# **Printing History**

New editions of this manual will incorporate all material updated since the previous edition. Update packages may be issued between editions and contain replacement and additional pages to be merged into the manual by the user. Each updated page will be indicated by a revision date at the bottom of the page. A vertical bar in the margin indicates the changes on each page. Note that pages which are rearranged due to changes on a previous page are not considered revised.

The manual printing date and part number indicate its current edition. The printing date changes when a new edition is printed. (Minor corrections and updates which are incorporated at reprint do not cause the date to change.) The manual part number changes when extensive technical changes are incorporated.

July 1985...Edition 1. This manual replaces HP-UX Reference Manual 09000-90007 and documents HP-UX Release 5.0 for Series 200, 300 and 500.

November 1985...Edition 2. Updated from Edition 1 to reflect Series 200/300 HP-UX Release 5.1 changes. Several omitted pages in Edition 1 were also added.

June 1986...Edition 3. Update 1 incorporated.

September 1986...Edition 3 Update 1. This update reflects additions and changes incorporated in Series 500 HP-UX Release 5.1. Added command *autobackup*(1M) and core files support (*core*(5)), changed blocksize limitations for SDF file formats, and fixed various bugs.

bdiff	
bfs	0
bifchmod	
bifchown change file ov	
bifcp copy to or i	
bifdf report number of fr	
biffind find files in	
biffsck Bell file system consistency check and inte	
biffsdb Bell file sys	stem debugger
bifls list contents of B	
bifmkdir make a	
bifmkfs construct a B	
bifrm remove BIF files	
bs compiler/interpreter for modest-si	
cal	
calendar ren	minder service
cat concatenate, copy, a	
cb	fier, formatter
cc	C compiler
cd	
cdb C, FORTRAN, Pascal symb	oolic debugger
cdc change the delta commentary of a	an SCCS delta
cflow generate	C flow graph
chatr	nal attributes
chmod	
chown	wner or group
chsh	ult login shell
clear te	erminal screen
cmp com	
col filter reverse linefeeds ar	
comm select/reject common lin	es of two files
compact compress and uncompress files,	and cat them
cp	
cpio	
cpp	
crontab use	
csh	
ctags cre	
	a sugo me

CII	call another HP-UX system
	cut out selected fields of each line of a file
	generate C program cross-reference
	print and set the date
	desk calculator
	convert, reblock, translate, and copy a (tape) file
	make a delta (change) to an SCCS file
deroff	remove nroff/troff, tbl, and eqn constructs
	differential file comparator
	mark differences between files
	directory difference comparison
du	summarize disk usage
	echo (print) arguments
	text editor
	text editor (variant of ex for casual users)
	enable/disable LP printers
	set environment for command execution
	report error information on last failure
	text editor commands
	expand tabs to spaces, and vice versa
	expand tabs to spaces, and vice versa evaluate arguments as an expression
	evaluate arguments as an expression see fc
	factor a number, generate large primes
	FORTRAN 77 compiler
	determine file type
	V-2
	find files
finding	create message catalog file for modification find strings for inclusion in message catalog
findstr	
f_1_J	
TOIQ	fold long lines for finite-width output device
	generate a formatted message-catalog file
	get a version of an SCCS file parse command options
	get special attributes for group
geoprivgrp	search an ASCII file for a pattern
	search an ASOH me for a pattern
groups show group memberships	give first few lines of file
	ask for help
	set or print name of current host system
	andle special functions of HP 2640 and 2621 series terminals
	find hyphenated words
10	print user, group IDs and names
	use findstring output to insert calls to getmsg
	nove a message queue, semaphore set, or shared memory id
	report inter-process communication facilities status
	relational database operator
	terminate a process
	indicate last logins of users and teletypes
	link editor
	remind you when you have to leave
	generate programs for lexical analysis of text
	copy to or from LIF files
	write LIF volume header on file
litls	list contents of LIF directory

lifrename	rename LIF files
	remove a LIF file
	read one line from user input
	object file link information utility
	a C program checker/verifier
	reserve a terminal
	sign on
	get login name
	find ordering relation for object library
	send or cancel requests to an LP line printer
	print LP status information
	list contents of directories
	list device drivers in the system
	macro processor
	provide truth value about your processor type
	send mail to users or read mail
	send and receive mail
	maintain, update, recompile programs
	on-line manual command
	initialize hard disc, flexible disc, or cartridge tape media
	permit or deny messages to terminal
	make a directory
	extract error messages from C source into a file
	print documents formatted with MM macros
	me perusar inter for cit viewing magnetic tape manipulating program
navarn	log in to a new group
	print news items
	run a command at low priority
	line numbering filter
	print name list (symbol table) of object file
nohun	run a command immune to hangups, logouts, and quits
	format text
	octal and hexadecimal dump
	compress and expand files
	merge lines in one or more files
	Pascal compiler
	print files
	print nes print nes print nes
	display profile data
	print and summarize an SCCS file
	report process status
•	create permuted index
	working directory name
	interactive IMAGE database access
	rational FORTRAN dialect
	reverse lines of a file
	get HP-UX revision information
	get HP-UX revision information remove files or directories
	remove a delta from an SCCS file
	remove a delta from an SCCS file remove extra new-line characters from file
	execute process with real-time priority
	execute process with real-time priority print current SCCS file editing activity
sact	1

scesdiff
sed
sh
sizeobject file size sleep suspend execution for an interval
slep suspend execution for an interval slp set printer options
sort sort and/or merge files
spell find spelling errors
split
ssp remove multiple line-feeds from output
strings
strip remove symbols and relocation bits
stty set the options for a terminal port
su become another user
sum print checksum and block count of a file
sync update the super block
tabs set tabs on a terminal
tail deliver the last part of a file
tar
tbl
tcio
tee pipe fitting test condition evaluation command
time time a command
touch update access/modification/change times of file
tput query terminfo database
tr
true provide truth values
tset terminal dependent initialization
tsort topological sort
tty get the terminal's name
ul do underlining
umask set file-creation mode mask
uname print name of current HP-UX version
unget undo a previous get of an SCCS file
uniq report repeated lines in a file
units unit conversion program
upm unpack cpio archives from HP media
uucp
uuls
uustat
uuto
uux
val validate SCCS file
vi visual text editor
vis make unprintable characters in a file visible or invisible
wait await completion of process
wc word, line, and character count
what identify files for SCCS information
whereis locate source, binary, and/or manual for program
who
whoami print effective current user id
write interactively write (talk) to another user
xargs construct argument list(s) and execute command

yacc		yet another co	ompiler-compiler
------	--	----------------	------------------

# 1M. System Maintenance Utilities

accept	allow or prevent LP requests
acct	. overview of accounting and miscellaneous accounting commands
acctems	command summary from per-process accounting records
acctcon	connect-time accounting
acctmerg	merge or add total accounting files
acctprc	process accounting
	shell procedures for accounting
	backup or archive file system
brc	system initialization shell scripts
captoinfo	convert a termcap description into a terminfo description
catman	create the cat files for the manual
chroot	change root directory for a command
	change to different operating system or version
	clear i-node
	clear x.25 switched virtual circuit
config	configure an HP-UX system
	install object files in binary directories
	clock daemon
	device name
	report number of free disk blocks
	generate disc accounting data by user ID
fsck	file system consistency check, interactive repair
fsclean	determine shutdown status of specified file system
fsdb	file system debugger
fwtmp	manipulate wtmp records
	set the modes of a terminal
	get x.25 line
	process control initialization
	install commands
	KERMIT-protocol file transfer program
Killali	send signal to all user processes
	exercise link and unlink system calls
	administer the LP spooling system
	start/stop the LP request scheduler and move requests
	generate encryption key make device files
	construct a file system
	configure the LP spooler system create special, fifo, files
	mount and unmount file system
mount	mount and diminount me system move a directory
	generate names from i-numbers
	construct a new file system
	execute HALGOL programs
	check integrity of OS in SDF boot area(s)
osmark	mark SDF OS file as loadable/unloadable
osmor	operating system manager package description
nwek	password/group file checkers
	reboot the system
100000	

revck	
rootmark	mark/unmark volume as HP-UX root volume
runacet	run daily accounting
sdfinit	initialize Structured Directory Format volume
setmnt	
setprivgrp	set special attributes for group
shutdown	terminate all processing
stopsys	stop operating system with optional reboot
swapon	enable additional devices for swapping and paging
syncer	periodically sync for file system integrity
syncertic	terminfo compiler
tunefs	tune a file system
uconfig	system reconfiguration
umodem	XMODEM protocol file transfer program
umodemuntic	terminfo de-compiler
uucico	uucp copy in and copy out
uuclean	uucp spool directory clean-up
uusub	monitor uucp network
uuxqt wall	uucp command execution
wall	write to all users
whodo	which users are doing what

# 2. System Calls

access determine accessibility of a file
alarm set process's alarm clock
brk
chdir
chmod
chown
chroot
close close a file descriptor
creat create new file, rewrite existing file
dup
duplicate an open file descriptor
ems Extended Memory System
errinfo error indicator
errno error indicator for system calls
exec
exit terminate process
fcntl file control
fork
fsync
ftime get date and time more precisely
get group access list
get name of current host
getitimer get/set value of interval timer
getpid get process, process group, and parent process IDs
getprivgrp get/set special attributes for group
get/set date and time
get real/effective user, real/effective group IDs
ioctl control device
kill send signal to process(s)
link to a file

lockf	nuovide comenhance and record leaking on files
10CK1	provide semaphores and record locking on mes
lseek	
memadvise	
memallc	
memchmd	
memlck	
memvary	
mkdir	create a directory file
mknod	make directory, special or ordinary file
mount	
msgctl	message control operations
msgget	get message queue
msgop	
nice	
open	
pause	
pipe	
plock	
prealloc	
profil	
ptrace	
read	
reboot	3
rmdir	
rtprio	change or read real-time priority
select	synchronous I/O multiplexing
semctl	semaphore control operations
semget	get set of semaphores
semop	semaphore operations
setgroups	
sethostname	9 <b>.</b>
setpgrp	
setuid	
shmctl	
shmget	
shmop	
sigblock	v 1
signal	set up signal nandling for program
sigpause automatica	
sigsetmask	
sigspace	
sigvector	· · · · · · · · · · · · · · · · · · ·
stat	
stime	
stty	
swapon add	d a swap device for interleaved paging/signalling
sync	update the super block
time	get time
times	o contract of the contract of
trapno	
truncate	
ulimit	
umask	
umount	
uname	
инаше	get name of current nr-UX system

unlink	remove directory entry; delete file
ustat	get file system statistics
utime	set file access and modification times
vfork	spawn new process in a virtual memory efficient way
vsadv	advise system about backing store usage
vson	advise OS about backing store devices
	wait for child process to terminate
write	write on a file

# 3. Subroutines

a64l convert between long and base-64 ASCII
abort generate an IOT fault
abs integer absolute value
assert program verification
atof
bessel bessel functions
bsearch binary search on a sorted table
catread
clock report CPU time used
conv
crypt
ctermid generate file name for terminal
ctime convert date and time to ASCII
ctype
curses
cuserid
dial establish an out-going terminal line connection
directory directory operations
drand48 generate uniformly-distributed pseudo-random numbers
ecvt output conversion
end last locations in program
erf error function and complementary error function
exp exponential, logarithm, power, square root functions
fclose
ferror stream file status inquiries
floor
fopen
fread buffered binary input/output to a stream file
frexp split into mantissa and exponent
fseek reposition a stream
ftw walk a file tree
gamma
getc get character or word from stream file
getcwd get pathname of current working directory
getenv
get file system descriptor file entry
get group file entry
getlogin get login name
get message from a catalog
getopt get option letter from argv
getpass read a password
get name from UID
get password file entry

gets	get a string from a stream file
	access utmp file entry
	return status lines of GPIO card
	set control lines on GPIO card
	stop activity on specified HP-IB bus
	return status of HP-IB interface
-	control response to parallel poll on HP-IB
	control EOI mode for HP-IB file
	perform I/O with an HP-IB channel from buffers
	change active controllers on HP-IB
	conduct parallel poll on HP-IB bus control response to parallel poll on HP-IB
haib and atl	control response to paramer poil on HP-1B
hpib_ren_cu	
	allow interface to enable SRQ line on HP-IB
	send command bytes over HP-IB
	conduct a serial poll on HP-IB bus
	wait until the requested status condition becomes true
	wait until a particular parallel poll value occurs
hsearch	manage hash search tables
hypot	Euclidean distance
	initialize group access list
	disable/enable integer trap handler
	perform low-overhead I/O on an HP-IB channel
	set up read termination character on special file
	determine how last read terminated
	enable/disable interrupts for associated eid
io_on_interrupt	device interrupt (fault) control
io_reset	reset an I/O interface
	inform system of required transfer speed
	establish time limit for I/O operations
	set width of data path
	convert between 3-byte integers and long integers
	NLS native language information
	return login name of user
lsearch	linear search and update
malloc	main memory allocator
matherr	mathematical error handling
memory	memory operations
mktemp	make a unique file name
monitor	prepare execution profile
nl_conv	translate characters for use with NLS
nl_ctype	classify characters for use with NLS
nl_string	non-ASCII string collation used by NLS
	get entries from name list
	system error messages
popen	initiate pipe I/O to/from a process
	output formatters
printmsg	print formatted output with numbered arguments
	put character or word on a stream
	change or add value to environment
	write password file entry
	put a string on a stream file
	put a string on a stream me quicker sort
	random number generator
	compile and execute regular expression
тевстр	compile and execute regular expression

scanf formatted input conversion, read from stream	
setbuf	file
setjmp non-local go	oto
sinh hyperbolic function	ns
sleep suspend execution for inter-	
sputl access long integer data in machine-independent mann	
ssignal software sign	
stdio standard buffered input/output stream file packa	
stdipc standard inter-process communication packet	
string	
strtod convert string to double-precision integrated to	,
strtol convert string to integ	
swap by	
system issue a shell comma	$\operatorname{nd}$
termcap access terminal capabilities in termcap	(5)
tmpfile create a temporary	file
tmpnam create a name for a temporary	file
trig trigonometric function	
tsearch manage binary search tre	
ttyname	
ttyslot	
ungetc push character back into input stree	
vprintf print formatted output from varargs argument l	ıst

NAME

m4 - macro processor

#### SYNOPSIS

m4 [ options ] [ files ]

#### HP-UX COMPATIBILITY

Level:

HP-UX/DEVELOPMENT

Origin: System V

# DESCRIPTION

 $M_4$  is a macro processor intended as a front end for Ratfor, C, and other languages. Each of the argument files is processed in order; if there are no files, or if a file name is -, the standard input is read. The processed text is written on the standard output.

The options and their effects are as follows:

- -e Operate interactively. Interrupts are ignored and the output is unbuffered. Using this mode requires a special state of mind.
- -s Enable line sync output for the C preprocessor (#line ...)
- -Bint Change the size of the push-back and argument collection buffers from the default of 4.096.
- -Hint Change the size of the symbol table hash array from the default of 199. The size should be prime.
- -Sint Change the size of the call stack from the default of 100 slots. Macros take three slots, and non-macro arguments take one.
- **-T***int* Change the size of the token buffer from the default of 512 bytes.

To be effective, these flags must appear before any file names and before any -D or -U flags:

-Dname[=val]

Defines name to val or to null in val's absence.

-Uname

undefines name.

Macro calls have the form:

```
name(arg1,arg2, ..., argn)
```

The (must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphabetic letters, digits, and underscore \_\_, where the first character is not a digit.

Leading unquoted blanks, tabs, and new-lines are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes.

When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be null. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses which happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned.

M4 makes available the following built-in macros. They may be redefined, but once this is done the original meaning is lost. Their values are null unless otherwise stated.

define the second argument is installed as the value of the macro whose name is the first argument. Each occurrence of n in the replacement text, where n is a digit, is

M4(1)

replaced by the *n*-th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; \$# is replaced by the number of arguments; \$\* is replaced by a list of all the arguments separated by commas; \$@ is like \$\*, but each argument is quoted (with the current quotes). All \$ metavariable replacement ignores quoting; every occurrence of a \$ metavariable is replaced.

undefine removes the definition of the macro named in its argument.

defin returns the quoted definition of its argument(s). It is useful for renaming macros,

especially built-ins.

pushdef like *define*, but saves any previous definition.

popdef removes current definition of its argument(s), exposing the previous one if any.

if the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is null. The word *unix* is predefined

on the HP-UX System versions of m4.

shift returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will

subsequently be performed.

change quote symbols to the first and second arguments. The symbols may be up to five characters long. *Changequote* without arguments restores the original values

(i.e., ` ').

change left and right comment markers from the default # and new-line. With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes new-line. With

two arguments, both markers are affected. Comment markers may be up to five

characters long.

divert m4 maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The divert macro changes the current output stream to its (digit-string) argument.

Output diverted to a stream other than 0 through 9 is discarded.

undivert causes immediate output of text from diversions named as arguments, or all diver-

sions if no argument. Text may be undiverted into another diversion. Undiverting

discards the diverted text.

divnum returns the value of the current output stream.

dnl reads and discards characters up to and including the next new-line.

ifelse has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is

either the fourth string, or, if it is not present, null.

incr returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number. Overflow is

not detected.

eval

decr returns the value of its argument decremented by 1. Underflow is not detected.

evaluates its argument as an arithmetic expression, using 32-bit arithmetic. Operators include +, -, \*, /, %, \*\* (exponentiation), bitwise &, |, ^, and ~; relationals; parentheses. Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result. Overflow and underflow

July 9, 1985

are not detected.

le	en	returns the number of characters in its argument.
iı	ndex	returns the position in its first argument where the second argument begins (zero origin), or -1 if the second argument does not occur. A null (or missing) second argument causes index to return $0$ .
S	ubstr	returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string.
t:	ranslit	transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.
iı	nclude	returns the contents of the file named in the argument.
S	include	is identical to include, except that it says nothing if the file is inaccessible.
S	yscmd	executes the HP–UX System command given in the first argument. No value is returned.
S	ysval	is the return code from the last call to syscmd.
n	naketemp	calls $\operatorname{mktemp}(3)$ to fill in a string of XXXXX in its argument with the current process ID.
n	n4exit	causes immediate exit from $m4$ . Argument 1, if given, is the exit code; the default is 0.
n	n4wrap	argument 1 will be pushed back at final EOF; example: m4wrap( `cleanup() ')
e	rrprint	prints its argument to stderr.
d	lumpdef	prints current names and definitions, for the named items, or for all if no arguments are given. Output goes to $stderr$ .
t	raceon	with no arguments, turns on tracing for all macros (including built–ins). Otherwise, turns on tracing for named macros.
t	raceoff	turns off trace globally and for any macros specified. Macros specifically traced by $traceon$ can be untraced only by specific calls to $traceoff$ .
	10

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

# DESCRIPTION

The following commands will return a true value (exit code of 0) if you are on a processor that the command name indicates.

## hp9000s200

True if you are on a Hewlett-Packard 9000 Series 200.

# hp9000s500

True if you are on a Hewlett-Packard 9000 Series 500.

pdp11

True if you are on a PDP-11/45 or PDP-11/70.

True if you are on a VAX-11/750 or VAX-11/780.

u3b

True if you are on a 3B 20S computer.

u3b5

True if you are on a 3B 5 computer.

vax

The commands that do not apply will return a false (non-zero) value. These commands are often used within make(1) makefiles and shell procedures to increase portability.

# SEE ALSO

make(1), sh(1), test(1), true(1).

#### NAME

mail, rmail - send mail to users or read mail

#### SYNOPSIS

```
mail [ -epqr ] [ -f file ]
mail [ -t ] persons
rmail [ -t ] persons
```

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

Native Language Support:

8-bit and 16-bit data.

#### DESCRIPTION

Note: An enhanced user mail interface is presented in mailx(1).

Mail without arguments prints a user's mail, message-by-message, in last-in, first-out order. For each message, the user is prompted with a ?, and a line is read from the standard input to determine the disposition of the message:

<new-line></new-line>	Go on to next message.
+	Same as <new-line>.</new-line>
d	Delete message and go on to next message.
p	Print message again.
-	Go back to previous message.
s [ files ]	Save message in the named files (mbox is default).
w [ files ]	Save message, without its header, in the named files (mbox is default).
m [ persons ]	Mail the message to the named <i>persons</i> (yourself is default).
q	Put undeleted mail back in the mailfile and stop.
EOT (control-d)	Same as q.
x	Put all mail back in the mailfile unchanged and stop.
!command	Escape to the shell to do command.
*	Print a command summary.

The optional arguments alter the printing of the mail:

- -e causes mail not to be printed. An exit value is returned:
  - 0 = mail present
  - 1 = no mail
  - 2 = other error
- -p causes all mail to be printed without prompting for disposition.
- -q causes mail to terminate after interrupts. Normally an interrupt only causes the termination of the printing of the current message.
- -r causes messages to be printed in first-in, first-out order.
- -ffile causes mail to use file (e.g., mbox) instead of the default mailfile.

When persons are named, mail takes the standard input up to an end-of-file (or up to a line consisting of just a.) and adds it to each person's mailfile. The message is preceded by the sender's name and a postmark. Lines that look like postmarks in the message, (i.e., "From ...") are preceded with a >. The -t option causes the message to be preceded by all persons the mail is sent to. A person is usually a user name recognized by login(1). If a person being sent mail is not recognized, or if mail is interrupted during input, the file dead.letter will be saved to allow editing and resending. Note that this is regarded as a temporary file in that it is recreated every time needed, erasing the previous contents of dead.letter.

To denote a recipient on a remote system, prefix person by the system name and exclamation mark (see uucp(1C)). Everything after the first exclamation mark in persons is interpreted by

the remote system. In particular, if *persons* contains additional exclamation marks, it can denote a sequence of machines through which the message is to be sent on the way to its ultimate destination. For example, specifying alblcde as a recipient's name causes the message to be sent to user **blcde** on system **a**. System **a** will interpret that destination as a request to send the message to user **cde** on system **b**. This might be useful, for instance, if the sending system can access system **a** but not system **b**, and system **a** has access to system **b**. *Mail* will not use *uucp* if the remote system is the local system name (i.e., localsystemluser).

The mailfile may be manipulated in two ways to alter the function of mail. The other permissions of the file may be read—write, read—only, or neither read nor write to allow different levels of privacy. If changed to other than the default, the file will be preserved even when empty to perpetuate the desired permissions. The file may also contain the first line:

#### Forward to person

which will cause all mail sent to the owner of the *mailfile* to be forwarded to *person*. This is especially useful to forward all of a person's mail to one machine in a multiple machine environment. In order for forwarding to work properly the *mailfile* should have "mail" as group ID, and the group permission should be read-write.

Rmail only permits the sending of mail; uucp(1C) uses rmail as a security precaution.

When a user logs in, the presence of mail, if any, is indicated. Also, notification is made if new mail arrives while using *mail*.

#### FILES

```
/etc/passwd to identify sender and locate persons
/usr/mail/user incoming mail for user; i.e., the mailfile
saved mail

*MAIL variable containing path name of mailfile
/tmp/ma* temporary file
/usr/mail/*.lock dead.letter lock for mail directory
unmailable text
```

#### SEE ALSO

login(1), mailx(1), uucp(1C), write(1).

#### BUGS

Conditions sometimes result in a failure to remove a lock file.

After an interrupt, the next message may not be printed; printing may be forced by typing a p.

#### NAME

mailx - interactive message processing system

#### SYNOPSIS

mailx [options] [name...]

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

UCB

Remarks: Not supported on the Integral Personal Computer.

#### DESCRIPTION

The command mailx provides a comfortable, flexible environment for sending and receiving messages electronically. When reading mail, mailx provides commands to facilitate saving, deleting, and responding to messages. When sending mail, mailx allows editing, reviewing and other modification of the message as it is entered.

Incoming mail is stored in a standard file for each user, called the system *mailbox* for that user. When *mailx* is called to read messages, the *mailbox* is the default place to find them. As messages are read, they are marked to be moved to a secondary file for storage, unless specific action is taken, so that the messages need not be seen again. This secondary file is called the *mbox* and is normally located in the user's HOME directory (see "MBOX" (ENVIRONMENT VARIABLES) for a description of this file). Messages remain in this file until forcibly removed.

On the command line, options start with a dash (-) and any other arguments are taken to be destinations (recipients). If no recipients are specified, mailx will attempt to read messages from the mailbox. Command line options are:

-d	Turn on debugging output. Neither particularly interesting nor recommended.	
-e	Test for presence of mail. Mailx prints nothing and exits with a success-	
	ful return code if there is mail to read.	
-f [filename]	Read messages from filename instead of mailbox. If no filename is	
	specified, the <i>mbox</i> is used.	
- <b>F</b>	Record the message in a file named after the first recipient. Overrides the	
	"record" variable, if set (see ENVIRONMENT VARIABLES).	
-h number	The number of network "hops" made so far. This is provided for network	
	software to avoid infinite delivery loops.	
-H	Print header summary only.	
-i	Ignore interrupts. See also "ignore" (ENVIRONMENT VARIABLES).	
-n	Do not initialize from the system default Mailx.rc file.	
-N	Do not print initial header summary.	
-r address	Pass address to network delivery software. All tilde commands are dis-	
	abled.	
-s subject	Set the Subject header field to <i>subject</i> .	
-u user	Read user's mailbox. This is only effective if user's mailbox is not read	
	protected.	
-U	Convert <i>uucp</i> style addresses to internet standards. Overrides the "conv"	
	environment variable.	

When reading mail, mailx is in command mode. A header summary of the first several messages is displayed, followed by a prompt indicating mailx can accept regular commands (see COMMANDS below). When sending mail, mailx is in input mode. If no subject is specified on the command line, a prompt for the subject is printed. As the message is typed, mailx will read the message and store it in a temporary file. Commands may be entered by beginning a line with the

tilde (~) escape character followed by a single command letter and optional arguments. See TILDE ESCAPES for a summary of these commands.

At any time, the behavior of *mailx* is governed by a set of *environment variables*. These are flags and valued parameters which are set and cleared via the **set** and **uns**et commands. See ENVIRONMENT VARIABLES below for a summary of these parameters.

Recipients listed on the command line may be of three types: login names, shell commands, or alias groups. Login names may be any network address, including mixed network addressing. If the recipient name begins with a pipe symbol (|), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as lp(1) for recording outgoing mail on paper. Alias groups are set by the alias command (see COMMANDS below) and are lists of recipients of any type.

Regular commands are of the form

```
[ command ] [ msglist ] [ arguments ]
```

If no command is specified in *command mode*, print is assumed. In *input mode*, commands are recognized by the escape character, and lines not treated as commands are taken as input for the message.

Each message is assigned a sequential number, and there is at any time the notion of a 'current' message, marked by a '>' in the header summary. Many commands take an optional list of messages (msglist) to operate on, which defaults to the current message. A msglist is a list of message specifications separated by spaces, which may include:

- n Message number n.
- The current message.
  - The first undeleted message.
- \$ The last message.
- \* All messages.
- n-m An inclusive range of message numbers.
- user All messages from user.

o

/string All messages with string in the subject line (case ignored).

:c All messages of type c, where c is one of:

d deleted messages

- n new messages
  - old messages
- r read messages
- u unread messages

Note that the context of the command determines whether this type of message specification makes sense.

Other arguments are usually arbitrary strings whose usage depends on the command involved. File names, where expected, are expanded via the normal shell conventions (see sh(1)). Special characters are recognized by certain commands and are documented with the commands below.

At start-up time, *mailx* reads commands from a system-wide file (/usr/lib/mailx/mailx.rc) to initialize certain parameters, then from a private start-up file (\$HOME/.mailrc) for personalized variables. Most regular commands are legal inside start-up files, the most common use being to set up initial display options and alias lists. The following commands are not legal in the start-up file: !, Copy, edit, followup, Followup, hold, mail, preserve, reply, Reply, shell, and visual. Any errors in the start-up file cause the remaining lines in the file to be ignored.

#### COMMANDS

The following is a complete list of *mailx* commands:

#### !shell-command

Escape to the shell. See "SHELL" (ENVIRONMENT VARIABLES).

## # comment

Null command (comment). This may be useful in .mailrc files.

=

Print the current message number.

?

Prints a summary of commands.

# alias alias name ...

#### group alias name ...

Declare an alias for the given names. The names will be substituted when alias is used as a recipient. Useful in the .mailre file.

#### alternates name ...

Declares a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, alternates prints the current list of alternate names. See also "allnet" (ENVIRONMENT VARIABLES).

# cd [directory]

# chdir [directory]

Change directory. If directory is not specified, \$HOME is used.

#### copy [filename]

# copy [msglist] filename

Copy messages to the file without marking the messages as saved. Otherwise equivalent to the save command.

# Copy [msglist]

Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise equivalent to the Save command.

## delete [msqlist]

Delete messages from the *mailbox*. If "autoprint" is set, the next message after the last one deleted is printed (see ENVIRONMENT VARIABLES).

# discard [header-field ...]

# ignore [header-field ...]

Suppresses printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are "status" and "cc." The fields are included when the message is saved. The Print and Type commands override this command.

# dp [msglist]

# dt [msglist]

Delete the specified messages from the *mailbox* and print the next message after the last one deleted. Roughly equivalent to a delete command followed by a print command.

#### echo strina ...

Echo the given strings (like echo(1)).

# edit [msglist]

Edit the given messages. The messages are placed in a temporary file and the "EDITOR" variable is used to get the name of the editor (see ENVIRONMENT VARIABLES). Default editor is ed(1).

#### exit

xit

Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

# file [filename]

#### folder [filename]

Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names, with the following substitutions:

% the current mailbox.

# %user

the mailbox for user.

the previous file.

& the current mbox.

Default file is the current mailbox.

# folders

Print the names of the files in the directory set by the "folder" variable (see ENVIRON-MENT VARIABLES).

# followup [message]

Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the "record" variable, if set. See also the Followup, Save, and Copy commands and "outfolder" (ENVIRONMENT VARIABLES).

# Followup [msglist]

Respond to the first message in the *msglist*, sending the message to the author of each message in the *msglist*. The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. See also the followup, Save, and Copy commands and "outfolder" (ENVIRONMENT VARIABLES).

#### from [msalist]

Prints the header summary for the specified messages.

# group alias name ...

#### alias alias name ...

Declare an alias for the given names. The names will be substituted when alias is used as a recipient. Useful in the .mailrc file.

# headers [message]

Prints the page of headers which includes the message specified. The "screen" variable sets the number of headers per page (see ENVIRONMENT VARIABLES). See also the  ${\bf z}$  command.

## help

Prints a summary of commands.

hold [msglist]
preserve [msglist]

Holds the specified messages in the mailbox.

if  $s \mid r$  mail-commandselse mail-commands

endif

Conditional execution, where s will execute following mail-commands, up to an else or endif, if the program is in send mode, and r causes the mail-commands to be executed only in receive mode. Useful in the .mailrc file.

 $\mathbf{ig} \mathbf{nore}\ \mathit{header-field}\ ...$ 

discard header-field ...

Suppresses printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are "status" and "cc." All fields are included when the message is saved. The Print and Type commands override this command.

list

Prints all commands available. No explanation is given.

mail name ...

Mail a message to the specified users.

# mbox [msglist]

Arrange for the given messages to end up in the standard *mbox* save file when *mailx* terminates normally. See "MBOX" (ENVIRONMENT VARIABLES) for a description of this file. See also the **exit** and **q**uit commands.

# next [message]

Go to next message matching message. A msglist may be specified, but in this case the first valid message in the list is the only one used. This is useful for jumping to the next message from a specific user, since the name would be taken as a command in the absence of a real command. See the discussion of msglists above for a description of possible message specifications.

 $\mathbf{pipe}\ [\mathit{msglist}]\ [\mathit{shell-command}]$ 

| [msglist] [shell-command]

Pipe the message through the given *shell-command*. The message is treated as if it were read. If no arguments are given, the current message is piped through the command specified by the value of the "cmd" variable. If the "page" variable is set, a form feed character is inserted after each message (see ENVIRONMENT VARIABLES).

preserve [msglist] hold [msglist]

Preserve the specified messages in the mailbox.

# Print [msglist]

Type [msglist]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ignore command.

print [msglist]

type [msglist]

Print the specified messages. If "crt" is set, the messages longer than the number of lines specified by the "crt" variable are paged through the command specified by the "PAGER" variable. The default command is pq(1) (see ENVIRONMENT VARIABLES).

quit

Exit from mailx, storing messages that were read in mbox and unread messages in the mailbox. Messages that have been explicitly saved in a file are deleted.

Reply [msqlist]

Respond [msglist]

Send a response to the author of each message in the *msglist*. The subject line is taken from the first message. If "record" is set to a filename, the response is saved at the end of that file (see ENVIRONMENT VARIABLES).

reply [message]

respond [message]

Reply to the specified message, including all other recipients of the message. If "record" is set to a filename, the response is saved at the end of that file (see ENVIRONMENT VARIABLES).

Save [msqlist]

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the Copy, followup, and Followup commands and "outfolder" (ENVIRONMENT VARIABLES).

save [filename]

save [msqlist] filename

Save the specified messages in the given file. The file is created if it does not exist. The message is deleted from the *mailbox* when *mailx* terminates unless "keepsave" is set (see also ENVIRONMENT VARIABLES and the **exit** and **quit** commands).

 $\mathbf{set}$ 

set name

 $\mathbf{set}$  name = string

set name=number

Define a variable called *name*. The variable may be given a null, string, or numeric value. Set by itself prints all defined variables and their values. See ENVIRONMENT VARIABLES for detailed descriptions of the *mailx* variables.

shell

Invoke an interactive shell (see also "SHELL" (ENVIRONMENT VARIABLES)).

size [msqlist]

Print the size in characters of the specified messages.

# source filename

Read commands from the given file and return to command mode.

# top [msqlist]

Print the top few lines of the specified messages. If the "toplines" variable is set, it is taken as the number of lines to print (see ENVIRONMENT VARIABLES). The default is 5.

# touch [msqlist]

Touch the specified messages. If any message in *msglist* is not specifically saved in a file, it will be placed in the *mbox* upon normal termination. See exit and quit.

# Type [msalist]

# Print [msqlist]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the **ig**nore command.

# $\mathbf{t} \mathbf{y} \mathbf{p} \mathbf{e} \; [\mathit{msglist}]$

# print [msglist]

Print the specified messages. If "crt" is set, the messages longer than the number of lines specified by the "crt" variable are paged through the command specified by the "PAGER" variable. The default command is pq(1) (see ENVIRONMENT VARIABLES).

# undelete [msglist]

Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If "autoprint" is set, the last message of those restored is printed (see ENVIRONMENT VARIABLES).

#### unset name ...

Causes the specified variables to be erased. If the variable was imported from the execution environment (i.e., a shell variable) then it cannot be erased.

#### version

Prints the current version and release date.

#### visual [msqlist]

Edit the given messages with a screen editor. The messages are placed in a temporary file and the "VISUAL" variable is used to get the name of the editor (see ENVIRONMENT VARIABLES).

# write [msglist] filename

Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the save command.

# $\mathbf{x}$ it

# exit

Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

#### $\mathbf{z}[+|-]$

Scroll the header display forward or backward one screen-full. The number of headers displayed is set by the "screen" variable (see ENVIRONMENT VARIABLES).

