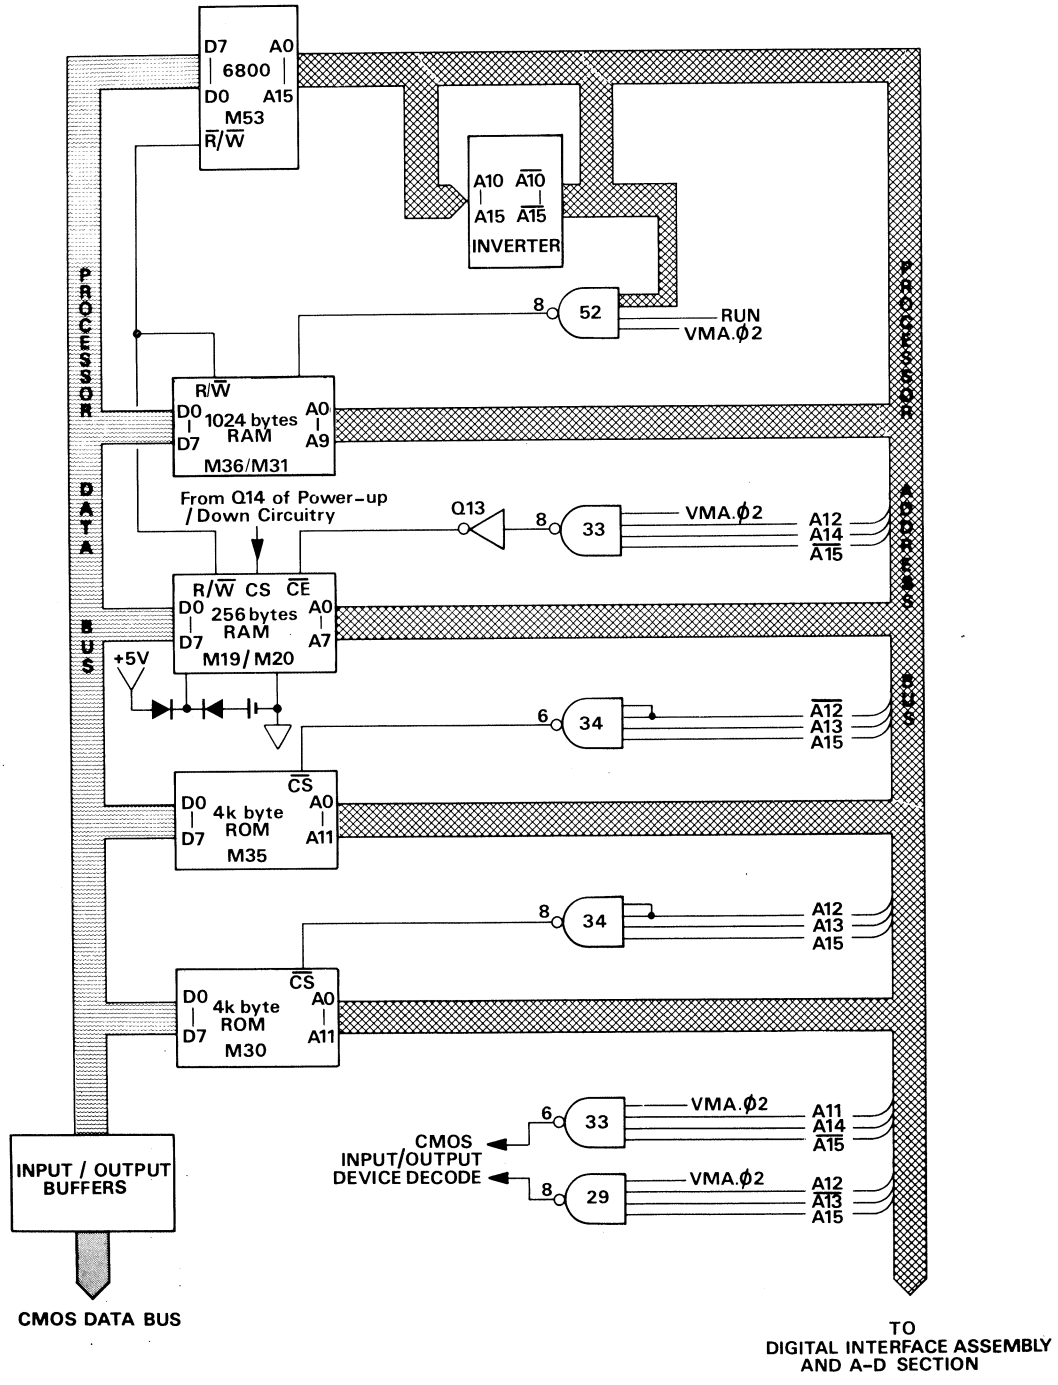

FIG. 3.37 SIMPLIFIED DIAGRAM OF MEMORY CIRCUITS

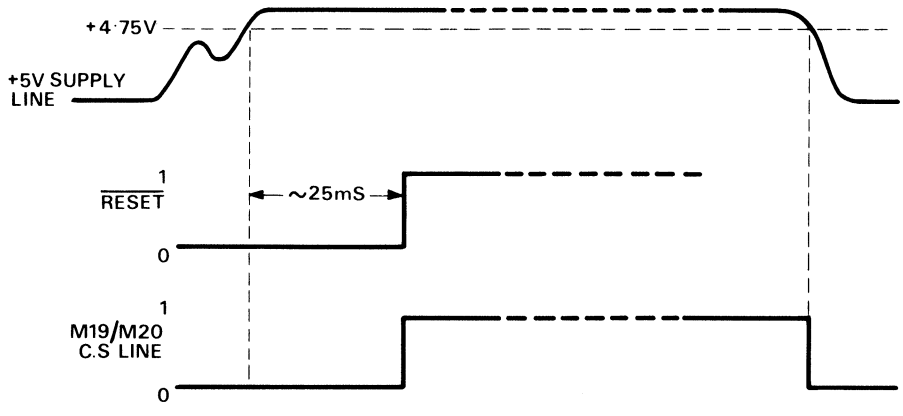

FIG. 3.38 START UP AND NON-VOLATILE RAM PROTECTION

3.8.1.2 The Two-Phase Clock

The 6800 requires a non-overlapping positive two-phase (Ø1, Ø2) clock and is derived from the line locked master clock (sheet 4) producing a 1.6MHz (50Hz supply) or 1.9MHz (60Hz supply) signal. M57 acts as a ÷2 thus antiphase 800kHz square-waves appear on pins 14 and 15. If data is not being transferred to the CMOS Bus, M57-11 is high, thus M56-8 follows M57-15. The non-overlapping of Ø1 and Ø2 is produced by the utilisation of the inherent propagation delay (approx. 10nS) through each gate of M54 and M55. This is best seen by referring to Fig. 3.35 the circuitry around the output stage increasing the voltage levels demanded by the processor (0V and +5V).

During a period when data is being transferred across the CMOS Data Bus, Ø1 and Ø2 are reduced to 400kHz by utilising the other half of M57. The signal CMOS I/O is high thus a 400kHz square-wave is output on M57-11, the waveforms of Ø1 and Ø2 are altered such that one half of the period is stretched, covering 1½ cycles of the normal 800kHz operation. (See Fig. 3.36).

3.8.1.3 RAM/ROM Circuit

The 6800 uses two ROM's which contain the programs necessary to run the instrument. Each ROM is able to store up to 4096, 8 bit 'words' of program information which are grouped in program modules. Both ROM's receive the address information output by the processor on to the Processor Address Bus. The particular ROM to be addressed being selected by decoding three of the address lines and applying the resultant to the 'chip select' line (via M34 pins 6 or 8) (See Fig. 3.37).

The information held in that particular location is sent back to the processor via the Processor Data Bus.

The processor also uses 1280 bytes of 8-bit wide RAM. 256 bytes of this memory (two 256 x 4-bit RAMs M19/20), are backed up by a battery to provide the non-volatile calibration and zero store which can only be over-written when 'CAL' or 'Zero' is selected. The remaining 1024 bytes, (two 1024 x 4-bit RAMs M36/31), are used as operating memory for scratch pad operations, and for storing volatile data (e.g. Max, Min). A particular location is set by the 6800 on the Process Address Bus using A_0 to A_9, the pair of the RAMs being selected by decoding other address lines with VMA.Ø2. Control of the read/write lines is performed by the MPU, the signal being gated with a 'Master Clock ÷ 2' signal to provide correct timing.

An instrument power up is detected by M60/M62 causing an initialisation $\overline{\text{RESET}}$ signal to be fed to the MPU via Q16. (See Fig. 3.38).

During a power-up or power-down (+5V supply line < +4.75 V) a signal from the supply-level detectors prevents RAMS M19 and M20 from being overwritten by holding the CS (chip select) lines low (<0.2 volts) via Q14 for a period of approx. 25mS determined by R55/C32.

3.8.2 CMOS Address Decode and Input/Output Circuits (430422 sheet 2)

Information is transferred to and from CMOS devices via the CMOS Data Bus during periods when the signal CMOS I/O is high (M33-6). This takes place when the Processor Address Bus bits A11, A14 and A15 are high. The transfer of data between the Processor Data Bus and the CMOS Data Bus takes place at 400kHz, the Read/Write lines selecting the direction of information through the tri-state buffers M4, M5 and M6.