#### TILDE ESCAPES

The following commands may be entered only from *input mode*, by beginning a line with the tilde

escape character  $(\tilde{\ })$ . See "escape" (ENVIRONMENT VARIABLES) for changing this special character.

~! shell-command

Escape to the shell.

Simulate end of file (terminate message input).

# ~: mail-command

### ~\_ mail-command

Perform the command–level request. Valid only when sending a message while reading mail.

~?

Print a summary of tilde escapes.

 $^{\sim}\mathbf{A}$ 

Insert the autograph string "Sign" into the message (see ENVIRONMENT VARIABLES).

~a

Insert the autograph string "sign" into the message (see ENVIRONMENT VARIABLES).

~b name ...

Add the names to the blind carbon copy (Bcc) list.

~c name ...

Add the *names* to the carbon copy (Cc) list.

~d

Read in the dead.letter file. See "DEAD" (ENVIRONMENT VARIABLES) for a description of this file.

~e

Invoke the editor on the partial message. See also "EDITOR" (ENVIRONMENT VARIABLES).

# ~f [msglist]

Forward the specified messages. The messages are inserted into the message, without alteration.

~h

Prompt for Subject line and To, Cc, and Bcc lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.

~i string

Insert the value of the named variable into the text of the message. For example,  ${}^{\sim}\mathbf{A}$  is equivalent to  ${}^{\sim}\mathbf{i}$  Sign.'

## ~m [msglist]

Insert the specified messages into the letter, shifting the new text to the right one tab stop. Valid only when sending a message while reading mail.

July 2, 1985

~p

Print the message being entered.

 $\mathbf{q}$ 

Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in *dead.letter*. See "DEAD" (ENVIRONMENT VARIABLES) for a description of this file.

# ~r filename

~< filename

~ < !shell-command

Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message.

s string ...

Set the subject line to string.

~t name ...

Add the given names to the To list.

 $\tilde{v}$ 

Invoke a preferred screen editor on the partial message. See also "VISUAL" (ENVIRON-MENT VARIABLES).

w filename

Write the partial message onto the given file, without the header.

~x

Exit as with ~q except the message is not saved in dead.letter.

# ~| shell-command

Pipe the body of the message through the given shell-command. If the shell-command returns a successful exit status, the output of the command replaces the message.

### ENVIRONMENT VARIABLES

The following are environment variables taken from the execution environment and are not alterable within mails.

#### **HOME**=directory

The user's base of operations.

## MAILRC=filename

The name of the start-up file. Default is \$HOME/.mailrc.

The following variables are internal *mailx* variables. They may be imported from the execution environment or set via the **set** command at any time. The **uns**et command may be used to erase variables.

#### allnet

All network names whose last component (login name) match are treated as identical. This causes the *msglist* message specifications to behave similarly. Default is **noallnet**. See also the **alternates** command and the "metoo" variable.

#### append

Upon termination, append messages to the end of the *mbox* file instead of prepending them. Default is **noappend**.

#### askcc

Prompt for the Cc list after message is entered. Default is noaskcc.

#### asksub

Prompt for subject if it is not specified on the command line with the -s option. Enabled by default.

#### autoprint

Enable automatic printing of messages after delete and undelete commands. Default is noautoprint.

#### bang

Enable the special-casing of exclamation points (!) in shell escape command lines as in vi(1). Default is **nobang**.

#### $\mathbf{cmd} = shell-command$

Set the default command for the pipe command. No default value.

#### conv = conversion

Convert uucp addresses to the specified address style. The only valid conversion now is *internet*, which requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing. Conversion is disabled by default. See also "sendmail" and the -U command line option.

# crt=number

Pipe messages having more than number lines through the command specified by the value of the "PAGER" variable (pq(1)) by default). Disabled by default.

#### **DEAD**=filename

The name of the file in which to save partial letters in case of untimely interrupt or delivery errors. Default is \$HOME/dead.letter.

#### debug

Enable verbose diagnostics for debugging. Messages are not delivered. Default is **node-bug**.

## dot

Take a period on a line by itself during input from a terminal as end-of-file. Default is **nodot**.

#### EDITOR=shell-command

The command to run when the edit or  $\tilde{e}$  command is used. Default is ed(1).

# escape = c

Substitute c for the  $\tilde{}$  escape character.

#### folder=directory

The directory for saving standard mail files. User specified file names beginning with a plus (+) are expanded by preceding the filename with this directory name to obtain the real filename. If *directory* does not start with a slash (/), \$HOME is prepended to it. In

order to use the plus (+) construct on a mailx command line, "folder" must be an exported sh environment variable. There is no default for the "folder" variable. See also "outfolder" below.

#### header

Enable printing of the header summary when entering mails. Enabled by default.

# hold

Preserve all messages that are read in the mailbox instead of putting them in the standard mbox save file. Default is **nohold**.

#### ignore

Ignore interrupts while entering messages. Handy for noisy dial-up lines. Default is **noignore**.

#### ignoreeof

Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the ~. command. Default is **noignoreeof**. See also "dot" above.

#### keep

When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.

#### keepsave

Keep messages that have been saved in other files in the *mailbox* instead of deleting them. Default is **nokeepsave**.

# MBOX=filename

The name of the file to save messages which have been read. The xit command overrides this function, as does saving the message explicitly in another file. Default is \$HOME/mbox.

#### metoo

If your login appears as a recipient, do not delete it from the list. Default is **nometoo**.

#### ${f LISTER} = shell-command$

The command (and options) to use when listing the contents of the "folder" directory. The default is ls(1).

## onehop

When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (i.e., one hop away).

#### outfolder

Causes the files used to record outgoing messages to be located in the directory specified by the "folder" variable unless the pathname is absolute. Default is **nooutfolder**. See "folder" above and the Save, Copy, followup, and Followup commands.

#### page

Used with the **pi**pe command to insert a form feed after each message sent through the pipe. Default is **nopage**.

#### PAGER=shell-command

The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is pq(1).

#### prompt=string

Set the command mode prompt to string. Default is "?".

#### auiet

Refrain from printing the opening message and version when entering *mailx*. Default is **noquiet**.

#### record=filename

Record all outgoing mail in *filename*. Disabled by default. See also "outfolder" above.

#### save

Enable saving of messages in *dead.letter* on interrupt or delivery error. See "DEAD" for a description of this file. Enabled by default.

#### screen = number

Sets the number of lines in a screen-full of headers for the headers command.

#### sendmail = shell-command

Alternate command for delivering messages. Default is mail(1).

#### sendwait

Wait for background mailer to finish before returning. Default is nosendwait.

#### SHELL=shell-command

The name of a preferred command interpreter. Default is sh(1).

## showto

When displaying the header summary and the message is from you, print the recipient's name instead of the author's name.

#### sign=string

The variable inserted into the text of a message when the  $\tilde{a}$  (autograph) command is given. No default (see also  $\tilde{i}$  (TILDE ESCAPES)).

#### Sign=string

The variable inserted into the text of a message when the **A** command is given. No default (see also **i** (TILDE ESCAPES)).

# toplines = number

The number of lines of header to print with the top command. Default is 5.

#### VISUAL = shell-command

The name of a preferred screen editor. Default is vi(1).

#### FILES

\$HOME/.mailrc	personal start-up file
\$HOME/mbox	secondary storage file
/usr/mail/*	post office directory
/usr/lib/mailx/mailx.help*	help message files
/usr/lib/mailx/mailx.rc	global start-up file

/tmp/R[emqsx]\*

temporary files

# SEE ALSO

mail(1), pg(1), ls(1).

# BUGS

Where shell-command is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be unset.

The full internet addressing is not fully supported by mailx. The new standards need some time to settle down.

Attempts to send a message having a line consisting only of a "." are treated as the end of the message by mail(1) (the standard mail delivery program).

MAKE(1) MAKE(1)

#### NAME

make - maintain, update, and regenerate groups of programs

#### SYNOPSIS

make [-f] makefile [-p] [-i] [-k] [-s] [-r] [-n] [-b] [-e] [-t] [-d] [-q] [names]

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

#### DESCRIPTION

The following is a brief description of all options and some special names. Options may occur in any order.

- -f makefile Description file name. Makefile is assumed to be the name of a description file. A file name of denotes the standard input. The contents of makefile override the built-in rules if they are present. Note that the space between -f and makefile must be present.
- -p Print out the complete set of macro definitions and target descriptions.
- -i Ignore error codes returned by invoked commands. This mode is also entered if the fake target name .IGNORE appears in the description file.
- -k When a command returns nonzero status, abandon work on the current entry, but continue on other branches that do not depend on that entry.
- -s Silent mode. Do not print command lines before executing. This mode is also entered if the fake target name .SILENT appears in the description file.
- -r Do not use the built-in rules.
- -n No execute mode. Print commands, but do not execute them. Even lines beginning with an @ are printed.
- -b Compatibility mode for old (Version 7) makefiles.
- **-e** Environment variables override assignments within makefiles.
- -t Touch the target files (causing them to be up-to-date) rather than issue the usual commands.
- -d Debug mode. Print out detailed information on files and times examined. (This is intended for debugging the *make* command itself.)
- -q Question. The make command returns a zero or non-zero status code depending on whether the target file is or is not up-to-date.

The "built-in" dependency targets are:

#### .DEFAULT

If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name .DEFAULT are used if it exists.

#### .PRECIOUS

Dependents of this target will not be removed when guit or interrupt are hit.

# .SILENT

Same effect as the -s option.

#### .IGNORE

Same effect as the -i option.

Make executes commands in makefile to update one or more target names. Name is typically a program. If no -f option is present, makefile, Makefile, s.makefile, and s.Makefile are tried in order. If makefile is -, the standard input is taken. More than one -f makefile argument pair may

MAKE(1) MAKE(1)

appear.

Make updates a target only if it depends on files that are newer than the target. All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be out of date.

Makefile contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, followed by a colon (:), followed by a (possibly null) list of prerequisite files or dependencies. Text following a ; and all following lines that begin with a tab are shell commands to be executed to update the target. The first line that does not begin with a tab or # begins a new dependency or macro definition. Shell commands may be continued across lines with the <br/>backslash><new-line> sequence. Everything printed by make (except the initial tab) is passed directly to the shell as is. Thus.

```
echo a\
b
```

will produce

ab

exactly the same as the shell would.

Sharp (#) and new-line surround comments.

The following *makefile* says that **pgm** depends on two files **a.o** and **b.o**, and that they in turn depend on their corresponding source files (**a.c** and **b.c**) and a common file **incl.h**:

```
pgm: a.o b.o
cc a.o b.o -o pgm
a.o: incl.h a.c
cc -c a.c
b.o: incl.h b.c
cc -c b.c
```

Command lines are executed one at a time, each by its own shell. The first one or two characters in a command can be the following:  $\neg$ , @,  $\neg$ @, or @-. If @ is present, printing of the command is suppressed. If  $\neg$  is present, make ignores an error. A line is printed when it is executed unless the  $\neg$ s option is present, or the entry .SILENT: is in makefile, or unless the initial character sequence contains a @. The  $\neg$ n option specifies printing without execution; however, if the command line has the string MAKE in it, the line is always executed (see discussion of the MAKEFLAGS macro under Environment). Note that this feature does not work if MAKE is enclosed in braces, as in MAKE. The  $\neg$ t (touch) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate *make*. If the -i option is present, or the entry .IGNORE: appears in *makefile*, or the initial character sequence of the command contains -. the error is ignored. If the -k option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

The -b option allows old makefiles (those written for the old version of make) to run without errors. The difference between the old version of make and this version is that this version requires all dependency lines to have a (possibly null or implicit) command associated with them. The previous version of make assumed, if no command was specified explicitly, that the command was null.

Interrupt and quit cause the target to be deleted unless the target depends on the special name .PRECIOUS.

#### Environment

The environment is read by make. All variables are assumed to be macro definitions and processed as such. The environment variables are processed before any makefile and after the

MAKE(1) MAKE(1)

internal rules; thus, macro assignments in a makefile override environment variables. The -e option causes the environment to override the macro assignments in a makefile.

The MAKEFLAGS environment variable is processed by make as containing any legal input option (except -f, -p, and -d) defined for the command line. Further, upon invocation, make "invents" the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, MAKEFLAGS always contains the current input options. This proves very useful for "super-makes". In fact, as noted above, when the -n option is used, the command \$(MAKE) is executed anyway; hence, one can perform a make -n recursively on a whole software system to see what would have been executed. This is because the -n is put in MAKEFLAGS and passed to further invocations of \$(MAKE). This is one way of debugging all of the makefiles for a software project without actually doing anything.

#### Macros

Entries of the form string1 = string2 are macro definitions. String2 is defined as all characters up to a comment character or an unescaped new-line. Subsequent appearances of \$(string1[:subst1=[subst2]]) are replaced by string2. The parentheses are optional if a single character macro name is used and there is no substitute sequence. The optional :subst1=subst2 is a substitute sequence. If it is specified, all non-overlapping occurrences of subst1 in the named macro are replaced by subst2. Strings (for the purposes of this type of substitution) are delimited by blanks, tabs, new-line characters, and beginnings of lines. An example of the use of the substitute sequence is shown under Libraries.

#### Internal Macros

or:

There are five internally maintained macros which are useful for writing rules for building targets.

- \$\* The macro \$\* stands for the file name part of the current dependent with the suffix deleted. It is evaluated only for inference rules.
- \$@ The \$@ macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.
- \$< The \$< macro is only evaluated for inference rules or the .DEFAULT rule. It is the module which is out-of-date with respect to the target (i.e., the "manufactured" dependent file name). Thus, in the .c.o rule, the \$< macro would evaluate to the .c file. An example for making optimized .o files from .c files is:

cc -c -O \$<

- \$? The \$? macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are out of date with respect to the target; essentially, those modules which must be rebuilt.
- \$\% The \$\% macro is only evaluated when the target is an archive library member of the form lib(file.o). In this case, \$\@ evaluates to lib and \$\% evaluates to the library member, file.o.

MAKE(1) MAKE(1)

Four of the five macros can have alternative forms. When an upper case **D** or **F** is appended to any of the four macros, the meaning is changed to "directory part" for **D** and "file part" for **F**. Thus, \$(@**D**) refers to the directory part of the string \$@. If there is no directory part, ./ is generated. The only macro excluded from this alternative form is \$?. The reasons for this are debatable.

#### Suffixes

Certain names (for instance, those ending with .o) have inferable prerequisites such as .c, .s, etc. If no update commands for such a file appear in *makefile*, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, *make* has inference rules which allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

To print out the rules compiled into the *make* on any machine in a form suitable for recompilation, the following command is used:

```
make -fp - 2>/dev/null </dev/null
```

The only peculiarity in this output is the (null) string which printf(3S) prints when handed a null string.

A tilde in the above rules refers to an SCCS file (see secsfile(5)). Thus, the rule  $.c^{\tilde{}}.o$  would transform an SCCS C source file into an object file (.o). Because the s. of the SCCS files is a prefix, it is incompatible with make's suffix point-of-view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (i.e.,  $\cdot$ c:) is the definition of how to build x from x.c. In effect, the other suffix is null. This is useful for building targets from only one source file (e.g., shell procedures, simple C programs).

Additional suffixes are given as the dependency list for .SUFFIXES. Order is significant; the first possible name for which both a file and a rule exist is inferred as a prerequisite.

The default list is:

```
.SUFFIXES: .o .c .y .l .s
```

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; .SUFFIXES: with no dependencies clears the list of suffixes.

#### Inference Rules

The first example can be done more briefly:

```
pgm: a.o b.o
cc a.o b.o -o pgm
a.o b.o: incl.h
```

This is because *make* has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, CFLAGS, LFLAGS, and YFLAGS are used for compiler options to cc(1), lex(1), and yacc(1), respectively. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix **.o** from a file with suffix **.c** is specified as an entry with **.c.o**: as the target and no dependents. Shell commands associated with the target define the rule for making a **.o** file from a **.c** file. Any target that has

MAKE(1) MAKE(1)

no slashes in it and starts with a dot is identified as a rule and not a true target.

#### Libraries

If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus lib(file.o) and \$(LIB)(file.o) both refer to an archive library which contains file.o. (This assumes the LIB macro has been previously defined.) The expression \$(LIB)(file1.o file2.o) is not legal. Rules pertaining to archive libraries have the form .XX.a where the XX is the suffix from which the archive member is to be made. An unfortunate byproduct of the current implementation requires the XX to be different from the suffix of the archive member. Thus, one cannot have lib(file.o) depend upon file.o explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
@echo lib is now up-to-date

.c.a:

$(CC) -c $(CFLAGS) $<
ar rv $@ $*.o
rm -f $*.o
```

In fact, the .c.a rule listed above is built into make and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o) $(CC) -c $(CFLAGS) $(?:.o=.c) ar rv lib $? rm $? @echo lib is now up-to-date .c.a:;
```

Here the substitution mode of the macro expansions is used. The \$? list is defined to be the set of object file names (inside lib) whose C source files are out-of-date. The substitution mode translates the .o to .c. (Unfortunately, one cannot as yet transform to .c~; however, this may become possible in the future.) Note also, the disabling of the .c.a: rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

#### FILES

[Mm]akefile and s.[Mm]akefile

## SEE ALSO

```
cc(1), cd(1), lex(1), sh(1), yacc(1).
```

## WARNING

Be wary of any file (such as an include file) whose access, modification, and last change times cannot be altered by the *make*-ing process. For example, if a program depends on an include file which in turn depends on another include file, and if one or both of these files are out-of-date, *make* will try to update these files each time it is run, thus unnecessarily re-*make*ing up-to-date files dependent on the include file. The solution is to manually update these files with the *touch*(1) command before running *make*. (Note that it is generally a bad idea to include the *touch*(1) command in your makefile, because it can cause *make* to update a program that otherwise did not need to be updated.)

#### BUGS

Some commands return non-zero status inappropriately; use -i to overcome the difficulty.

File names with the characters = : @ will not work.

Commands that are directly executed by the shell, notably cd(1), are ineffectual across new-lines in make.

The syntax lib(file1.o file2.o file3.o) is illegal.

You cannot build lib(file.o) from file.o.

The macro \$(a:.o=.c~) does not work.

There is a limit of 2500 characters, including the terminating new-line, for expanded dependency lines.

Make will not properly expand a macro within another macro when string substitution is involved.

MAN(1) MAN(1)

#### NAME

man - find manual information by keywords; print out the manual

## SYNOPSIS

```
man -k keyword ...
man -f file ...
man [ - ] [ section ] title ...
```

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: UCB

#### DESCRIPTION

Man is a program which gives information from the programmer's manual. It can be asked to form one line descriptions of commands specified by name, or for all commands whose description contains any of a set of keywords. It can also provide on–line access to the sections of the printed manual.

When given the option -k and a set of keywords, man prints out a one line synopsis of each manual section whose listing in the table of contents contains that keyword.

When given the option -f and a list of file names, man attempts to locate manual sections related to those files, printing out the table of contents lines for those sections.

When neither -k nor -f is specified, man formats a specified set of manual pages. If a section specifier is given man looks in that section of the manual for the given titles. Section is an arabic section number, i.e. 3, which may be followed by a single letter classifier, i.e. 1g indicating a graphics program in section 1. If section is omitted, man searches all sections of the manual, giving preference to commands over subroutines in system libraries, and printing the first section it finds, if any.

If the standard output is a teletype, or if the flag - is given, then man pipes its output through rmnl(1) to delete useless blank lines, ul(1) to create proper underlines for different terminals, and through more(1) to stop after each page. Hit a space to continue.

If the /usr/man/cat? directory is present and the file is not in it, but the file exists in /usr/man/man?, then the page is formatted and installed in /usr/man/cat? on first access. If only the /usr/man/cat? directories are present and/or nroff is not installed then only those pages which have been preformatted are displayable.

The Berkeley command whatis(1) is provided by man -f.

## FILES

```
/usr/man/man?/*
/usr/man/cat?/*
/usr/local/man?/*
/usr/local/cat?/*
/usr/contrib/man?/*
/usr/contrib/cat?/*
```

## SEE ALSO

```
rmnl(1), ul(1), more(1), whereis(1), catman(1M).
```

#### BUGS

The manual is supposed to be reproducible either on the phototypesetter or on a typewriter. However, on a typewriter some information is necessarily lost.

mediainit - initialize hard disc, flexible disc, or cartridge tape media

## SYNOPSIS

mediainit [-vr] [-f fmt\_optn] [-i interleave] pathname

## HP-UX COMPATIBILITY

Level: HP-UX/NON-STANDARD

Origin: H

Remarks: Mediainit is implemented on Series 200 only.

#### DESCRIPTION

Mediainit initializes mass storage media by formatting the media, writing and reading test patterns to verify media integrity, then sparing any defective blocks found. This process prepares the disc or tape for error-free operation.

The following command options are recognized. They can be specified in any order, but all must precede the pathname. Options without parameters can be listed individually or grouped together. Options with parameters must be listed individually, but white space between the option and its parameter is discretionary.

- -v Normally, mediainit provides only fatal error messages, and they are directed to diagnostic output (stderr). The verbose option sends device-specific error information related to low-level operation of mediainit to standard output (stdout). This option is most useful to trained service personnel because it usually requires detailed knowledge of device operation before the error information can be interpreted correctly.
- -r The re-certify option forces a complete tape certification whether or not the tape has been certified previously. All record of any previously spared blocks is discarded, so any bad blocks will have to be rediscovered. This option should be used only if: (a) it is suspected that numerous blocks on the tape have been spared which should not have been, or (b) it is necessary to destroy (overwrite) all previous data on the tape.

## $-\mathbf{f} fmt\_optn$

The format option is a device-specific number in the range 0 through 239. It is intended solely for use with certain SS/80 devices that support multiple media formats (disregarding interleave factor). For example, certain microfloppy drives support 256, 512, and 1024-byte sectors. *Mediainit* passes any supplied format option directly through to the device. The device then either accepts it or rejects it if it is not supported. Refer to device operating manuals for additional information. The default format option is 0.

## -i interleave

Interleave refers to relationship between sequential logical records and sequential physical records. It defines the number of physical records that lie between the beginning points of two consecutively numbered logical records. The choice of interleave factor can have a substantial impact on disc performance. For CS/80 and SS/80 devices, consult the appropriate operating manual for details. Acceptable interleave factors for non-CS/80 devices are as follows:

Device	Range	Default
HP9895 SS/DS	1 - 29	<b>2</b>
HP8290X	1 - 15	3
HP9121	1 - 15	<b>2</b>
HP913X_A	na	9
HP913X_B	na	9
$\mathrm{HP}913\mathrm{X}\mathrm{\_C}$	na	9

Hewlett-Packard - 1 - November 15, 1985

The following operand is required:

Pathname is the path name to the character (raw) device special file associated with the volume (or single-volume device) containing the media to be initialized. Mediainit aborts if you lack either read or write permission to the device special file, or if the volume has already been opened by any other process. Also, mediainit locks the volume during initialization so that no other processes can access it. Thus it is impossible to initialize any mounted volume; in particular, the root volume.

For CS/80 and SS/80 drives, a given device may contain multiple units or a given unit may contain multiple volumes. Any available volume can be initialized, even while other volumes are open. However, the initialization process tends to dominate device resources while initialization is in progress, thus causing delays in handling requests from other processes that need to access the same drive. In the case of non-CS/80 devices, the entire device is locked and no other processes can access the device until the target unit is completely initialized.

In general, *mediainit* attempts to carefully scrutinize any format or interleave options supplied, and aborts if an option is out of range or inappropriate for the media being initialized. Specifying an interleave factor or format option value of 0 has the same effect as not specifying the option at all.

For discs that support interleave factors, the acceptable range is usually 1 (no interleave) through N-1, where N is the number of sectors per track. With SS/80 hard discs, the optimum interleave factor is usually determined by the speed (normal or high) of the HP-IB interface card used and whether DMA is present in the system. The optimum interleave factor for SS/80 flexible disc drives is usually a constant (often 2), and is independent of the type of HP-IB interface used. The optimum interleave factor for CS/80 discs is usually 1, and is also usually not related to the type of HP-IB interface being used. In any case, refer to the appropriate device operating manual for recommended values.

If a disc being initialized requires an interleave factor but none is specified, *mediainit* provides an appropriate, though not necessarily optimum default. For CS/80 and SS/80 discs, *mediainit* uses whatever the device reports as its current interleave factor. SS/80 floppy drives report their minimum (usually best) interleave factor, if the currently installed media is unformatted.

When a given device supports format options, the allowable range of interleave factors may be related to the specified format option. In such instances, *mediainit* cannot range-check the interleave factor if one is specified.

Mediainit returns a value of 0 upon successful completion, a value of 1 if there was a device-related error, or a value of 2 if there was a syntax-related error.

#### EXAMPLES

The following example formats an HP 9122 SS/80 3 1/2" flexible disc with an interleave factor of 2, 1024-byte sectors, double-sided HP format:

Using defaults, the next example initializes an HP 9135A non-CS/80 4.6-Mbyte Winchester hard disc with an interleave factor of 9, HP format, with the verbose mode switch invoked.

mediainit -v /dev/r9135A

#### SEE ALSO

mkfs(1M), lifinit(1).

## DIAGNOSTICS

Appropriate error messages are given.

## WARNINGS

Aborting *mediainit* is likely to leave the medium in a useless state, even if it was previously initialized.

Hewlett-Packard - 2 - November 15, 1985

#### BACKGROUND INFORMATION

Most types of mass storage media must be initialized before they can be used. HP hard discs, flexible discs, and cartridge tapes require some form of initialization, but 9-track tapes do not. Initialization usually involves formatting the media, writing and reading test patterns, then sparing any defective blocks. Depending upon the media and device type, none, some, or all of the initialization process may have been performed at the factory. *Mediainit* completes whatever steps are appropriate for the media to prepare it for error-free operation.

Most HP hard discs are formatted and exhaustively tested at the factory by use of a process more thorough but also more time-consuming than appropriate for *mediainit*. However, *mediainit* is still valuable for ensuring the integrity of the media after factory shipment, formatting with the correct interleave factor, and sparing any blocks which may have become defective since original factory testing was performed.

HP flexible discs are not usually formatted prior to shipment, so they must undergo the entire initialization process before they can be used.

All HP CS/80 cartridge tapes are formatted prior to shipment from the factory, but certification is optional at additional cost. If the tape is certified, it has been tested and sparing is already complete. *Mediainit* usually certifies a tape only if it has not been certified previously. On previously-certified tapes, *mediainit* usually re-organizes the tape's spare block table, retaining any previous spares, but optimizing their assignment for maximum performance under sequential access. Re-organizing the spare block table takes only a few seconds, whereas complete certification takes about a half-hour for 150-foot tapes, and over an hour for 600-foot tapes.

HP CS/80 cartridge tape drives have a feature called "auto-sparing", where if under normal usage the drive has trouble reading a block, the drive logs the fact then automatically spares out that block the next time data is written to it. Thus, as a tape is used, any marginal blocks that were not spared during certification are spared automatically if they cause problems. This sparing is automatic within the device, and is totally independent of *Mediainit*.

Reorganization of a tape's spare block table technically renders any existing data undefined, but the data is not usually destroyed by overwriting. To ensure that old tape data is destroyed (useful for security reasons among other things), complete tape re-certification can forced with the  $-\mathbf{r}$  option.

Some applications may require that a file system be placed on the media before use. Mediainit does not create a file system; it only prepares media for writing and reading. Other utilities such as newfs(1m) or lifinit(1) must be invoked after running mediainit, if such a file system is required.

Hewlett-Packard - 3 - November 15, 1985

MESG(1)

## NAME

mesg - permit or deny messages to terminal

# SYNOPSIS

mesg [ n ] [ y ]

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

Remarks: Not supported on the Integral Personal Computer.

# DESCRIPTION

Mesg with argument  ${\bf n}$  forbids messages via write(1) by revoking non-user write permission on the user's terminal. Mesg with argument  ${\bf y}$  reinstates permission. All by itself, mesg reports the current state without changing it.

# FILES

/dev/tty\*

# SEE ALSO

write(1).

# DIAGNOSTICS

Exit status is 0 if messages are receivable, 1 if not, 2 on error.

MKDIR(1) MKDIR(1)

#### NAME

mkdir - make a directory

# SYNOPSIS

mkdir dirname ...

# HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System V

Native Language Support: 8-bit filenames.

# DESCRIPTION

Mkdir creates specified directories in mode 777 (possibly altered by umask(1)). Standard entries, , for the directory itself, and .., for its parent, are made automatically.

Mkdir requires write permission in the parent directory.

## SEE ALSO

sh(1), rm(1), umask(1).

# DIAGNOSTICS

Mkdir returns exit code 0 if all directories were successfully made; otherwise, it prints a diagnostic and returns non-zero.

mkstr - extract error messages from C source into a file

## SYNOPSIS

```
mkstr [ - ] messagefile prefix file ...
```

## HP-UX COMPATIBILITY

Level: HP-UX/DEVELOPMENT

Origin: UCB

#### DESCRIPTION

Mkstr examines a C program and creates a file containing error message strings used by the program. Programs with many error diagnostics can be made much smaller by referring to places in the file, and reduce system overhead in running the program.

Mkstr processes each of the specified files, placing a revised version of each in a file whose name consists of the specified prefix concatenated to the original name. A typical usage of mkstr would be

```
mkstr mystrings xx *.c
```

This command would cause all the error messages from the C source files in the current directory to be placed in the file *mystrings* and revised copies of the source for these files to be placed in files whose names are prefixed with xx.

To process the error messages in the source to the message file *mkstr* keys on the string **error**(" in the input file. Each time it is encountered, the C string starting after the '"' is placed in the message file followed by a null character and a new-line character; the null character terminates the message so it can be easily used when retrieved, and the new-line character makes it possible to sensibly *cat* the error message file to see its contents.

The new copy of the input file is the same as the original, except that each occurrence of a string that is in the error message file is replaced by an offset pointer usable by *lseek* to retrieve the message.

The optional - on the command line causes the error messages to be placed at the end of the specified message file instead of overwriting it. When many source files constitute a large mkstr ed program, this can be used to avoid reprocessing all the files.

All functions used by the original program whose names end in "error" and that can take a constant string as their first argument should be rewritten so that they search for the string in the error message file.

For example:

```
#include <stdio.h>
#include <sys/types.h>
#include <fcntl.h>

char errfile[] = "mystrings";
error(offset, a2, a3, a4)
int offset, a1, a2, a3;
{
   char msg[256];
   static int fd = -1;

   if (fd < 0)
   {</pre>
```

```
fd = open(errfile, O_RDONLY);
    if (fd < 0)
    {
        perror(errfile);
        exit(1);
    }
}

if (lseek(fd, (off_t) offset, 0) | | read(fd, msg, 256) <= 0)
    {
        printf("? Can't find error message in %s:\n", errfile);
        perror(errfile);
        exit(1);
    }

    printf(msg, a1, a2, a3);
}</pre>
```

# SEE ALSO

lseek(2), perror(3C), xstr(1)

# BUGS

Strings in calls to functions whose names end in 'error', notably perror(3C), may be replaced with offsets.

Calls to error functions whose first argument is not a string constant are left unmodified without warning.

MM(1)

#### NAME

mm, osdd, checkmm - print/check documents formatted with the MM macros

## SYNOPSIS

```
mm [ options ] [ files ]
osdd [ options ] [ files ]
checkmm [ files ]
```

#### HP-UX COMPATIBILITY

Level:

HP-UX/EXTENDED

Origin: System III

## DESCRIPTION

Mm can be used to type out documents using nroff(1) and the MM text-formatting macro package. It has options to specify preprocessing by tbl(1) and/or neqn(1) and postprocessing by various terminal-oriented output filters. The proper pipelines and the required arguments and flags for nroff(1) and MM are generated, depending on the options selected.

Osdd is equivalent to the command **mm-mosd**. For more information about the OSDD adapter macro package, see mosd(5).

Options for mm are given below. Any other arguments or flags (e.g., -rC3) are passed to nroff(1) or to MM, as appropriate. Such options can occur in any order, but they must appear before the files arguments. If no arguments are given, mm prints a list of its options.

- -Tterm Specifies the type of output terminal; for a list of recognized values for term, type help term2. If this option is not used, mm will use the value of the shell variable \$TERM from the environment (see profile(5) and environ(7)) as the value of term, if \$TERM is set; otherwise, mm will use 450 as the value of term. If several terminal types are specified, the last one takes precedence.
- -12 Indicates that the document is to be produced in 12-pitch. May be used when **\$TERM** is set to one of **300**, **300s**, **450**, and **1620**. (The pitch switch on the DASI 300 and 300s terminals must be manually set to **12** if this option is used.)
- -c Causes mm to invoke col(1); note that col(1) is invoked automatically by mm unless term is one of 300, 300s, 450, 37, 4000a, 382, 4014, tek, 1620, and X.
- Causes mm to invoke negn; also causes negn to read the /usr/pub/eqnchar file (see eqnchar(5)).
- -t Causes mm to invoke tbl(1).
- **-E** Invokes the **-e** option of *nroff*.
- -y Causes mm to use the non-compacted version of the macros (see mm(7)).

As an example (assuming that the shell variable **\$TERM** is set in the environment to **450**), the two command lines below are equivalent:

```
mm -t -rC3 -12 ghh*
tbl ghh* | nroff -cm -T450-12 -h -rC3
```

Mm reads the standard input when - is specified instead of any file names. (Mentioning other files together with - leads to disaster.) This option allows mm to be used as a filter, e.g.:

```
cat dws | mm -
```

Checkmm is a program for checking the contents of the named files for errors in the use of the Memorandum Macros, missing or unbalanced neqn delimiters, and  $\mathbf{EQ/EN}$  pairs. Note: The user need not use the checkeq program (see eqn(1)). Appropriate messages are produced. The program skips all directories, and if no file name is given, standard input is read.

#### HINTS

 Mm invokes nroff with the -h flag. With this flag, nroff assumes that the terminal has tabs set every 8 character positions.

- 2. Use the -olist option of nroff to specify ranges of pages to be output. Note, however, that mm, if invoked with one or more of the -e, -t, and options, together with the -olist option of nroff may cause a harmless "broken pipe" diagnostic if the last page of the document is not specified in list.
- 3. If you use the -s option of *nroff* (to stop between pages of output), use line-feed (rather than return or new-line) to restart the output. The -s option of *nroff* does not work with the -c option of *mm*, or if *mm* automatically invokes *col*(1) (see -c option above).
- 4. If you lie to *mm* about the kind of terminal its output will be printed on, you'll get (often subtle) garbage; however, if you are redirecting output into a file, use the **-T37** option, and then use the appropriate terminal filter when you actually print that file.

## SEE ALSO

 $\operatorname{col}(1)$ ,  $\operatorname{cw}(1)$ ,  $\operatorname{env}(1)$ ,  $\operatorname{eqn}(1)$ ,  $\operatorname{greek}(1)$ ,  $\operatorname{mmt}(1)$ ,  $\operatorname{nroff}(1)$ ,  $\operatorname{tbl}(1)$ ,  $\operatorname{profile}(5)$ ,  $\operatorname{mm}(7)$ ,  $\operatorname{mosd}(7)$ ,  $\operatorname{term}(7)$ .

MM-Memorandum Macros in HP-UX Concepts and Tutorials.

## DIAGNOSTICS

mm

"mm: no input file" if none of the arguments is a readable file and mm is not used as a filter.

checkmm "Cannot open filename" if file(s) is unreadable. The remaining output of the program is diagnostic of the source file.