In order to uniquely address the various CMOS input/output devices, the address lines must be further decoded. M16 and M32 are dual 2 to 4-line decoders using the states of CMOS I/O and address lines A0, A1, A4, A5 to enable or partially enable the input/output devices, except the output of M16 pins 2 and 15 which are inverted and gated with data line A2 to produce the required decode.

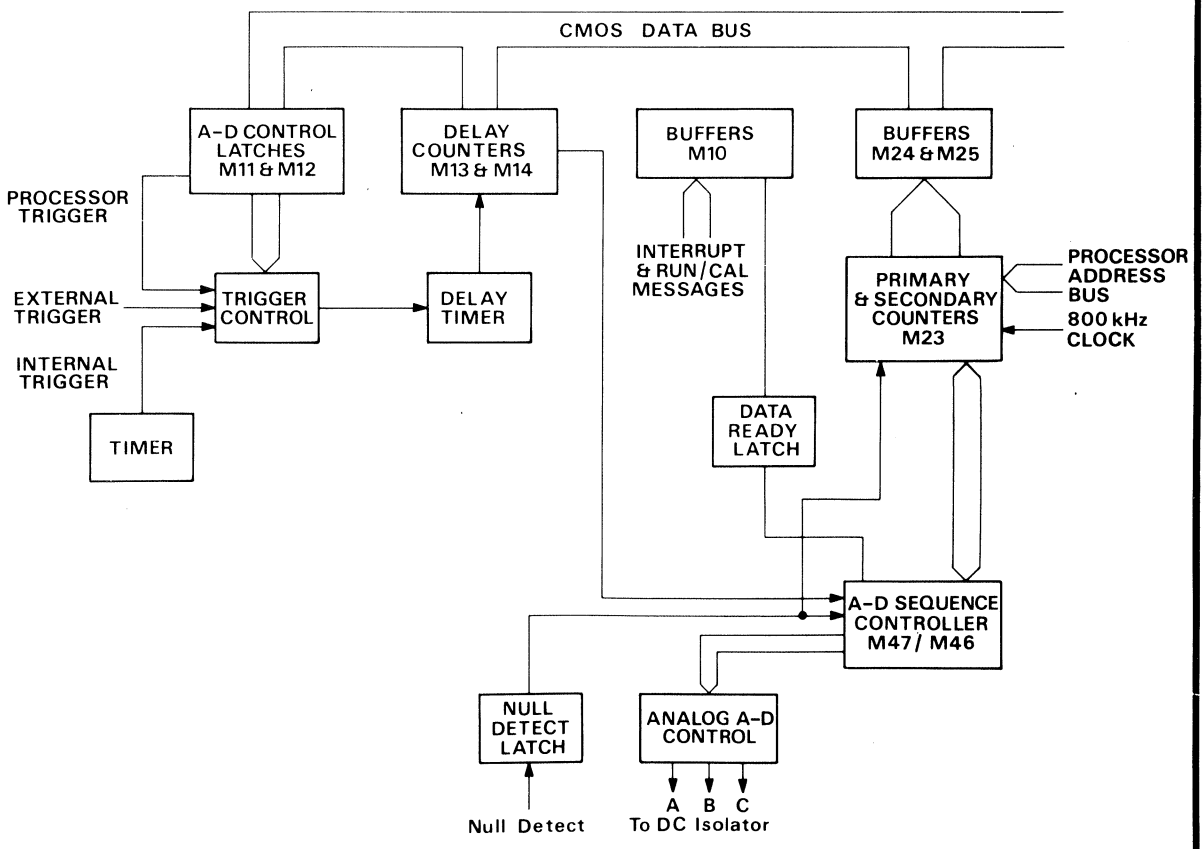

FIG. 3.40 SIMPLIFIED DIAGRAM OF DIGITAL SECTION OF A–D CONVERTER

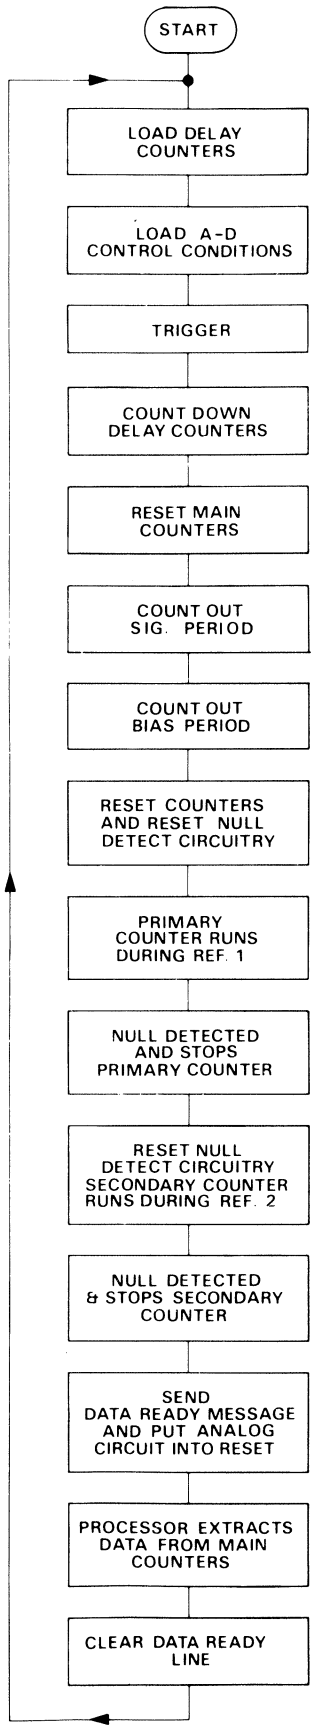

FIG. 3.41 FLOWCHART OF A–D DIGITAL SECTION

3.8.3 Analog to Digital Conversion (Digital Section)

3.8.3.1 General Principle

Block diagram Fig. 3.40 outlines the essentials of the digital section and should be used with flowchart Fig. 3.41 in order to follow the operation of this section.

The function of this section of the circuitry is to generate the sequence that when transferred to the analog section, controls the sequence from RESET through the integration cycle and back to RESET. The circuitry controls the length of SIG and BIAS and counts during REF 1 and REF 2, the accumulated count being proportional to the length of the reference periods, which in turn is proportional to the measured input signal. At the end of each reading cycle the count is read by the MPU, processed and displayed.

3.8.3.2 Preset Procedure

As part of the initialisation routine (at switch on), M47 (used as the sequence controller), is reset from M37-11, causing M47-2 to be logic '1'. Thus the control lines $\overline{A}$, $\overline{B}$ and $\overline{C}$ put the analog section of the A-D into RESET (See Fig. 3.42). The Address Bus decoded signal $\overline{XADDLY}$ is taken low, enabling the presetting of the delay counters M13 and M14 from the CMOS Data Bus, the amount of delay being determined by the selected range, function and filter state, see Fig. 3.43. The A-D control latches, M11 and M12 are then enabled by $\overline{XADCTL}$ to (i) reset the command latch M1 (from M11-4), (ii) set the resolution of the main counter (M11-5 and 6), (iii) select trigger gate (M12-3, 4 or 5) and (iv) reset the data ready latch (M12-6).

FIG. 3.43 COMMAND DELAYS

3.8.3.3 A-D Measurement Sequence

Trigger. The trigger, required to initiate the measurement sequence, is generated from one of three possible sources:

1. Internally generated 3/second trigger, from timer M61-7.
2. Externally generated trigger, from EXT TRIG on rear panel via M24-13.
3. A MPU derived trigger from M11-3 generated when auto-ranging, pressing MANUAL when HOLD selected, during calibration, an INPUT ZERO sequence or via the digital interface.

The trigger source is selected by the latched data on M12, enabling one of the three gates of M2.

Delay. The trigger pulse clocks the 'command latch' M1 causing the timer, M15, to output clock pulses (200Hz) to the delay counters (M13 and M14) after a delay of approx. 1.5mS set by C5, R8, R9, R11. The delay counters proceed to count down to zero, at which time the delay latch (M26) is clocked. Thus M26-14 becomes a logic '1', enabling the sequencer M47 (an octal counter) to proceed on to the next step via M46-2.

SYNC. The SYNC phase from the sequencer resets the counters of M23 and places the analog section of the A-D into SIG. The pulse is fed back to M47 via M46-3 to step on the sequencer.

SIG. During the time the SIG line is high (M47-3), the primary counter in M23 is enabled and counts out the signal period (2.5mS superfast or 20mS normal mode). At the end of this period, M23-23 goes high and passes via M46-10 enabling the sequencer to step on once again.

BIAS. The BIAS signal (M47-7) is transferred to the analog section of the A-D by changing the state of the $\overline{A}$ line (M38-9 to a logic '0'). BIAS also enables the secondary counter of M23 to count out the BIAS period (20μS). The signal indicating the end of this period is passed via M46-9 causing the sequencer to carry on to the next step. The BIAS signal also resets the 'delay latch' (M26) ready for the next measurement cycle, and the 'null detector' latch (M22A).

WAIT. The WAIT pulse resets the counter of M23 via M39-10, keeps the $\overline{A}$ line to the analog section low, clocks the polarity null detect latch M22(B) causing a logic '1' on pin 1 if the signal applied to the analog section of the A-D converter was positive (logic '0' if negative) and is fed back to enable the sequencer via M46-3.

REF 1. The high to low edge of WAIT causes the $\overline{A}$ to change state and going into REF 1 makes $\overline{B}$ a logic '0'. The analog side is then in the condition to start 'ramping down'. While REF 1 is high the primary counter of M23 is enabled (pin 3) and counts the period of REF 1.

REF 1 is ended when a null detector pulse is detected and latched on to M22. This causes the sequencer to step on once more from M46-3, the low to high edge from pin 4 disabling the primary counter.

REF 2. The REF 2 signal changes the state of the $\overline{A}$ line (causing the analog section to ramp down at a slower rate), reset the 'null detect' latch and enable the secondary counter of M23 (Pin 13) to count the period of REF 2. If the secondary counter overflows the primary counter is incremented from M26-16.

As in REF 1, a null detector pulse causes the counting period to end (M26-13) and increment the sequencer via M46-3 causing the $\overline{A}$ and $\overline{B}$ lines to change state.

END. The low to high edge from M47-10 is fed back to M47, via M48-6 giving a master reset. Thus the sequencer is placed into RESET.

RESET. The sequence pulse from M47-2 clocks the 'data ready' latch M1-3 placing a signal on to the CMOS Data Bus via tri-state buffer M10 indicating to the MPU that a reading is ready to be taken from the main counter M23. Data is extracted from the counters in three bytes (controlled by the A1 and A0 lines of the processor address bus) with the counter output buffers, M24 and M25 being enabled by $\overline{\text{XADDT}}$, a decoded processor address.

The RESET signal is also passed to the analog section of the A-D by changing the state of the C line.

Once the data has been extracted from the main counter the set-up procedure is then repeated to await a further trigger.

3.8.3.4 Master Clock and Line Locking (430422 sheet 4)

To give improved rejection of line frequency related noise, the 1065 is linelocked. The line frequency is sampled and compared to the internal master clock. Synchronisation is achieved by adjusting the master clock frequency.

A sinusoidal line frequency signal from the 5V mains tap is converted to a square-wave (M25-13) and ÷2(M26-1) before being fed to the comparator section of the ULA M23 (sheet 3). The MASTER CLOCK ÷2 signal is fed to ripple counter M27 which outputs a signal of twice the estimated line frequency, for line related periods, controlled by the ULA (M23-18). This signal is fed to M23-19 (via inverter M39) and after a further ÷2, is compared with the actual line frequency (see Fig 3.44).

The ULA determines whether the master clock is running too slow or too fast, producing a signal on pin 20 whose pulse-width is proportional to the difference. The output of pin 21 is a 25Hz square-wave which is fed to the up/down input of counters M41/50. Thus depending on the position and down period of the pulse, the count held is increased or decreased.

Latches M42/51 are updated with this new count during the A-D RESET period and applies the count to resistor network AN4 which forms a D-A converter. Changing the voltage applied to varicap D9 alters its capacitance, thus adjusting the LC of the Colpitts oscillator. Therefore the frequency of the Master Clock is increased or decreased to be an exact multiple of the mains frequency.

3.9 FRONT PCB ASSEMBLY (Circuit Drawing No. 430417)

The front pcb assembly performs the following functions:

1. Accepts the analog measurement signals.
2. Provides manual control of the measurement circuits and data conditioning, via the microprocessor data bus.
3. Digitally decodes and displays measurement values and instrument messages input from the microprocessor data bus.
4. Visually indicates the selectable instrument states.

3.9.1 Analog Input Signals

The signals applied to the front panel input terminals are routed directly to the rear panel board via the L.H. pcb. The Hi, I+, Lo and I– tracks are shielded by guard tracks throughout.

3.9.2 Keyboard and Display. (Circuit drawing No. 430417)

The front pcb houses the functional and range keys (S1 - S18) with associated LEDs (SD1 - SD18), and the 8 segment, 11 block digital displays (block 9 not used). These are served by the Programmable Keyboard/Display Interface M1 and scan decoder M3.

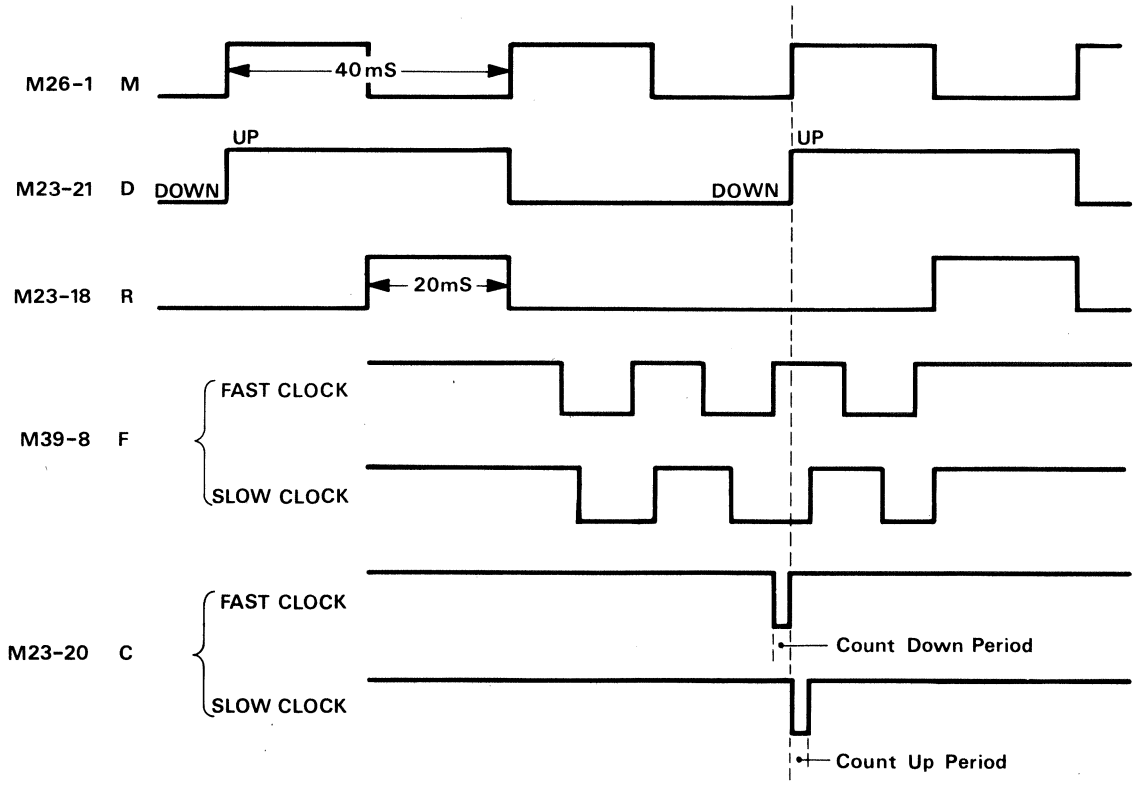

FIG. 3.44 LINE LOCKING TIMING DIAGRAM (50Hz)

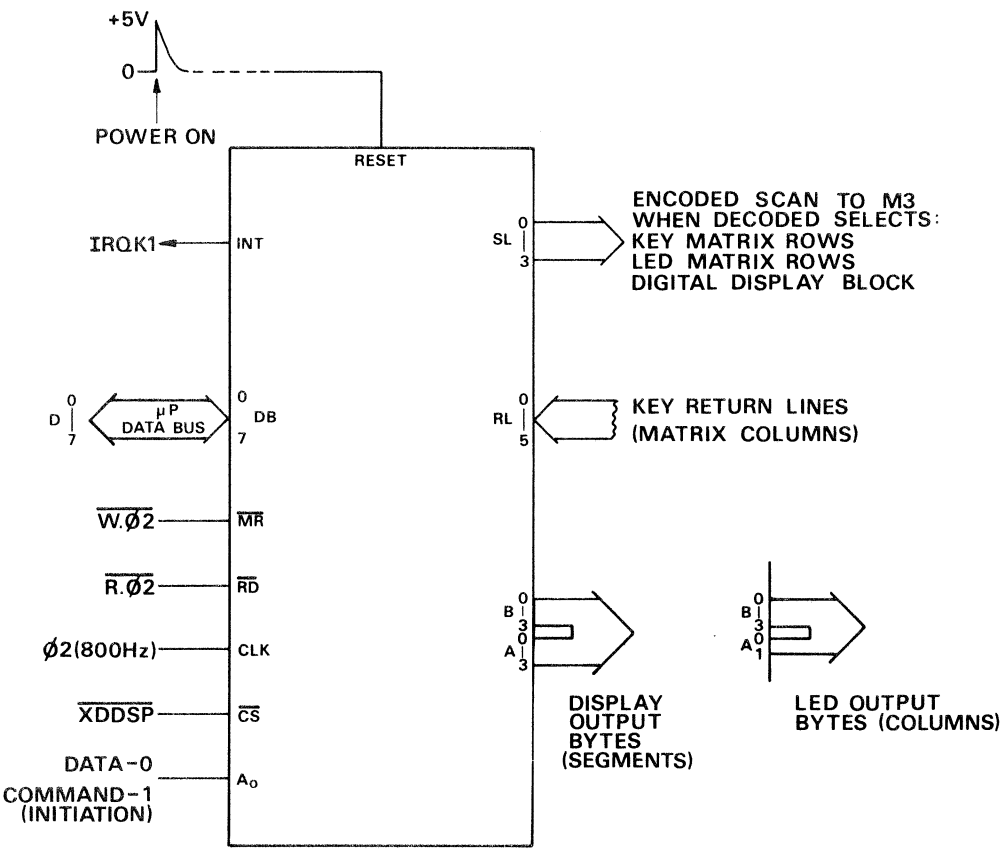

FIG. 3.45 M1 INTERFACE (P8279) SIMPLIFIED SCHEMATIC

3.9.3 Programmable Interface M1 (Fig. 3.45)

M1 interfaces the keyboard, LEDs and display to the instrument data bus. It is addressed by $\overline{XDDSP}$ from the digital pcb to chip-select $\overline{CS}$, which enables either command or data flows via the data bus. For data flow, the processor address: Ao = 0, and for programming the interface during initialisation: Ao = 1. Commands and data flow via DB_0-DB_7.