MORE(1) MORE(1)

#### NAME

more - file perusal filter for crt viewing

## SYNOPSIS

```
more [ -cdflsu ] [ -n ] [ +linenumber ] [ +/pattern ] [ name ... ] page [ more options ]
```

## HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: UCB

Jigin. OCE

Native Language Support:

8-bit data.

## DESCRIPTION

More is a filter which allows examination of continuous text, one screenful at a time, on a soft-copy terminal. It normally pauses after each screenful, printing --More-- at the bottom of the screen. If the user then types a carriage return, one more line is displayed. If the user hits a space, another screenful is displayed. Other possibilites are enumerated later.

The command line options are:

- -n An integer which is the size (in lines) of the window which more will use instead of the default.
- -c More will draw each page by beginning at the top of the screen and erasing each line just before it draws on it. This avoids scrolling the screen, making it easier to read while more is writing. This option will be ignored if the terminal does not have the ability to clear to the end of a line.
- -d More will prompt the user with the message "Hit space to continue, Rubout to abort" at the end of each screenful. This is useful if more is being used as a filter in some setting, such as a class, where many users may be unsophisticated.
- -f This causes *more* to count logical lines, rather than screen lines. That is, long lines are not folded. This option is recommended if *nroff* output is being piped through *ul*, since the latter may generate escape sequences. These escape sequences contain characters which would ordinarily occupy screen postions, but which do not print when they are sent to the terminal as part of an escape sequence. Thus *more* may think that lines are longer than they actually are, and fold lines erroneously.
- -1 Do not treat ^L (form feed) specially. If this option is not given, *more* will pause after any line that contains a ^L, as if the end of a screenful had been reached. Also, if a file begins with a form feed, the screen will be cleared before the file is printed.
- -s Squeeze multiple blank lines from the output, producing only one blank line. Especially helpful when viewing nroff output, this option maximizes the useful information present on the screen.
- -u Normally, more will handle underlining and bold such as produced by nroff in a manner appropriate to the particular terminal: if the terminal can perform underlining or has a stand-out mode, more will output appropriate escape sequences to enable underlining, else stand-out mode, for underlined information in the source file. If the terminal can perform stand-out, more uses that mode for bold information. The -u option suppresses this processing, as do the "ul" and "os" terminfo flags.

#### +linenumber

Start up at linenumber.

## +/pattern

Start up two lines before the line containing the regular expression pattern.

MORE(1) MORE(1)

If the program is invoked as page, then the screen is cleared before each screenful is printed (but only if a full screen is being printed), and k-1 rather than k-2 lines are printed in each screenful, where k is the number of lines the terminal can display. More looks in the file /usr/lib/terminfo to determine terminal characteristics, and to determine the default window size. On a terminal capable of displaying 24 lines, the default window size is 22 lines.

More looks in the environment variable MORE to pre-set any flags desired. For example, if you prefer to view files using the -c mode of operation, the shell command sequence MORE='-c'; export MORE or the csh command setenv MORE -c would cause all invocations of more, including invocations by programs such as man and msgs, to use this mode. Normally, the user will place the command sequence which sets up the MORE environment variable in the .profile or esher file

If *more* is reading from a file, rather than a pipe, then a percentage is displayed along with the **--More--** prompt. This gives the fraction of the file (in characters, not lines) that has been read so far.

Other sequences which may be typed when more pauses, and their effects, are as follows (i is an optional integer argument, defaulting to 1):

## i < space >

display i more lines, (or another screenful if no argument is given).

- ^D display 11 more lines (a "scroll"). If i is given, then the scroll size is set to i.
- d same as ^D (control-D).
- iz same as typing a space except that i, if present, becomes the new window size.
- is skip i lines and print a screenful of lines.
- if skip i screenfuls and print a screenful of lines.
- q or Q Exit from more.
- Display the current line number.
- v Start up the editor vi at the current line.
- h Help command; give a description of all the *more* commands.
- i/expr search for the i-th occurrence of the regular expression expr. If there are less than i occurrences of expr, and the input is a file (rather than a pipe), then the position in the file remains unchanged. Otherwise, a screenful is displayed, starting two lines before the place where the expression was found. The user's erase and kill characters may be used to edit the regular expression. Erasing back past the first column cancels the search commend.
- in search for the i-th occurrence of the last regular expression entered.
- (single quote) Go to the point from which the last search started. If no search has been performed in the current file, this command goes back to the beginning of the file.

#### !command

invoke a shell with *command*. The characters "%" and "!" in "command" are replaced with the current file name and the previous shell command respectively. If there is no current file name, "%" is not expanded. The sequences " $\$ %" and " $\$ !" are replaced by "%" and "!" respectively.

- i:n skip to the i-th next file given in the command line (skips to last file if n doesn't make sense).
- *i*:p skip to the *i*-th previous file given in the command line. If this command is given in the middle of printing out a file, then *more* goes back to the beginning of the file. If *i* doesn't make sense, *more* skips back to the first file. If *more* is not reading from a file, the bell is

MORE(1) MORE(1)

rung and nothing else happens.

:f display the current file name and line number.

q or :Q

exit from more (same as q or Q).

(dot) repeat the previous command.

The commands take effect immediately, i.e., it is not necessary to type a carriage return. Up to the time when the command character itself is given, the user may hit the line kill character to cancel the numerical argument being formed. In addition, the user may hit the erase character to redisplay the --More-(xx%).

At any time when output is being sent to the terminal, the user can hit the quit key (normally control-\). *More* will stop sending output, and will display the usual **--More--** prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, due to the fact that any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

The terminal is set to *noecho* mode by this program so that the output can be continuous. What you type will thus not show on your terminal, except for the / and ! commands.

If the standard output is not a teletype, then *more* acts just like *cat*, except that a header is printed before each file (if there is more than one).

A sample usage of more in previewing nroff output would be

 $nroff - ms + 2 doc.n \mid more - s$ 

#### FILES

/usr/lib/terminfo/?/\*

terminfo data base

help file

## VARIABLES

MORE Default paging mode.

#### SEE ALSO

csh(1), man(1), msgs(1), sh(1), terminfo(5), environ(5).

## BUGS

Core will be dumped if *more* is invoked withtout TERM in the environment.

When invoked from a shell such that *stderr* is write-only, and if *stderr* is interactive (e.g., 2>*fname*), then input to *stderr* must be redirected in one of the following ways:

2 < & 0

2</dev/tty

mt - magnetic tape manipulating program

# SYNOPSIS

mt [ -t tapename ] command [ count ]

## HP-UX COMPATABILITY

Level:

HP-UX/STANDARD

Origin:

UCB

## DESCRIPTION

Mt is used to give commands to the tape drive. If tapename is not specified, /dev/mt/0mn is used. If count is not specified, 1 is assumed.

Here are the commands:

eof write count end-of-file marks
fsf space forward count files
fsr space forward count records
bsf space backward count files
bsr space backward count records
rew rewind tape
offl rewind tape and go offline.

## EXAMPLE

The following command will rewind the default mag tape unit and take it off line:

mt offl

## FILES

/dev/mt/\* Magnetic tape interface /dev/rmt/\* Raw magnetic tape interface

/dev/fint/\* fraw magnetic tape interface

/dev/rmt/0mn (or whatever drive is used) must be described as a Berkeley–compatibility mode tape drive (without rewind) for mt to operate as expected.

# SEE ALSO

mt(4), dd(1).

NEWGRP(1) NEWGRP(1)

#### NAME

newgrp - log in to a new group

## SYNOPSIS

newgrp [-] [ group ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Native Language Support:

8-bit passwords.

#### DESCRIPTION

Newgrp changes a user's group identification. The user remains logged in and the current directory is unchanged, but calculations of access permissions to files are performed with respect to the new real and effective group IDs. The user is always given a new shell, replacing the current shell. by newgrp, regardless of whether it terminated successfully or due to an error condition (i.e., unknown group).

Exported variables retain their values after invoking newgrp; however, all unexported variables are either reset to their default value or set to null. System variables (such as PS1, PS2, PATH, MAIL, and HOME), unless exported by the system or explicitly exported by the user, are reset to default values. For example, a user has a primary prompt string (PS1) other than \$ (default) and has not exported PS1. After an invocation of newgrp, successful or not, their PS1 will now be set to the default prompt string \$. Note that the shell command export (see sh(1)) is the method to export variables so that they retain their assigned value when invoking new shells.

With no arguments, newgrp changes the group identification back to the group specified in the user's password file entry.

If the first argument to newgrp is a -, the environment is changed to what would be expected if the user actually logged in again.

A password is demanded if the group has a password and the user does not, or if the group has a password and the user is not listed in /etc/group as being a member of that group.

#### FILES

/etc/group

system's group file

/etc/passwd

system's password file

#### SEE ALSO

login(1), sh(1), group(5), passwd(5), environ(7).

## DIAGNOSTICS

Sorry:

You didn't qualify as a group member.

Unknown group:

The group name was not in /etc/group.

Permission denied:

stdin is a non-tty file, this message is given.

You have no shell:

Exec of the shell failed.

## **BUGS**

There is no convenient way to enter a password into /etc/group.

Use of group passwords is not encouraged, because, by their very nature, they encourage poor security practices. Group passwords may disappear in the future.

If a password must be given, it can only come from a teletype port. If the

Shell variables which are not exported are lost.

NEWS(1)

#### NAME

news - print news items

#### SYNOPSIS

```
news [ -a ] [ -n ] [ -s ] [ items ]
```

# HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: System V

## DESCRIPTION

*News* is used to keep the user informed of current events. By convention, these events are described by files in the directory /usr/news.

When invoked without arguments, *news* prints the contents of all current files in /usr/news, most recent first, with each preceded by an appropriate header. *News* stores the "currency" time as the modification date of a file named .news\_time in the user's home directory (the identity of this directory is determined by the environment variable \$HOME); only files more recent than this currency time are considered "current."

The following options can be used with news:

- -a causes news to print all items, regardless of currency. In this case, the stored time is not changed.
- -n causes news to report the names of the current items without printing their contents, and without changing the stored time.
- -s causes *news* to report how many current items exist, without printing their names or contents, and without changing the stored time. It is useful to include such an invocation of *news* in one's .profile file, or in the system's /etc/profile.

Note that only one of the -a, -n, and -s options can be used at a time.

All other arguments are assumed to be specific news items that are to be printed.

If an interrupt is typed during the printing of a news item, printing stops and the next item is started. Another *delete* within one second of the first causes the program to terminate.

# FILES

```
/etc/profile
/usr/news/*
$HOME/.news__time
```

## SEE ALSO

mail(1), profile(5), environ(7).

NICE(1)

## NAME

nice - run a command at low priority

# SYNOPSIS

nice [ -increment ] command [ arguments ]

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

# DESCRIPTION

Nice executes command with a lower CPU scheduling priority. If the increment argument (in the range 1–19) is given, it is used; if not, an increment of 10 is assumed.

The super–user may run commands with priority higher than normal by using a negative increment, e.g., --10.

# SEE ALSO

nohup(1), nice(2).

# DIAGNOSTICS

Nice returns the exit status of the subject command.

## BUGS

An increment larger than 19 is equivalent to 19.

nl - line numbering filter

## SYNOPSIS

nl [-htype] [-btype] [-ftype] [-vstart#] [-iincr] [-p] [-lnum] [-ssep] [-wwidth] [-nformat] [-ddelim] file

#### HP-UX COMPATIBILITY

Origin:

Level: HP-UX/STANDARD

System V

# DESCRIPTION

NI reads lines from the named file or the standard input if no file is named and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.

Nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (e.g., no numbering of header and footer lines while numbering blank lines only in the body).

The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):

$Line\ contents$	Start o
\:\:\:	header
\:\:	body
\:	footer

Unless told otherwise, nl assumes the text being read is in a single logical page body.

Command options may appear in any order and may be intermingled with an optional file name. Only one file may be named. The options are:

Specifies which logical page body lines are to be numbered. Recognized types and their

-btype

meaning are: number all lines; а

t

number lines with printable text only: no line numbering; n

number only lines that contain the regular expression pstring specified in string.

The default type for logical page body is t (text lines numbered).

-htypeSame as -btype except for header. Default type for logical page header is n (no lines numbered).

-ftype Same as -btype except for footer. Default for logical page footer is n (no lines numbered).

Do not restart numbering at logical page delimiters. -p

-vstart#Start# is the initial value used to number logical page lines. Default is 1.

-iincr *Incr* is the increment value used to number logical page lines. Default is 1.

Sep is the character(s) used in separating the line number and the corresponding text -ssep line. Default sep is a tab.

-wwidth Width is the number of characters to be used for the line number. Default width is 6.

-nformat Format is the line numbering format. Recognized values are: ln left justified, leading zeroes suppressed;
 rn right justified, leading zeroes supressed;
 rz right justified, leading zeroes kept.

Default format is rn (right justified).

-lnum

Num is the number of blank lines to be considered as one. For example, -12 results in only the second adjacent blank being numbered (if the appropriate -ha, -ba, and/or -fa option is set). Default is 1.

 $-\mathbf{d}xx$ 

The delimiter characters specifying the start of a logical page section may be changed from the default characters (\:) to two user–specified characters. If only one character is entered, the second character remains the default character (:). No space should appear between the -d and the delimiter characters. To enter a backslash, use two backslashes.

#### EXAMPLE

The command:

nl - v10 - i10 - d! + file1

will number file 1 starting at line number 10 with an increment of ten. The logical page delimiters are ! and +.

## SEE ALSO

pr(1).

nm - print name list (symbol table) of object file

## SYNOPSIS

nm [ -gnoprsu ] [filename ...]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

Remarks: This manual page describes nm as implemented on the Series 200 computers. Refer to

other nm(1) manual pages for information valid for other implementations.

## DESCRIPTION

Nm prints the name list (symbol table) of each object file in the argument list. If an argument is an archive, a listing for each object file in the archive will be produced. If no file is given, the symbols in **a.out** are listed.

Each symbol name is preceded by its value printed in a representation appropriate to the architecture of the machine (blanks if undefined) and one of the letters  $\mathbf{U}$  (undefined),  $\mathbf{A}$  (absolute),  $\mathbf{T}$  (text segment symbol),  $\mathbf{D}$  (data segment symbol),  $\mathbf{B}$  (bss segment symbol),  $\mathbf{R}$  (register symbol),  $\mathbf{F}$  (file symbol), or  $\mathbf{C}$  (common symbol). If the symbol is local (non-external) the type letter is in lower case. The output is sorted alphabetically.

# Options are:

- -g Print only global (external) symbols.
- -n Sort numerically rather than alphabetically.
- -o Prepend file or archive element name to each output line rather than only once. This option can be used to make piping to grep(1) more meaningful.
- -p Don't sort; print in symbol-table order.
- -r Sort in reverse order.
- -s Sort according to the size of the external symbol (computed from the difference between the value of the symbol and the value of the symbol with the next highest value). This difference is the value printed. This flag turns on -g and -n and turns off -u and -p.
- -u Print only undefined symbols.

If the symbol was an align symbol, the letter L will be printed after the letter describing its type.

nm - print name list (symbol table) of object file

#### SYNOPSIS

nm [ -gnopru ] [ file ... ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

Remarks: This manual page describes nm as implemented on the Series 500 computers. Refer to

other nm manual pages for information valid for other implementations.

## DESCRIPTION

Nm prints the name list (symbol table) of each object file in the argument list. If an argument is an archive, a listing for each object file in the archive will be produced, preceded by the member name on a separate line. If no file is given, the symbols in **a.out** are listed.

# Options are:

- -g Print only global (external) symbols.
- -n Sort numerically rather than alphabetically.
- -o Prepend file or archive element name to each output line rather than only once. This option can be used to make piping to grep(1) more meaningful.
- -p Don't sort; print in symbol-table order.
- -r Sort in reverse order.
- -u Print only undefined symbols.

The output from nm consists of five columns of data. The following is a portion of a typical output:

	X	IDATA	00000108	$A\_iob$
	X	IDATA	000002a0	$A\_sctab$
	X	ICOMM	00000400 0 00000440	$A$ _sibuf
	X	ICOMM	00000400 0 00000840	$A\_sobuf$
		UDATA	00000c40	Aallocs
	$\mathbf{X}$	FUNC	EDS c04 002a8 00000003	cleanup
	X	DDATA	DR 00000098	ctype
٠.	X	FUNC	EDS c0c 00000 00000001	doscan
	X	SYSTEM	EPP 004 0000e	exit
	X	DDATA	DR 00000038	iob
	X	DCOMM	00000004 000000b0	pfile
	X	DDATA	DR 00000090	$\_\_sctab$
	X	PTR	1 00000a 000000b4	$\_\_$ sibuf
	X	PTR	1 00000c 000000b8	$\_\_sobuf$
		FILENAME	0000000a	_exit.o
		FILENAME	000000f	_print.o

>From left to right, the first column specifies whether the symbol is defined (.) or undefined (U). The second column specifies whether the symbol is non-external (.) or external (X). The third column gives the linker symbol type (as defined in a.out.h and described below). The fourth column lists the data associated with the specified symbol type. The fifth column gives the name of the system call, file, variable, array, common, etc., described by that entry in the symbol table.

Up to four data elements are reported in the fourth column. If they are not symbolic values (such as 'EDS' or 'DR'), then they are hexadecimal values. The number of data elements reported depends on the symbol type. Each symbol type has one to four parameters associated with it, whose values are given by the data elements in the fourth column. The symbol types and associated parameters are discussed below.

The following symbol types are supported:

ABS

not currently generated; reserved for future use.

FUNC or ENTRY specifies that the entry refers to a function or procedure call. Four numbers, ptr\_type, segment, offset, and stt\_index, are associated. Their values are given in order, from left to right, by the data elements. Ptr\_type consists of a single bit that is always cleared. It is symbolically represented by 'EDS'.  $Ptr\_type$  is meaningful to the linker (see ld(1)), and specifies the storage format of the call in the symbol table. Seament specifies the code segment number (a number in the range 3073 to 4095, that indicates which code segment in the user's program space contains the desired code). Offset specifies the number of bytes from the beginning of the code segment where the function or procedure code begins. Stt\_index is an indirect reference to the beginning of the function or procedure code.

SYSTEM

specifies that the entry refers to a procedure call directly into the system kernel. Three numbers, entry\_type, segment, and stt, are associated. Their values are given by the data elements. Entry\_type consists of a single bit that is always set. Its value is symbolically represented by 'EPP'. Entry\_type is meaningful to the linker, and specifies the storage format of the call in the symbol table. Segment specifies the system code segment number (the number of a code segment among those set aside for system use; typically in the range 0 to 64). Stt is an indirect pointer to the beginning of the procedure code.

LABEL

specifies that the entry is the destination address for a branch instruction. Three numbers, ptr\_type, segment, and offset, are associated. Their values are given by the data elements. Ptr\_type consists of a single bit which is always cleared. Its value is symbolically represented by 'EDS'. Ptr\_type is meaningful to the linker, and specifies the storage format of the address in the symbol table. Segment specifies the user code segment number. Offset specifies the number of bytes from the beginning of the code segment where the label begins.

**DDATA** 

specifies that the entry is a directly-addressable, initialized data structure (a variable, or the beginning of an array, common, structure, etc.). Two numbers, base\_reg and displacement, are associated. Their values are given by the data elements. Base\_reg is assigned one of nine possible symbolic values which describe the addressing scheme used to find the data structure. It is meaningful to the linker. The possible symbolic values are P+, P-, DB, DL, Q+, Q-, SB, S-, and DR. Displacement specifies the byte offset where the data structure is located. Note that this offset is measured relative to the beginning of the data space of the file for which the nm listing is made. The actual byte offset of the data structure in the executable a.out file could change.

#### IDATA or UDATA

specifies that the entry refers to an indirectly-addressable, uninitialized array, or an indirectly-addressable, initialized common block. One number, displacement, is associated. Its value is given by the data element. It is identical to the *displacement* described above under **DDATA**.

#### DCOMM or ICOMM

specifies that the entry is treated as a common block. Three numbers, blocksize, needs\_length\_word, and displacement, are associated. Their values are given by the data elements. Blocksize is the size, in bytes, of the common block. Needs\_length\_word is a boolean value which appears in a print-out as either 0 or 1. If its value is 1, the linker places the value of (blocksize - 4) in the first four bytes of the common block. This information is necessary when linking FORTRAN programs. Displacement is identical to that described under DDATA above.

PTR

specifies that the entry is a pointer to an indirectly-addressable data structure (variable, array, common block, etc.). Three numbers,  $ptr\_to\_common$ , target, and address, are associated. Their values are given by the data elements.  $Ptr\_to\_common$  is an eight-bit boolean expression. Its value is given as 1 (true) or 0 (false). If true, then the entry is a pointer to a common block. If false, the entry is a pointer to some other type of data structure. Target is an index into the symbol table to the entry that describes the target of the data structure pointer. Address is a pointer to the data structure pointer; that is, an indirect pointer to the data structure.

SEGMENT

not currently generated; reserved for future use.

FILENAME

specifies that the entry is a file name. One number, sequence, is associated. Its value is given by the data element. Sequence reflects the order in which the linker encountered each file name.

SEE ALSO

## DIAGNOSTICS

Nm generates an error message for the following conditions:

invalid option cannot open file bad magic number read error NOHUP(1) NOHUP(1)

#### NAME

nohup - run a command immune to hangups, logouts, and quits

#### SYNOPSIS

nohup command [ arguments ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Nohup executes command with hangups and quits ignored. If output is not re-directed by the user, both standard output and standard error are sent to **nohup.out**. If **nohup.out** is not writable in the current directory, output is redirected to **\$HOME/nohup.out**; otherwise, nohup will fail.

If output from nohup is redirected to a terminal, or is not redirected at all, the output is sent to nohup.out.

#### EXAMPLE

It is frequently desirable to apply nohup to pipelines or lists of commands. This can be done only by placing pipelines and command lists in a single file, called a shell procedure. One can then issue:

nohup sh file

and the *nohup* applies to everything in *file*. If the shell procedure *file* is to be executed often, then the need to type sh can be eliminated by giving *file* execute permission. Add an ampersand and the contents of *file* are run in the background with interrupts also ignored (see sh(1)):

nohup file &

An example of what the contents of file could be is:

tbl ofile | eqn | nroff > nfile

#### SEE ALSO

chmod(1), nice(1), sh(1), signal(2).

## WARNINGS

nohup command1; command2 nohup applies only to command1 nohup (command1; command2) is syntactically incorrect.

Be careful of where standard error is redirected. The following command may put error messages on tape, making it unreadable:

nohup cpio -o t >/dev/rmt/1m &

while

nohup cpio -o t >/dev/rmt/1m 2>errors &

puts the error messages into file errors.

NROFF(1) NROFF(1)

NAME

nroff - format text

SYNOPSIS

nroff [ options ] [ files ]

HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

## DESCRIPTION

Nroff formats text contained in *files* (standard input by default) for printing on typewriter–like devices and line printers. Its capabilities are described in the NROFF/TROFF User's Manual cited below.

*Nroff* is best not used directly, but rather via macro packages such as mm or ms which provide a high-level interface to document processing, as opposed to the very low level one provided directly in nroff.

An argument consisting of a minus (-) is taken to be a file name corresponding to the standard input. The *options*, which may appear in any order, but must appear before the *files*, are:

- -olist Print only pages whose page numbers appear in the list of numbers and ranges, separated by commas. A range N-M means pages N through M; an initial -N means from the beginning to page N; and a final N- means from N to the end. (See BUGS below.)
- $-\mathbf{n}N$  Number first generated page N.
- -sN Stop every N pages. Nroff will halt after every N pages (default N=1) to allow paper loading or changing, and will resume upon receipt of a line-feed or new-line (new-lines do not work in pipelines, e.g., with mm(1)). When nroff halts between pages, an ASCII BEL is sent to the terminal.
- -raN Set register a (which must have a one-character name) to N.
- -i Read standard input after files are exhausted.
- -q Invoke the simultaneous input-output mode of the .rd request.
- -z Print only messages generated by .tm (terminal message) requests.
- -mname Precede the input *files* with the non-compacted (ASCII text) macro file /usr/lib/tmac/tmac.name.
- -cname Precede the input files with the compacted macro files

  /usr/lib/macros/cmp.[nt].[dt].name and /usr/lib/macros/ucmp.[nt].name.
- -kname Compact the macros used in this invocation of nroff, placing the output in files [dt].name in the current directory (see the May 1979 Addendum to the NROFF/TROFF User's Manual for details of compacting macro files).
- -Tname Prepare output for specified terminal. Known names are 37 for the (default) TELE—TYPE Model 37 terminal, tn300 for the GE TermiNet 300 (or any terminal without half-line capability), 300s for the DASI 300s, 300 for the DASI 300, 450 for the DASI 450, lp for a (generic) ASCII line printer, 382 for the DTC-382, 4000A for the Trendata 4000A, 832 for the Anderson Jacobson 832, X for a (generic) EBCDIC printer, and 2631 for the Hewlett Packard 2631 line printer.
- Produce equally-spaced words in adjusted lines, using the full resolution of the particular terminal.
- -h Use output tabs during horizontal spacing to speed output and reduce output character count. Tab settings are assumed to be every 8 nominal character widths.
- -un Set the emboldening factor (number of character overstrikes) for the third font position (bold) to n, or to zero if n is missing.

HP-UX nroff differs from other versions of nroff as follows:

1) New facilities for handling of the revision bar (.mc) feature are provided:

NROFF(1) NROFF(1)

The read/write number register *ic* holds the revision bar character (as an ordinal) that will be printed on the current line, if any. The number registers .m and .e contain respectively the revision bar character and offset as set by the .mc command, and are read only. These make it possible to deal with the revision bar information in a macro, thus making it possible for the printed result to properly reflect the revision information in the source.

2) The date and time used are the appropriate local time.

Series 500:

The -c and -k options are not currently supported.

## FILES

```
/usr/lib/suftab suffix hyphenation tables
/tmp/ta$# temporary file
/usr/lib/tmac/tmac.* standard macro files and pointers
/usr/lib/term/* standard macro files
/usr/lib/term/* terminal driving tables for nroff
```

#### SEE ALSO

mm(1).

NROFF/TROFF User's Manual in HP-UX: Selected Articles.

## BUGS

Nroff is keyed to Eastern Standard Time; as a result, depending on the time of the year and on your local time zone, the date that nroff generates may be off by one day from your current date. When nroff is used with the -olist option inside a pipeline, it may cause a harmless "broken pipe" diagnostic if the last page of the document is not specified in list.

Hewlett-Packard - 2 - July 9, 1985

od, xd - octal and hexadecimal dump

## SYNOPSIS

```
od [ -bcdox ] [ file ] [ [ + ]offset[ . ][ b ] ] xd [ -bcdox ] [ file ] [ [ + ]offset[ . ][ b ] ]
```

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III and HP

## DESCRIPTION

Od(xd) dumps file in one or more formats as selected by the first argument. If the first argument is missing,  $-\mathbf{o}(-\mathbf{x})$  is the default. Each line is prepended with an offset field. For od, the offset is in octal, for xd the offset is in hexadecimal. The meanings of the format options are:

- -b Interpret bytes in octal (hexadecimal).
- -c Interpret bytes in ASCII. Certain non-graphic characters appear as C escapes: null=\0, backspace=\b, form-feed=\f, new-line=\n, return=\r, tab=\t; others appear as 3-digit octal numbers.
- -d Interpret 16-bit words in decimal.
- -o Interpret 16-bit words in octal.
- -x Interpret 16-bit words in hexadecimal.

The file argument specifies which file is to be dumped. If no file argument is specified, the standard input is used.

The offset argument specifies the offset in the file where dumping is to commence. This argument is normally interpreted as octal bytes. If . is appended, offset is interpreted in decimal. If **0**x is prepended, offset is interpreted in hexadecimal. If **b** is appended, offset is interpreted in blocks of 512 bytes. If the file argument is omitted, offset must be preceded by +.

Dumping continues until end-of-file.

PACK(1) PACK(1)

#### NAME

pack, pcat, unpack - compress and expand files

## SYNOPSIS

```
pack [-] [-f] name ...
pcat name ...
unpack name ...
```

# HP-UX COMPATIBILITY

Level: HP-U

HP-UX/STANDARD

Origin: System V

Remarks: Not supported on the Integral Personal Computer.

## DESCRIPTION

Pack attempts to store the specified files in a compressed form. Wherever possible (and useful), each input file name is replaced by a packed file name.z with the same access modes, access and modified dates, and owner as those of name. The -f option will force packing of name. This is useful for causing an entire directory to be packed even if some of the files will not benefit. If pack is successful, name will be removed. Packed files can be restored to their original form using unpack or pcat.

Pack uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the - argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of - in place of name will cause the internal flag to be set and reset.

The amount of compression obtained depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each z file, it is usually not worthwhile to pack files smaller than three blocks, unless the character frequency distribution is very skewed, which may occur with printer plots or pictures.

Typically, text files are reduced to 60–75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.

Pack returns a value that is the number of files that it failed to compress.

No packing will occur if:

```
the file appears to be already packed; the file is all nulls; the file name has more than 12 characters; the file has links; the file is a directory; the file cannot be opened; no disk storage blocks will be saved by packing; a file called name.z already exists; the .z file cannot be created; an I/O error occurred during processing.
```

The last segment of the file name must contain no more than 12 characters to allow space for the appended x extension. Directories cannot be compressed.

Pcat does for packed files what cat(1) does for ordinary files, except that pcat can not be used as a filter. The specified files are unpacked and written to the standard output. Thus to view a packed file named name.z use:

pcat name.z

PACK(1)

or just:

pcat name

To make an unpacked copy, say nnn, of a packed file named name.z (without destroying name.z) use the command:

pcat name >nnn

Pcat returns the number of files it was unable to unpack. Failure may occur if:

the file name (exclusive of the .z) has more than 12 characters;

the file cannot be opened;

the file does not appear to be the output of pack.

Unpack expands files created by pack. For each file name specified in the command, a search is made for a file called name.z (or just name, if name ends in .z). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the .z suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.

Unpack returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in pcat, as well as for the following:

a file with the "unpacked" name already exists; if the unpacked file cannot be created.

## SEE ALSO

cat(1).

pam - Personal Applications Manager, a visual shell

SYNOPSIS

pam [ -c args ... ]

HP-UX COMPATIBILITY

Level: NON-STANDARD

Origin: HP

## DESCRIPTION

Pam is a program that helps provide a friendlier, less intimidating means of communication between HP-UX and system users. It provides many of the traditional capabilities supported by other shell programs such as executing commands as foreground processes (where you must wait until one command has been completed before the system accepts the next command) or background processes (where the command runs in the background while you perform other tasks in the foreground). Pam also supports other useful capabilities such as using substituted files instead of standard input and standard output, pipelining several processes into a single command, and handling shell scripts and programs. Pam maintains a continuous display of the open folder (current directory), and makes use of windowing and mouse I/O facilities when they are available on the system.

# Display

The pam display has two parts. The top two lines are called the command area, while the remainder of the display is the folder (directory) area. The first line in the command area displays messages (such as prompts and errors) from the system to the user, while the second line displays input commands and text from the user to the system. Pam maintains a buffer of 20 command lines. You can use shifted arrow keys, BACK SPACE, INSERT CHARACTER, and DELETE CHARACTER to access and edit any existing current or previous command line in the 20-line command buffer. For example, each time you press SHIFT-UP ARROW, the next previous command line in the buffer is displayed.

The folder (lower) area is used by pam to display those files that reside in the currently open folder; that is, the current directory. One of the file names displayed in the folder area is highlighted. This highlighted filename identifies which file in the folder is to be used as a filename parameter for pam commands that are invoked using the pam menu. The highlighted file name can be changed by using TAB, SHIFT-TAB and arrow keys.

#### Commands

A command is a sequence of non-blank words separated by blanks. In general, the first word is the name of the command, and the words that follow are passed as arguments to the invoked command. Two or more commands (together with their associated arguments, if any) separated by a vertical bar (|) form a pipeline. To provide a path for passing data between commands in a pipeline, the standard output from one command in the pipeline is connected to the standard input of the next command in the pipe.

To force pam to complete execution of the current command or pipeline before running another command, place a semicolon (;) at the end of the line. If you prefer to perform other tasks while the command or pipeline is being executed, run the first command as a "background" process by adding an ampersand (&) at the end of the command line. Pam then starts the command, and, without waiting for completion, returns for your next instruction.

In a windowed system, interactive command inputs are treated as background processes (&) unless a semicolon is present at the end of the line. In non-windowed systems, commands taken from a script or from interactive command inputs are run to completion before the next command is accepted for execution (;) unless an ampersand is present at the end of the command line.

Sequences of more than one command or pipeline can be joined on a single command line by placing a semicolon or ampersand (but not both) between each adjacent pair of commands/pipelines in the line. In such constructs, commands separated by ";" are executed in sequence (the first command is run to completion before the next is begun). Commands separated by "&" are executed simultaneously on a timesharing basis (this does not necessarily result in the most efficient use of computer resources due to timesharing overhead as sharing processes compete for processor time). Note that when ";" or "&" is used to separate commands, standard output from one command is not automatically connected to standard input for the next. Use the pipeline connector (1) instead when data must be passed between successive commands or programs, or redirect standard output and input to and from a specified

Pam runs commands based on the file type of the command name:

program (executable) - The command name is run (exec'ed) or, if it is a shell script, the commands in the script are run.

folder (directory) - The command name (folder) becomes the new open folder. This is equivalent to cd folder.

data (non-executable) - The command name (data file) is displayed one page at a time.

## Standard Input, Output, and Error Files

The standard input, output and error of a command can be redirected using the following syntax:

< name Use the file name as standard input for the command.

> name Use the file name as standard output for the command.

>> name Use the file name as standard output for the command, but concatenate the output to the end of the file.

^ name Use the file name as standard error for the command.

^^ name Use the file name as standard error for the command, but concatenate the output to the current end of the file, if it exists.

# name [For windowed systems only] Use the named window as standard input, output and error for the command. If the window doesn't exist then a window is created. Specific redirection of I/O with >, >>, <, I, ^, or ^^ overrides any redirection specified with "#".

I/O redirection is possible only with an associated command. Multiple redirections of standard input, output, and error associated with a command are not allowed. The I/O redirection can be placed anywhere in the command.

If a command is followed by "&" (background process), the default standard input for the command is the empty file "/dev/null".

#### Using Patterns to Represent Filenames

Each word in the command line (command name, parameter, redirection file name, window name) is scanned for the characters \*, ?, and [. If one of these characters appears, the word is treated as a pattern that represents more than one filename. Pam replaces the pattern word with alphabetically sorted filenames corresponding to the pattern. If no file name is found that matches the pattern, the word is left unchanged. A period character (.) at the start of a filename or immediately following a /, as well as the character / itself, must be matched explicitly.

\* Matches any string, including the null string.

- Matches any single character.
- Matches any one of the enclosed characters. A pair of characters separated by matches any character lexically between the pair, inclusive. A NOT operator, !, can be specified immediately following the left bracket to match any single character not enclosed in the brackets.

# Quoting

Characters can be quoted on the pam command line to prevent pam from performing special processing on the characters (such as <, >, #, space, I, ;, &, \*, ?, [). A pair of double (") or single (') quote characters can be used to enclose the character string being quoted. The character quotes only the single following character.