3.9.4. Read/Write Control

The processor R/$\overline{W}$ signal is decoded into $\overline{WR}$ and $\overline{RD}$ by M2 and synchronised with the processor Ø2 clock. Data or Command is input to M1 from the processor data bus on $\overline{WR}$ low, and $\overline{CS}$ low is latched on the $\overline{WR}$ positive-going edge. Data is output from M1 onto the databus during $\overline{RD}$ low and $\overline{CS}$ low. Naturally $\overline{WR}$ low AND $\overline{RD}$ low is an excluded combination.

3.9.5 Initialisation Commands

On power up M1 is cleared by a RESET input pulse of time constant 10ms. The interface is then programmed during initialisation as follows:

Clock divider set to ÷ 8 - The Ø2 clock at 800KHz is divided by 8 to give internal clock frequency of 100KHz. An inherent division by 16 reduces the scan clock to 6.25KHz giving approx. 400Hz scan cycling frequency.

Encoded Scan - The scan output from SL_{0-3} is a 4-bit binary count. SL_3 = MSB, SL_0 = LSB.

Keyboard Mode - The internal keyboard RAM is programmed as FIFO, input via RL_5 - RL_0 return lines. N-key rollover is employed with de-bounce. (Selective 2-key lockout performed by main software).

Display Mode - 16 x 8-bit character display with left entry, to accommodate both LEDs and display. The internal scan multiplexes LEDs with display blocks, (see fig. 3.46), on output port B_{0-3} A_{0-3}.

M1, SL_{0-3} SCAN OUTPUT				M3 OUTPUT (Low Active)	ENERGISED LINE (Display and Keyboard)
SL_3 Data 4	SL_2 Data 3	SL_1 Data 2	SL_0 Data 1

1	1	0	1	S_{13}	A1
1	1	1	0	S_{14}	K lower row (S13-18)
1	1	1	1	S_{15}	A10

FIG 3.46 KEYBOARD AND DISPLAY SCAN ENERGISING SEQUENCE

3.9.6 Keyboard and Display Scan

The encoded scan output from M1 (approx. 400Hz cycle frequency at SL_{0-3}) is decoded by M3 to energise each key and its associated LED twice in every scan cycle, and each display block once in every scan cycle. In addition, the Display Blocks are activated alternately to avoid inter-block "streaming".

3.9.7 Key selection (Drawing 430417 sheet 1)

The keys are electrically grouped in a matrix of 3 rows of 6, as laid out in Drawing 430417 sheet 1. (NB. This does not conform to their physical grouping on the front panel). The six return lines RL_{0-5} define columns in the matrix and the rows are scanned by SL_{0-4}. The internal keyboard RAM receives the column information, and its internal scan is synchronised to SL_{0-4}, uniquely recognising each of the eighteen keys. The use of "N-Key Rollover" mode debounces single key depressions, and simultaneous key contacts are recognised and stored. Any Key depression initiates the interrupt IRQK1 to the microprocessor, which identifies the keys. The DVM main program software performs 2-key lockout except for AC and DC function keys, which may be selected together for the AC + DC RMS function of the instrument.

3.9.8 Key LED operation

After performing the range or functional change requested by the key depression, the microprocessor reselects the state of the assigned LED bits in M1 internal display RAM. As the display RAM is scanned internally in synchronism with the decoded scan outputs of M3, each LED output byte on B_{0-3} A_{0-1} drives the row of LEDs accessed by M3 output lines (Fig. 3.46 refers). The bit-pattern of the byte selects the LEDs to be lit in that row. (B_{0-3} A_{0-1} bits high = unlit, low = lit). Transistors Q1-7, Q10-14 provide the energising currents.

3.9.9 Digital display operation

When the microprocessor system has data to display, it is transferred into M1 internal display RAM via the data bus at M1-DB_{0-7} reselecting the bit-patterns of the assigned display bytes. Each display output byte on B_{0-3} A_{0-3} drives a specified digital block, energised in synchronism by M3 decoded outputs (see Fig. 3.46). This may be illustrated by an example:

Say block 4 on the display is to be a figure 6. M3 selects display anode A4 (S_{10} on M3-20 - low) during its scan. Q16 conducts to raise A4 from −70v to +3.5v, the other anodes remaining at −70v.

Simultaneously, M1 internal scan sets the block-4 byte on A_{3-0} B_{3-0} to 10001000 (for figure 6). Switch transistors Q_5 and Q_9 remain cut off, with collectors at digital common. For bits at logic 0, switch transistors Q8, 10, 11, 4, 6 and 7 conduct, and their collector potentials rise. This rise is passed through line capacitors C6, 10, 12, 7, 11 and 13, reverse-biassing their DC restoration diodes and drawing base current through their driver transistors. The resulting collector currents pull the selected segment cathodes from −70v to almost −175v, striking the gas discharge on segments A, C, D, E, F and G only of block 4. The driver emitter-resistors control the segment cathode currents for uniform display brilliance, and the charging time for the line capacitors.

3.9.10 Keep-alive electrodes

Four keep-alive electrodes in each digit block (2 anodes and 2 cathodes) are maintained at +5v and −175v respectively. All main block anodes and segment cathodes are held at −70v (D14 anode) except when activated. This ensures rapid discharge when energised, and helps to avoid inter-block "streaming".

3.9.11 Blanking

Spurious flashes on LED and digital displays are avoided by blanking. As M1 display and LED drive outputs change from one byte to the next, A_{3-0} B_{3-0} lines are set to logic 1 for 150μS. This causes a partial discharge of the line capacitors through the DC restoration diodes, turning off the drive transistors and blanking the display. The multiplex scan frequency is high enough, so that this blanking cannot be observed visually.

3.11 IEEE 488 STANDARD DIGITAL INTERFACE (Circuit Drawing No. 430427)

The IEEE Digital Interface assembly contains the extra memory and circuitry required for the execution and decoding of interface functions, and to perform data input/output transfers. Simplified diagram Fig. 3.47 shows the essential features of this board.

3.11.1 ROM Circuit

The IEEE Digital Interface assembly acts as an extension to the Digital assembly with connections to both the Processor Address and Data Buses. The board contains 4k bytes of program memory (M3) containing the subroutines to control the instrument from the IEEE 488 Bus. The ROM receives the address information, with chip selection being made by decoding address lines A3-A11 with $\overline{\text{XIOBD}}$.

3.11.2 Interface Circuit

The General Purpose Interface Adapter (GPIA). M9, provides the interface between the IEEE 488 Standard Instrument Bus and the 6800 microprocessor. The MPU can receive, process and send messages to the interface through the GPIA.

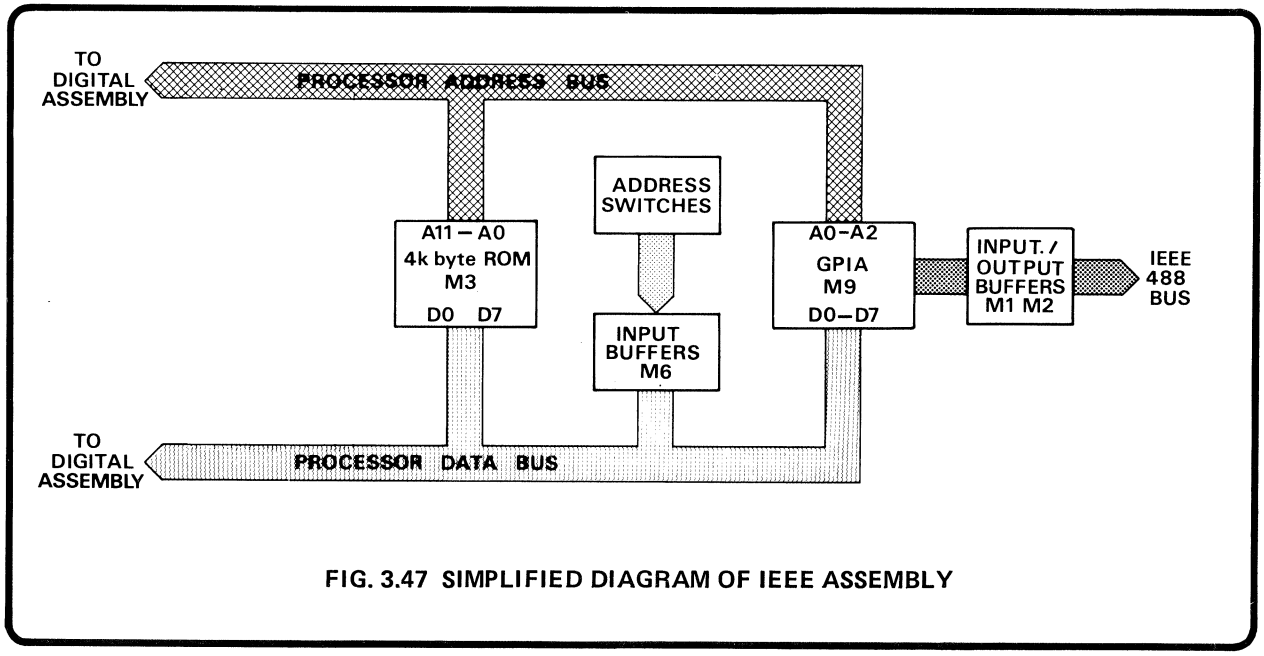

FIG. 3.47 SIMPLIFIED DIAGRAM OF IEEE ASSEMBLY

The GPIA is able to automatically handle the following interface protocol[1]:–

Single address capability
Source and acceptor handshake
Talker and Listener states
Service Request
Parallel Poll
Device Clear
Device Trigger

With the MPU it is also capable of:–
Programmable Interrupts
Storing the instrument's address
Control of the interface input/output buffers.

The GPIA is selected by decoding address lines A3-A11 with $\overline{XIOBD}$. Address lines A0-A2 with the state of the MPU R/$\overline{W}$ line select one of the 8 read-only or 7 write-only registers in the GPIA, enabling the MPU to send or receive data over the interface.

The two signals T/$\overline{R}$1 and T/$\overline{R}$2 are used to control low power transceivers (formed from M1, 2) which drive the interface bus.

[1] For further information refer to 'Getting aboard the 488 Bus' published by Motorola.

3.13 REAR (POWER SUPPLY AND REAR INPUT) PCB ASSEMBLY) Circuit Drawing No. 430418)

3.13.1 General

The line transformer and power supply components are situated at the rear right hand side of the instrument, when viewed from the front. Transformers T1 and T2 are of toroidal construction mounted one on top of the other and bolted to the rear panel. T1 has a split primary comprising two 115V windings, intended for either series or parallel connection depending on the line voltage. An earth screen is interposed between primary and secondary windings to minimise electrostatic coupling, and is grounded to line earth. The second transformer T2 is driven from T1. It also possesses an electrostatic screen, this time being connected to Guard.

The Rear PCB assembly also contains the switching circuitry to enable one of two analog signal sources to be connected to the measurement circuits of the DVM.

3.13.2 180V Supply

The 180V supply is required for the gas discharge display. Bridge rectifier W1 and C6 convert the 200V AC from the secondary of T1, to DC. R6, D3, R4 and Q2 act as a constant current source being regulated by D4, R5 and Q1. The +5V line (TP2) is connected to the digital +5V line on the Front PCB assembly.

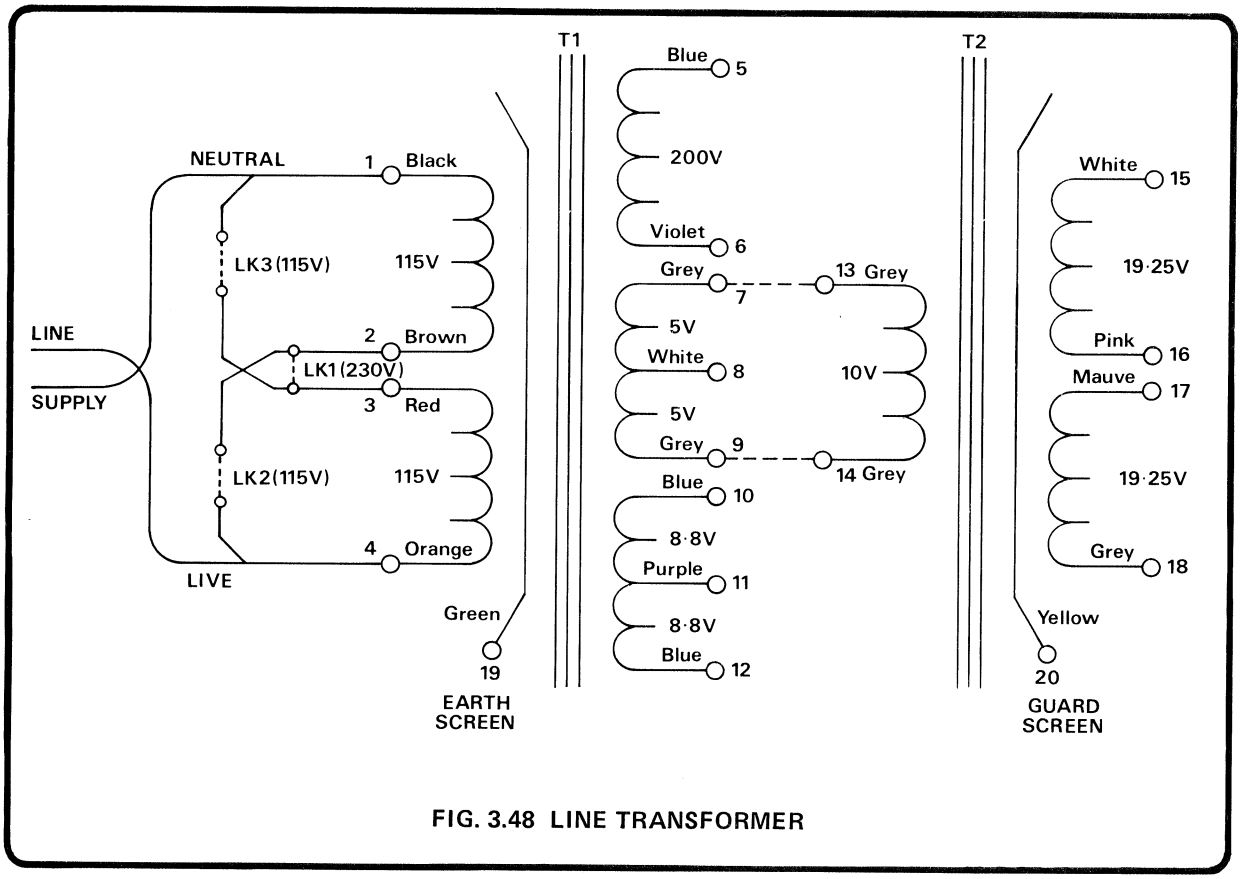

FIG. 3.48 LINE TRANSFORMER

3.13.3 5V Supply

All the logic circuitry to the right of the central printed circuit board is powered from the supply generated from the two 8.8 volt 750mA secondary windings on transformer T1. The centre tap (digital common) is referenced to line earth via a 100kΩ resistor, R1 in parallel with a 100nF capacitor, C1. The output of rectifying diodes D1 and D2 is smoothed by C7 and C8 before being fed to regulator M1. This regulator is capable of 1 amp output and has foldback current limiting and thermal shut-down, to provide short circuit protection.

3.13.4 ±15V Supply

The third secondary winding of T1 (10V centre-tapped) drives the primary of the ±15V Analog supply transformer T2. The two 19.25V secondary windings of T2 are connected in series by an external short to leads 16-17 at J6-5/8. This centre tap is connected to analogue common. The output of bridge rectifier W2 is fed to voltage regulators M2 and M3 (wired in series), to produce positive and negative 15 volt supplies to power the analog circuitry. These regulators also include foldback current limiting and thermal shut-down, to provide short-circuit protection.

3.13.5 Front Panel/Rear Panel Input (Drawing 430418 Sheet 2)

When Front Input is slelected, either remotely or on the front panel, this causes the base of Q3 to be connected to 0 volts, turning on the transistor. Thus relays RL1 and RL2 are energised, causing the front signal input terminals to be connected to the measurement circuits. Should Rear Input be selected relays RL1 and RL2 are de-energised, connecting the rear input to the measurement circuits.

3.14 SELF TEST SEQUENCE

Selection of the TEST key places the instrument into a test routine, checking the display and basic measuring circuits. A flowchart for the routine is given in Fig. 3.49. The analog circuitry conditions for each test are given in the last subsection of the circuit description for the particular board, and the range 'F.E.T.' patterns in Appendix 1.