# Scripts

A script is an executable file containing command lines and comments. A comment is a line that begins with "!" or "#"; comments are ignored by pam. The command lines in the script file are executed in sequence (unless non-sequential execution is explicitly specified using the "&" character).

Script arguments that are specified when a script is run can be accessed by script commands using the notation "\$1" for the first argument, "\$2" for the second argument, etc. All arguments can be accessed at once using "\$\*". The name of the script can be accessed using "\$0".

#### Autost

If a file named Autost exists in the open folder when pam is started, it is automatically processed as a command. If Autost is a script file, it is run as source Autost (see Built-In Commands described later). Otherwise, it is processed as if it were entered as a command (for example, if Autost is a data file, it is viewed). Pam does not process any command input until processing of the Autost file is complete.

#### Environment

of up when nam is run and can be reset at any time by using The pcomma checke and us

$\frac{1}{1}$ nand $getenv$ . The $\frac{1}{1}$ $\frac{1}{$	is set up when pam is run, and can be reset at any time by using the environment variables are read from a file and are not sorted or pam. Pam passes the current environment to commands that it starts environment variables in running commands:
ACTION	The ACTION variable specifies a command name (corresponding to an executable file), and is used whenever a data file is specified as a command. The ACTION command is run in this case and the data file is passed as the first argument. The default value for ACTION is "view".
НОМЕ	The HOME variable specifies a folder and is used whenever the "cd" command is run without an argument. The HOME folder specifies the directory to change to in this case. The default value for HOME is "/".
LANG	The LANG variable is added by $pam$ to its environment file if it is not already there. This happens when $pam$ is initialized or when the getenv command is done. The value of the LANG variable is set to match the language that the system is localized for.
PATH	The PATH variable specifies a list of folders. When $pam$ runs a command it looks for it in the folders in the PATH list.
SCRSHELL	The SCRSHELL variable specifies the shell to be used by $pam$ in run-

ning scripts. If the specified name does not contain a "/" then pam searches for the shell using the PATH environment variable. If the SCRSHELL is undefined or the specified shell does not exist, the script

Hewlett-Packard - 3 -November 15, 1985 is processed by pam.

### Menu

The pam menu displays the following softkey menu labels corresponding to the indicated function keys:

[function key 1] open, view, or start (a program), or reread

- [f2] echo
- [f3] send or arrow (toggle key)
- [f4] move
- [f5] copy
- [f6] rename
- [f7] delete
- [f8] close

The command associated with a menu item is run whenever the item is selected by pressing the corresponding function key. The highlighted file name in the folder area of the display is used as a parameter for the command.

The menu item associated with f3 is used to toggle the semantics of the arrow keys and is available only in non-windowed systems. f3 is initially set to use the arrow keys for manipulating the position of the file highlight in the folder area. f3 alternately controls movement of the cursor on the command line.

## **Built-In Commands**

Several commands are executed directly by pam:

cd [name]

Make the named folder (directory) the open folder (current directory). If no folder is specified, the HOME environment variable is used to determine which folder to open.

close

Closes the open folder and displays the parent folder.

copy name1 [name2]

copy name1 [name2 ...] folder\_name

Copy name1 to name2; if exists and is not a folder, it is overwritten. If only name1 is specified, the copy is completed with the command toname2. If the last parameter specified is a folder, all the specified files are copied into that folder.

delete name1 [name2 ...]

The named files and folders (if empty) are deleted.

echo [arg ...]

Arguments are written to standard output. The echo menu item (menu item 2 and/or function key 2) writes the full pathname of the highlighted file in the folder area of the display to the command line.

getenv name

The named file is read in and used as the active environment.

makefolder name1 [name2 ...]

Folders are created and given the specified name(s).

move name1 [name2]

move name1 [name2] folder\_name

Rename file or folder name1 to name2. If name2 exists and is a file, it is overwritten. If only name1 is specified, use the command to name2 to complete the move. If the last parameter is a folder, all the specified files are moved

into that folder.

netunam pathname [string]

Initiate a network connection to the specified system (as indicated by *pathname*) using the specified login (as indicated by *string*). If *string* is omitted, the network connection to the specified system, if currently active, is disconnected.

print name1 [name2 ...]

Print the specified files on the designated system printer.

rename name1 [name2]

rename file\_name1 [file\_name2 ...] folder\_name

Same as move.

reread

Reread the open folder and update the display. The keys-

troke CONTROL-L also does a reread.

send

Send the full pathname of the highlighted filename in the folder area to an application as if it were typed from the

keyboard (windowed systems only).

source name [arg ...]

Read command lines from the named script file and execute them. A shell is NOT forked to execute the commands. Parameter substitution for the arguments (arg ...) is handled the same way as during regular script exe-

cution.

stopprint

Stop current printing activity if it was started by the

print command.

to [name]

Complete a pending copy, move or rename. The file or folder *name* identifies the destination for a preceding **copy**, **move**, or **rename** command that had no destination specified. If *name* is omitted, the destination defaults to the current open folder.

view name1 [name2 ...]

Copy the specified file(s) to standard output. If standard output is the screen (default), the file is displayed one

page at a time.

# Signals

Pam ignores INTERRUPT and QUIT signals if the command is followed by an "&"; otherwise pam uses default signal handling when running commands.

## Invoking Pam

Pam can be invoked as a keyboard command or from a program. When pam is invoked without -c as the first argument, pam acts as an interactive, display-oriented command interpreter.

When pam is invoked with -c as the first argument (either from the keyboard or from a running program), the remaining arguments in the command are interpreted as command inputs intended for processing by pam. The list of arguments intended as commands for pam must not exceed a total of 160 characters. When the -c option is used, pam executes the list of command arguments (built-in commands, redirection, pipes, and most other pam facilities can be used), then exits.

### Exiting from Pam

To terminate pam and return to normal HP-UX operation, press CONTROL-D or CONTROL-C.

## HARDWARE DEPENDENCIES

With a non-windowed pam running on certain terminals the shifted right and left arrow keys cannot be used to move the cursor on the command line.

IPC:

pam runs commands with the SIGHUP signal ignored.

The netunam built-in command is not supported.

Series 300/500: The built-in commands print, stopprint, and send are not supported.

The environment variable LANG is not set up by pam.

PASSWD(1) PASSWD(1)

### NAME

passwd - change login password

### SYNOPSIS

passwd [ name ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Native Language Support:

8-bit passwords.

Remarks: Not supported on the Integral Personal Computer.

## DESCRIPTION

This command changes or installs a password associated with the login name. If name is omitted, it defaults to getlogin(3) name.

Ordinary users may change only the password which corresponds to their login name.

Passwd prompts ordinary users for their old password, if any. It then prompts for the new password twice. The first time the new password is entered passwd checks to see if the old password has "aged" sufficiently. If "aging" is insufficient the new password is rejected and passwd terminates: see passwd(4).

Assuming "aging" is sufficient, a check is made to insure that the new password meets construction requirements. When the new password is entered a second time the two copies of the new password are compared. If the two copies are not identical the cycle of prompting for the new password is repeated for at most two more times.

Passwords must be constructed to meet the following requirements:

Each password must have at least six characters. Only the first eight characters are significant.

Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, "alphabetic" means upper and lower case letters.

Each password must differ from the user's login *name* and any reverse or circular shift of that login *name*. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

One whose effective user ID is zero is called a super–user; see id(1), and su(1). Super–users may change any password; hence, passwd does not prompt super–users for the old password. Super–users are not forced to comply with password aging and password construction requirements. A super–user can create a null password by entering a carriage return in response to the prompt for a new password.

## FILES

Cannot create temporary file see the super-user.

Cannot unlink 'filename' see the super-user.

cannot link 'file' to 'file'. see the super-user.

cannot recover 'file'.
see the super-user.

 $Password\ unchanged.$ 

the new and old passwords are the same.

PASTE(1) PASTE(1)

### NAME

paste - merge same lines of several files or subsequent lines of one file

# SYNOPSIS

```
paste file1 file2 ...
paste -d list file1 file2 ...
paste -s [-d list] file1 file2 ...
```

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

# DESCRIPTION

In the first two forms, paste concatenates corresponding lines of the given input files file1, file2, etc. It treats each file as a column or columns of a table and pastes them together horizontally (parallel merging). If you will, it is the counterpart of cat(1) which concatenates vertically, i.e., one file after the other. In the last form above, paste replaces the function of an older command with the same name by combining subsequent lines of the input file (serial merging). In all cases, lines are glued together with the tab character, or with characters from an optionally specified list. Output is to the standard output, so it can be used as the start of a pipe, or as a filter, if - is used in place of a file name.

The meanings of the options are:

- -d Without this option, the new-line characters of each but the last file (or last line in case of the -s option) are replaced by a tab character. This option allows replacing the tab character by one or more alternate characters (see below).
- list One or more characters immediately following -d replace the default tab as the line concatenation character. The list is used circularly, i.e., when exhausted, it is reused. In parallel merging (i.e., no -s option), the lines from the last file are always terminated with a new-line character, not from the list. The list may contain the special escape sequences:  $\n$  (new-line),  $\t$  (tab),  $\t$  (backslash), and  $\n$  (empty string, not a null character). Quoting may be necessary, if characters have special meaning to the shell (e.g., to get one backslash, use -d"\\\").
- -s Merge subsequent lines rather than one from each input file. Use *tab* for concatenation, unless a *list* is specified with -d option. Regardless of the *list*, the very last character of the file is forced to be a new-line.
- May be used in place of any file name, to read a line from the standard input. (There is no prompting).

## EXAMPLES

### SEE ALSO

```
grep(1), cut(1), pr(1): pr - t - m ... works similarly, but creates extra blanks, tabs and new-lines for a nice page layout.
```

## DIAGNOSTICS

line too long

Output lines are restricted to 511 characters.

too many files

Except for -s option, no more than 12 input files may be specified.

NAME

pc - Pascal compiler

SYNOPSIS

pc [ options ] files

HP-UX COMPATIBILITY

Level: HP-

HP-UX/STANDARD

Origin: H

Native Language Support:

8-bit and 16-bit characters in strings and comments.

Remarks: This manual page describes the generic HP Pascal compiler; implementation depen-

dencies for different machines are noted as needed. Currently the Series 300 and Series 500 computers support HP Pascal under HP-UX, as described in this document.

# DESCRIPTION

Pc is the HP standard Pascal compiler. It accepts several types of file arguments:

- (1) Arguments whose names end with .p are taken to be Pascal source files. They are each compiled, and each corresponding archived object program or module(s) is left in the current directory in a file whose name is that of the source, with .a substituted for .p. Note that the Series 500 does not produce archived object (.a) files, instead it produces simple object (.o) files (where the .p is replaced with .o). The .a (or .o) file will not be created if only a single source is compiled and linked, if the -C option is specified, or if the source fails to compile correctly.
- (2) All other file arguments, including those whose names end with .o or .a are passed on to the linker (ld(1)) to be linked into the final program.

Arguments can be passed to the compiler through the PCOPTS environment variable as well as on the command line. The compiler picks up the value of PCOPTS and places its contents before any arguments on the command line. For example (in sh(1) notation),

```
$ PCOPTS=-v
```

\$ export PCOPTS

\$ pc -L prog.p

is equivalent to

The following options are recognized:

- -A Produce warnings for the use of non ANSI-Pascal features. (same as \$ANSI ON\$).
- -C Suppress code generation no .a (or .o) files will be created and linking will be suppressed. This is effectively a request for syntax/semantic checking only (same as \$CODE OFF\$).
- -c Suppress linking and only produce object (.a or .o) files from source files.
- -g Generate additional information needed by the Pascal Symbolic Debugger (pdb), and ensure that the program is linked as required by pdb. See the appropriate implementation reference manual for more information on symbolic debugging support.
- -L Write a program listing to *stdout* (or for the Series 300 only, to the file given in the **\$LIST filename\$** option in the source).
- -lx Cause the linker to search the library named either /lib/libx.a (tried first) or /usr/lib/libx.a. (See ld(1).)

-N Cause the output file from the linker to be marked as unshareable (see -n). For details and system defaults, refer to the linker documentation (ld(1)).

-n Cause the output file from the linker to be marked as shareable (see -N). For details and system defaults, refer to the linker documentation (ld(1)).

-o outfile Name the output file from the linker outfile instead of a.out.

-P lines Specifies the number of lines (including any header or trailer) which should be listed per page of generated listing (same as \$LINES n\$).

-Q Cause the output file from the linker to be marked as not demand loadable (see -q). For details and system defaults, refer to the linker documentation (ld(1)).

-q Cause the output file from the linker to be marked as demand loadable (see -Q). For details and system defaults, refer to the linker documentation (ld(1)).

-s Cause the output of the linker to be stripped of symbol table information (see ld(1) and strip(1)). (This option is incompatible with symbolic debugging).

-t c,name Substitute or insert subprocess c with name where c is one or more of a set of identifiers indicating the subprocess(es). This option works in two modes: 1) if c is a single identifier, name represents the full path name of the new subprocess; 2) if c is a set of (more than one) identifiers, name represents a prefix to which the standard suffixes are concatenated to construct the full path name of the new subprocesses.

The values c can take on are:

c compiler body (standard suffix is pascomp)

0 same as c

l linker (standard suffix is ld)

Enable verbose mode, producing a step-by-step description of the compilation process on stderr.

-w Suppress warning messages (same as \$WARN OFF\$);

-W c, arg1/, arg2, ..., argN

Cause arg1 through argN to be handed off to subprocess c. The argi are of the form -argoption[,argvalue], where argoption is the name of an option recognized by the subprocess and argvalue is a separate argument to argoption where necessary. The values that c can assume are those listed under the -t option, as well as the value d (driver program) which has a special meaning explained below.

For example, the specification to pass the -r (preserve relocation information) option to the linker would be:

-W l,-r

The -W d option specification allows additional, implementation–specific options to be recognized and passed through the compiler driver to the appropriate compiler subprocesses. For example,

-W d,-U (Series 500)

will send the option -*U* to the driver and compiler. Furthermore, a shorthand notation for this mechanism can be used by prepending + to the option name; as in

+U

which is equivalent to the previous option expression. Note that for simplicity this shorthand is applied to each implementation-specific option individually, and that the argualue is no longer separated from the argoption by a comma (see -W).

-Y Enable 16-bit Native Language Support when parsing string literals and comments (same as \$HP16 ON\$). Note that 8-bit parsing is always supported.

The implementation-specific options on the Series 500 are:

 $+\mathbf{E}$ Cause the program to be linked with the library /lib/libpcesc.a which transforms all execution errors (HP-UX signals, Pascal run-time errors, Pascal I/O errors and HP-UX errors) into escapes. This differs from the default library /lib/libpccat.a which prints the appropriate error message and aborts the program.

 $+\mathbf{F}$ Cause the compiler to generate information which is used by various program analyzers.

+H [bytes] Display (if butes is omitted) or set a Pascal program's maximum heap size. Butes is the maximum number of bytes in the heap.

+Q dfile Cause dfile to be read before compilation of each source file. Dfile may only contain compiler options.

+UCause the compiler to upshift externally visible names, default is lower case (same as **\$UPSHIFT\_LEVEL1 ON\$).** 

+W [bytes] Display (if bytes is omitted) or set a Pascal program's working set size. Bytes is the number of bytes in the program's working set:

### FILES

file.p input file (Pascal source file)

file.a generated object archive file (except for the Series 500) or any archive file to

be searched at link time

file.o object file to be relocated at link time (or generated object file for the Series 500 only)

linked executable output file a.out /bin/pc compiler and linker driver program

/usr/lib/pascomp

/usr/lib/paserrs compiler error message file

/usr/lib/escerrs Pascal escape codes (Series 300 only) /usr/lib/syserrs HP-UX system messages (Series 300 only) /usr/lib/ioerrs Pascal I/O results (Series 300 only) /lib/crt0.o runtime startup (Series 300 only)

/lib/prt0.o runtime startup (Series 500 only)

/lib/libpc.a

Pascal run-time library /lib/libm.a HP-UX math library (Series 300 only)

/lib/libpccat.a Pascal run-time library, reports errors and aborts program (Series 500 only) /lib/libpcesc.a Pascal run-time library, translates errors into escapes (Series 500 only) /usr/tmp/\* temporary files used by the compiler; names are created by tmpnam(3S).

# SEE ALSO

HP Pascal Language Reference, HP Part No. 98680-90015 (Series 300).

Pascal/9000 Language Reference Manual. HP Part No. 97082-90001 (Series 500).

Programming in Pascal with Hewlett-Packard Pascal, by Peter Grogono (Series 300/500).

# DIAGNOSTICS

The diagnostics produced by pc are intended to be self-explanatory. Occasional messages may be produced by the linker.

A list of all compiler errors may be found in /usr/lib/paserrs.

If a listing is requested (-L option), errors are written to the listing file (stdout). If a listing is requested and either or both of stdout/stderr has been redirected to something other than a terminal, errors will also be written to stderr. If no listing is requested (no -L option), errors are written to stderr. This effectively guarantees that stderr will always recieve error messages, unless that would result in duplication of error messages printed on the terminal.

# HARDWARE DEPENDENCIES

Series 500:

The following options are no longer supported: -b, -e, and -f.

The following options must now be specified with the **-W**  $\mathbf{d}$ ,... option or the + shorthand: **-E**, **-F**, **-H** [bytes], and **-W** [bytes].

To use the  $+\mathbf{H}$  or  $+\mathbf{W}$  options on an executable file other than **a.out**, the file to be examined (modified) must be specified with the  $-\mathbf{o}$  option. To set the heap of program foo to 1000000

use:

pc +H 1000000 -o foo

do not use:

pc +H 1000000 -W l,-o,foo

### NAME

pr - print files

### SYNOPSIS

pr [ options ] [ files ]

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Native Language Support:

8-bit data, customs, messages.

## DESCRIPTION

Pr prints the named files on the standard output. If file is -, or if no files are specified, the standard input is assumed. By default, the listing is separated into pages, each headed by the page number, a date and time, and the name of the file.

By default, columns are of equal width, separated by at least one space; lines which do not fit are truncated. If the -s option is used, lines are not truncated and columns are separated by the separation character.

If the standard output is associated with a terminal, error messages are withheld until pr has completed printing.

The below options may appear singly or be combined in any order:

- +k Begin printing with page k (default is 1).
- -k Produce k-column output (default is 1). The options -e and -i are assumed for multicolumn output.
- -a Print multi-column output across the page.
- -m Merge and print all files simultaneously, one per column (overrides the -k, and -a options).
- -d Double-space the output.
- -eck Expand input tabs to character positions k+1, 2\*k+1, 3\*k+1, etc. If k is 0 or is omitted, default tab settings at every eighth position are assumed. Tab characters in the input are expanded into the appropriate number of spaces. If c (any non-digit character) is given, it is treated as the input tab character (default for c is the tab character).
- -ick In output, replace white space wherever possible by inserting tabs to character positions k+1, 2\*k+1, 3\*k+1, etc. If k is 0 or is omitted, default tab settings at every eighth position are assumed. If c (any non-digit character) is given, it is treated as the output tab character (default for c is the tab character).
- -nck Provide k-digit line numbering (default for k is 5). The number occupies the first k+1 character positions of each column of normal output or each line of -m output. If c (any non-digit character) is given, it is appended to the line number to separate it from whatever follows (default for c is a tab).
- -wk Set the width of a line to k character positions (default is 72 for equal-width multi-column output, no limit otherwise).
- -ok Offset each line by k character positions (default is 0). The number of character positions per line is the sum of the width and offset.

July 2, 1985

- -1k Set the length of a page to k lines (default is 66).
- -h Use the next argument as the header to be printed instead of the file name.

- -p Pause before beginning each page if the output is directed to a terminal (pr will ring the bell at the terminal and wait for a carriage return).
- -f Use form-feed character for new pages (default is to use a sequence of line-feeds). Pause before beginning the first page if the standard output is associated with a terminal.
- -r Print no diagnostic reports on failure to open files.
- -t Print neither the five-line identifying header nor the five-line trailer normally supplied for each page. Quit printing after the last line of each file without spacing to the end of the page.
- -sc Separate columns by the single character c instead of by the appropriate number of spaces (default for c is a tab).

# **EXAMPLES**

Print file1 and file2 as a double-spaced, three-column listing headed by "file list":

pr -3dh "file list" file1 file2

Write file1 on file2, expanding tabs to columns 10, 19, 28, 37, ...:

pr -e9 -t <file1 >file2

## FILES

/dev/tty\* to suspend messages

### SEE ALSO

cat(1), lp(1), ul(1).

PREALLOC(1) PREALLOC(1)

### NAME

prealloc - preallocate disk storage

### SYNOPSIS

prealloc name size

## HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: HP

## DESCRIPTION

Prealloc will preallocate at least size bytes of disk space for an ordinary file name of zero length. It will create the file if it does not already exist. The space will be allocated in an implementation dependent fashion for fast sequential reads and writes for the file.

Prealloc will fail and no disk space will be allocated if name already exists and is not an ordinary file of zero length, if there is not enough space left on disk, or if size exceeds the maximum file size or the process' file size limit (see ulimit(2)). The EOF is left at the end of the preallocated area. The current file pointer is left at zero. The file is zero-filled.

# DIAGNOSTICS

Upon successful completion, prealloc exits with a 0 status. Exit status is 1 if name already exists and is not an ordinary file of zero length, 2 if there is not enough room on disk, or 3 if size exceeds file size limits.

## SEE ALSO

prealloc(2), ulimit(2)

# BUGS

The allocation of the file space is highly dependent on the current disk usage. A successful return does not tell you how fragmented the file actually might be if the disk is reaching its capacity.

Hewlett-Packard - 1 - July 2, 1985

### NAME

prof - display profile data

## SYNOPSIS

prof [ -a ] [ -l ] [ file ]

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

Remarks: Prof(1) is implemented on the Series 200 only.

# DESCRIPTION

Prof interprets the file **mon.out** produced by the monitor(3C) subroutine. Under default modes, the symbol table in the named object file (a.out default) is read and correlated with the **mon.out** profile file. For each external symbol, the percentage of time spent executing between that symbol and the next is printed (in decreasing order), together with the number of times that routine was called and the number of milliseconds per call.

If the -a option is used, all symbols are reported rather than just external symbols. If the -l option is used, the output is listed by symbol value rather than decreasing percentage.

In order for the number of calls to a routine to be tallied, the **-p** option of *cc* must have been given when the file containing the routine was compiled. This option also arranges for the **mon.out** file to be produced automatically.

# FILES

mon.out for profile a.out for namelist

## BUGS

Beware of quantization errors.

PRS(1) PRS(1)

### NAME

prs - print and summarize an SCCS file

## SYNOPSIS

prs [-d[dataspec]] [-r[SID]] [-e] [-l] [-c[date-time]] [-a] files

### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

### DESCRIPTION

Prs prints, on the standard output, parts or all of an SCCS file (see sccsfile(5)) in a user-supplied format. If a directory is named, prs behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with s.), and unreadable files are silently ignored. If a name of - is given, the standard input is read; each line of the standard input is taken to be the name of an SCCS file to be processed; non-SCCS files and unreadable files are silently ignored.

Arguments to prs, which can appear in any order, consist of keyletter arguments and file names.

All the described keyletter arguments apply independently to each named file:

-d[dataspec] Used to specify the output data specification. The dataspec is a string consisting of SCCS file data keywords (see Data Keywords below) interspersed with optional user-supplied text.

 $-\mathbf{r}[SID]$ 

Used to specify the SCCS ID entification (SID) string of a delta for which information is desired. If no SID is specified, the SID of the most recently created delta is assumed. If an SID is specified, it must agree exactly with an SID in the file (i.e., the SID structure used by get(1) does not work here).

 $-\mathbf{e}$ 

Requests information for all deltas created *earlier* than and including the delta designated via the  $-\mathbf{r}$  keyletter or the date given by the  $-\mathbf{c}$  option.

 $-\mathbf{l}$ 

Requests information for all deltas created *later* than and including the delta designated via the  $-\mathbf{r}$  keyletter or the date given by the  $-\mathbf{c}$  option.

-c[cutoff]

Cutoff date-time, in the form

# YY[MM[DD[HH[MM[SS]]]]]

Units omitted from the date-time default to their maximum possible values. Thus,  $-\mathbf{c7502}$  is equivalent to  $-\mathbf{c750228235959}$ . One or more non-numeric characters can be used to separate the various 2-digit segments of the cutoff date (for example  $-\mathbf{c77/2/2}$  9:22:25).

 $-\mathbf{a}$ 

Requests printing of information for both removed; i.e., delta type = R, (see rmdel(1)) and existing; i.e., delta type = D, deltas. If the -a keyletter is not specified, information for existing deltas only is provided.

If no option letters (or only -a) are given, prs prints the file name using the default dataspec and the -e option. This produces information on all deltas.

### Data Keywords

Data keywords specify which parts of an SCCS file are to be retrieved and output. All parts of an SCCS file (see *sccsfile*(5)) have an associated data keyword. There is no limit on the number of times a data keyword can appear in a *dataspec*.

The information printed by *prs* consists of: (1) the user supplied text; and (2) appropriate values (extracted from the SCCS file) substituted for recognized data keywords in their order of appearance in the *dataspec*. The format of a data keyword value is either *Simple* (S), where keyword substitution is direct, or *Multi-line* (M), where keyword substitution is followed by a carriage return.

User-supplied text is any text other than recognized data keywords. Escapes can be used as follows:

ab	\t
new-line	\n
colon	\:
backspace	\b
carriage-return	\r
form feed	\f
backslash	//
single quote	\/

The default dataspec is:

### NAME

ps - report process status

### SYNOPSIS

ps [-edafi] [-c corefile] [-s swapdev] [-n namelist] [-t tlist] [-p plist] [-u ulist] [-g glist]

## HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System V and HP

## DESCRIPTION

Ps prints certain information about active processes. Without options, information is printed about processes associated with the current terminal. The output consists of a short listing containing only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the selection of options.

*Options* using lists as arguments can have the list specified in one of two forms: a list of identifiers separated from one another by a comma, or a list of identifiers enclosed in double quotes and separated from one another by a comma and/or one or more spaces.

# The options are:

-e Print information about all processes.

-d Print information about all processes, except process group leaders.

 Print information about all processes, except process group leaders and processes not associated with a terminal.

-f Generate a full listing. (See below for meaning of columns in a full listing.)

-l Generate a *long* listing. (See below.)

-c corefile Use the file corefile in place of /dev/mem.

-s swapdev Use the file swapdev in place of /dev/swap. This is useful when examining a corefile; a swapdev of /dev/null will cause the user block to be zeroed out.

-n namelist The argument will be taken as the name of an alternate system namelist file in place of /hp-ux.

-t termlist Restrict listing to data about the processes associated with the terminals given in termlist. Terminal identifiers may be specified in one of two forms: the device's file name (e.g., tty04) or if the device's file name starts with tty, just the digit identifier (e.g., 04).

-p proclist Restrict listing to data about processes whose process ID numbers are given in pro-

-u uidlist Restrict listing to data about processes whose user ID numbers or login names are given in uidlist. In the listing, the numerical user ID will be printed unless the -f option is used, in which case the login name will be printed.

-g grplist Restrict listing to data about processes whose process group leaders are given in grplist.

The column headings and the meaning of the columns in a ps listing are given below; the letters f and 1 indicate the option (full or long) that causes the corresponding heading to appear. All means that the heading always appears. Note that these two options determine only what information is provided for a process; they do not determine which processes will be listed.

- F (1) Flags (octal and additive) associated with the process:
  - 0 swapped;
  - 1 in core;
  - 2 system process;
  - 4 locked in core (e.g., for physical I/O);
  - 10 being swapped:
  - 20 being traced by another process;

		40 another tracing flag:		
G	(1)			
$\mathbf{S}$	(1)	The state of the process:		
		0 non-existent;		
		S sleeping;		
		W waiting;		
		R running;		
		I intermediate;		
		${f Z}$ terminated;		
		${f T} = {f stopped};$		
		X growing.		
UID	(f,l)	The user ID number of the process owner; the login name is printed under the -f		
		option.		
PID	(all)	The process ID of the process; it is possible to kill a process if you know this		
***		datum.		
PPID	(f,l)	The process ID of the parent process.		
$\mathbf{C}$	(f,l)	Processor utilization for scheduling.		
PRI	(1)	The priority of the process; higher numbers mean lower priority.		
NI	(l)	Nice value; used in priority computation.		
ADDR	(1)	The memory address of the process, if resident; otherwise, the disk address.		
$\mathbf{SZ}$	(1)	The size in blocks of the core image of the process.		
WCHAN	(1)	The event for which the process is waiting or sleeping; if blank, the process is		
	` '	running.		
STIME	(f)	Starting time of the process.		
TTY	(all)	The controlling terminal for the process (without the initial "tty", if any).		
TIME	(all)	The cumulative execution time for the process (reported in the form "min:sec").		
CMD	(all)	The command name; the full command name and its arguments are printed		
	()	under the -f option.		

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked <defunct> (see "zombie process" in exit(2)).

Under the -f option, ps tries to determine the command name and arguments given when the process was created by examining memory or the swap area. Failing this, the command name, as it would appear without the -f option, is printed in square brackets.

To make ps output safer to display and easier to read, all control characters in the CMD field are mapped to "visible" equivalents. These are of the form  $\hat{\ }$  C where the original character was in the range 0 - 037 and c is that value plus 040.

# HARDWARE DEPENDENCIES

Series 500:

The  $\mathbf{F}$  field is always 01.

In the S field, I means "waiting for input from terminal".

In the S field, the P (paused) state is added.

In the S field, the T state is not currently supported.

In the S field, L means "waiting on a file lock via lock f(2)".

In the S field, the B (blocked) state means "blocked via an IPC system call such as semop(2), msgrcv(2), or msgsnd(2)".

The C field is always zero.

The ADDR field reports the partition number.

In the SZ field, the block size is 1K bytes.

The WCHAN field is always blank.

The CMD field is renamed COMMAND except when the -fl option is specified.

The definition of **STIME** is as follows:

The time when the process was forked, not the time when it was modified by

exec; the date is included only if the elapsed time is greater than 24 hours.

The  $\mathbf{s},\ \mathbf{n},$  and  $\mathbf{c}$  options are not currently supported. A diagnostic is printed if they are used.

The files /dev/mem, /dev/swap,  $/etc/ps\_data$ , and /hp-ux do not exist.

# FILES

# SEE ALSO

acctcom(1), kill(1), nice(1), exec(2), exit(2) lockf(2), msgop(2), semop(2).

# BUGS

Things can change while ps is running; the picture it gives is only a snapshot in time. Some data printed for defunct processes are irrelevant.

If two special files for terminals are located at the same select code, they are reported in the order in which they appear in /dev, not in alphabetical order.

PTX(1) PTX(1)

### NAME

ptx - permuted index

# SYNOPSIS

```
ptx [ options ] [ input [ output ] ]
```

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Remarks: Not supported on the Integral Personal Computer.

### DESCRIPTION

Ptx generates the file output that can be processed with a text formatter to produce a permuted index of file input (standard input and output default). It has three phases: the first does the permutation, generating one line for each keyword in an input line. The keyword is rotated to the front. The permuted file is then sorted. Finally, the sorted lines are rotated so the keyword comes at the middle of each line. Ptx output is in the form:

.xx "tail" "before keyword" "keyword and after" "head"

where  $\mathbf{x}\mathbf{x}$  is assumed to be an nroff or troff(1) macro provided by the user, or provided by the mptx(7) macro package. The before keyword and keyword and after fields incorporate as much of the line as will fit around the keyword when it is printed. Tail and head, at least one of which is always the empty string, are wrapped-around pieces small enough to fit in the unused space at the opposite end of the line.

The following options can be applied:

- -f Fold upper and lower case letters for sorting.
- -t Prepare the output for the phototypesetter by using a line length of 100.
- -w n Use the next argument, n, as the length of the output line. The default line length is 72 characters for nroff and 100 for troff.
- -g n Use the next argument, n, as the number of characters that ptx will reserve in its calculations for each gap among the four parts of the line as finally printed. The default gap is 3.
- **-o** only Use as keywords only the words given in the only file.
- -i ignore Do not use as keywords any words given in the ignore file. If the -i and -o options are missing, use /usr/lib/eign as the ignore file.
- -b break Use the characters in the break file to separate words. Tab, new-line, and space characters are always used as break characters. Punctuation characters are treated as part of the word in the absence of this option.
- -r Take any leading non-blank characters of each input line to be a reference identifier (as to a page or chapter), separate from the text of the line. Attach that identifier as a 5th field on each output line.

The index for this manual was generated using ptx.

# FILES

```
/bin/sort
/usr/lib/eign
/usr/lib/tmac/tmac.ptx
```

### SEE ALSO

 $\operatorname{nroff}(1), \operatorname{troff}(1), \operatorname{mm}(7), \operatorname{mptx}(7).$ 

### BUGS

Line length counts do not account for overstriking or proportional spacing.

Lines that contain tildes ( $\tilde{}$ ) are botched, because ptx uses that character internally.

PWD(1)

# NAME

pwd - working directory name

# SYNOPSIS

pwd

# HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: System V

# DESCRIPTION

Pwd prints the path name of the working (current) directory.

# SEE ALSO

cd(1).

# DIAGNOSTICS

"Cannot open .." and "Read error in .." indicate possible file system trouble and should be referred to the system manager.

### NAME

query - interactive IMAGE database access

## SYNOPSIS

query

### HP-UX COMPATIBILITY

Level:

HP-UX/NON-STANDARD

Origin: H

. . .

Remarks: Query is implemented on the Series 500 only. IMAGE must be previously installed on

the system for query to function.

### DESCRIPTION

Query is an interactive, command driven program to simplify IMAGE database access. It can be used to generate reports from the database, add information to the database, change information in the database, and aid in developing programs that access databases using IMAGE library subroutines.

Consistent with the HP–UX environment in which it operates, query is initiated by simply typing its name. There are no options or parameters. Input and output redirection can be done at the shell level (<>) although more convenient methods are available via query commands.

A list of the available commands:

data-base=	$_{ m help}$	exit	!
list	form	$\operatorname{find}$	xeq
update a	update d	update r	report

Query accepts these commands in upper- or lower-case. Special care must be taken in the case of set names, item names, and item values since these are case sensitive. That is, Setname, setname, and SETNAME are three unique sets.

All query commands must be followed by a semicolon. Query waits silently for a semicolon or a zero-length record before processing a command. A zero-length record is entered as a solitary carriage return. This method of signaling the end of a command line enables you to enter commands which are several lines long. Line length is limited to 256 characters. At any point in a line, you may type a carriage return and continue the command line, thus improving the readability of long command lines.

Once initiated, query identifies itself and gives the prompt:

NEXT?

Whenever this prompt appears, you may enter any of the query commands, which are described below.

# DATA-BASE=

The **data-base**= command opens a database. You can type:

data-base=data\_base\_name;

where data\_base\_name is the name of a database. If you are presently in the directory where the database exists, you need only give the database name. If the database is in another directory, you need to supply a partial or complete path name.

Some examples are:

data-base=/users/fred/inventory;

specifies a database called "inventory" in the directory /users/fred.

data-base=equipment;

specifies a database called "equipment" in the current directory.

As part of the **data-base=** command, *query* asks for a password for that database with the prompt:

## PASSWORD?

The password is not echoed on the terminal as you type it. As usual, the password must be followed by a semicolon. If no password is required, simply press RETURN.

Provided the database name and password are valid, the database is opened with "modify shared" access (DBOPEN mode 1). The command prompt "NEXT?" appears.

### HELP

!

The **help** command provides a syntax model, a brief description, and examples of itself or any other *query* command. It can be invoked in the following ways:

```
help [ command ];
    or
? [ command ];
```

where *command* is any *query* command. If no command is supplied, **help** describes itself and gives a list of the commands for which help is available.

**EXIT** The **exit** command provides you with a graceful way to terminate the *query* program. It is entered thus:

exit:

Query can also be terminated by hitting the BREAK key in response to a command prompt.

At any time, in response to a "NEXT?" prompt, you may wish to execute a shell command without leaving the *query* program. This is useful when debugging report procedure files from within *query*, or routing output files to a printer during a *query* session. For example:

```
!pr filename | lpr
```

runs the formatter/printer pr on a file called *filename*, and pipes the output into the lpr program.

A shell command following an exclamation mark is executed, and *query* is suspended until that command is completed. *Query* processing can be continued when the "[Hit return to continue QUERY]" message appears.

LIST The list command is a convenient method of redirecting output from within the query program. Query sends output to stdout (the input device) by default. To send output elsewhere, type:

```
list=filename;
```

Output is sent to *filename* in the current directory. It may be sent to a file in another directory by specifying the desired pathname.

An example is:

```
list=/usr/spool/uucppublic/report;
```

which specifies that the output file is /usr/spool/uucppublic/report.

If query finds that the named file already exists, it prints the message:

```
FILE ALREADY EXISTS. (O)VERWRITE IT, (A)PPEND TO IT, OR (N)EITHER?
```

You type o, a, or n to select an option. If you choose n, query prompts:

### NEW FILE NAME=

in response to which you provide a (presumably) different file name. Otherwise, query overwrites or appends to the selected file, as instructed. Output directed to a file is properly formatted for direct submission to lpr(1). At any time during a query session, you may return output to the terminal by typing:

list:

This can be repeated as often as necessary, using the same file or many different files for output. When the **list** command appears in an XEQ file, no choices are offered. The specified file is silently opened and any output is appended to it.

### FORM

The **form** command outputs a *schema* description for the open database. It lists each data set name, its type (automatic master, manual master, or detail), the set capacity, and the current number of entries in the set. With each data set, each item is listed including its name, type (alphanumeric, integer, or real), length in bytes, and number of elements in the item. *Query* also identifies key items, sort items (the sort item name may be truncated), and indicates whether you have write access for the item. It is initiated by typing:

form:

Form's output is directed to the file specified by the list command, or stdout by default. Its output can be terminated by hitting the BREAK key. Within a few seconds, output stops and a command prompt (NEXT?) appears.

#### FIND

A major use of any *query* program is to search a database for an arbitrary group of entries meeting some criteria. **Find** is used in conjunction with the **update** or **report** commands, providing "victims" for the update or report. It is entered by typing:

find retrieve\_procedure end;

where retrieve\_procedure is a group of data item names, data item values, and relational operators joined together by logical connectors.

A retrieve procedure defines a relationship between a data item and a data item value, and the find command collects entries which satisfy that relationship for later use by **update** or **report**. A typical retrieve procedure looks like this:

[setname.]itemname operator "value"

where *setname* is the name of a data set which contains the data item. It is always accepted, but is not necessary when the item name exists in only one data set, or when the set name has been previously established in the retrieve procedure. *Itemname* is simply the name of a data item. For compound items, only the first element is used. *Operator* is one of the following relational operators:

is, ie equal to
isnot, ine not equal to
ilt less than
inlt not less than
igt greater than
ingt not greater than

Value is enclosed in quotation marks ("") and is compared to the value of the named item for each entry in the specified (or implied) set. It should be appropriate for the data item type.

Two or more retrieve procedures can be joined by the logical operators **and** and **or** to make a more complex procedure. Parentheses are not allowed in **find** procedures, so care should be taken in ordering statements in a compound retrieve procedure.

Some examples are:

find inventory quantity is "324" end:

searches all entries in the "inventory" set for a "quantity" equal to "324". This would be appropriate for a quantity of any type (alphanumeric, integer, or real).

find part\_description ie "widgit" end:

searches all entries in the set which contains the item "part\_description" for a value of "widgit". The value would obviously be inappropriate for an item type of integer or real. This example generates an error if "part\_description" exists in more than one set in the database.

find inventory quantity igt "324" and part\_description is not "widgit" end; searches all entries in the set "inventory", collecting those that show a quantity greater than 324, excluding widgits. The items "quantity" and "part\_description" must both be items contained in the set "inventory".

XEQ The xeq command allows any number of commands to be read from a file created by any of the HP-UX editors. Commands must appear in the file exactly as they would be entered interactively, one command per line. The xeq command is entered:

xeq=filename;

The filename may be an absolute pathname, if necessary. Query reads commands from that file until it encounters either an end-of-file or another **xeq** command. When end-of-file is reached, query returns to an interactive state. When an **xeq** command is encountered within an **xeq** file, query closes the current **xeq** file and begins reading commands from the new one. The old one is not re-opened. **Xeq** files can be nested up to 10 deep.

A few commands behave differently when they occur in an **xeq** file. The "list=file" command silently opens the specified file and appends data to it. The update mode of the **update** r command can be terminated only by a lone semicolon. (In interactive use, **update** r can be terminated by a semicolon or a zero-length record.)

### UPDATE A

**Update a** (add) adds entries to a data set. It is the only update which does not require a preceding **find**. The **update a**dd command is entered:

update a, setname;

or

update add, setname;

Query checks the validity of the set name, and then prompts for item values one at a time. The item name is displayed followed by an "=". The value to be assigned to that item should then be entered, enclosed in quotes, and followed by a semicolon. Query then prompts for the next item value. Only one prompt is given for compound data items; the item values should be entered each in quotes, separated by commas. Null values may be entered by a lone carriage return in response to a prompt, but query insists on valid values for key items. Addition of detail entries requires that values for key items already exist in the corresponding master set(s).

The BREAK key can be used to abort an **update a** command. No update takes place, and a command prompt appears.

### UPDATE D

**Update d** (delete) deletes entries from a data set. It requires a preceding find, and complains if not satisfied. The command is entered:

update d:

or

update delete:

As a safety check, query asks "OK TO DELETE?(YES/NO)". Upon receipt of a y or n, query proceeds as directed. It refuses to delete master set entries which contain chain heads with non-empty chains (i.e. connected detail sets), and displays a message to that effect.

### UPDATE R

**Update** r (replace) also must be preceded by a find. It is a means of changing item values in an existing entry. It is invoked by typing:

```
update r;
or
update replace:
```

Query responds with the prompt "ITEM =". You then enter:

```
item_name="value";
```

where *item\_name* is an item name which exists in the entries in the select file. *Value* is a value appropriate to the item type (alpha, integer, or real) enclosed in double quotes.

When you have finished entering the changes desired, a lone carriage return or a lone semicolon exits this update mode, and *query* executes the changes and returns to the command level. (In an **xeq** file, only the semicolon suffices.) The new value(s) are inserted into all entries collected in the select file. Updates are refused for key items and sort items in master sets. Updating key or sort items in detail sets causes that record to be deleted and reentered with the new values. A report following such an update may give an "EMPTY RECORD" error message. Don't panic. The record may be found at its new location by a find command.

The BREAK key can be used to abort an **update r** command. No update takes place, and a command prompt appears.

### REPORT

The report command provides many features to display information about the entries in the select file. The information is sent to the list device (the input device, by default). Report's output can be terminated by using the BREAK key, which yields a command prompt (NEXT?). You can request the name and value of each data item for all the data entries specified in the select file, or request the data item values for all of the data entries without printing the data item name. Also you may create output formats complete with page headings, page numbers, column headings, space and page control, and selectivity in item value display. Report can be invoked in one of three ways:

```
report all [,character];
    or
report name=procedure_name;
    or
report;
body
end:
```

where *character* is any ASCII printing character which determines the printing of certain optional information.

Procedure\_name is the name of a file (specified as a relative or absolute pathname) which contains **report** commands stored via a system editor, such as ed or vi.

Body consists of header, detail, edit, and sort commands as outlined below.

The three forms of the report command are described below.

# REPORT ALL [,CHARACTER];

prints the entire data item and all elements of a compound item. This report form prints the item name, followed by "=", followed by the item value. The optional character causes query to print only the item value, without the item name and "=". All item values appear left justified, and numbers are stripped of insignificant zeros. Real numbers may appear in decimal form or scientific notation, as necessary. This is the only report form which shows all values for compound data items.

# REPORT NAME=PROCEDURE\_NAME;

gets header, detail, edit, and sort commands from a file, reading commands until an "end;" or an error is encountered. The contents of a procedure file are identical to the "body" in the next form of the **report** command. It should be noted that the use of the shell escape (!) is a valuable aid in the development of procedure files. It enables you to invoke an editor, modify a file, exit it, and return to the same point in query to test the file, without having to re-define the database or re-establish a select file.

# REPORT;

## BODY

END; accepts report commands from the user, scanning each line as it is entered for syntax errors. The entry of an "end;" command initiates the execution of the commands, producing a report. The body is a collection of the following commands:

Header Prints title, column headings, and page numbers at the top of each

report page.

**Detail** Prints data item values in the column position specified.

Edit Describes the number of decimal places to be displayed for real numbers.

**Sort** Sorts data entries based upon the value of a specified data item.

### Report Formatting

The above commands can be formatted using the following parameters. (Note: these are *parameters* to the **report** commands, not commands themselves.)

## print position

Specifies the ending column for an item value or heading.

space and space control

Causes line skips between item values or heading lines.

skip and skip control

Causes page skips between item values or heading lines.

edit

Specifies edit commands to which output item values should conform.

These parameters are described below.

# print position

This parameter is an integer between 1 and 132 which indicates the column number in which the last character of an item value should appear in a header or detail line. It is your responsibility to avoid overlap between fields on the same line. However, in most cases *query* replaces an overlapping value with asterisks to indicate an error.

# space and space control

This parameter outputs blank lines either before or after the printing of a header string or detail line value. The keyword **space** should be followed by either an **a** or **b**, indicating where the blank line should appear - after or before the line to be printed. The **a** or **b** may be followed by an integer in the range 1 - 5, to skip

multiple lines. Absence of the integer causes *query* to skip 1 line. These may appear more than once in a command, as in spacing before and after a line:

h1, "page", 35, space b2, space a3;

This generates two blank lines before printing "page", and three blank lines afterward.

# skip and skip control

Similar to **space**, **skip** yields page feeds either before or after the printing of a line. Unlike **space**, **skip** can only be used with a "detail" command. The keyword **skip** is followed by an **a** or **b** to direct where the page feed should be placed (see "space and space control" above). Normally, *query* prints 54 lines per page before skipping to a new page.

## edit

The **edit** parameter is the letter **e** followed by an integer in the range 0 - 9. This number corresponds to a numbered edit command which specifies the number of decimal places (for real numbers) or the number of characters (for alphanumeric strings) to be printed.

# Report Commands

### h (header command)

The **header** command is used to print heading information of your choice at the top of each page of the report. A maximum of five lines of header information can appear at the top of each report page. The format of the header command is:

hnumber,data\_type,print\_position[,space space-control];

where *number* is an integer from 1 to 5 specifying on which header line (out of five possible lines) the information is to appear. Header information in a header command labeled "h1" appears in the first line, "h2" appears in the second line, etc.

Data\_type is either an ASCII character string enclosed in double quotes, or the word **pageno** (without quotes). If **pageno** appears in the header command, query prints the page number of the report in the position specified by print\_position. Query increments the page number automatically for each page printed.

*Print\_position*, space, and space-control are parameters defined in the section on report formatting.

An example is:

h1,"PAGE",70,space b2; h1,pageno,76; h2,"DAILY REPORT".50,space a3;

which prints the word "PAGE" with the letter "E" in column 70, on the second line from the top of a page (via the "space b2" parameter). On the same line, the page number is printed ending in column 76. The next line contains "DAILY REPORT" ending in column 50, followed by three blank lines.

# d (detail command)

The detail command indicates which data items of a data entry specified in the select file are to be printed in the report. Data items can be printed on up to 10 different lines. *Query* prints only the values of data items which appear in a detail command.

If an ASCII value length exceeds the distance between a preceding value on the same line or the left margin, it is silently truncated on the left. If a numeric value overlaps in the same manner, it is replaced by a series of asterisks, indicating the error.

Detail commands without an edit parameter print numeric values in whatever format necessary to give maximum accuracy.

The format of a detail command is:

```
d[n],data_type,print_position[, space space-control][, skip
skip-control][, edit];
```

where n is an integer from 1 to 9. Each number specifies a different line on which the data items are printed. If the number is omitted, the unnumbered detail item is printed on a separate line above any numbered detail item lines. The lowest numbered command is printed first and all others follow in numeric order. Detail commands with the same number are printed on the same line.

Data\_type is either an ASCII character string enclosed in double quotes, or the name of a data item contained in the data entries specified in the select file. NOTE: the **report** command processor expects the data item name by itself. Preceding the item name with a set name generates an error.

Print\_position, space, space-control, skip, skip-control, and edit are parameters defined in the section on report formatting.

# e (edit command)

The **edit** command is used to format the printing of real and/or alphanumeric item values. Up to ten edit commands, labeled from e0 to e9, can be used in a report. To edit output from a detail command, you include the label of the desired edit command. Query refers to the labeled edit command to edit the value printed by the detail command. The same edit command can be referenced by more than one detail command in the same report, and each edit command must be referenced at least once in the report body. The format of the edit command is:

```
enumber, "places, format";
```

where *number* is an integer from 0 to 9, identifying the edit command. An integer cannot be used to identify more than one edit command.

*Places* is an integer indicating the number of digits to follow the decimal point (for real numbers) or the number of characters to be printed (for alphanumeric strings).

Format is one of the following single letters:

- f indicating that the number should be formatted in decimal form, with the specified number of digits following the decimal point. Numbers accurate to more than the specified number of places are rounded.
- e indicating that the number should be formatted in scientific notation with the specified number of digits following the decimal point.
- s indicating that the data item is an alphanumeric string. The number of characters printed is specified by the accompanying integer. If you specify 10 characters for a data item 40 characters in length, the leftmost 10 characters are printed. If you specify 100 characters for the same data item, only 40 characters are printed.

Here are some examples:

```
\begin{array}{c} e1,"6f";\\ d1,real\_number,40,e1;\\ \\ might\ yield\ such\ numbers\ as: \end{array}
```

2.340000 25487.123456

```
1.000000 and e1, "4e"; \\ d1, realnum, 40, e1; \\ might yield \\ 2.3400e+0 \\ 3.2549e+5 \\ 1.0000e+0 \\ and \\ e1, "15s"; \\ d1, String, 40, e1; \\ might yield \\ Smith, Jame \\ truncate ri \\ Walker, Mau
```

Doe, John

Finally, the difference between the edit *command* and the edit *parameter* should be emphasized. For example,

```
e1,"7f";
d1,Any_real,30,e1;
end;
```

The first line is an edit command, specifying a format for real numbers. In the second line, the "e1" is a parameter, indicating that the real number(s) "Any\_real" should be printed according to the format shown in the "e1" command.

# s (sort command)

The **sort** command specifies an item upon which you want the entries in the select file sorted. The format of the sort command is:

```
s,itemname;
```

where *itemname* is the name of a data item which appears in entries currently stored in the select file.

A sort item value may not exceed 80 bytes in length. In the case of a compound data item, sort uses only the first value in that item. After a "find", the entries appear in the select file in the order the find command encounters them. The sort command will rearrange those entries in ascending alphabetic or numeric order, depending on the sort item.

# Report Example

Assuming that  $Emp\_name$  is a 20-byte alphanumeric item,  $Emp\_age$  is a 2-byte integer, and  $Emp\_wage$  is a 4-byte real:

```
H1, "EMPLOYEE REPORT",34,space b3; h1,"PAGE",52; h1,pageno,56,space a2; h2,"NAME",7; H2,"AGE",27; H2, "HOURLY WAGE",52; e1,"2f"; s,Emp_name; d1,Emp_name,20;
```

```
d1,Emp\_age,27; d1,"$",44; d1,Emp\_wage,50,e1,space a; end:
```

This report might yield:

	EMI LOTEE REPORT	TAGET
NAME	AGE	HOURLY WAGE
Anderson, Richard	32	\$ 14.75
Carr,Elaine	21	\$ 11.50
Wilson, Kathy	42	\$ 17.25
•

EMBLOVEE DEDODO

DAOR 1

# Summary

Although the commands appear throughout this document in lower-case, query accepts them in upper-case also. This is helpful when working with databases ported from Series 500 BASIC, in which database names, data set names, and data item names are frequently in upper-case.

It should be stressed that all commands must end with a semicolon or zero–length entry. If *query* seems to have "gone away", be sure that a semicolon followed tha last command entered. If this is not the case, an extra carriage return serves to terminate the command and prompt *query* into action.

Query sometimes appears to be "eating" report commands and doing nothing about them, other than supplying the "NEXT?" prompt. This is usually the result of having used the "list" command to re-route output earlier in the session, and having forgotten about it. Typing

list:

re-routes output to the terminal again.

Abnormal termination of *query* leaves files in */usr/tmp*. It is your responsibility to remove these files or they may accumulate and use up large amounts of memory. The files can be identified by the owner id, shown by typing "ll /usr/tmp". Do not attempt to remove files belonging to anyone else.

# FILES

```
/usr/lbin/query
/usr/lbin/querysort query's own sort routine
/usr/lib/query.help help file
/usr/tmp/* temporary files
```

RATFOR(1) RATFOR(1)

```
NAME
        ratfor - rational Fortran dialect
SYNOPSIS
        ratfor [ options ] [ files ]
HP-UX COMPATIBILITY
       Level:
                  HP-UX/STANDARD
        Origin:
                   System V
        Remarks: Not supported on the Integral Personal Computer.
DESCRIPTION
        Ratfor converts a rational dialect of Fortran into ordinary irrational Fortran. Ratfor provides
        control flow constructs essentially identical to those in C:
               statement grouping:
                       { statement; statement; statement }
               decision-making:
                       if (condition) statement [ else statement ]
                       switch (integer value) {
                               case integer:
                                               statement
                                [ default: ]
                                               statement
               loops:
                        while (condition) statement
                       for (expression; condition; expression) statement
                       do limits statement
                        repeat statement [ until (condition) ]
                       break
                       next
        and some syntactic sugar to make programs easier to read and write:
               free form input:
                       multiple statements/line; automatic continuation
               comments:
                       # this is a comment.
               compiler directives:
                        directives beginning with a dollar sign ($) in column one are passed through to
                       the compiler unchanged.
               translation of relationals:
                        >, >=, etc., become .GT., .GE., etc.
               return expression to caller from function:
                        return (expression)
                define:
                        define name replacement
                include:
                        include file
```

RATFOR(1) RATFOR(1)

The options are as follows:

- -h causes quoted strings to be turned into Hollerith constructs.
- -C copies comments to the output and attempts to format it neatly.
- -6c Normally, continuation lines are marked with an & in column 1; the option -6c makes the continuation character c and places it in column 6.

*Ratfor* is best used with fc(1).

-d compatibility mode for earlier versions of ratfor.

# HARDWARE DEPENDENCIES

Series 500:

Fc(1) does not recognize **ratfor.r** files. Therefore, ratfor must be called directly.

The -h option should not be used.

The -6x option must be used for successful automatic continuation.

REV(1)

NAME

rev - reverse lines of a file

SYNOPSIS

rev [ file ] ...

HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

Remarks: Not supported on the Integral Personal Computer.

# DESCRIPTION

Rev copies the named files to the standard output, reversing the order of characters in every line. If no file is specified, the standard input is copied.

Hewlett-Packard - 1 - July 2, 1985

RESTOREALL - Restore All Files

SYNOPSIS

restoreall

HP-UX COMPATIBILITY

Level: HP-UX/WAGNER DEVELOPED

Origin: System V

Native Language Support:

8-bit filenames.

# DESCRIPTION

The shell command retrieves all files from a full or incremental backup tape. The tape must be inserted and allowed to "condition" (it is conditioned when the busy light remains off).

# SEE ALSO cpio(1), tcio(1)

revision - get HP-UX revision information

# **SYNOPSIS**

/usr/bin/revision

# HP-UX COMPATIBILITY

Level:

HP-UX/NON-STANDARD

Origin:

HP

Remarks: Revision is implemented on the Series 500 only.

# DESCRIPTION

This command prints six lines to standard output. Those six lines consist of the six data items output by uname(2), which give information on the kernel.

The following is a sample output from a machine whose loader chip was not programmed with a serial number:

System:

HP-UX

Release:

TEST23#

Version:

В

Machine:

HP-UX

Identity: Nodename:

hpfcla

# SEE ALSO

uname(2).

rm, rmdir - remove files or directories

#### SYNOPSIS

 $\mathbf{rm} \ [\ \textbf{-fri}\ ] \ \mathrm{file}\ \dots$ 

rmdir dir ...

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

#### DESCRIPTION

*Rm* removes the entries for one or more files from a directory. If an entry was the last link to the file, the file is destroyed. Removal of a file requires write permission in its directory, but neither read nor write permission on the file itself.

If a file has no write permission and the standard input is a terminal, its permissions are printed and a line is read from the standard input. If that line begins with y the file is deleted, otherwise the file remains. No questions are asked when the -f option is given or if the standard input is not a terminal.

If a designated file is a directory, an error comment is printed unless the optional argument  $-\mathbf{r}$  has been used. In that case, rm recursively deletes the entire contents of the specified directory, and the directory itself. (Note that rm can recursively remove a maximum of 17 directory levels.)

If the -i (interactive) option is in effect, rm asks whether to delete each file, and, under -r, whether to examine each directory.

*Rmdir* removes entries for the named directories, which must be empty and have execute permission for the user trying to remove them.

# SEE ALSO

unlink(2).

# DIAGNOSTICS

Generally self-explanatory. It is forbidden to remove the file .. merely to avoid the consequences of inadvertently doing something like:

rm -r .\*

RMDEL(1) RMDEL(1)

#### NAME

rmdel - remove a delta from an SCCS file

#### SYNOPSIS

rmdel -rSID files

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

#### DESCRIPTION

Rmdel removes the delta specified by the SID from each named SCCS file. The delta to be removed must be the newest (most recent) delta in its branch in the delta chain of each named SCCS file. In addition, the SID specified must not be that of a version being edited for the purpose of making a delta (i. e., if a p-file (see get(1)) exists for the named SCCS file, the SID specified must *not* appear in any entry of the p-file).

If a directory is named, rmdel behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with s.) and unreadable files are silently ignored. If a name of - is given, the standard input is read; each line of the standard input is taken to be the name of an SCCS file to be processed; non-SCCS files and unreadable files are silently ignored.

The exact permissions necessary to remove a delta are documented in the Source Code Control System User's Guide. Simply stated, they are either (1) if you make a delta you can remove it; or (2) if you own the file and directory you can remove a delta.

#### FILES

```
x.file
             (see delta(1))
z.file
             (see delta(1))
```

RMNL(1) RMNL(1)

#### NAME

rmnl - remove extra new-line characters from file

# SYNOPSIS

rmnl

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

UCB

# DESCRIPTION

Rmnl is useful for removing excess white space from files for display on a crt terminal. Groups of more than one \n character are compressed to one \n character, effectively removing all blank lines. This is used by the man command.

Ssp(1) can be used to remove redundant blank lines, rather than all blank lines.

# SEE ALSO

ssp(1), man(1).

July 2, 1985 Hewlett-Packard -1RTPRIO(1) RTPRIO(1)

#### NAME

rtprio - execute process with realtime priority

#### SYNOPSIS

rtprio priority command [ arguments ] rtprio priority -pid

## HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: HP

# DESCRIPTION

Rtprio executes command with a realtime priority, or changes the realtime priority of currently executing process pid. Realtime priorities range from one (highest) to 127 (lowest), a priority of zero indicates normal unix process scheduling which effectively makes the process non-realtime. Realtime processes are not subject to priority degradation and are all of greater (scheduling) importance than non-realtime processes. See rtprio(2) for more details.

Command will not be scheduled, or pid's realtime priority will not be changed, if the user is not a member of a group having PRIV\_RTPRIO access or is not the super-user. When changing the realtime priority of a currently executing process, the effective user ID of the calling process must be superuser, or the real or effective user ID must match the real or effective user ID of the process to be modified.

#### SEE ALSO

rtprio(2), getprivgrp(2)

#### DIAGNOSTICS

Rtprio returns exit status 0 if command is successfully scheduled or if pid's realtime priority is successfully changed, 1 if command is not executable or pid does not exist, 2 if command (pid) lacks realtime capability, or the invoker's effective user ID is not superuser or effective user ID does not match the real or effective user ID of the process to be changed.

Hewlett-Packard - 1 - July 2, 1985

SACT(1) SACT(1)

#### NAME

sact - print current SCCS file editing activity

#### SYNOPSIS

sact files

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

#### DESCRIPTION

Sact informs the user of any impending deltas to a named SCCS file. This situation occurs when get(1) with the -e option has been previously executed without a subsequent execution of delta(1). If a directory is named on the command line, sact behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of path name does not begin with s.) and unreadable files are silently ignored. If a name of - is given, the standard input is read with each line being taken as the name of an SCCS file to be processed.

The output for each named file consists of five fields separated by spaces.

Field 1 specifies the SID of a delta that currently exists in the SCCS file to which changes will be made to make the new delta.

Field 2 specifies the SID for the new delta to be created.

Field 3 contains the logname of the user who will make the delta (i.e., executed a get

for editing).

Field 4 contains the date that **get -e** was executed.

Field 5 contains the time that **get -e** was executed.

# SEE ALSO

delta(1), get(1), unget(1).

## DIAGNOSTICS

Use help(1) for explanations.

SCCSDIFF(1) SCCSDIFF(1)

#### NAME

sccsdiff - compare two versions of an SCCS file

#### SYNOPSIS

sccsdiff -rSID1 -rSID2 [-p] [-sn] files

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

# DESCRIPTION

Sccsdiff compares two versions of an SCCS file and generates the differences between the two versions. Any number of SCCS files may be specified, but arguments apply to all files.

-rSID?

SID1 and SID2 specify the deltas of an SCCS file that are to be compared. Versions are passed to bdif(1) in the order given. The SID's accepted, and the corresponding version retrieved for the comparison are the same as for qet(1).

-p

pipe output for each file through pr(1).

-sn

n is the file segment size that bdiff will pass to diff(1). This is useful when diff fails due to a high system load.

/tmp/get????? Temporary files

# FILES

SEE ALSO bdiff(1), diff(1), get(1), help(1), pr(1).

# Source Code Control System User's Guide in HP-UX: Selected Articles.

DIAGNOSTICS

"file: No differences" if the two versions are the same.

Use help(1) for explanations.

SED(1) SED(1)

#### NAME

sed - stream text editor

#### SYNOPSIS

```
sed [-n] [-e script] [-f sfile] [files]
```

#### HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Sed copies the named files (standard input default) to the standard output, edited according to a script of commands. The  $-\mathbf{f}$  option causes the script to be taken from file sfile; these options accumulate. If there is just one  $-\mathbf{e}$  option and no  $-\mathbf{f}$  options, the flag  $-\mathbf{e}$  may be omitted. The  $-\mathbf{n}$  option suppresses the default output. A script consists of editing commands, one per line, of the following form:

```
[ address [ , address ] ] function [ arguments ]
```

In normal operation, sed cyclically copies a line of input into a pattern space (unless there is something left after a **D** command), applies in sequence all commands whose addresses select that pattern space, and at the end of the script copies the pattern space to the standard output (except under  $-\mathbf{n}$ ) and deletes the pattern space.

Some of the commands use a *hold space* to save all or part of the *pattern space* for subsequent retrieval.

An address is either a decimal number that counts input lines cumulatively across files, a \$ that addresses the last line of input, or a context address, i.e., a  $/regular\ expression/$  in the style of ed(1) modified thus:

In a context address, the construction \( ?regular expression? \), where ? is any character, is identical to \( /regular expression/ \). Note that in the context address \( \xabc\xdef x \), the second \( x \) stands for itself, so that the regular expression is \( abc xdef x \).

The escape sequence  $\setminus \mathbf{n}$  matches a new-line *embedded* in the pattern space.

A period . matches any character except the terminal new-line of the pattern space.

A command line with no addresses selects every pattern space.

A command line with one address selects each pattern space that matches the address.

A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second. (If the second address is a number less than or equal to the line number first selected, only one line is selected.) Thereafter the process is repeated, looking again for the first address.

Editing commands can be applied only to non-selected pattern spaces by use of the negation function! (below).

In the following list of functions the maximum number of permissible addresses for each function is indicated in parentheses.

The *text* argument consists of one or more lines, all but the last of which end with  $\setminus$  to hide the new-line. Backslashes in text are treated like backslashes in the replacement string of an s command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. Each *wfile* is created before processing begins. There can be at most

Hewlett-Packard - 1 - November 19, 1985

SED(1) SED(1)

10 distinct wfile arguments.

(1)a\

text Append. Place text on the output before reading the next input line.

(2) b label Branch to the : command bearing the label. If label is empty, branch to the end of the script.

(2) **c**\ *text* 

Change. Delete the pattern space. With 0 or 1 address or at the end of a 2-address range, place *text* on the output. Start the next cycle. Ignores any subsequent operations related to the deleted space.

- (2)  $\mathbf{d}$  Delete the pattern space. Start the next cycle. Ignores any subsequent operations related to the deleted pattern space.
- (2) D Delete the initial segment of the pattern space through the first new-line. Start the next cycle.
- (2) g Replace the contents of the pattern space by the contents of the hold space.
- (2) G Append the contents of the hold space to the pattern space.
- (2) h Replace the contents of the hold space by the contents of the pattern space.
- (2) **H** Append the contents of the pattern space to the hold space.

(1) i\
text

Insert. Place *text* on the standard output.

- (2)1 List the pattern space on the standard output in an unambiguous form. Non-printing characters are spelled in two-digit ASCII and long lines are folded.
- (2) n Copy the pattern space to the standard output. Replace the pattern space with the next line of input.
- (2) N Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.)
- (2) **p** Print. Copy the pattern space to the standard output.
- (2) P Copy the initial segment of the pattern space through the first new-line to the standard output.
- (1) **q** Quit. Branch to the end of the script. Do not start a new cycle.
- (2) **r** rfile Read the contents of rfile. Place them on the output before reading the next input line.
- (2) s/regular expression/replacement/flags

Substitute the replacement string for instances of the regular expression in the pattern space. Any character may be used instead of /. For a fuller description see ed(1). Flags is zero or more of:

- n = 1 512. Substitute for just the n th occurrence of the regular expression.
- g Global. Substitute for all nonoverlapping instances of the *regular* expression rather than just the first one.
- Print the pattern space if a replacement was made.

w wfile Write. Append the pattern space to wfile if a replacement was made.

- (2) t label Test. Branch to the : command bearing the label if any substitutions have been made since the most recent reading of an input line or execution of a t. If label is empty, branch to the end of the script.
- (2) w wfile Write. Append the pattern space to wfile.
- (2) x Exchange the contents of the pattern and hold spaces.
- (2) y/string1/string2/

Transform. Replace all occurrences of characters in *string1* with the corresponding character in *string2*. The lengths of *string1* and *string2* must be equal.

(2)! function

Don't. Apply the function (or group, if function is  $\{$ ) only to lines not selected by the address(es).

SED(1) SED(1)

(0): label This command does nothing; it bears a label for b and t commands to branch to.

- (1) = Place the current line number on the standard output as a line.
- (2) { Execute the following commands through a matching } only when the pattern space is selected. The syntax is:

{ cmd1 cmd2 cmd3 . . . . . . . . . . .

- (0) An empty command is ignored.
- (0) # If a # appears as the first character on the first line of a script file, then that entire line is treated as a comment, with one exception. If the character after the # is an 'n', then the default output will be suppressed. The rest of the line after #n is also ignored. A script file must contain at least one non-comment line.

# SEE ALSO

awk(1), ed(1), grep(1).

# **BUGS**

There is a limit of 100 commands in the script.

SH(1)

#### NAME

sh, rsh - shell, the standard/restricted command programming language

#### SYNOPSIS

```
sh [ -acefhiknrstuvx ] [ args ]
rsh [ -acefhiknrstuvx ] [ args ]
```

#### HP-UX COMPATIBILITY

Level: HP-UX/NUCLEUS

Origin: System V

Native Language Support:

8-bit filenames.

#### DESCRIPTION

Sh is a command programming language that executes commands read from a terminal or a file. Rsh is a restricted version of the standard command interpreter sh; it is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. See *Invocation* below for the meaning of arguments to the shell.

#### Definitions

A blank is a tab or a space. A name is a sequence of letters, digits, or underscores beginning with a letter or underscore. A parameter is a name, a digit, or any of the characters \*, @, #, ?, -, \$, and !.

#### Commands

A simple-command is a sequence of non-blank words separated by blanks. The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see exec(2)). The value of a simple-command is its exit status if it terminates normally, or (octal) 200+status if it terminates abnormally (see signal(2) for a list of status values).

A pipeline is a sequence of one or more commands separated by | (or, for historical compatibility, by ^). The standard output of each command but the last is connected by a pipe(2) to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command.

A list is a sequence of one or more pipelines separated by ;, &, &&, or  $|\cdot|$ , and optionally terminated by ; or &. Of these four symbols, ; and & have equal precedence, which is lower than that of && and  $|\cdot|$ . The symbols && and  $|\cdot|$  also have equal precedence. A semicolon (;) causes sequential execution of the preceding pipeline; an ampersand (&) causes asynchronous execution of the preceding pipeline (i.e., the shell does not wait for that pipeline to finish). The symbol && (||) causes the list following it to be executed only if the preceding pipeline returns a zero (non-zero) exit status. An arbitrary number of new-lines may appear in a list, instead of semicolons, to delimit commands.

A *command* is either a simple-command or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

#### for name [ in word ... ] do list done

Each time a **for** command is executed, *name* is set to the next *word* taken from the **in** *word* list. If **in** *word* ... is omitted, then the **for** command executes the **do** *list* once for each positional parameter that is set (see *Parameter Substitution* below). Execution ends when there are no more words in the list.

```
case word in [ pattern [ | pattern ] ... ) list ;; ] ... esac
```

A case command executes the *list* associated with the first pattern that matches word. The form of the patterns is the same as that used for file-name generation (see File Name Generation) except that a slash, a leading dot, or a dot immediately following a slash

need not be matched explicitly.

## if list then list [ elif list then list ] ... [ else list ] fi

The *list* following if is executed and, if it returns a zero exit status, the *list* following the first **then** is executed. Otherwise, the *list* following **elif** is executed and, if its value is zero, the *list* following the next **then** is executed. Failing that, the **else** *list* is executed. If no **else** *list* or **then** *list* is executed, then the **if** command returns a zero exit status.

#### while list do list done

A while command repeatedly executes the while *list* and, if the exit status of the last command in the list is zero, executes the **do** *list*; otherwise the loop terminates. If no commands in the **do** *list* are executed, then the while command returns a zero exit status; until may be used in place of while to negate the loop termination test.

(list)

Execute list in a sub-shell.