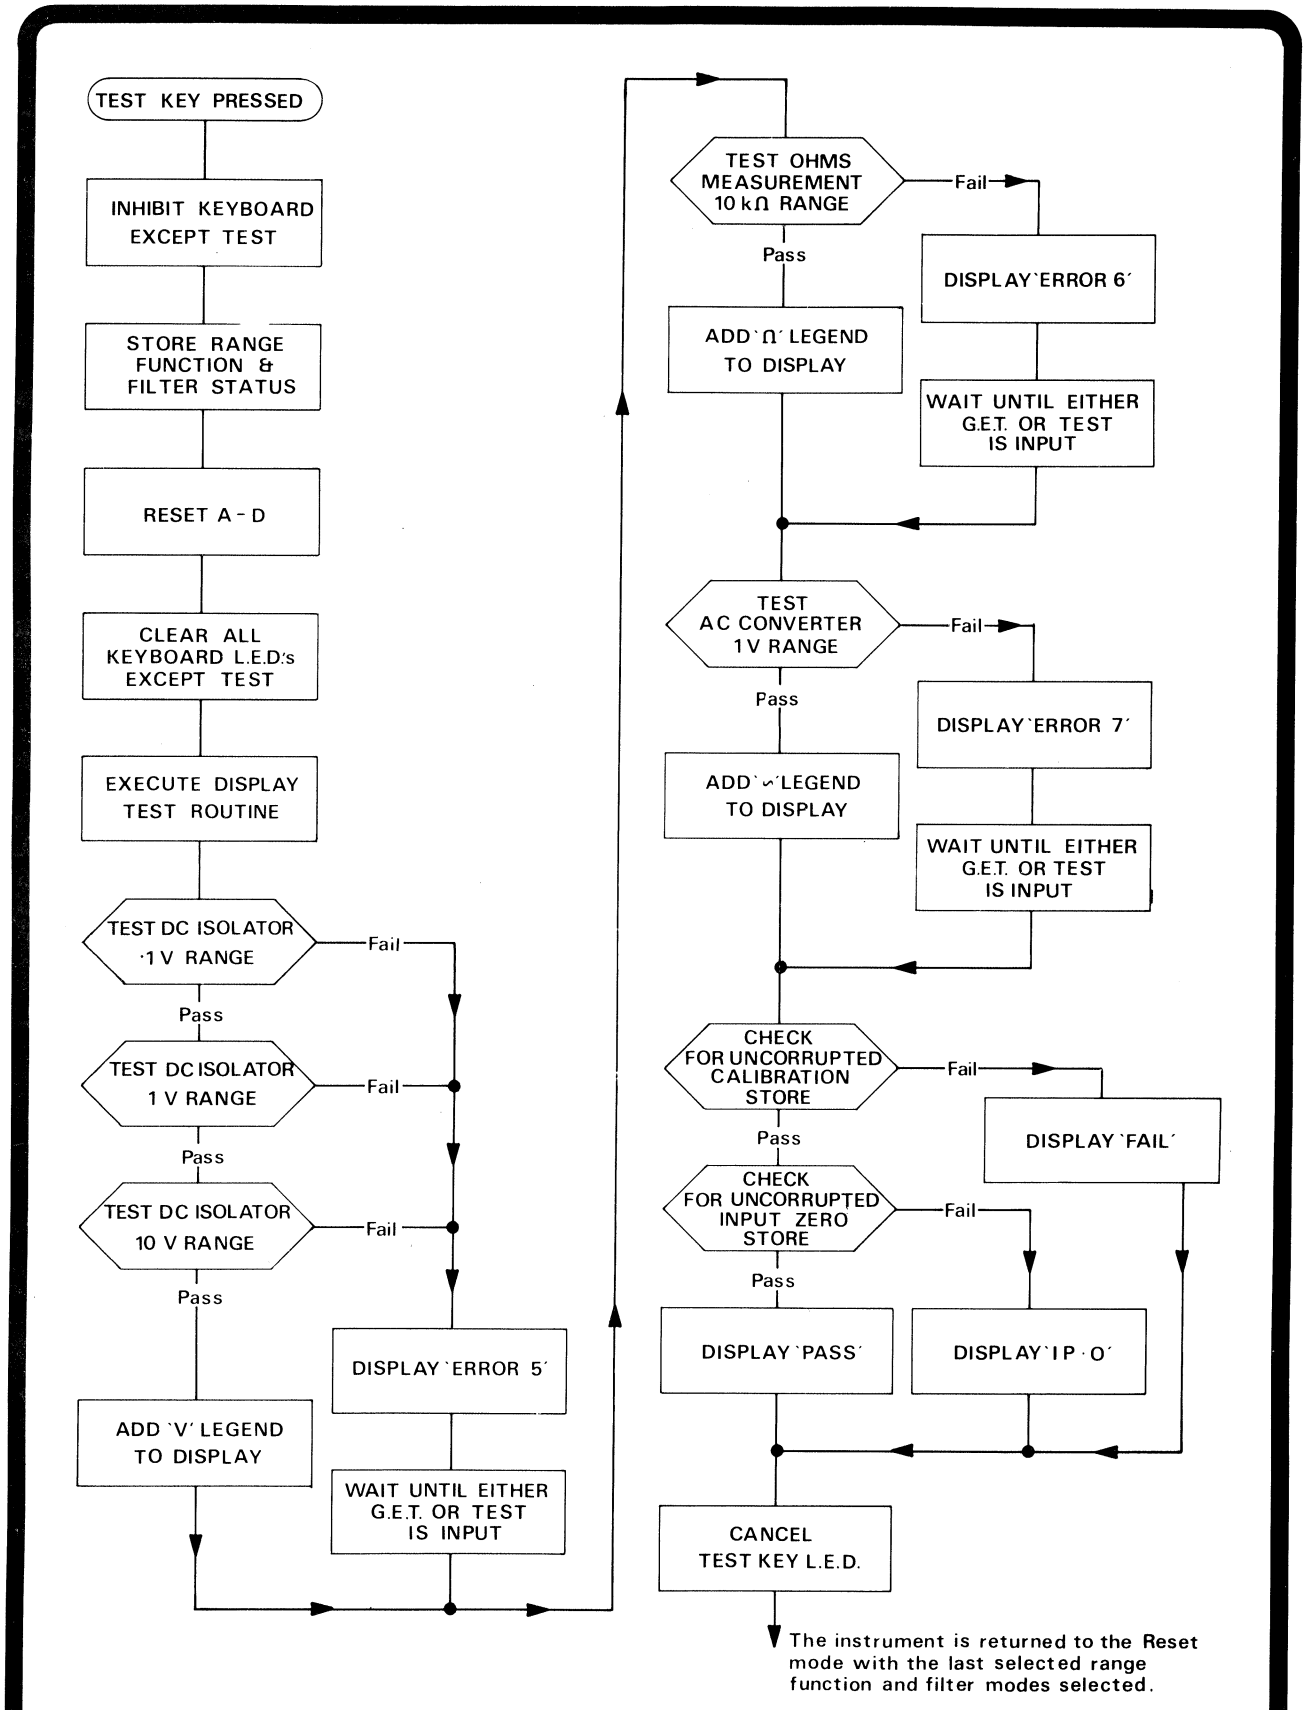

FIG. 3.49 FLOWCHART OF SELF-TEST ROUTINE

SECTION 4

INTERNAL ADJUSTMENT PROCEDURES

4.1 CHANGING LINE VOLTAGE AND FREQUENCY

The instrument is set to 50Hz, 205V to 255V supplies unless otherwise specified on the instrument identification label located on the rear panel. Alteration to a different line voltage/line frequency may necessitate an instrument recalibration.

4.1.1 Changing Line Voltage

1. Disconnect power and all signal input/output leads.
2. Remove the lower cover.
3. Locate the link(s) connecting the split primary on the printed circuit board in front of the toroidal line transformer, Fig. 2.1 and Drawing No 400418.
4. 115V Operation:– Remove LK1 (link 1) and fit LK2 and LK3[1].
   230V Operation:– Remove links LK2 and LK3, and fit LK1[1].
5. Amend instrument identification label.
6. Replace lower cover.
7. Replace power fuses with 160mA anti-surge (230V) or 500mA anti-surge (115V).
8. Carry out the Specification Verification tests (Section 7, User's Handbook) and recalibrate if necessary.

4.1.2 Changing Line Frequency

1. Disconnect power and all signal input/output leads.
2. Remove the top cover.
3. 400Hz Operation:– Remove link LK5 and fit LK7[1] on the Digital assembly, (Drawing No. 400422.
   50/60Hz Operation:– Remove link LK7 and fit LK5[1] on the Digital assembly (Drawing No. 400422).
4. Place instrument into 'Reset'. Adjust L2 (Digital assembly) so that TP7 is 1.05V ±0.03V with respect to Digital Common (TP28), with new supply ON.

NOTE: This signal contains about 200mV peak-to-peak high frequency noise.

5. Amend instrument identification label.
6. Replace the top cover.
7. Carry out the Specification Verification tests (Section 7, User's Handbook) and recalibrate if necessary.

[1] Links should be 22 SWG TIN.Cu wire with silicone rubber sleeving.

4.2 BATTERY REPLACEMENT

The battery should be replaced on or before the date indicated on the rear panel instrument identification label. To retain the calibration memory, the instrument must be powered-up during replacement. Therefore great care must be taken due to voltages up to 260 volts being present inside the instrument.

1. Remove top cover and locate battery on the Digital assembly (see Fig. 2.1).
2. Power-up instrument.
3. Desolder battery at end of tags and remove from clip.
4. Replace with new battery, (Datron Part No. 920049) positive terminal to resistor.
5. Replace top cover.
6. Amend instrument identification label (Current date + 5 years).
7. Carry out the Specification Verification tests (Section 7, User's Handbook) and recalibrate if necessary.

4.3 POST-REPAIR PROCEDURES

Apart from the RMS Module (which is available only from Datron), all integrated circuits and semiconductor devices are standard manufacturers' products, and special selection is unnecessary. During manufacture certain resistors are selected in value (FSV = Factory Selected Value) to accommodate circuit component tolerances, or to bring the desired setting of a preset control to the middle of its adjustment range.