 $\{list;\}$ 

list is simply executed.

name () {list;}

Define a function which is referenced by name. The body of the function is the list of commands between  $\{$  and  $\}$ . Execution of functions is described below (see Execution).

The following words are only recognized as the first word of a command and when not quoted:

if then else elif fi case esac for while until do done { }

#### Comments

A word beginning with # causes that word and all the following characters up to a new-line to be ignored.

#### Command Substitution

The standard output from a command enclosed in a pair of grave accents (``) may be used as part or all of a word; trailing new-lines are removed.

#### Parameter Substitution

The character \$\$ is used to introduce substitutable parameters. There are two types of parameters, positional and keyword. If parameter is a digit, it is a positional parameter. Positional parameters may be assigned values by set. Keyword parameters (also known as variables) may be assigned values by writing:

```
name=value [ name=value ] ...
```

Pattern-matching is not performed on *value*. There cannot be a function and a variable with the same *name*.

# **\$**{parameter}

The value, if any, of the parameter is substituted. The braces are required only when parameter is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If parameter is \* or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.

# **\$**{parameter:-word}

If parameter is set and is non-null, substitute its value; otherwise substitute word.

#### $\{parameter:=word\}$

If *parameter* is not set or is null set it to *word*; the value of the parameter is then substituted. Positional parameters may not be assigned to in this way.

#### \${parameter:?word}

If parameter is set and is non–null, substitute its value; otherwise, print word and exit from the shell. If word is omitted, then the message "parameter null or not set" is printed.

## \${parameter:+word}

If parameter is set and is non-null then substitute word; otherwise substitute nothing.

In the above, word is not evaluated unless it is to be used as the substituted string, so that, in the following example, **pwd** is executed only if **d** is not set or is null:

If the colon (:) is omitted from the above expressions, then the shell only checks whether parameter is set or not.

The following parameters are automatically set by the shell:

- # The number of positional parameters in decimal.
- Flags supplied to the shell on invocation or by the **set** command.
- ? The decimal value returned by the last synchronously executed command.
- \$ The process number of this shell.
- ! The process number of the last background command invoked.

The following parameters are used by the shell:

**HOME** The default argument (home directory) for the *cd* command.

PATH The search path for commands (see *Execution* below). The user may not change PATH if executing under rsh.

## CDPATH

The search path for the cd command.

MAIL If this parameter is set to the name of a mail file and the MAILPATH parameter is not set, the shell informs the user of the arrival of mail in the specified file.

#### MAILCHECK

This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the MAILPATH or MAIL parameters. The default value is 600 seconds (10 minutes). If set to 0, the shell will check before each prompt.

#### MAILPATH

A colon (:) separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by % and a message that will be printed when the modification time changes. The default message is you have mail.

PS1 Primary prompt string, by default "\$".

PS2 Secondary prompt string, by default ">".

IFS Internal field separators, normally space, tab, and new-line.

#### SHACCT

If this parameter is set to the name of a file writable by the user, the shell will write an accounting record in the file for each shell procedure executed. Accounting routines such as acctcom(1) and acctcms(1M) can be used to analyze the data collected.

#### SHELL

When the shell is invoked, it scans the environment (see *Environment* below) for this name. If it is found and there is an 'r' in the file name part of its value, the shell becomes a restricted shell. **SHELL** is also used by some to run.

The shell gives default values to PATH, PS1, PS2, MAILCHECK and IFS. HOME and MAIL are set by login(1).

#### Blank Interpretation

After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in IFS) and split into distinct arguments where such characters are found. Explicit null arguments ("" or '') are retained. Implicit null arguments (those resulting from parameters that have no values) are removed.

## File Name Generation

Following substitution, each command word is scanned for the characters \*, ?, and [. If one of these characters appears then the word is regarded as a pattern. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, then the word is left unchanged. The character  $\cdot$  at the start of a file name or immediately following a /, as well as the character / itself, must be matched explicitly.

- \* Matches any string, including the null string.
- ? Matches any single character.
- [...] Matches any one of the enclosed characters. A pair of characters separated by matches any character lexically between the pair, inclusive. If the first character following the opening ``['' is a "!'" any character not enclosed is matched.

## Quoting

The following characters have a special meaning to the shell and cause termination of a word unless quoted:

; & ( ) 
$$| \hat{} < >$$
 new-line space tab

A character may be *quoted* (i.e., made to stand for itself) by preceding it with a \. The pair \new-line is ignored. All characters enclosed between a pair of single quote marks ('''), except a single quote, are quoted. Inside double quote marks (""), parameter and command substitution occurs and \ quotes the characters \, \, \, ", and \\$. "\\$\*" is equivalent to "\\$1 \\$2 \dots", whereas "\\$@" is equivalent to "\\$1" "\\$2" \dots".

## Prompting

When used interactively, the shell prompts with the value of **PS1** before reading a command. If at any time a new-line is typed and further input is needed to complete a command, then the secondary prompt (i.e., the value of **PS2**) is issued.

## Input/Output

Before a command is executed, its input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a *command* and are *not* passed on to the invoked command; substitution occurs before *word* or *digit* is used:

**<word** Use file *word* as standard input (file descriptor 0).

>word Use file word as standard output (file descriptor 1). If the file does not exist then

it is created; otherwise, it is truncated to zero length.

>>word Use file word as standard output. If the file exists then output is appended to it

(by first seeking to the end-of-file); otherwise, the file is created.

 $\ll$ [-]word The shell input is read up to a line that is the same as word, or to an end-of-file.

The resulting document becomes the standard input. If any character of word is quoted, then no interpretation is placed upon the characters of the document; otherwise, parameter and command substitution occurs, (unescaped)  $\mbox{new-line}$  is ignored, and  $\mbox{must}$  be used to quote the characters  $\mbox{, $\$, $}$ , and the first character of word. If - is appended to  $\mbox{\ll}$ , then all leading tabs are stripped from

word and from the document.

<&digit Use the file associated with file descriptor digit as standard input. Similarly for

the standard output using >& digit. (See dup(2)).

<&- The standard input is closed. Similarly for the standard output using >&-.

If any of the above is preceded by a digit, then the file descriptor which will be associated with the file is that specified by the digit (instead of the default 0 or 1). For example:

associates file descriptor 2 with the file currently associated with file descriptor 1. Note that this type of I/O redirection is necessary if you want to *synchronously* collect stdout and stderr output in the same file. Redirecting stdout and stderr separately will cause asynchronous collection of

data at the destination (i.e. things written to stdout can subsequently be over-written by things written to stderr, and vice-versa).

The order in which redirections are specified is significant. The shell evaluates redirections left-to-right. For example:

```
... 1>xxx 2>&1
```

first associates file descriptor 1 with file xxx. It associates file descriptor 2 with the file associated with file descriptor 1 (i.e. xxx). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file xxx.

If a command is followed by & then the default standard input for the command is the empty file /dev/null. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

Redirection of output is not allowed in the restricted shell.

#### Environment

The environment (see environ(7)) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. Executed commands inherit the same environment. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the export command is used to bind the shell's parameter to the environment (see also set -a). A parameter may be removed from the environment with the unsetcommand. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by unset, plus any modifications or additions, all of which must be noted in export commands.

The environment for any *simple-command* may be augmented by prefixing it with one or more assignments to parameters. Thus:

```
TERM=450 cmd and (export TERM; TERM=450; cmd)
```

are equivalent (as far as the execution of *cmd* is concerned).

If the -k flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name. The following first prints  $\mathbf{a} = \mathbf{b} \mathbf{c}$  and then  $\mathbf{c}$ :

```
echo a=b c
set -k
echo a=b c
```

#### Signals

The INTERRUPT and QUIT signals for an invoked command are ignored if the command is followed by &; otherwise signals have the values inherited by the shell from its parent, with the exception of signal 11 (but see also the trap command below).

## Execution

Each time a command is executed, the above substitutions are carried out. If the command name matches one of the *Special Commands* listed below, it is executed in the shell process. If the command name does not match a *Special Command*, but matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of shell procedures). The positional parameters \$1, \$2, ... are set to the arguments of the function. If the command name matches neither a *Special Command* nor the name of a defined function, a new process is created and an attempt is made to execute the command via exec(2).

The shell parameter PATH defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is :/bin:/usr/bin

(specifying the current directory, /bin, and /usr/bin, in that order). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If the command name contains a / then the search path is not used; such commands will not be executed by the restricted shell. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an a.out file, it is assumed to be a file containing shell commands. A subshell (i.e., a separate process) is spawned to read it. A parenthesized command is also executed in a sub-shell.

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary *execs* later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the **PATH** variable is changed or the **hash** -**r** command is executed (see below).

# Special Commands

The following commands are executed in the shell process. Input/output redirection is permitted for these commands. File descriptor 1 is the default output location.

- : No effect; the command does nothing. A zero exit code is returned.
- . file Read and execute commands from file and return. The search path specified by PATH is used to find the directory containing file. Note that this command does not spawn another shell to execute file, and thus differs in behavior and output from executing file as a shell script.
- break [ n

Exit from the enclosing for or while loop, if any. If n is specified then break n levels.

## continue [n]

Resume the next iteration of the enclosing for or while loop. If n is specified then resume at the n-th enclosing loop.

cd [ arg ]

Change the current directory to arg. The shell parameter **HOME** is the default arg. The shell parameter **CDPATH** defines the search path for the directory containing arg. Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If arg begins with a / the search path is not used. Otherwise, each directory in the path is searched for arg. The cd command may not be executed by rsh.

- echo [ arg ... ]
  - Echo arguments. See echo(1) for usage and description.
- eval  $[arg \dots]$

The arguments are read as input to the shell and the resulting command(s) executed.

exec [arq...]

The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

exit [ n

Causes a shell to exit with the exit status specified by n. If n is omitted then the exit status is that of the last command executed (an end-of-file will also cause the shell to exit.)

export [ name ... ]

The given *names* are marked for automatic export to the *environment* of subsequently–executed commands. If no arguments are given, then a list of all names that are exported in this shell is printed. Function names may *not* be exported.

hash [ -r ] [ name ... ]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The -r option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. There are certain situations which require that the stored location of a command be recalculated. Commands for which this will be done are indicated by an asterisk (\*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

newgrp [ arg ... ]

Equivalent to exec newgrp  $arg \dots$  See newgrp(1) for usage and description.

pwd Print the current working directory. See pwd(1) for usage and description.

road [

One line is read from the standard input and the first word is assigned to the first name, the second word to the second name, etc., with leftover words assigned to the last name. The return code is 0 unless an end-of-file is encountered.

readonly [ name ... ]

The given names are marked readonly and the values of the these names may not be changed by subsequent assignment. If no arguments are given, then a list of all readonly names is printed.

return [ n ]

Causes a function to exit with the return value specified by n. If n is omitted, the return status is that of the last command executed.

set [ --aefhkntuvx [ arg ... ] ]

- -a Mark variables which are modified or created for export.
- -e Exit immediately if a command exits with a non-zero exit status.
- -f Disable file name generation
- -h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
- -k All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- -n Read commands but do not execute them.
- -t Exit after reading and executing one command.
- -u Treat unset variables as an error when substituting.
- -v Print shell input lines as they are read.
- -x Print commands and their arguments as they are executed.
- -- Do not change any of the flags; useful in setting \$1 to -.

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$-. The remaining arguments are positional parameters and are assigned, in order, to \$1, \$2, .... If no arguments are given then the values of all names are printed.

shift [n]

The positional parameters from n+1 ... are renamed 1 .... If n is not given, it is assumed to be 1.

test

Evaluate conditional expressions. See test(1) for usage and description. Note that "[...]" in an **if** list is interpreted the same as "**test** ...". There must be blanks around the brackets.

times

Print the accumulated user and system times for processes run from the shell.

trap [arg][n]...

The command arg is a command to be read and executed when the shell receives signal(s) n. (Note that arg is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number. Any attempt to set a trap on a

signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If arg is absent then all trap(s) n are reset to their original values. If arg is the null string then this signal is ignored by the shell and by the commands it invokes. If n is 0 then the command arg is executed on exit from the shell. The **trap** command with no arguments prints a list of commands associated with each signal number.

type [  $name \dots$  ]

For each *name*, indicate how it would be interpreted if used as a command name.

ulimit [ -fp ] [ n ]

imposes a size limit of n

-f imposes a size limit of *n* blocks on files written by child processes (files of any size may be read). With no argument, the current limit is printed.

If no option is given, -f is assumed.

umask [ nnn ]

The user file-creation mask is set to nnn (see umask(2)). If nnn is omitted, the current value of the mask is printed.

unset [ name ... ]

For each name, remove the corresponding variable or function. The variables PATH, PS1. PS2. MAILCHECK and IFS cannot be unset.

wait [ n ]

Wait for the specified process and report its termination status. If n is not given, all currently active child processes are waited for and the return code is zero.

#### Invocation

If the shell is invoked through exec(2) and the first character of argument zero is -, commands are initially read from /etc/profile and then from \$HOME/.profile, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as /bin/sh. The flags below are interpreted by the shell on invocation only; Note that unless the -c or -s flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

- -c string If the -c flag is present then commands are read from string.
- -s If the -s flag is present or if no arguments remain then commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for *Special Commands*) is written to file descriptor 2.
- -i If the -i flag is present or if the shell input and output are attached to a terminal, then this shell is interactive. In this case TERMINATE is ignored (so that kill 0 does not kill an interactive shell) and INTERRUPT is caught and ignored (so that wait is interruptible). In all cases, QUIT is ignored by the shell.
- -r If the -r flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the set command above.

## Rsh Only

Rsh is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of rsh are identical to those of sh, except that the following are disallowed:

changing directory (see cd(1)), setting the value of **\$PATH**, specifying path or command names containing /, redirecting output (> and >>).

The restrictions above are enforced after **.profile** is interpreted.

When a command to be executed is found to be a shell procedure, rsh invokes sh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the

end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the .profile has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (i.e., /usr/rbin) that can be safely invoked by rsh. Some systems also provide a restricted editor red.

#### FILES

```
/etc/profile
$HOME/.profile
/tmp/sh*
/dev/null
```

#### RETURN VALUE

The error codes returned by the shell are:

```
0 - success:
```

- 1 a built-in command failure (see Special Commands);
- 2 syntax error;
- 3 signal received that is not trapped.

If the shell is non-interactive, it will terminate and pass one of the above as its exit status. If it is interactive, it will not terminate, but \$? will be set to one of the above values.

Whenever a child process of the shell dies due to a signal, the shell returns an exit status of 80 hexadecimal + the number of the signal.

#### SEE ALSO

 $\begin{array}{lll} \operatorname{acctcms}(1M), \ \operatorname{acctcom}(1), \ \operatorname{cd}(1), \ \operatorname{echo}(1), \ \operatorname{env}(1), \ \operatorname{login}(1), \ \operatorname{newgrp}(1), \ \operatorname{pwd}(1), \ \operatorname{test}(1), \ \operatorname{umask}(1), \\ \operatorname{dup}(2), \ \operatorname{exec}(2), \ \operatorname{fork}(2), \ \operatorname{pipe}(2), \ \operatorname{signal}(2), \ \operatorname{ulimit}(2), \ \operatorname{umask}(2), \ \operatorname{wait}(2), \ \operatorname{a.out}(5), \ \operatorname{profile}(5), \\ \operatorname{environ}(7). \end{array}$ 

#### CAVEATS

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to exec the original command. Use the hash command to correct this situation.

The shell assumes it is talking to terminals that only process the least significant seven bits of a character. If your terminal uses all eight bits, you may see some strange strings.

When the shell encounters >>, it does not open the file in append mode. Instead, it opens the file for writing and seeks to the end. If you move the current directory or one above it, **pwd** may not give the correct response. Use the **cd** command with a full path name to correct this situation.

The command **readonly** (without arguments) produces the same output as the command **export**.

SIZE(1)

#### NAME

size - print section sizes of common object files

#### SYNOPSIS

**size** [ **-o** ] [ **-x** ] files

#### HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: System V

# DESCRIPTION

The size command produces section size information for each section in common object files. The size of the text, data and bss (uninitialized data) sections are printed along with the total size of the object file. If an archive file is input to the size command the information for all archive members is displayed.

By default, numbers are printed in decimal, unless altered by the options described below.

-o print numbers in octal.

-x print numbers in hexadecimal.

#### HARDWARE DEPENDENCIES

Series 500:

The text size shown is the sum of the sizes of all code segments.

The *data* size shown is the sum of the initialized portions of the ddata and idata segments (which may be one or two data segments).

The bss size shown is the sum of the uninitialized portions of the ddata and idata segments.

If *size* is run on any commands shipped with HP-UX, the *text* size does not include any shared library segments referenced by the command.

if *name* is not an appropriate common object file.

SLEEP(1) SLEEP(1)

## NAME

sleep - suspend execution for an interval

# SYNOPSIS

sleep time

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

# DESCRIPTION

Sleep suspends execution for time seconds. It is used to execute a command after a certain amount of time, as in:

(sleep 105; command)&

or to execute a command every so often, as in:

while true

do

command sleep 37

done

#### SEE ALSO

alarm(2), sleep(3C).

# BUGS

Time must be less than 65536 seconds.

slp - set the options for a printer

#### SYNOPSIS

slp [-a] [-c cols] [-d] [-i indent] [-l lines] [-n]

#### HP-UX COMPATIBILITY

Level:

HP-UX/NON-STANDARD

Origin: H

Jiigiii. II.

Remarks: Slp is implemented on the Series 200 only.

#### DESCRIPTION

Slp sets certain printer options for the device that is the current standard output.

The meanings of the options are:

-a Reports all of the option settings.

-c cols The number of columns which are to be printed is indicated by the cols argument.

Characters beyond the last specified column will be truncated.

-d Resets options to the defaults for the device. (This action is not taken until the next open occurs on the device.)

-iindent Indent selects the number of columns to indent before the first printed column.

-1 lines The number of lines per page is set to lines. The last new-line character of each page will be changed to a form-feed.

-n Set the page size to infinity. (Since the last new-line of the page is never encountered, no new-line characters will be changed to form-feeds.)

#### EXAMPLES

A typical case is to set the printer to 80 columns, no indentation, and no form-feeds between pages:

slp -c80 -i0 -n >/dev/lp

# HARDWARE DEPENDENCIES

Series 200:

The value of *cols* will be forced into the range of 1 to 227, the value of *indent* from 0 to 227, and the value of *lines* from 1 to MAXSHORT.

SORT(1) SORT(1)

#### NAME

sort - sort and/or merge files

## SYNOPSIS

sort [ [-cmu] [-ooutput] [-ykmem] [-zrecsz] [-dfilkMnr [-Llanguage] [-Ktable]] [-btx] [+pos1 [-pos2]]] [files]

## HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: System V

Native Language Support:

8-bit and 16-bit data, customs, messages

#### DESCRIPTION

Sort sorts lines of all the named files together and writes the result on the standard output. The standard input is read if - is used as a file name or no input files are named.

Comparisons are based on one or more sort keys extracted from each line of input. By default, there is one sort key, the entire input line, and ordering is lexicographic by bytes in machine collating sequence.

The following options alter the default behavior:

- -c Check that the input file is sorted according to the ordering rules; give no output unless the file is out of sort.
- -m Merge only, the input files are already sorted.
- -u Unique: suppress all but one in each set of lines having equal keys.

#### -ooutput

The argument given is the name of an output file to use instead of the standard output. This file may be the same as one of the inputs. There may be optional blanks between **-o** and *output*.

#### -ykmem

The amount of main memory used by the sort has a large impact on its performance. Sorting a small file in a large amount of memory is a waste. If this option is omitted, sort begins using a system default memory size, and continues to use more space as needed. If this option is presented with a value, kmem, sort will start using that number of kilobytes of memory, unless the administrative minimum or maximum is violated, in which case the corresponding extremum will be used. Thus, -y0 is guaranteed to start with minimum memory. By convention, -y (with no argument) starts with maximum memory.

#### -zrecsz

The size of the longest line read is recorded in the sort phase so buffers can be allocated during the merge phase. If the sort phase is omitted via the **-c** or **-m** options, a popular system default size will be used. Lines longer than the buffer size will cause *sort* to terminate abnormally. Supplying the actual number of bytes in the longest line to be merged (or some larger value) will prevent abnormal termination.

The following options override the default ordering rules.

- -d "Dictionary" order: only letters, digits and blanks (spaces and tabs) are significant in comparisons.
- -f Fold lower case into upper case, for purposes of comparison.
- -i Ignore characters outside the ASCII range 040-0176 in non-numeric comparisons.
- -M Compare as months. The first three non-blank characters of the field are folded to upper case and compared so that "JAN" < "FEB" < ... < "DEC". Invalid field compare low to

- "JAN". The -M option implies the -b option (see below).
- -n An initial numeric string, consisting of optional blanks, optional minus sign, and zero or more digits with optional decimal point, is sorted by arithmetic value. The -n option implies the -b option (see below). Note that the -b option is only effective when restricted sort key specifications are in effect.
- -r Reverse the sense of comparisons.

The following two options apply to extended ASCII character sets.

 Collate characters using the table associated with the user's LANG variable (See environ(7)).

# -Llanguage

Allow the user to specify his/her local language. The  $-\mathbf{f}$  and  $-\mathbf{l}$  options are to behave in a language dependent fashion, the  $-\mathbf{d}$ ,  $-\mathbf{i}$ ,  $-\mathbf{M}$  and  $-\mathbf{n}$  options are not. The *language* overrides the *LANG* variable.

The following two options apply to data containing 16-bit characters.

- -k 16-bit characters data appears in canonical 8-bit form. This option implies -b. If -K is not specified native machine collation is used.
- -Ktable Name of a file which contains a 16-bit character set collation table as specified in nl\_col\_seq\_16(5).

When ordering options appear before restricted sort key specifications, the requested ordering rules are applied globally to all sort keys. When attached to a specific sort key (described below), the specified ordering options override all global ordering options for that key.

The notation +pos1 - pos2 restricts a sort key to one beginning at pos1 and ending at pos2. The characters at positions pos1 and pos2 are included in the sort key (provided that pos2 does not precede pos1). A missing -pos2 means the end of the line.

Specifying pos1 and pos2 involves the notion of a field, a minimal sequence of characters followed by a field separator or a new-line. By default, the first blank (space or tab) of a sequence of blanks acts as the field separator. All blanks in a sequence of blanks are considered to be part of the next field; for example, all blanks at the beginning of a line are considered to be part of the first field. The treatment of field separators can be altered using the options:

- -tx Use x as the field separator character; x is not considered to be part of a field (although it may be included in a sort key). Each occurrence of x is significant (e.g., xx delimits an empty field).
- -b Ignore leading blanks when determining the starting and ending positions of a restricted sort key. If the -b option is specified before the first +pos1 argument, it will be applied to all +pos1 arguments. Otherwise, the b flag may be attached independently to each +pos1 or -pos2 argument (see below).

Pos1 and pos2 each have the form m.n optionally followed by one or more of the flags **bdfinr**. A starting position specified by +m.n is interpreted to mean the n+1st character in the m+1st field. A missing .n means .0, indicating the first character of the m+1st field. If the b flag is in effect n is counted from the first non-blank in the m+1st field; +m.0b refers to the first non-blank character in the m+1st field.

A last position specified by -m.n is interpreted to mean the nth character (including separators) after the last character of the m th field. A missing .n means .0, indicating the last character of the mth field. If the b flag is in effect n is counted from the last leading blank in the m+1st field; -m.1b refers to the first non-blank in the m+1st field.

When there are multiple sort keys, later keys are compared only after all earlier keys compare equal. Lines that otherwise compare equal are ordered with all bytes significant.

SORT(1) SORT(1)

#### HARDWARE DEPENDENCIES

Series 200/500: 16-bit collation currently is not supported.

#### EXAMPLES

Sort the contents of *infile* with the second field as the sort kev:

sort 
$$+1$$
 -2 infile

Sort, in reverse order, the contents of *infile1* and *infile2*, placing the output in *outfile* and using the first character of the second field as the sort key:

Sort, in reverse order, the contents of *infile1* and *infile2* using the first non-blank character of the second field as the sort key:

Print the password file (passwd(5)) sorted by the numeric user ID (the third colon–separated field):

Print the lines of the already sorted file *infile*, suppressing all but the first occurrence of lines having the same third field (the options -um with just one input file make the choice of a unique representative from a set of equal lines predictable):

sort -um 
$$+2$$
 -3 infile

#### FILES

/usr/tmp/stm???

#### SEE ALSO

comm(1), join(1), uniq(1), nl\_col\_seq\_16(5), nl\_col\_seq\_8(5), environ(7), hpnls(7), langid(7).

#### DIAGNOSTICS

Comments and exits with non-zero status for various trouble conditions (e.g., when input lines are too long), and for disorder discovered under the -c option. When the last line of an input file is missing a **new-line** character, *sort* appends one, prints a warning message, and continues.

# BUGS

Sort does not understand "missing" fields. For example, consider a file with the following contents:

Doe,John	$_{ m mailman}$	17550	8
Spencer, Joe	$_{ m plumber}$		4
Johns,Ann	secretary	15950	
Malley.Dean	engineer	26750	4

You may get unexpected results if you try to sort on the third or fourth fields (all names and associated data are fictitious).

Sort does not expand tabs when counting characters to locate a field.

Sort does not perform "-fl" in which it would fold lower to upper, then compare in language-dependent sequence. Instead, it performs "-fl" as though it were "-l".

SPELL(1) SPELL(1)

#### NAME

spell, spellin, spellout - find spelling errors

#### SYNOPSIS

```
spell [ options ] [ files ]
/usr/lib/spell/spellin [ list ]
/usr/lib/spell/spellout [ -d ] list
```

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System III

## DESCRIPTION

Spell collects words from the named files and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, and/or suffixes) from words in the spelling list are printed on the standard output. If no files are named, words are collected from the standard input.

Spell ignores most nroff(1), and tbl constructions.

The options are:

- -v all words not literally in the spelling list are printed, and plausible derivations from the words in the spelling list are indicated.
- -b British spelling is checked. Besides preferring centre, colour, speciality, travelled, etc., this option insists upon -ise in words like standardise, Fowler and the OED to the contrary notwithstanding.
- -x every plausible stem is printed with = for each word.

The spelling list is based on many sources, and while more haphazard than an ordinary dictionary, is also more effective with respect to proper names and popular technical words. Coverage of the specialized vocabularies of biology, medicine, and chemistry is light.

Pertinent auxiliary files may be specified by name arguments, indicated below with their default settings. Copies of all output are accumulated in the history file. The stop list filters out misspellings (e.g., thier=thy-y+ier) that would otherwise pass.

Two routines help maintain the hash lists used by *spell* (both expect a list of words, one per line, from the standard input):

spellin

adds the words on the standard input to the pre–existing *list* and places a new list on the standard output. If no *list* is specified, the new list is created from scratch.

Spellout

looks up each word read from the standard input, and prints on the standard output those that are missing from (or, with the **-d** option, present in) the hash list.

#### HARDWARE DEPENDENCIES

Series 200/500:

eqn, typo and troff are not currently supported.

#### FILES

D\_SPELL=/usr/lib/spell/hlist[ab] hashed spelling lists, American & British S\_SPELL=/usr/lib/spell/hstop hashed stop list history file temporary program

hashed spelling lists, American & British hashed stop list history file temporary program

SPELL(1) SPELL(1)

# SEE ALSO

deroff(1), nroff(1), sed(1), sort(1), tbl(1), tee(1).

# BUGS

The spelling list's coverage is uneven; new installations will probably wish to monitor the output for several months to gather local additions; typically, these are kept in a separate local dictionary that is added to the hashed *list* via *spellin*. British spelling was done by an American.

SPLIT(1) SPLIT(1)

#### NAME

split - split a file into pieces

# SYNOPSIS

```
split [-n] [ file [ name ] ]
```

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

# DESCRIPTION

Split reads file and writes it in n-line pieces (default 1000 lines) onto a set of output files. The name of the first output file is name with  ${\bf aa}$  appended, and so on lexicographically, up to  ${\bf zz}$  (a maximum of 676 files). Name cannot be longer than 12 characters. If no output name is given,  ${\bf x}$  is default.

If no input file is given, or if - is given instead, then the standard input file is used.

# SEE ALSO

bfs(1), csplit(1).

ssp - remove multiple line-feeds from output

# SYNOPSIS

ssp

# HP-UX COMPATIBILITY

Level: HP-

HP-UX/STANDARD

Origin:

UCB

Remarks: Not supported on the Integral Personal Computer.

# DESCRIPTION

Ssp (single–space) removes redundant blank lines from the standard input and sends the result to the standard output. It is typically used in pipelines like

nroff -ms file1 | ssp

Ssp is equivalent the the 4.2BSD cat -s command.

# SEE ALSO

cat(1), rmnl(1).

STRINGS(1) STRINGS(1)

#### NAME

strings - find the printable strings in a object, or other binary, file

#### SYNOPSIS

```
strings [ -a ] [ -o ] [ -number ] [ file ] ...
```

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

UCB

Remarks: Not supported on the Integral Personal Computer.

#### DESCRIPTION

Strings looks for ascii strings in a file. If no files are specified, stdin is used. A string is any sequence of 4 or more printing characters ending with a new-line or a null.

The following flags are defined.

- a By default, strings only looks in the initialized data space of object files (as recognised by their magic numbers). If this flag is used, the whole file is inspected. This flag is always set if stdin is being read or the file is not recognized as an object file. For backward compatability, is taken as a synonym for -a.
- **o** Each string is preceded by its offset in the file (in octal).

number number is used as the minimum string length rather than 4.

Strings is useful for identifying random object files and many other things.

#### SEE ALSO

od(1)

# BUGS

The algorithm for identifying strings is extremely primitive.

strip - remove symbols and debug information

#### SYNOPSIS

strip name ...

#### HP-UX COMPATIBILITY

Level:

HP-UX/DEVELOPMENT

Origin:

System V

# DESCRIPTION

Strip removes the symbol table and debug information from an executable object file. Once this is done, no symbolic debugging access will be available for that file; therefore this command is normally run only on production modules that have been debugged and tested. The effect is the same as use of the -s option of ld.

If name is a relocatable file, strip removes the debug information.

If the strip command is executed on an archive file (see ar (5)) the archive symbol table will be removed. The archive symbol table must be restored by executing the ar (1) command with the s option before the archive can be link-edited by the ld (1) command. Also, strip removes the debug information from any a.out file it finds in the archive.

The purpose of this command is to reduce the file storage overhead taken by the object file.

#### HARDWARE DEPENDENCIES

Series 200:

If name is a relocatable file, strip will remove the local symbols from it. If name is an archive file, strip will remove the local symbols from any a.out format files it finds in the archive. Certain libraries, such as those residing in /lib, have no need for local symbols. By deleting them, the size of the archive is decreased and link editing performance is increased.

#### FILES

/tmp/s\*

temporary files

STTY(1)

#### NAME

stty - set the options for a terminal port

#### SYNOPSIS

stty [ -a ] [ -g ] [ options ]

## HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin: System III

#### DESCRIPTION

Stty sets certain terminal I/O options for the device that is the current standard input; without arguments, it reports the settings of certain options; with the -a option, it reports all of the option settings; with the -g option, it reports current settings in a form that can be used as an argument to another stty command. Detailed information about the modes listed in the first five groups below may be found in termio(4) for asynchronous lines. Options in the last group are implemented using options in the previous groups. Note that many combinations of options make no sense, but no sanity checking is performed. The options are selected from the following:

#### Control Modes

parenb (-parenb) enable (disable) parity generation and detection.

parodd (-parodd) select odd (even) parity.

cs5 cs6 cs7 cs8 select character size (see termio(4)).

0 hang up phone line immediately.

50 75 110 134.5 150 200 300 600 900 1200

## 1800 2400 3600 4800 7200 9600 19200 38400 exta extb

Set terminal baud rate to the number given, if possible. (All speeds are not

supported by all hardware interfaces.)

hupcl (-hupcl) hang up (do not hang up) modem connection on last close.

hup (-hup) same as hupcl (-hupcl).

**cstopb** (-cstopb) use two (one) stop bits per character.

**cread** (-**cread**) enable (disable) the receiver.

crts (-crts) enable (disable) request-to-send.

**clocal** (-clocal) assume a line without (with) modem control.

Input Modes

ignbrk (-ignbrk) ignore (do not ignore) break on input.

 ${\bf ienqak} \ ({\bf -ienqak}) \qquad {\rm enable} \ ({\rm disable}) \ {\rm ENQ-ACK} \ {\rm handshaking}.$ 

brkint (-brkint) signal (do not signal) INTR on break.

ignpar (-ignpar) ignore (do not ignore) parity errors.

parmrk (-parmrk) mark (do not mark) parity errors (see termio(4)).

inpck (-inpck) enable (disable) input parity checking.

**istrip** (-istrip) strip (do not strip) input characters to seven bits.

inler (-inler) map (do not map) NL to CR on input.

igner (-igner) ignore (do not ignore) CR on input.

icrnl (-icrnl) map (do not map) CR to NL on input.

iucle (-iucle) map (do not map) upper-case alphabetics to lower case on input.

ixon (-ixon) enable (disable) START/STOP output control. Output is stopped by send-

ing an ASCII DC3 and started by sending an ASCII DC1.

STTY(1) STTY(1)

ixany (-ixany) allow any character (only DC1) to restart output. ixoff (-ixoff) request that the system send (not send) START/STOP characters when the input queue is nearly empty/full. Output Modes opost (-opost) post-process output (do not post-process output; ignore all other output modes). olcuc (-olcuc) map (do not map) lower-case alphabetics to upper case on output. onlcr (-onlcr) map (do not map) NL to CR-NL on output. ocrnl (-ocrnl) map (do not map) CR to NL on output. onocr (-onocr) do not (do) output CRs at column zero. onlret (-onlret) on the terminal NL performs (does not perform) the CR function. ofill (-ofill) use fill characters (use timing) for delays. ofdel (-ofdel) fill characters are DELs (NULs). cr0 cr1 cr2 cr3 select style of delay for carriage returns (see termio(4)). nl0 nl1 select style of delay for line-feeds (see termio(4)). tab0 tab1 tab2 tab3 select style of delay for horizontal tabs (see termio (4). bs0 bs1 select style of delay for backspaces (see termio(4)). ff0 ff1 select style of delay for form-feeds (see termio(4)). vt0 vt1 select style of delay for vertical tabs (see termio(4)). Local Modes isig (-isig) enable (disable) the checking of characters against the special control characters INTR and QUIT. icanon (-icanon) enable (disable) canonical input (ERASE and KILL processing). xcase (-xcase) canonical (unprocessed) upper/lower-case presentation. echo (-echo) echo back (do not echo back) every character typed. echoe (-echoe) echo (do not echo) ERASE character as a backspace-space-backspace string. Note: this mode will erase the ERASEed character on many CRT terminals; however, it does not keep track of column position and, as a result, may be confusing on escaped characters, tabs, and backspaces. echok (-echok) echo (do not echo) NL after KILL character. lfkc (-lfkc) the same as echok (-echok); obsolete. echonl (-echonl) echo (do not echo) NL. noflsh (-noflsh) disable (enable) flush after INTR or QUIT. Control Assignments control-character c set control-character to c, where control-character is erase, kill, intr, quit, swtch, eof, min, or time (min and time are used with -icanon; see termio(4)). If c is preceded by an (escaped from the shell) caret ( $\hat{}$ ), then the value used is the corresponding CTRL character (e.g., "^d" is a CTRL-d); "^?" is interpreted as DEL and "^-" is interpreted as

undefined.

STTY(1) STTY(1)

line i

set line discipline to i (0 < i < 127). (See termio(4)).

Combination Modes

evenp or parity

enable parenb and cs7.

oddp

enable parenb, cs7, and parodd.

-parity, -evenp, or -oddp

disable parenb, and set cs8.

raw (-raw or cooked)

enable (disable) raw input and output (no ERASE, KILL, INTR, QUIT, EOT,

or output post processing).

same as lcase (-lcase).

nl (-nl)

unset (set) icrnl, onler. In addition -nl unsets inler, igner, ocrnl, and

onlret.

lcase (-lcase)

set (unset) xcase, iuclc, and olcuc.

LCASE (-LCASE)

tabs (-tabs or tab3) preserve (expand to spaces) tabs when printing.

 $\mathbf{e}\mathbf{k}$ 

reset ERASE and KILL characters back to normal # and @.

sane

resets all modes to some reasonable values.

term

set all modes suitable for the terminal type term, where term is one of tty33, tty37, vt05, tn300, ti700, hp,

### HARDWARE DEPENDENCIES

Series 200/500:

Refer to termio(4) for a description of the capabilities that are not supported.

# SEE ALSO

tabs(1), ioctl(2), termio(4).

#### NAME

su - become super-user or another user

#### SYNOPSIS

```
su [ - ] [ name [ arg ... ] ]
```

### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Su allows one to become another user without logging off. The default user name is **root** (i.e., super-user).

To use su, the appropriate password must be supplied (unless one is already **root**). If the password is correct, su will execute a new shell with the real and effective user ID, real and effective group ID, and group access list set to that of the specified user. The new shell will be the optional program named in the shell field of the specified user's password file entry (see passwd(4)), or /bin/sh if none is specified (see sh(1)). To restore normal user ID privileges, type an **EOF** to the new shell.

Any additional arguments given on the command line are passed to the program invoked as the shell, permitting the super-user to run shell procedures with restricted privileges. When using programs like sh(1), an arg of the form -c string executes string via the shell and an arg of -r will give the user a restricted shell.

The following statements are true only if the optional program named in the shell field of the specified user's password file entry is like sh(1). If the first argument to su is a -, the environment will be changed to what would be expected if the user actually logged in as the specified user. This is done by invoking the program used as the shell with an  $arg\theta$  value whose first character is -, thus causing first the system's profile (/etc/profile) and then the specified user's profile (.profile in the new HOME directory) to be executed. Otherwise, the environment is passed along unchanged, except that \$PATH, is unconditionally set to /bin:/etc:/usr/bin for root. Note that if the optional program used as the shell is /bin/sh, the user's .profile can check  $arg\theta$  for -sh or -su to determine if it was invoked by login(1) or su(1), respectively. If the user's program is other than /bin/sh, then .profile is invoked with an  $arg\theta$  of -program by both login(1) and su(1).

The - option always resets **\$PATH** to **/bin:/etc:/usr/bin** for the super-user, and **/bin:/usr/bin** for all others. However, the files **/etc/profile** and **.profile** are normally executed anyway, thus restoring the intended value of **\$PATH**.

All attempts to become another user are logged in /usr/adm/sulog, including failures. Successful attempts are flagged with "+", failures with "-".

#### **EXAMPLES**

To become user bin while retaining your previously exported environment, execute:

su bin

To become user **bin** but change the environment to what would be expected if **bin** had originally logged in, execute:

su – bin

To execute command with the temporary environment and permissions of user bin, type:

su - bin -c "command args"

# FILES

/etc/passwd

system's password file

/etc/logingroup /etc/profile system's default group access list file

\$HOME/.profile

system's profile user's profile

/usr/adm/sulog

log of all attempts

# VARIABLES

HOME LOGNAME the user's home directory the user's login name

PATH

the command name search path

PS1

SUM(1) SUM(1)

## NAME

sum - print checksum and block count of a file

## SYNOPSIS

**sum** [ **-r** ] [ file ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Remarks: Not supported on the Integral Personal Computer.

# DESCRIPTION

Sum calculates and prints a 16-bit checksum for the named file, and also prints the number of 512-byte blocks in the file. Stdin is used if no file names are given. Sum is typically used to look for bad spots, or to validate a file communicated over some transmission line. The option -r causes an alternate algorithm to be used in computing the checksum.

### SEE ALSO

wc(1).

### DIAGNOSTICS

"Read error" is indistinguishable from end of file on most devices; check the block count.

SYNC(1) SYNC(1)

### NAME

sync - update the super block

## **SYNOPSIS**

sync

# HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System V

Remarks: Not supported on the Integral Personal Computer.

# DESCRIPTION

Sync executes the sync system intrinsic. If the system is to be stopped, sync must be called to insure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See sync(2) for details.

## SEE ALSO

sync(2).

# REDUCED SEMANTICS

If sync(2) is a no–op and the system is RUN ONLY or NUCLEUS, the sync command need not be present.

TABS(1) TABS(1)

#### NAME

tabs - set tabs on a terminal

### SYNOPSIS

tabs [ tabspec ] [ +mn ] [ -Ttype ]

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

### DESCRIPTION

Tabs sets the tab stops on the user's terminal according to the tab specification tabspec, after clearing any previous settings. The user's terminal must have remotely-settable hardware tabs.

If you are using a non-HP terminal, you should keep in mind that behavior will vary for some tab settings.

Four types of tab specification are accepted for tabspec: "canned," repetitive, arbitrary, and file. If no tabspec is given, the default value is -8, i.e., HP-UX "standard" tabs. The lowest column number is 1. Note that for tabs, column 1 always refers to the leftmost column on a terminal, even one whose column markers begin at 0.

- -code Gives the name of one of a set of "canned" tabs. The legal codes and their meanings are as follows:
  - -a 1.10.16.36.72

Assembler, IBM S/370, first format

-a2 1,10,16,40,72

Assembler, IBM S/370, second format

**-c** 1,8,12,16,20,55

COBOL, normal format

-c2 1,6,10,14,49

COBOL compact format (columns 1–6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows:

## <:t-c2 m6 s66 d:>

-c3 1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67

COBOL compact format (columns 1-6 omitted), with more tabs than -c2. This is the recommended format for COBOL. The appropriate format specification is:

<:t-c3 m6 s66 d:>

-f 1,7,11,15,19,23

FORTRAN

 $\textbf{-p} \quad 1,5,9,13,17,21,25,29,33,37,41,45,49,53,57,61 \\$ 

PL/I

-s 1,10,55

SNOBOL

-u 1.12.20.44

UNIVAC 1100 Assembler

In addition to these "canned" formats, three other types exist:

- A repetitive specification requests tabs at columns 1+n, 1+2\*n, etc. Of particular importance is the value -8: this represents the HP-UX "standard" tab setting, and is the most likely tab setting to be found at a terminal. It is required for use with the nroff(1) -h option for high-speed output. Another special case is the value -0, implying no tabs at all.
- n1,n2,... The arbitrary format permits the user to type any chosen set of numbers, separated by commas, in ascending order. Up to 40 numbers are allowed. If any number (except the

TABS(1) TABS(1)

first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the tab lists 1,10,20,30 and 1,10,+10,+10 are considered identical.

--file If the name of a file is given, tabs reads the first line of the file, searching for a format specification. If it finds one there, it sets the tab stops according to it, otherwise it sets them as -8. This type of specification may be used to make sure that a tabbed file is printed with correct tab settings, and would be used with the pr(1) command:

tabs -- file; pr file

Any of the following may be used also; if a given flag occurs more than once, the last value given takes effect:

-Ttype Tabs usually needs to know the type of terminal in order to set tabs and always needs to know the type to set margins. Type is a name listed in term(7). If no -T flag is supplied, tabs searches for the \$TERM value in the environment (see environ(7)). If no type can be found, tabs tries a sequence that will work for many terminals.

+mn The margin argument may be used for some terminals. It causes all tabs to be moved over n columns by making column n+1 the left margin. If +m is given without a value of n, the value assumed is 10. The normal (leftmost) margin on most terminals is obtained by +m0. The margin for most terminals is reset only when the +m flag is given explicitly.

Tab and margin setting is performed via the standard output.

## DIAGNOSTICS

illegal tabs when arbitrary tabs are ordered incorrectly.

illegal increment when a zero or missing increment is found in an arbitrary specification.

unknown tab code when a "canned" code cannot be found.

can't open if --file option used, and file can't be opened.

file indirection if --file option used and the specification in that file points to yet another file.

Indirection of this form is not permitted.

### SEE ALSO

pr(1), nroff(1), tset(1), environ(7), term(7).

### BUGS

There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.

It is generally impossible to usefully change the left margin without also setting tabs.

Tabs clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.

TAIL(1)

#### NAME

tail - deliver the last part of a file

#### SYNOPSIS

 $tail [\pm [number][lbc[f]]] [file]$ 

### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Tail copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.

Copying begins at distance +number from the beginning, or -number from the end of the input (if number is null, the value 10 is assumed). Number is counted in units of lines, blocks, or characters, according to the appended option  $\mathbf{l}$ ,  $\mathbf{b}$ , or  $\mathbf{c}$ . When no units are specified, counting is by lines.

With the -f ("follow") option, if the input file is not a pipe, the program will not terminate after the line of the input file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input file. Thus it may be used to monitor the growth of a file that is being written by some other process.

### EXAMPLES

Tail accepts at most two arguments: the first consists of specified options, and the second specifies the file of interest. If the *number* and **f** options are both desired, they must be concatenated to create a single option argument, as follows:

tail -3lf john

This example prints the last three lines in the file john to the standard output, and leaves tail in "follow" mode.

If only the f option is desired, it must be preceded by a -, as follows:

tail -f fred

This example prints the last ten lines of the file *fred*, followed by any lines that are appended to *fred* between the time *tail* is initiated and killed. Note that this output may build up very quickly for rapidly changing input files, perhaps too fast to read on a CRT.

As another example, the command:

tail -15cf fred

will print the last 15 characters of the file fred, followed by any lines that are appended to fred between the time tail is initiated and killed.

The + option starts at the number indicated from the beginning of the file (rather than skipping the number of units indicated and then starting). For example:

tail +1b fred

prints the entire contents of the file fred.

## SEE ALSO

head(1).

## BUGS

Tails relative to the end of the file are stored in a buffer, and thus are limited in length. Thus, be wary of the results when piping output from other commands into tail.

Various kinds of anomalous behavior may happen with character special files.

Tail can pick up a maximum of 4K bytes of data from the specified file.

NAME

tar - tape file archiver

SYNOPSIS

tar [key] [ [file | -C directory ] ... ]

HP-UX COMPATIBILITY

Level:

HP-UX/DEVELOPMENT

Origin:

System III and UCB

Native Language Support:

8-bit filenames.

#### DESCRIPTION

Tar saves and restores files on magnetic tape or flexible disc. Its actions are controlled by the key argument. The key is a string of characters containing at most one function letter and possibly one or more function modifiers. The key string may be preceded by a dash (-) (similar to the way options are specified in other HP-UX commands), but it is not necessary. Other arguments to the command are files (or directory names) specifying which files are to be dumped or restored. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory.

The function portion of the key is specified by one of the following letters:

- The named files are added to the end of the archive. The c function implies this funcr
- $\mathbf{x}$ The named files are extracted from the archive. If a named file matches a directory whose contents had been written onto the archive, this directory is (recursively) extracted. If a named file on tape does not exist on the system, the file is created as follows:

The user, group, and other protections are restored from the tape.

The modification time is restored from the tape unless the m option is specified. The file owner and group owner are normally that of the restoring process.

The set-user-ID, set-group-ID and sticky bits are normally not set. The o and

p options control the restoration of protection; see below for more details.

If the files exist, their modes are not changed except that the set-user-ID, set-group-ID and sticky bits are cleared. If no files argument is given, the entire content of the archive is extracted. Note that if several files with the same name are on the archive, the last one overwrites all earlier ones.

- t The names of all the files on the archive are listed. Adding the v option will expand this listing to include the file modes and owner numbers. The names of all files are listed each time that they occur on the tape.
- The named files are added to the archive if they are not already there, or have been u modified since last written on that archive.
- C Create a new archive; writing begins at the beginning of the archive, instead of after the last file. This command implies the r function.

The following function modifiers may be used in addition to the function letters listed above:

- #s Where # is a tape drive number  $(0, \dots, 7)$ , and s is the density (1 - low (800 bpi), m medium (1600 bpi), or h - high (6250 bpi)). This modifier selects the drive on which the 9 track tape is mounted. The default is 0m.
- Normally, tar does its work silently. The v (verbose) option causes it to type the name of each file it treats, preceded by the function letter. With the t function, v gives more information about the tape entries than just the name.
- Causes tar to print the action to be taken, followed by the name of the file, and then w wait for the user's confirmation. If a word beginning with y is given, the action is performed. 'Any other input means "no".

f Causes tar to use the next argument as the name of the archive instead of /dev/rmt/??. If the name of the file is -, tar writes to the standard output or reads from the standard input, whichever is appropriate. Thus, tar can be used as the head or tail of a pipeline. Tar can also be used to move hierarchies with the command:

cd fromdir; tar cf - . | (cd todir; tar xf -)

- b Causes tar to use the next argument as the blocking factor for archive records. If both f and b modifiers are specified, their arguments must match the order in which they are specified. This option should only be used when a blocking factor other than 1 is desired. The default is 1 (512 bytes) and the maximum is 20. The block size is determined automatically when reading 9 track tapes (key letters x and t). The blocking factor must be specified when reading flexible discs and cartridge tapes if they were written with a blocking factor different than the default.
- Tells tar to complain if it cannot resolve all of the links to the files being dumped. If 1 is not specified, no error messages are printed.
- m Tells tar to not restore the modification time written on the archive. The modification time of the file will be the time of extraction.
- h Forces tar to follow symbolic links as if they were normal files or directories. Normally, tar does not follow symbolic links. Not all HP-UX systems support symbolic links.
- o For writing:

This option suppresses writing certain directory information that older versions of tar cannot handle on input. Tar normally writes information specifying owners and modes of directories in the archive. Former versions of tar, when encountering this information, will give error message of the form

"<name>/: cannot create".

This option will suppress writing that information.

#### For reading:

Causes extracted files to take on the user and group identifier of the user running the program rather than those on the tape. This is the default for the ordinary user, and may be overridden, to the extent the system protections allow, by the **p** option.

p This option causes files to be restored to the original modes and ownerships written on the archive, if possible. This is the default for the super-user, and may be overridden by the **o** option. For the ordinary used, if the system protections forbid the *chown*(2) operation needed to do this, the error will be ignored, and the ownership left with the restoring process. Set-user-ID, set-group-ID and sticky information will be restored as allowed by the protections defined by *chmod*(2), if the *chown* operation above succeeded.

The following option may be included in the file list:

-Cdirectory tar will perform a chdir(2) to directory. This allows multiple directories not related by a close common parent to be archived using short relative path names.

If a 9 track tape drive is used as the output device, it must be configured in Berkeley compatability mode; see mt(4).

### **EXAMPLES**

tar cvf /dev/rfd.0 file1 file2

This example creates a new archive on /dev/rfd.0 and copies file1 and file2 onto it, using a blocking factor of 20. The key is made up of one function letter (c) and two function modifiers (v, and f).

tar cv -C /usr include -C / etc

This example archives files from /usr/include and from /etc.

### FILES

/dev/rmt/\*

/dev/rfd.\* /tmp/tar\*

### SEE ALSO

ar(1), cpio(1), mt(4).

# DIAGNOSTICS

Complaints about bad key characters and tape read/write errors. Complaints if enough memory is not available to hold the link tables.

### BUGS

There is no way to ask for the n-th occurrence of a file.

Tape errors are handled ungracefully.

The **u** option can be slow.

If the archive is on a flexible disc or cartridge tape, and if the blocking factor specified on output was not the default, the same blocking factor must be specified on input. This is because the blocking factor is not explicitly stored on the archive. Not following this rule and updating the archive can destroy it.

The current limit on file-name length is 100 characters.

Some previous versions of tar have claimed to support selective listing of file names using the t option with a list. To our knowledge this was an error in the documentation and does not appear in the original source code.

There is no way to restore an absolute path name to a relative position.

Archives should never be created on block special devices (e.g., /dev/fd.o).

Tar always pads information written to an archive up to the next multiple of the block size. Therefore, if you are creating a small archive and write out one block of information, tar reports that one block was written, but the actual size of the archive may be larger if the **b** option was used.

Note that tar c0m is not the same as tar cm0.

TAR(1)

NAME

tbl - format tables for nroff

SYNOPSIS

tbl [ -TX ] [ files ]

HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Tbl is a preprocessor that formats tables for nroff(1). The input files are copied to the standard output, except for lines between .TS and .TE command lines, which are assumed to describe tables and are re-formatted by tbl. (The .TS and .TE command lines are not altered by tbl).

.TS is followed by global options. The available global options are:

center center the table (default is left-adjust);

expand make the table as wide as the current line length;

box enclose the table in a box;

doublebox

enclose the table in a double box;

allbox enclose each item of the table in a box;

tab(x) use the character x instead of a tab to separate items in a line of input data.

The global options, if any, are terminated with a semi-colon (;).

Next come lines describing the format of each line of the table. Each such format line describes one line of the actual table, except that the last format line (which must end with a period) describes all remaining lines of the table. Each column of each line of the table is described by a single key-letter, optionally followed by specifiers that determine the font and point size of the corresponding item, that indicate where vertical bars are to appear between columns, that determine column width, inter-column spacing, etc. The available key-letters are:

- **c** center item within the column;
- r right-adjust item within the column;
- l left-adjust item within the column;
- n numerically adjust item in the column: units positions of numbers are aligned vertically;
- s span previous item on the left into this column;
- a center longest line in this column and then left-adjust all other lines in this column with respect to that centered line;
- span down previous entry in this column;
- replace this entry with a horizontal line;
- = replace this entry with a double horizontal line.

The characters  ${\bf B}$  and  ${\bf I}$  stand for the bold and italic fonts, respectively; the character | indicates a vertical line between columns.

The format lines are followed by lines containing the actual data for the table, followed finally by .TE. Within such data lines, data items are normally separated by tab characters.

If a data line consists of only  $\_$  or =, a single or double line, respectively, is drawn across the table at that point; if a *single item* in a data line consists of only  $\_$  or =, then that item is replaced by a single or double line.

Full details of all these and other features of tbl are given in the reference manual cited below.

The -TX option forces tbl to use only full vertical line motions, making the output more suitable for devices that cannot generate partial vertical line motions (e.g., line printers).

TBL(1) TBL(1)

If no file names are given as arguments (or if - is specified as the last argument), tbl reads the standard input, so it may be used as a filter. When it is used with neqn(1), neqn, tbl should come first to minimize the volume of data passed through pipes.

### **EXAMPLE**

If we let <tab> represent a tab (which should be typed as a genuine tab), then the input:

```
center box;
cB s s
cI | cI s
^ | c c
l|nn.
Household Population
```

Town<tab>Households

<tab>Number<tab>Size

Bedminster<tab>789<tab>3.26 Bernards Twp.<tab>3087<tab>3.74 Bernardsville<tab>2018<tab>3.30 Bound Brook<ab>3425<ab>3.04

Bridgewater<tab>7897<tab>3.81

Far Hills<tab>240<tab>3.19

.TE

yields:

Household Population		
Town	Households	
	Number	Size
Bedminster	789	3.26
Bernards Twp.	3087	3.74
Bernardsville	2018	3.30
Bound Brook	3425	3.04
Bridgewater	7897	3.81
Far Hills	240	3.19

### BUGS

See BUGS under nroff(1).

#### NAME

tcio - Command Set 80 Cartridge Tape Utility

## SYNOPSIS

tcio -o[dervV] [-S buffersize ] [-l number ] [-n limit ] filename tcio -i[drv] [-S buffersize] [-l number] [-n limit] filename tcio -u[rvV] [-m blocknumber] [-l number] filename

#### HP-UX COMPATIBILITY

Level:

HP-UX/NON-STANDARD

Origin:

Remarks: Not supported on the Integral Personal Computer.

#### DESCRIPTION

Tcio is an effective utility for optimizing the data transfer rate between a cartridge tape unit and the host processor. When used in conjunction with other utilities such as cpio, a significant improvement in transfer efficiency results while simultaneously reducing wear and tear on tape cartridges. When used with autochanger mechanisms, tcio can load a specified cartridge or automatically switch to successive cartridges as needed. The tcio utility option supports functions that are unique to cartridge tape operations.

- (copy out) reads the standard input and writes the data to the raw CS/80 Cartridge Tape Unit associated with the special file filename.
- Tcio -i(copy in) reads from the CS/80 Cartridge Tape Unit associated with the special file filename in raw mode and writes the data to the standard output.
- (utility option) performs utility functions on the cartridge tape, such as release, mark, Tcio -uand/or verify the cartridge.

In all cases, filename must refer to a character (raw) special file associated with a CS/80 cartridge tape unit.

Trio input and output (read/write) operations enable immediate report which can yield a significant increase in the tape performance (see BACKGROUND INFORMATION in this section for details). In addition, tcio puts a tape mark in the first block on each tape to prevent the tape from being image restored over a disc. A flag is also placed in the last block on each tape to identify whether the tape is the last tape in a multiple-tape sequence.

The following command options are recognized. At least one option, -o, -i, or -u must be specified. Additional options can be specified in any order, but all must precede the file name. Options without parameters can be listed individually or grouped together. Options with parameters require the parameter, and must be listed individually. Available modifiers and their meanings are:

- -v Verbose mode; prints information and error messages to stderr.
- -d Prints a checksum to stderr. The checksum is a 32-bit unsigned addition of the bytes in the data stream, thus providing an extra data integrity check in addition to tape verification. The checksum value is reported to the user, but it is not written on the media. It is up to the user to manually record and verify it. The checksum is valid only if the same number of bytes are read from the tape as were written to it. This option is independent of the verbose
- -e Applies only to output operation, and causes a tape mark to be written on the nearest 1024byte boundary following the end of the data. When a tape containing an end-of-data tape mark is read back, the read terminates upon encountering the tape mark. When this option is used, checksums generated by corresponding input and output operations always agree.
- -V This option disables tape verification. Newer cartridge tape units using the HP 9144 drive provide hardware for verifying output data as it is written on the tape (called read-while-

write). This improves the integrity of recorded data as it is written on tape. HP 7908/11/12/14 drives do not have read-while-write verification hardware, so they require a separate verification operation after writing. This option should not be used with such units.

-r Releases the tape from the drive. On autochanger units, the tape is returned to the magazine.

## -S [ buffersize ]

Enables specification of buffer size. This option forces the allocation of a block of memory to be used in reading or writing the tape. The buffer size in bytes is 1024 times the value specified for buffersize. A buffersize less than 4 or greater than 512 causes the program to terminate. If buffersize is not specified, tcio allocates a 64-Kbyte buffer. On tape units such as an HP 9144A or 7942/6 that support immediate report, a significant performance increase can sometimes be obtained by using smaller buffer sizes. For instance, if tcio is used as part of a pipeline, an appropriate buffer size is 8 (see BACKGROUND INFORMATION for further details).

## -m [ blocknumber ]

This option writes a tape mark on a tape at the specified block. If a tape is created by some means other than tcio, a tape mark in block 0 of the tape prevents it from being image restored to a disc.

### -l [number]

Autochanger mode: This option is intended solely for autochanger type tape units (such as the HP 35401). During input or output operations (-i or -o) the autochanger option automatically selects the target cartridge from the magazine and begins the transfer. When utility function are used instead, (-u option) tcio loads the specified cartridge into the drive, but performs no read/write operations. (Note: the autochanger must be in selective mode for the autochanger option to work properly.)

## -**n** [ limit ]

Applies only to autochanger units, and must be preceded by the -1 option. This option specifies the maximum number of cartridges to be used in a multi-tape transfer. Thus, -1 starts the transfer by loading cartridge number and uses at most limit cartridges. If -1 is specified without  $-\mathbf{n}$ , toio quietly assumes the remaining cartridges (in ascending order) from the magazine.

### HARDWARE DEPENDENCIES

Due to I/O software architecture, a buffersize greater than 64 provides no increase in performance, but merely ties up system memory. Thus, the default buffersize is 64. If buffersize is specified greater than 64, it is silently truncated back to 64.

# BACKGROUND INFORMATION

Tcio enables immediate report on cartridge tape units that support this mode (such as the HP 9144A, HP 7942/6, and HP 35401). Thus, the drive is able to return status before it completes writing data to the tape, allowing the host to send (or receive) data to the drive's buffer while the drive is simultaneously transferring data from the drive to the tape. If the host is able to transfer data to (or from) the tape unit fast enough (so the drive does not need to reposition the tape between requests) the tape is said to stream. Streaming dramatically increases tape drive read/write data rates.

Two basic strategies are available to the user. If the —S option is not specified, teio uses as large a buffer as possible. The tape streams within the large transaction, but must reposition itself between successive requests (this strategy is recommended for the HP 7942/6 when transferring data between disk and tape). An alternate strategy is to use small buffers which can allow continuous streaming. Continuous streaming is more efficient, provided the drive's timing requirements are met. Use of small buffers minimizes the time necessary for the host to refill the drive's buffer. When reading or writing more than 8 Kbytes to a pipe, a small additional overhead is incurred. Thus, when tcio is used as part of a pipeline, a buffersize of 8 is recommended. This

alternate strategy for continuous streaming is sensitive to competing HP-IB activity.

#### EXAMPLES

The first example below copies the contents of a directory into an archive; the second restores it:

ls | cpio 
$$-o$$
 | tcio  $-o$  /dev/rct

To unload the cartridge from the drive without verifying the tape, execute:

This example copies all files in the current directory (by executing find) to the tape specified by the device file /dev/rct. A checksum (option -d) is performed to verify that the data was written correctly on the tape, and verbose mode (-v) is used so you can see the names of all files being copied. In addition, a buffer size (option -S) of 8 blocks (i.e. 8 Kbytes) is specified:

The next example assumes that the cartridge tape unit is an autochanger, with 8 slots in the magazine. The device has a read after write head, so verify is disabled. The tcio operation will start writing with cartridge 3, and will use at most 4 cartridges before prompting for additional media:

The following example copies all the files and directories from the tape (specified by /dev/rct) to the current directory. Data is transferred through an 8-block buffer.

The  $\mathbf{r}$  flag in this example releases the tape *after* upon completion of the transfer.

## SEE ALSO

cpio(1).

### BUGS

If the cartridge drive cannot read the manufacturer's block on the tape, the cartridge is locked in the drive and it cannot be extracted without removing power from the disc/tape drive. This failure is usually caused by faulty tape or a dirty drive mechanism.

#### NAME

tcio - Command Set 80 Cartridge Tape Utility

#### SYNOPSIS

```
/etc/tcio -o [ dervSVC ] [ buffersize ] filename
/etc/tcio -i [ drvS ] [ buffersize ] filename
/etc/tcio -u [ cmrvV ] [ blocknumber ] [ save | restore ] filename [ disc_filename ]
```

### HP-UX COMPATIBILITY

Level: HP-UX/NON-STANDARD

Origin: HI

Remarks: T

s: This manual page describes the Series 500 implementation only. See other manual

page for Series 200/300 implementation. Not supported on the Integral Personal Com-

puter.

#### DESCRIPTION

Tcio -o (copy out) reads the standard input and writes the data to the raw Command Set 80 Cartridge Tape Unit specified by filename.

 $Tcio\ -i$  (copy in) reads the Command Set 80 Cartridge Tape Unit specified by filename in raw mode and writes the data to the standard output.

Tcio -u (utility) performs utility functions on the cartridge tape, such as image backup and restore, release, mark, and/or verify cartridge.

In all cases, filename MUST refer to a character special file associated with a Command Set 80 cartridge tape unit.

With the output and input operations, *tcio* utilizes a large buffer to transfer data to/from the cartridge tape, yielding a significant increase in performance, as well as a savings in wear and tear on the media and the mechanism. In addition, *tcio* puts a tape mark in the first block on each tape to prevent the tape from being image restored over a disc; it also utilizes the last block on each tape to flag whether the tape is the last tape in a multi-tape sequence or not.

With the utility operation, tcio provides functions that are unique to cartridge tapes.

One of the options o, i, or u must be specified. The meanings of the available modifiers are:

- v Verbose mode; prints information and error messages to stderr.
- d Prints a checksum to stderr. The checksum is a 32-bit unsigned addition of the bytes, providing an extra check of the validity of the tape in addition to tape verification. The value is only reported to the user and is not written on the media; thus, it's left up to the user to manually record and check it. The checksum is valid only for the i and o operations, and if the same number of bytes are read from the tape as were written to it. This option is independent of the verbose modifier.
- e Applies only to the output operation, and causes a tape mark to be written on the nearest 1024-byte boundary following the end of the data. When a tape containing an end-of-data tape mark is read back, the read will terminate upon encountering the tape mark. Thus, with the use of this option, the checksums generated by the input and output operations are guaranteed to agree.
- S Enables specification of buffer size. This option forces the allocation of a block of memory to be used in reading or writing the tape. The size in bytes of the buffer is 1024 times the value specified for buffersize. A buffersize less than 32 or greater than 512 will cause the program to terminate. If buffersize is not specified, tcio will attempt to allocate buffer sizes in powers of 2 from 512 down to 64, taking the largest one possible. The primary uses of this option are to allow buffer sizes smaller than 64 Kbytes, and to allow the user to pick a buffer size that is most suitable for his application.

- V This option turns off tape verification. It is suggested that this option not be used, for the sake of the integrity of the data output to tape.
- m This option writes a tape mark on a tape at the specified block. If a tape is created by some other means than *tcio*, a tape mark in block 0 of the tape will prevent it from being image restored to a disc. Note that *blocknumber* must be specified.
- r Releases the tape from the mechanism, unlocking the door.
- c Image copy option. Provides the same capability as the push-button save and restore available in the HP 79XX single controller drive. The save and restore keywords are the same as the labels on those switches. Save implies disc to tape; restore implies tape to disc. Currently only single controller disc/tape units can be backed up in this way.
- C Check read option. Provides a measure of data security not found in the tape verification or check digit options. Check read requires two I/O buffers of the size indicated by buffersize, one for writing and one for reading. The data in the first buffer is written to the tape. Then the tape is backspaced and read into the second buffer. The two buffers are then compared. If a difference occurs, tcio reports the error and terminates. This option forces no tape verification. Note that this option promotes wear and tear on both the media and the drive, and should only be used when complete assurance of the data's integrity is required.

#### HARDWARE DEPENDENCIES

In general, tapes which have any tape marks other than in the first or the last block cannot be read successfully.

The **e** option is not supported, and because of the above restriction, tapes which have been written under the **e** option cannot be read successfully.

### EXAMPLES

The first example below copies the contents of a directory into an archive; the second restores it:

```
ls | cpio -o | tcio -o /dev/rct
tcio -i /dev/rct | cpio -i
```

The next example copies all files in the current directory (via executing find) to the tape specified by the device file /dev/rct; a checksum (option -d) is performed to verify that the write to tape was performed correctly; verbose mode (-v) is used so that you can see the file names of files being copied; in addition, a buffer size (option -S) is specified at 128 memory blocks:

The following example copies all the files and directories from the tape (specified by /dev/rct) to the current directory; the data is transferred through a 128-block buffer. Note that with the *cpio* command, the wildcard character \* is inclosed in double quotes "\*"; this must be done so that the shell doesn't expand the \* to all the files in the current directory—i.e., you want the \* to be interpreted as all the files on the tape, not your current directory. Here is the command:

tcio -ivS 128 /dev/rct |cpio -icdvu "\*"

#### SEE ALSO

cpio(1).

#### WARNING

To be able to use the save/restore facility, the following two conditions must be met:

your system must be in single-user mode;

you must never have used networking on your system. If networking has been used on your system, you must reboot the system before using the save/restore facility.

Tcio can tie up substantial portions of memory, creating a situation where progress on other processes (including those processes feeding tcio) is hindered. If this should occur, it is best to kill

tcio and re-execute using a smaller buffersize. This problem is especially acute when using the C option, because two buffers are required.

## **BUGS**

If the cartridge drive cannot read the manufacturer's block on the tape, the cartridge is locked in the drive and cannot be extracted without turning off the disc/tape drive. This failure is usually the result of faulty tapes or a dirty drive mechanism.

Hewlett-Packard - 3 - November 15, 1985

TEE(1)

## NAME

tee - pipe fitting

## SYNOPSIS

tee [-i][-a][file]...

# HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System V

Native Language Support:

8-bit data.

## DESCRIPTION

Tee transcribes the standard input to the standard output and makes copies in the files. The -i option ignores interrupts; the -a option causes the output to be appended to the files rather than overwriting them.

TEST(1) TEST(1)

#### NAME

test, [ - condition evaluation command

### SYNOPSIS

test expr

#### HP-UX COMPATIBILITY

Level: H

HP-UX/NUCLEUS

Origin: System III

### DESCRIPTION

Test evaluates the expression expr and, if its value is true, returns a zero (true) exit status; otherwise, a non-zero (false) exit status is returned; test also returns a non-zero exit status if there are no arguments. The following primitives are used to construct expr:

-r file true if file exists and is readable.

-w file true if file exists and is writable.

-x file true if file exists and is executable.

**-f** *file* true if *file* exists and is a regular file.

**-d** *file* true if *file* exists and is a directory.

-c file true if file exists and is a character special file.

-b file true if file exists and is a block special file.

-p file true if file exists and is a named pipe (fifo).

-u file true if file exists and its set-user-ID bit is set.

**-g** file true if file exists and its set-group-ID bit is set.

-k file true if file exists and its sticky bit is set.

-s file true if file exists and has a size greater than zero.

-t [ fildes ] true if the open file whose file descriptor number is fildes (1 by default) is associated with a terminal device.

-z s1 true if the length of string s1 is zero.

-n s1 true if the length of the string s1 is non-zero.

s1 = s2 true if strings s1 and s2 are identical.

s1 != s2 true if strings s1 and s2 are not identical.

s1 true if s1 is not the null string.

n1 -eq n2 true if the integers n1 and n2 are algebraically equal. Any of the comparisons -ne, -gt, -ge, -lt, and -le may be used in place of -eq.

These primaries may be combined with the following operators:

! unary negation operator.

-a binary and operator.

**-o** binary *or* operator (**-a** has higher precedence than **-o**).

( expr ) parentheses for grouping.

Notice that all the operators and flags are separate arguments to *test*. Notice also that parentheses are meaningful to the shell and, therefore, must be escaped.

TEST(1) TEST(1)

Test is directly interpreted by the shell.

## SEE ALSO

eval(1) (see sh(1)), find(1), sh(1).

## WARNING

In the second form of the command (i.e., the one that uses [], rather than the word test), the square brackets must be delimited by blanks.

The second form of the command ([]) is not recognized by csh.

TIME(1)

#### NAME

time - time a command

## SYNOPSIS

time command

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

## DESCRIPTION

The *command* is executed; after it is complete, *time* prints the elapsed time during the command, the time spent in the system, and the time spent in execution of the command. Times are reported in seconds.

The execution time can depend on the performance of the memory in which the program is running.

The times are printed on standard error.