The thermal tracking of the DC Preamplifier is particularly important, to ensure a low order of zero drift with variations of temperature. This rather time consuming procedure is carried out initially during manufacture, and need only be repeated following replacement of Q12 or any component associated with the temperature compensation circuitry.

NOTE: A routine calibration as detailed in Section 1 should be carried out after completion of the following procedures.

CAUTION : Up to 260 volts is present inside the instrument. Personal contact with these points may result in injury.

4.3.1 Basic DC Instrument

Equipment Requirements:

4½ digit Digital Voltmeter e.g. Datron 1041
Variable 5V, 1 amp DC supply
5mV/division Oscilloscope e.g. Telequipment D83
10MΩ5% resistor in parallel with 10nF capacitor
DC Voltage Calibrator, e.g. Fluke 332D with correction figures.

Procedure:

Power Supplies

1. Turn instrument on and allow 5 minutes warm-up period.

2. Connect DVM Hi to TP8 and Lo to TP28 on the Digital assembly. Adjust R2 on the Rear pcb assembly to give +5.100V ±25mV.

3. Connect DVM Hi to TP1 and Lo to TP20 on the Analog assembly. Adjust R7 on the Rear pcb assembly to give +15.000V ±15mV.

4. Connect DVM Hi to TP2 and Lo to TP20 on the Analog assembly. Adjust R12 on the Rear pcb assembly to give −15.000V ±15mV.

Digital Assembly

5. Switch the instrument off and disconnect the power lead.

6. Isolate the Digital Board by removing the connectors along the centre panel (J1-J5).

7. Connect variable 5V supply and DVM Hi's to TP8, Lo's to TP28. Reduce supply to 4.750V ±10mV.

8. Set R83 fully clockwise. Connect oscilloscope Lo to TP28 and monitor M35 pin 40. Turn R83 anti-clockwise until TP30 undergoes a high to low transition (or begins to pulse low).

9. Remove variable supply and reconnect items disconnected in steps 5 and 6. Disconnect the oscilloscope. Switch on the instrument.

10. Connect DVM Hi to battery positive terminal, Low to TP28. Check battery voltage is >2.5 volts.

11. Disconnect DVM and connect oscilloscope Hi to TP25, Lo to TP28. Adjust R11 to give a 5mS ±0.5mS period, mark-space ratio approx 100:1.
NOTE: This signal appears in short 'bursts' every reading.

12. Place instrument into 'Reset'. Connect oscilloscope Hi to TP7. Adjust L2 to give a stable +1.05V ±0.03V.
NOTE: This signal contains about 200mV peak to peak high frequency noise.

13. Insert calibration key into keyswitch on the back panel and turn, placing the instrument into CAL mode.
NOTE: The display CAL legend will be lit.

14. Short together pins 'D' and 'E' on Digital assembly.
NOTE: All the calibration store correction factors are now reset to zero.

15. Turn the calibration key back to RUN mode.

Analog Assembly (DC Isolator Section)

16. Centralize R150 and R160.

17. Select 0.1V range DC with 'Filter' out. Apply a 10MΩ resistor between instrument Hi and Lo. Connect DVM Hi to TP13, Lo to TP20.
Adjust FSV R152 with a metal film resistor (50ppm/°C) for a reading of < 10mV, using R159 for 'fine' adjustments.
Do not solder in R152.

18. Apply a short circuit across the input terminals and adjust R150 for a reading of <4mV ±0.1mV at TP13.

19. Connect DVM Hi to TP33 and adjust R160 for a reading of <20μV.

20. Repeat steps 17 to 19 until readings are within specified limits.

21. Select 100V range and apply short circuit between Hi and Lo. Connect DVM Hi to TP7, Lo to TP20. If reading is +6.42V ±0.03V proceed to step 23.

22. Switch off instrument and make positive reference links A to C, if cut i.e. the links alongside TP7. Switch on instrument and measure voltage on TP7 once again. Consult Fig. 4.1 and cut links as indicated. Repeat step 21.

Voltage on TP7 or TP8	TL'B'	TL'C'
6.42	—	—
6.47	—	✓
6.525	✓	—
6.58	✓	✓

Select voltage closest to measured value and cut links

FIG 4.1 REFERENCE SELECTION VOLTAGES

23. Connect DVM Hi to TP8. If reading is −6.42V ±0.03V proceed to step 25.

24. Switch off instrument and make negative reference links B and C, if cut i.e. the links alongside TP8. Switch on instrument and measure voltage on TP8 once again. Consult Fig. 4.1 and cut links as indicated. Repeat Step 23.

25. Select 'Reset'. Connect DVM Hi to TP9. Select correct resistance value for FSV R11 or R15 to give a reading of 0V ±1mV. Solder in resistor.

26. Deselect 'Reset' and disconnect DVM. Select 1000V range and apply −100mV. Connect oscilloscope Lo to TP21, Hi to TP5. Adjust R20 for noisy waveform at zero point.

27. Remove oscilloscope. Replace covers but do not replace screws. Select 10V, DC, filter out and apply s/c across input terminals. Turn rear panel key-switch to CAL mode and select LIN.

28. Select 10V range, 'Filter' and apply short copper link across input terminals. Select 'Zero'.

29. Apply +10 volts and select GAIN. Repeat until display reads +10.0000 ± ½ digit.

30. Apply +19 volts. If the display reads within the limits +18.9999 to +19.0001, proceed to step 32.

31. Calculate E = (19 - displayed reading)/2.
Re-apply +10 Volts and adjust R23 for a displayed reading of 10 - E.
Repeat steps 29-31 until both readings are within the limits indicated.

32. Turn rear panel keyswitch to RUN mode.

The basic DC only instrument set-up procedure is complete.

4.3.2 Ohms Assembly

Equipment Required :

5½ digit Digital Voltmeter e.g. Datron 1051 or 1061.
10MΩ5% resistor in parallel with 10nF capacitor.
Copper shorting links.

Procedure

1. Centralize R26 and R27.

2. Select kΩ, 10kΩ range and Rear and use the rear panel input. Connect I− to Ω GUARD, I+ to Hi and 10MΩ between Hi and Lo. Connect DVM Hi to TP4, Lo to TP1. Adjust R26 for zero ± 300μV.

3. Remove 10MΩ resistor and replace with a short circuit. Connect DVM Hi to TP14 and adjust R27 for zero ± 2μV.

4. Repeat steps 2 and 3 until readings are within specified limits.

The basic Ohms set-up procedure is complete.

4.3.3 AC Assembly

Equipment required:

4½ digit Digital Voltmeter e.g. Datron 1041.
5mV/division Oscilloscope e.g. Telequipment D83.
AC Calibrator e.g. Fluke 5200A.
5:1 asymmetric crest factor signal, 1 volt r.m.s., 0.02% accuracy.

Procedure

1. Select AC 1000V range and HOLD. Short Hi to Lo. Connect DVM Hi to TL7, Lo to TP8 and note reading. Select 1V range and adjust R121 (bias current) to give same reading ±10μV.

2. Select 1V range, AC + DC and adjust R112 (offset adjust) for an indication of zero ±50μV on the DVM.

3. Repeat steps 1. and 2. until readings are within the specified limits.

4. Select 10V range and HOLD. Connect oscilloscope Hi to TP5, Lo to TP8 and adjust R90 (rectifier zero) for maximum noise about zero. Remove the oscilloscope.

5. Connect DVM Hi to TP2, Lo to TP8 and adjust R75 (linearity) for an indication on the DVM of 5mV ±10%.

6. Select AC, 1V range, FILTER and apply 1V 500Hz. Connect DVM Hi to TL5, Lo to TP8. If reading is +3.157V ±0.01V proceed to step 8.

7. Disconnect input signal and switch off instrument, Make links TL1 to TL4 if cut. Switch on instrument, reselect AC, 1V range, FILTER and reapply 1V, 500Hz. Measure voltage on TL5. Consult Fig. 4.2 and cut links as indicated. Check voltage on TL5 is 3.157V ±0.01V. Remove the DVM.

Voltage on TL5	TL1	TL2	TL3	TL4
3.157	–	–	–	–
3.178	–	–	–	✓
3.198	–	–	✓	–
3.218	–	–	✓	✓

3.420	✓	✓	–	✓
3.440	✓	✓	✓	–
3.460	✓	✓	✓	✓

Select voltage closest to measured value and cut links

FIG 4.2 AC BOARD OUTPUT SELECTION VOLTAGES

8. Deselect HOLD and short circuit instrument Hi and Lo. Turn rear panel key switch to CAL mode and select ZERO. Repeat for all ranges.

9. Select 1V range. Apply 1 volt (d.c.) and note reading on display. Apply −1 volt (d.c.) and adjust R50 (d.c. turnover) for same display indication ±10 digits.

10. This part of the procedure must be performed with the high frequency compensation voltage, at J1-11/ R57, at −5V ±0.2V.

    a. Select AC 100V range, FILTER and apply 100V, 500Hz. Select GAIN. Apply 100V, 30kHz and adjust C62 for a display of 100.000V ±20 digits.

    b. Select 1V range and apply 1 volt, 500Hz. Select GAIN. Apply 1V 30kHz and adjust C63 for a display of 1.00000 ±20 digits.

11. Apply 1 volt 5:1 crest factor signal. Adjust R35 (crest factor) for a display of 1.00000V ±30 digits.

12. Open circuit input. Turn rear panel key switch to RUN. Select TEST and check for a display of PASS. Turn rear panel key switch to CAL.

13. Select 10V range and apply 10V, 30kHz. Check display is 10.0000V ±1200 digits. Check that the display can be calibrated to 10.0000 ±20 digits by less than 5 presses of the AC Hf key.

14. Select 1000V range and apply 1000V, 500Hz. Select GAIN.

15. Apply 1000V, 25kHz and check display is 1000.00V ±1200 digits. Check that display can be calibrated to 1000.00V ±20 digits by less than 5 presses of the AC Hf key. Remove 1000V and turn rear panel key switch to RUN.

    The basic AC set-up procedure is complete.

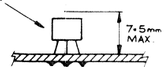
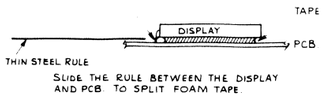
N.B. NO COMPONENTS TO STAND HIGHER THAN 7·5 (EXCEPT SWITCHES & TERMINALS)



TO REMOVE DISPLAY, CUT PINS HERE



SLIDE THE RULE BETWEEN THE DISPLAY AND PCB. TO SPLIT FOAM TAPE.

DISPLAY TO HAVE 4 PIECES (25mm LONG) OF PRESSURE SENSITIVE TAPE - PART Nº 630029, STUCK TO REVERSE OF DISPLAY IN POSITIONS SHOWN. LINE-UP & PRESS DISPLAY FIRMLY INTO PLACE. THEN SOLDER THE 24 PINS ONLY, WHICH ARE SHOWN BELOW. (THERE ARE SOLDER PADS ONLY FOR THESE PINS.)

FIT WARNING LABEL 420080-1 IN APPROX. POSITION SHOWN, ON CIRCUIT SIDE OF PCB NEAR MAINS AND DISPLAY CONNECTIONS

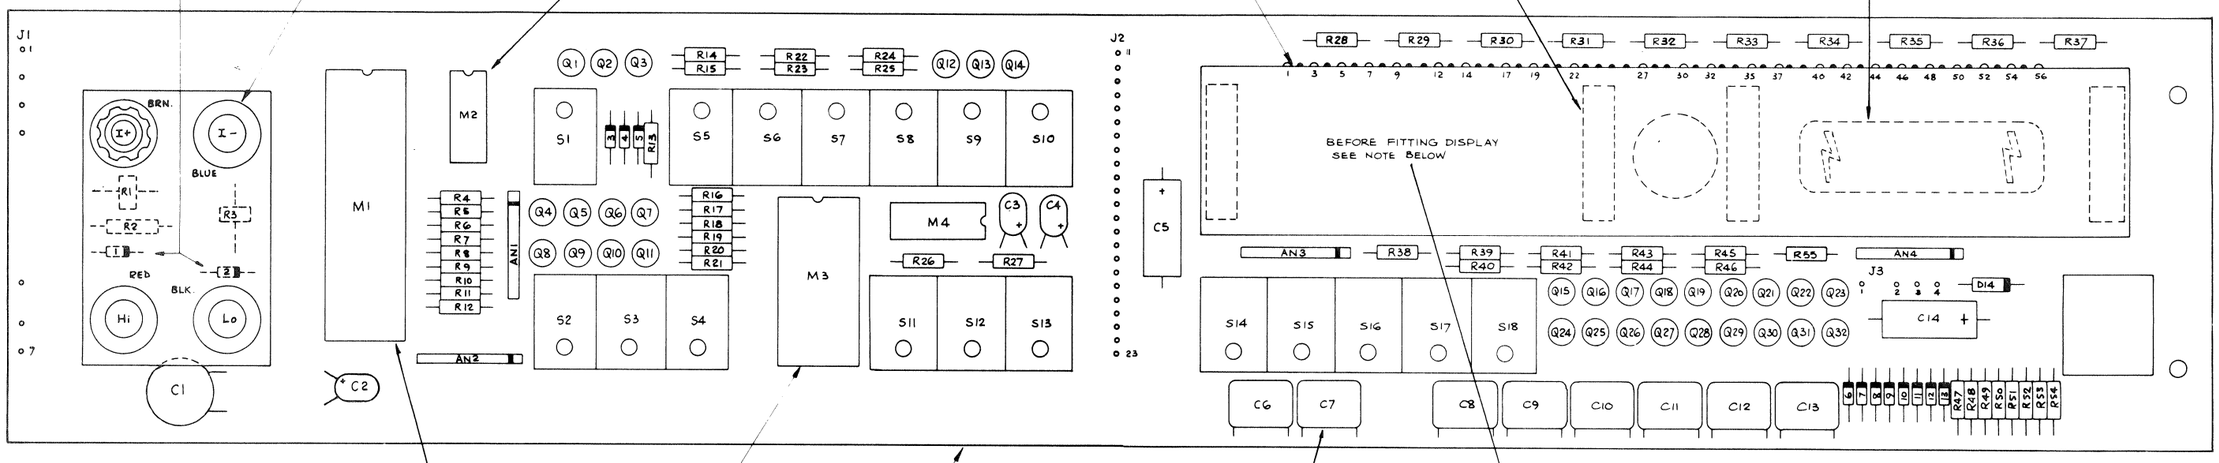
N.B. SLEEVE BODY OF D1 & D2 (LIGHT SENSITIVE!) WITH SLEEVE 590001 – 2 OFF BEFORE SOLDERING.

ASSEMBLE 4 TERMINALS TO TERMINAL PLATE (PART Nº 450295 AND PCB., AS SHOWN ABOVE. TERMINAL COLOURS MUST BE AS INDICATED BELOW.

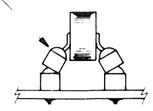
MOUNT M2 & M4 INTO 14 WAY DIL SOCKET - PART Nº 605060, 2 OFF

8½ DIGIT DISPLAY (PART Nº 800017)

BEFORE FITTING DISPLAY SEE NOTE BELOW



RESISTORS R1–R3 & DIODES D1-D2 TO BE MOUNTED ON UNDERSIDE OF BOARD. R1 & R3 TO BE MOUNTED ON INSULATING BEADS – 2 PER LEG – AS SHOWN, BEFORE SOLDERING. (PART Nº OF BEADS 630024 8 OFF)

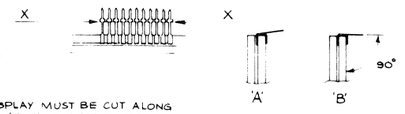


MOUNT M1 ON 40 PIN DIL SOCKET - PART Nº 605098

MOUNT M3 ON 24 PIN DIL SOCKET SOCKET – PART Nº 605097

PCB 410149-3A

ALL CAPACITORS TO BE LAID DOWN WHERE POSSIBLE; LEADS TO BE BENT AT RIGHT ANGLE THEN INSERTED INTO PCB., THIS IS TO KEEP CAPACITORS AS LOW AS POSSIBLE.



PINS OF THE DISPLAY MUST BE CUT ALONG THE LINE SHOWN 'X–X'. THEN THE PINS MUST BE BENT FROM POSITION 'A' TO POSITION 'B' BEFORE INSERTION INTO PCB.

N.B. FIT FROM COMPONENT SIDE OF PCB.

SECTION A-A

FSV TERMINAL PART No 602001 5 OFF

COLOUR DOTS TO BE ON TOP

3mm APPROX

PCB 400395-5A

LOOP D35 & D60 LEADS AS ABOVE

MOUNT M39, Q35, Q36, M24 ON 8 WAY DIL SOCKET No 605058 - 4 OFF

NOTE: THESE PINS TO BE PAIRED TOGETHER BY CUTTING, BENDING & SOLDERING

10 OFF UNSLEEVED LINKS

AN3 TO BE EMBEDDED IN SILICONE RUBBER COMPOUND. PART Nº 900004 BEFORE SOLDERING.

SLEEVE LEADS OF D68 BEFORE SOLDERING TO UNDERSIDE OF PCB. USE 590004.

CLOVERLEAF TERMINALS PART No 620005 5 OFF

TO SOLDER TERMINAL A WIRE LENGTH 25 mm

TO STANDOFF PIN AT B WIRE LENGTH 35 mm

TO STANDOFF PIN AT C WIRE LENGTH 70 mm

TO SOLDER TERMINAL E WIRE LENGTH 40 mm

WIRE 25 mm LONG JOINING THESE TERMINALS TOGETHER SLEEVED (AS SHOWN)

VIEW IN DIRECTION OF ARROW

SLEEVE ALL JOINTS WITH ½ PIECE OF 550001

1 OFF NUT G15005

1 OFF WASHER M2.5 INT SHAKEPROOF G13014

JOIN BOTTOM TERMINAL OF RELAY INTO HOLE IN PCB WITH TINNED COPPER WIRE.

WIRE/TERMINAL ASSY 400379/2 4 OFF

8 WAY POLARISED SOCKET 605052 - 2 OFF

NOTE ! ALL RELAY WIRES USE 7/2 PTFE INSULATED WHITE 540008 STRIP 5mm FROM EACH END.