## HARDWARE DEPENDENCIES

Series 500:

For those computers with multiple CPU's, the child CPU times listed may be greater than the actual real elapsed time, since CPU time is counted on a per-CPU basis. Thus, if three CPUs are executing, the times listed are obtained by adding the execution times of each CPU.

## SEE ALSO

times command in sh(1), times(1), times(2).

TOUCH(1) TOUCH(1)

### NAME

touch - update access, modification, and/or change times of file

#### SYNOPSIS

touch [ -amc ] [ mmddhhmm[yy] ] files

# HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System V

### DESCRIPTION

Touch causes the access, modification, and last change times of each argument to be updated. The file name is created if it does not exist. If no time is specified (see date(1)) the current time is used. The -a and -m options cause touch to update only the access or modification times respectively (default is -am). The -c option silently prevents touch from creating the file if it did not previously exist.

The return code from *touch* is the number of files for which the times could not be successfully modified (including files that did not exist and were not created).

## SEE ALSO

date(1), utime(2).

-1-

TPUT(1) TPUT(1)

#### NAME

tput - query terminfo database

### SYNOPSIS

tput [-Ttype] capname

### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

### DESCRIPTION

Tput uses the terminfo(5) database to make terminal-dependent capabilities and information available to the shell. Tput outputs a string if the attribute (capability name) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, tput simply sets the exit code (0 for TRUE, 1 for FALSE), and does no output.

 $-\mathbf{T}type$ 

indicates the type of terminal. Normally this flag is unnecessary, as the default is taken from the environment variable \$TERM.

Capnameindicates the attribute from the terminfo database. See terminfo (5).

### **EXAMPLES**

tput clear tput cols

Echo clear-screen sequence for the current terminal. Print the number of columns for the current terminal.

tput -Thp2623 cols

Print the number of columns for the hp2623 terminal.

bold='tput smso' Set shell variable "bold" to stand-out mode sequence for current terminal.

This might be followed by a prompt: echo "\${bold}Please type in your name: \c"

tput hc

Set exit code to indicate if current terminal is a hardcopy terminal.

## FILES

/usr/lib/terminfo/?/\*

Terminal descriptor files

/usr/include/term.h

Definition files

/usr/include/curses.h

## DIAGNOSTICS

Tput prints error messages and returns the following error codes on error:

Usage error. -1

-2

Bad terminal type.

-3

Bad capname.

In addition, if a capname is requested for a terminal that has no value for that capname (e.g., tput -T450 lines), -1 is printed.

#### SEE ALSO

stty(1), terminfo(5).

#### NAME

tr - translate characters

#### SYNOPSIS

tr [ -cds ] [ string1 [ string2 ] ]

### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

## DESCRIPTION

Tr copies the standard input to the standard output with substitution or deletion of selected characters. Input characters found in *string1* are mapped into the corresponding characters of *string2*. Any combination of the options **-cds** may be used:

- -c Complements the set of characters in string1 with respect to the universe of characters whose ASCII codes are 001 through 377 octal.
- -d Deletes all input characters in string1.
- -s Squeezes all strings of repeated output characters that are in string2 to single characters.

The following abbreviation conventions may be used to introduce ranges of characters or repeated characters into the strings:

- [a-z] Stands for the string of characters whose ASCII codes run from character a to character z. inclusive.
- [a\*n] Stands for n repetitions of a. If the first digit of n is 0, n is considered octal; otherwise, n is taken to be decimal. A zero or missing n is taken to be huge; this facility is useful for padding string?.

The escape character  $\setminus$  may be used as in the shell to remove special meaning from any character in a string. In addition,  $\setminus$  followed by 1, 2, or 3 octal digits stands for the character whose ASCII code is given by those digits.

## EXAMPLE

The following creates a list of all the words in *file1* one per line in *file2*, where a word is taken to be a maximal string of alphabetics. The strings are quoted to protect the special characters from interpretation by the shell; 012 is the ASCII code for newline.

tr -cs "[A-Z][a-z]" "[
$$\012*$$
]" file2

#### SEE ALSO

ed(1), sh(1), ascii(7).

#### BUGS

Will not handle ASCII NUL in string1 or string2; always deletes NUL from input.

-1-

TRUE(1) TRUE(1)

NAME

true, false - provide truth values

SYNOPSIS

true

false

## HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System V

# DESCRIPTION

True does nothing, successfully. False does nothing, unsuccessfully. They are typically used in input to sh(1) such as:

while true

do

command

done

### SEE ALSO

machid(1), sh(1).

# DIAGNOSTICS

True has exit status zero, false nonzero.

TSET(1) TSET(1)

#### NAME

tset - terminal dependent initialization

### SYNOPSIS

```
 \begin{tabular}{ll} \bf tset \ [ \ options \ ] \ [ \ -m \ [ \ ident \ ] \ [ \ test \ baudrate \ ] : type \ ] \ ... \ [ \ type \ ] \\  \ reset \ ... \end{tabular}
```

### HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: UCE

Tset sets up your terminal when you first log in to an HP-UX system. It does terminal-dependent processing such as setting erase and kill characters, setting or resetting delays, and sending any sequences needed to properly initialize the terminal. It first determines the type of terminal involved, then performs the necessary initializations and mode settings. The type of terminal attached to each HP-UX port is specified in the /etc/ttytype data base. Type names for terminals are stored in the /usr/lib/terminfo/?/\* data base. If a port is not hardwired directly to a specific terminal (thus considered a modem connection), it is given an appropriate generic identifier, such as dialup.

In the case where no arguments are specified, *tset* simply reads the terminal type out of the environment variable TERM and re-initializes the terminal. The rest of this manual entry concerns itself with mode and environment initialization, typically done once at login, and options used at initialization time to determine the terminal type and set up terminal modes.

When used in a startup script (.profile for sh(1) users, or .login for csh(1) users) it is desirable to give information about the type of terminal you will usually use on ports which are not hardwired. These ports are identified in /etc/ttytype as dialup or plugboard, etc. To specify what terminal type you usually use on these ports, the -m (map) option flag is followed by the appropriate port type identifier, an optional band rate specification, and the terminal type. (The effect is to "map" from some conditions to a terminal type, that is, to tell tset, "If I'm on this kind of port, then I'll probably be on this kind of terminal".) If more than one mapping is specified, the first applicable mapping prevails. A missing port type identifier matches all identifiers. A bandrate is specified as with sty(1), and is compared with the speed of the diagnostic output (which should be the control terminal). The band rate test may be any combination of >, =, <, @, and !; @ is a synonym for = and ! inverts the sense of the test. To avoid problems with metacharacters, it is best to place the entire argument to -m within single quotes; users of csh(1) must also put a "\" before any "!" used.

Thus,

```
tset -m 'dialup>300:2622' -m 'dialup:2624' -m 'plugboard:?2623'
```

causes the terminal type to be set to an HP 2622 if the port in use is a dialup at a speed greater than 300 baud, or to an HP 2624 if the port is otherwise a dialup (i.e. at 300 baud or less). If the type finally determined by tset begins with a question mark, the user is asked if he or she really wants that type. A null response means to use that type; otherwise, another type can be entered. Thus, in the above case, if the user is on a plugboard port, he or she will be asked whether or not he or she is actually using an HP 2623.

If no mapping applies and a final type option, not preceded by a -m, is given on the command line, then that type is used. Otherwise, the identifier found in the /etc/ttytype data base will be taken to be the terminal type. The latter should always be the case for hardwired ports.

It is usually desirable to return the terminal type, as finally determined by tset, and information about the terminal's capabilities to a shell's environment. This can be done using the -s option. Using the Bourne shell (sh(1)), the command

eval `tset -s options...`

Hewlett-Packard - 1 - November 15, 1985

TSET(1)

or using the C shell, csh(1):

```
set noglob; eval `tset -s options...`
```

These commands cause tset to generate as output a sequence of shell commands which place the variable TERM in the environment; see environ(5).

Once the terminal type is known, *tset* engages in terminal mode setting. This normally involves sending an initialization sequence to the terminal, setting the single character erase (and optionally the full line erase or line-kill) characters, and setting special character delays. Tab and new-line expansion are turned off during transmission of the terminal initialization sequence.

On terminals that can backspace but not overstrike (such as a CRT), and when the erase character is the default erase character ("#" on standard systems), the erase character is changed to BACKSPACE (^H).

The options are:

- -ec sets the erase character to be the named character c; c defaults to  $^{\circ}H$  (BACKSPACE). The character c can either be typed directly, or entered using the "hat" notation used here (e.g. the "hat" notation for control-H is  $^{\circ}H$ ; in sh(1), the  $^{\circ}$  character should be escaped ( $^{\circ}$ )).
- $-\mathbf{k}c$  sets the kill character to c. The default c is  $^{\circ}X$ . If c is not specified, the kill character will remain unchanged unless the original value of the kill character is null. In this case, the kill character is set to an "at" sign (@).
- report terminal type. Whatever type is decided on is reported. If no other flags are given, the only effect is to write the terminal type on the standard output.
- -s generates appropriate commands (depending on your SHELL environment variable) to set TERM.
- -I suppresses transmitting terminal initialization strings.
- -Q suppresses printing the "Erase set to" and "Kill set to" messages.
- **−A** asks the user for the TERM type.
- -S Outputs the string that would be assigned to TERM in the environment rather than generating commands for a shell. In sh(1), the following is an alternate way of setting TERM.

```
set -- `tset -S ...`
TERM=$1
```

For compatibility with earlier versions of *tset*, the following flags are accepted, but their use is discouraged:

- -r report to the user in addition to other flags.
- $-\mathbf{E}c$  sets the erase character to c only if the terminal can backspace. C defaults to  $\hat{H}$ .

#### **EXAMPLES**

These examples all assume the Bourne shell (sh(1)). Note that a typical use of *tset* in a *.profile* will also use the  $-\mathbf{e}$  and  $-\mathbf{k}$  options, and often the  $-\mathbf{n}$  or  $-\mathbf{Q}$  options as well. These options have not been included here to keep the examples small.

Assume, for the moment, that you are on an HP 2622. This is suitable for typing by hand but not for a .profile, unless you are always on a 2622.

```
export TERM; TERM=`tset - 2622`
```

Now, you have an HP 2623 at home which you dial up on, but your office terminal is hardwired and known in /etc/ttytype.

Hewlett-Packard - 2 - November 15, 1985

TSET(1) TSET(1)

```
export TERM: TERM=`tset - -m dialup:2623`
```

You have a switch which connects everything to everything, making it nearly impossible to key on what port you are coming in on. You use an HP 2622 in your office at 9600 baud, and dial up to switch ports at 1200 baud from home on an HP 2623. Sometimes you use someone else's terminal at work, so you want it to ask you to make sure what terminal type you have at high speeds, but at 1200 baud you are always on a 2623. Note the placement of the question mark, and the quotes to protect the > and? from interpretation by the shell.

```
export TERM; TERM=`tset - -m 'switch>1200:?2622' -m 'switch<=1200:2623'`
```

All of the above entries will fall back on the terminal type specified in /etc/ttytype if none of the conditions hold. The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals. Your most common terminal is an HP 2622. It always asks you what kind of terminal you are on, defaulting to 2622.

```
export TERM; TERM=`tset - ?2622`
```

If the file /etc/ttytype is not properly installed and you want to key entirely on the baud rate, the following can be used:

```
export TERM; TERM=`tset - -m '>1200:2624' 2622`
```

### FILES

```
/etc/ttytype port name to terminal type mapping data base; /usr/lib/terminfo/?/* terminal information data base.
```

#### VARIABLES

SHELL if "csh" then generate csh(1) commands, otherwise generate sh(1) commands. TERM the (canonical) terminal name.

#### SEE ALSO

```
csh(1), sh(1), stty(1), ttytype(5), terminfo(5), environ(7).
```

TSORT(1) TSORT(1)

### NAME

tsort - topological sort

## **SYNOPSIS**

tsort [ file ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

## DESCRIPTION

Tsort produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input file. If no file is specified, the standard input is understood.

The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.

## SEE ALSO

lorder(1).

## DIAGNOSTICS

Odd data: there is an odd number of fields in the input file.

### BUGS

Uses a quadratic algorithm; not worth fixing for the typical use of ordering a library archive file.

TTY(1)

### NAME

tty - get the name of the terminal

## SYNOPSIS

tty [ -s ]

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

## DESCRIPTION

Tty prints the path name of the user's terminal. The -s option inhibits printing of the terminal path name, allowing one to test just the exit code.

## RETURN VALUE

- 0 if standard input is a terminal,
- 1 otherwise.
- 2 if invalid options were specified,

## DIAGNOSTICS

"not a tty" if the standard input is not a terminal and -s is not specified.

July 2, 1985

 $\mathrm{UL}(1)$ 

#### NAME

ul - do underlining

### SYNOPSIS

```
ul [-i] [-t terminal] [name ...]
```

# HP-UX COMPATIBILITY

Level: HP-UX/STANDARD

Origin: UCB

### DESCRIPTION

Ul reads the named files (or standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable **TERM**. The **-t** option overrides the terminal kind specified in the environment. The terminfo(5) file corresponding to **TERM** is read to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout, mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to cat(1). If the terminal cannot underline, underlining is ignored.

The -i option causes *ul* to indicate underlining on a separate line containing appropriate dashes '-'; this is useful when you want to look at the underlining which is present in an *nroff* output stream on a CRT.

### FILES

/usr/lib/terminfo/?/\* terminal capability files

### SEE ALSO

man(1), nroff(1).

### BUGS

*Nroff* usually outputs a series of backspaces and underlines intermixed with the text to indicate underlining. No attempt is made to optimize the backward motion.

UMASK(1) UMASK(1)

## NAME

umask - set file-creation mode mask

## SYNOPSIS

umask [ ooo ]

### HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin:

System III

Remarks: Not supported on the Integral Personal Computer.

# DESCRIPTION

The user file-creation mode mask is set to ooo. The three octal digits refer to read/write/execute permissions for owner, group, and others, respectively (see chmod(2) and umask(2)). The value of each specified digit is subtracted from the corresponding "digit" specified by the system for the creation of a file (see creat(2)). For example, umask 022 causes files to be created without write permission for group or other. (files normally created with mode 777 become mode 755; files created with mode 666 become mode 644). Existing files are not affected.

If ooo is omitted, the current value of the mask is printed with four octal digits. The first digit, a zero, specifies that the output is expressed in octal.

Umask is recognized and executed by the shell.

Note that the file creation mask does not affect the set-user-ID, set-group-ID, or "sticky" bits.

#### SEE ALSO

 $\operatorname{chmod}(1)$ ,  $\operatorname{sh}(1)$ ,  $\operatorname{chmod}(2)$ ,  $\operatorname{creat}(2)$ ,  $\operatorname{umask}(2)$ .

UNAME(1) UNAME(1)

## NAME

uname - print name of current HP-UX version

## SYNOPSIS

uname [ -snrvmia ]

## HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin: System V

### DESCRIPTION

*Uname* prints the current system name of the HP-UX system on the standard output file. It is mainly useful to determine which system one is using. The options cause selected information returned by *uname*(2) to be printed:

- -s print the system name (default).
- -n print the nodename (the nodename may be a name that the system is known by on a communications network). (e.g. uucp).
- -r print the operating system release.
- -v print the operating system version.
- -m print the machine hardware name.
- -i print the machine identification number.
- -a print all the above information.

## SEE ALSO

hostname(1), gethostname(2), sethostname(2), uname(2).

## BUGS

The -i option reports the nodename if and only if the machine has no promid.

UNGET(1) UNGET(1)

#### NAME

unget - undo a previous get of an SCCS file

#### SYNOPSIS

unget [-rSID] [-s] [-n] files

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

### DESCRIPTION

Unget undoes the effect of a **get** -e done prior to creating the intended new delta. If a directory is named, unget behaves as though each file in the directory were specified as a named file, except that non-SCCS files and unreadable files are silently ignored. If a name of - is given, the standard input is read with each line being taken as the name of an SCCS file to be processed. Refer to sact(1), which describes how to determine what deltas are currently binding for an s-file.

Keyletter arguments apply independently to each named file.

-rSID

Uniquely identifies which delta is no longer intended. (This would have been specified by *get* as the "new delta"). The use of this keyletter is necessary only if two or more outstanding *gets* for editing on the same SCCS file were done by the same person (login name). A diagnostic results if the specified *SID* is ambiguous, or if it is necessary and omitted on the command line (see sact(1)).

-s

Suppresses the printout, on the standard output, of the intended delta's SID.

-n

Causes the retention of the gotten file which would normally be removed from the current directory.

Note: unget can only be executed by the user who did the corresponding get -e. If a system administrator needs to unget a get -e done by another user, he must either use su(1) to change into that user, or edit the p-file directly (which can be done either by the s-file owner of the super-user).

### FILES

```
p-file see delta(1).
g-file see delta(1).
```

## SEE ALSO

```
delta(1), get(1), help(1), sact(1).
```

### DIAGNOSTICS

Use help(1) for explanations.

UNIQ(1)

#### NAME

uniq - report repeated lines in a file

## SYNOPSIS

uniq [ -udc [ +n ] [ -n ] ] [ input [ output ] ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Native Language Support:

8-bit data, customs, messages.

## DESCRIPTION

Uniq reads the input file comparing adjacent lines. In the normal case, the second and succeeding copies of repeated lines are removed; the remainder is written on the output file. Input and output should always be different. Note that repeated lines must be adjacent in order to be found; see sort(1). If the -u flag is used, just the lines that are not repeated in the original file are output. The -d option specifies that one copy of just the repeated lines is to be written. The normal mode output is the union of the -u and -d mode outputs.

The -c option supersedes -u and -d and generates an output report in default style but with each line preceded by a count of the number of times it occurred.

The n arguments specify skipping an initial portion of each line in the comparison:

- -n The first n fields together with any blanks before each are ignored. A field is defined as a string of non-space, non-tab characters separated by tabs and spaces from its neighbors.
- +n The first n characters are ignored. Fields are skipped before characters.

## SEE ALSO

comm(1), sort(1).

UNITS(1) UNITS(1)

#### NAME

units - conversion program

#### SYNOPSIS

units

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Remarks: Not supported on the Integral Personal Computer.

#### DESCRIPTION

*Units* converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:

```
You have: inch
You want: cm
* 2.540000e+00
/ 3.937008e-01
```

A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, and division by the usual sign:

```
You have: 15 lbs force/in2
You want: atm
* 1.020689e+00
/ 9.797299e-01
```

*Units* only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:

```
pi ratio of circumference to diameter
```

c speed of light

e charge on an electron

acceleration of gravity

force same as g,

mole Avogadro's number,water pressure head per unit height of water,

au astronomical unit.

**Pound** is not recognized as a unit of mass; **lb** is. Compound names are run together, (e.g., **lightyear**). British units that differ from their U.S. counterparts are prefixed thus: **brgallon**. For a complete list of units, type:

cat /usr/lib/unittab

## FILES

/usr/lib/unittab

#### BUGS

units(1) expects the singular form of each unit to be entered, but will attempt to form the singular by deleting a trailing "s" if the singular form is not found. Thus, some plurals will be correctly recognized, while others will not.

#### NAME

upm - unpack cpio archives from HP media

### SYNOPSIS

upm -E [ cdmtuvx ] pathname chardevice [ patterns ] upm -iM [ cdmtuvx ] [ patterns ] </dev/rmf?

## HP-UX COMPATIBILITY

Level:

HP-UX/NON-STANDARD

Origin:

Remarks: *Upm* is implemented on the Series 500 only.

#### DESCRIPTION

Upm is similar to cpio(1), and is included to enable you to restore files from 88140L/S tape cartridges or 5.25-inch flexible discs more efficiently.

Upm -E (copy in from tape cartridge) extracts all files specified by patterns from the file named by pathname (assumed to be the product of a previous cpio -o). Patterns is a series of zero or more blank-separated character strings given in the name-generating notation of sh(1). Note that the metacharacters?, \*, and [...] match the slash (/) when used in patterns. The default pattern is '\*', which selects all files. Chardevice identifies the character special device file describing the volume containing pathname. (Note that, if this volume is not the root, it must be mounted at the time upm is used, and pathname must include the directory name on which the volume is mounted.)

Upm -iM (copy in) extracts all files selected by zero or more of the specified patterns (see above for a description of patterns). The files are extracted from the standard input, which is redirected from a raw miniature flexible disc device /dev/rmf?. The resulting standard input is assumed to be the product of a previous cpio -o.

Any other options specified must be concatenated with the initial E or iM options. The options have the following meanings:

- read header information which was previously written in ASCII character form for portability;
- directories are to be created as needed:
- m retain previous file modification time. This option is ineffective on directories that are being
- print a table of contents of the input; no files are created;
- copy unconditionally (normally, an older file will not replace a newer file with the same
- verbose; causes a list of file names to be printed. When used with the t option, the table of contents looks like the output of an ls -l command (see ls(1));
- restore device special files; mknod(2) is used to recreate these files, and thus  $-\mathbf{E}\mathbf{x}$  or  $-\mathbf{i}\mathbf{M}\mathbf{x}$  can only be used by the super-user. Restoring device files onto a different system can be very dangerous. This is intended for backup use;

When the end of a volume is reached, upm will prompt the user for the next flexible disc and con-

The number of blocks reported by upm is always in units of 512-byte blocks, regardless of the block size of the initialized media.

### SEE ALSO

cpio(1), tcio(1), mknod(2).

## WARNING

The -B option must not be used when performing raw I/O using the HP 9130K miniature flexible disc drive.

# BUGS

Only the super-user can copy special files.

If /dev/tty is not accessible, upm issues a complaint, or refuses to work.

The -Edr and -iMdr options will not make empty directories.

UUCP(1C) UUCP(1C)

### NAME

uucp, uulog, uuname - HP-UX system to HP-UX system copy

## SYNOPSIS

```
uucp [ options ] source-files destination-file
uulog [ options ]
uuname [ -l ] [ -v ]
```

## HP-UX COMPATIBILITY

Level: HP-U

HP-UX/STANDARD

Origin: System V

## DESCRIPTION

Uucp.

*Uucp* copies files named by the *source-file* arguments to the *destination-file* argument. A file name may be a path name on your machine, or may have the form:

system-name!path-name

where system-name is taken from a list of system names which uucp knows about. The system-name may also be a list of names such as

system-name!system-name!...!system-name!path-name

in which case an attempt is made to send the file via the specified route, and only to a destination in PUBDIR (see below). Care should be taken to insure that intermediate nodes in the route are willing to foward information.

The shell metacharacters ?, \* and [...] appearing in path-name will be expanded on the appropriate system.

Path names may be one of:

- (1) a full path name;
- (2) a path name preceded by ~user where user is a login name on the specified system and is replaced by that user's login directory;
- (3) a path name preceded by ~/user where user is a login name on the specified system and is replaced by that user's directory under PUBDIR (see FILES);
- (4) anything else is prefixed by the current directory.

The local and remote system access to the path name is specified in the USERFILE. If the result is an erroneous path name for the remote system the copy will fail. If the *destination-file* is a directory, the last part of the *source-file* name is used. The accessibility of the file or path name is specified in USERFILE.

*Uucp* preserves execute permissions across the transmission and gives 0666 read and write permissions (see chmod(2)).

The following options are interpreted by *uucp*:

- -d Make all necessary directories for the file copy (default).
- -f Do not make intermediate directories for the file copy.
- -c Use the source file when copying out rather than copying the file to the spool directory (default).
- -C Copy the source file to the spool directory immediately and use the copy.
- -mfile Report status of the transfer in file. If file is omitted, send mail to the requester when the copy is completed.

UUCP(1C) UUCP(1C)

- -nuser Notify user on the remote system that a file was sent.
- -esys Send the uucp command to system sys to be executed there. (Note: this will only be successful if the remote machine allows the uucp command to be executed by /usr/lib/uucp/uuxqt.)

#### -ggrade

Request grade as a priority for the work sequencing. Grades are specified in the order A - Z, a - z, with A specifying that the work should be done first, and z specifying that the work should be done last. All other grades specify a sequence somewhere in between. The default is  $\mathbf{n}$ .

- -r Queue job but do not start the file transfer process. By default a file transfer process is started each time uucp is evoked.
- -j Control writing of the *uucp* job number to standard output (see below).

*Uucp* associates a job number with each request. This job number can be used by *uustat* to obtain status or terminate the job.

The environment variable **JOBNO** and the **-j** option are used to control the listing of the *uucp* job number on standard output. If the environment variable **JOBNO** is undefined or set to **OFF**, the job number will not be listed (default). If *uucp* is then invoked with the **-j** option, the job number will be listed. If the environment variable **JOBNO** is set to **ON** and is exported, a job number will be written to standard output each time uucp is invoked. In this case, the **-j** option will supress output of the job number.

## Uulog

Uulog queries a summary log of uucp and uux(1C) transactions in the file uur/spool/uucp/LOGFILE.

The options cause *uulog* to print logging information:

- -ssys Print information about work involving system sys. If sys is not specified, then logging information for all systems will be printed.
- -uuser Print information about work done for the specified user. If user is not specified then logging information for all users will be printed.

## Uuname.

*Uuname* lists the uucp names of known systems. Duplicate lines are not shown, but blank lines are. The -l option returns the local system name. The -v option will print additional information about each system. A description will be printed for each system that has a line of information in /usr/lib/uucp/ADMIN. The format of ADMIN is:

sysname tab description tab.

## FILES

```
/usr/spool/uucp
/usr/spool/uucppublic directory for receiving and sending (PUBDIR)
/usr/lib/uucp/* other data and program files
```

## SEE ALSO

mail(1), uux(1C), chmod(2).

## WARNING

The domain of remotely accessible files can (and for obvious security reasons, usually should) be severely restricted. You will very likely not be able to fetch files by path name; ask a responsible person on the remote system to send them to you. For the same reasons, you will probably not be able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin /usr/spool/uucppublic (equivalent to ~uucp or just ~). Note that, if /etc/passwd contains a blank line, a null user entry, or an entry for ~uucp, then ~ and ~uucp will not expand properly. Because of this, the uuto script will not send files to the proper directory.

UUCP(1C) UUCP(1C)

## NOTES

In order to send files that begin with a dot (e.g., .profile) the files must by qualified with a dot. For example: .profile, .prof\*, .profil? are correct; whereas \*prof\*, ?profile are incorrect.

*Uucp* will not generate a job number for a strictly local transaction.

## **BUGS**

All files received by *uucp* will be owned by *uucp*.

The -m option will only work sending files or receiving a single file. Receiving multiple files specified by special shell characters ? \* [...] will not activate the -m option.

The -m option will not work if all transactions are local or if uucp is executed remotely via the -e option.

The -n option will function only when the source and destination are not on the same machine. Any excess characters are ignored.

If *uulog* is issued with no parameters when a *uucp* process is writing to a temporary logfile, some log information (that information written after the **LOG**.\* files are unlinked) may be lost.

Uucp, when used to copy files locally, will create the new file with mode 644 instead of 666.

UULS(1) UULS(1)

#### NAME

uuls - list spooled uucp transactions grouped by transaction

## SYNOPSIS

```
uuls [-m] [directories...]
uuls -s [-m] [directories...]
uuls -k [-m] [directories...]
```

## HP-UX COMPATIBILITY

Level: HF

HP-UX/STANDARD

Origin: H

711giii. 11

Remarks: Not supported on the Integral PC.

#### DESCRIPTION

This command lists the contents of uncp spool directories (default "/usr/spool/uncp") with the files grouped into three categories:

## Transactions:

Each line starts with a transaction control filename and includes the name of each local (same-directory) subfile referenced by the control file (see below). Each is possibly followed by the total size in bytes (-s option) or Kbytes (-k option) in the transaction (see below). The -m (meanings) option replaces the subfile names with nodename, user, and commandline information (see below).

## Orphans:

All subfiles not referenced by any control file.

#### Others:

All other files in the directory (all files not listed under one of the above categories).

Filenames are columnated so there may be more than one file per line. If a transaction has more subfiles than fit on one line, it is followed by continuation lines which are indented further.

The -s (size in bytes) and -k (Kbytes) options cause the command to follow each transaction in the *Transactions* section with a total size for all stat-able, sendable files in that transaction. This includes "D.\*" files only, not "C.\*" or "X.\*" files. It does include stat-able files outside the spool directory which are indirectly referenced by "C.\*" files. Sizes are either in bytes or rounded to the nearest Kbyte (1024 bytes), respectively. A totals line is also added at the end of the *Transactions* section.

The -m (meanings) option causes the command to follow "C.\*" and "X.\*" files with a "nodename!username commandline" line, instead of subfilenames. For "C" files, one line is printed per remote execution ("D\*X\*") subfile it references. Nodename is truncated at seven characters, username at eight, and commandline at however much fits on one line.

If -m is given, for each "C" file with no remote execution files, the command instead shows the meaning of the "C" file itself on one or more lines. Each line consists of a username, then "R" (receive) or "S" (send), then the name of the file to be transferred. See below for details.

Filenames are listed in alphabetical order within each section, except that the first section is only sorted by the control filename. Every file in the directory except "." and ".." appears exactly once in the entire list, unless -m is used.

## Details

Transaction files are those whose names start with "C." or "X.". Subfilenames, which usually start with "D.", are gleaned from control file lines, at most one per line, from blank-separated fields, as follows:

C.\*: R <remotefrom> <localto> <user> -<options>

C.\*: S <localfrom> <remoteto> <user> -<options> <subfile> <mode>

X.\*: F < subfile >

UULS(1)

Lines that don't begin with the appropriate character ('R', 'S', or 'F') are ignored.

In the "R" (receive) case, <remotefrom> is used to print the "C"-file meaning, and its transaction size is taken as zero (unknown).

In the "S" (send) case, if <subfile> is "D.0", <localfrom> is a file not in the spool directory, resulting from a typical **uucp** call without the -C (copy) option. In this case <localfrom> is used for the transaction size, if stat-able, and to print the "C"-file meaning.

uucp -C and uux both set <subfile> to a true (spooled) subfile name.

Orphan files are those whose names start with "D." and which are not referenced by any control files.

This algorithm extracts from control files the names of all subfiles which should exist in the spool directory when the transaction is not being actively processed. It is not unusual to see "missing subfiles" and "orphans" if you uuls a spool directory while uucico, uucp, uux, or uuxqt is active.

Meanings information is gotten by reading each "D\*X\*" subfile referenced by each "C.\*" file, and by reading "X\*X\*" files. Nodename!username is taken from the last line in the file which is of the form:

U <username> <nodename>

Likewise, *commandline* is taken from the last line of the form:

C <commandline>

If a subfile name is referenced more than once, references after the first show the subfile as missing. If a subfile name appears in a (corrupt) directory more than once, the name is only found once, but then it is listed again under *Orphans*.

#### HARDWARE DEPENDENCIES

**Uuls** uses *directory*(3x), but it truncates filenames to 14 characters. This should cause no problems, even if longer names are allowed, due to the **uucp** file naming conventions.

## SEE ALSO

mail(1), uucp(1), uuto(1), uux(1), uuxqt(1), stat(2).

## DIAGNOSTICS

The program writes an appropriate message to standard error if it has any problems dealing with a specified file (directory), including failure to get heap space. It always returns zero as its exit value.

If a control file is unopenable (wrong permissions or it disappeared while **uuls** was running), its name is preceded by a "\*" and the size of the transaction is zero. If a subfile is missing (filename not found in the directory being listed) or un-stat-able (if required for -s or -k), its name is preceded by a "\*" and it contributes zero bytes to the size of the transaction.

If -m is specified and a "D\*X\*" file is missing or unreadable, its name is given with a "\*" prepended, as usual.

## BUGS

This command uses *chdir*(2) to change to each directory in turn. If more than one is specified, the second through last directories must be absolute (not relative) pathnames, or the chdir() may fail. (This could be fixed, but might result in the program running slower.)

UUSNAP(1) UUSNAP(1)

#### NAME

uusnap - show snapshot of the UUCP system

## SYNOPSIS

uusnap

# HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

UCB

## DESCRIPTION

Uusnap displays in tabular format a synopsis of the current UUCP situation. The format of each line is as follows:

site N Cmds N Data N Xqts Message

Where "site" is the name of the site with work, "N" is a count of each of the three possible types of work (command, data, or remote execute), and "Message" is the current status message for that site as found in the STST file.

Included in "Message" may be the time left before UUCP can re-try the call, and the count of the number of times that UUCP has tried to reach the site. The process ID of a UUCICO or other demon may also be shown if it is in a "Talking of LOCKED" state.

## SEE ALSO

uucp(1C), Serial Network Communications Guide.

UUSTAT(1C) UUSTAT (1C)

#### NAME

uustat - uucp status inquiry and job control

## SYNOPSIS

uustat [ options ]

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

## DESCRIPTION

Uustat will display the status of, or cancel, previously specified uucp commands, or provide general status on uucp connections to other systems. At most one of the following options may be specified:

-iiobn

Report the status of the *uucp* request *jobn*. If all is used for *jobn*, the status of all uucp requests is reported. An argument must be supplied otherwise the usage message will be printed and the request will fail.

-kiobn

Kill the uucp request whose job number is jobn. The killed uucp request must belong to the person issuing the *uustat* command unless one is the super-user.

-rjobn

Rejuvenate jobn. That is, jobn is touched so that its modification time is set to the current time. This prevents uuclean from deleting the job until the jobs modification time reaches the limit imposed by uuclean.

-chour

Remove the status entries which are older than hour hours. This administrative option can only be initiated by the user **uucp** or the super-user.

 $-\mathbf{m}mch$ 

Report the status of accessibility of machine mch. If mch is specified as all, then the status of all machines known to the local uucp are provided.

-Mmch

This is the same as the -m option except that two times are printed. The time that the last status was obtained and the time that the last successful transfer to that system occurred.

If none of the above options are specified, any or all of the following options may appear:

-uuser

Report the status of all *uucp* requests issued by *user*.

-ssys

Report the status of all *uucp* requests which communicate with remote system sys.

-ohour

Report the status of all *uucp* requests which are older than *hour* hours.

-yhour Report the status of all *uucp* requests which are younger than *hour* hours.

-O

Report the *uucp* status using the octal status codes listed below. If this option is not specified, the verbose description is printed with each *uucp* request.

-q

List the number of jobs and other control files queued for each machine and the time of the oldest and youngest file queued for each machine. If a lock file exists for that system, its date of creation is listed.

When no options are given, uustat outputs the status of all uucp requests issued by the current

For example, the command:

uustat -uhdc -smhtsa -y72

will print the status of all uucp requests that were issued by user hdc to communicate with system *mhtsa* within the last 72 hours. The meanings of the job request status are:

job-number user remote-system command-time status-time status

where the status may be either an octal number or a verbose description. The octal code corresponds to the following description:

UUSTAT(1C) UUSTAT(1C)

OCTAL	STATUS
000001	the copy failed, but the reason cannot be determined
000002	permission to access local file is denied
000004	permission to access remote file is denied
000010	bad <i>uucp</i> command is generated
000020	remote system cannot create temporary file
000040	cannot copy to remote directory
000100	cannot copy to local directory
000200	local system cannot create temporary file
000400	cannot execute uucp
001000	copy (partially) succeeded
002000	copy finished, job deleted
004000	job is queued
010000	job killed (incomplete)
020000	job killed (complete)

The meanings of the machine accessibility status are:

system-name time status

where time is the latest status time and status is a self–explanatory description of the machine status.

# FILES

```
/usr/spool/uucp spool directory
/usr/lib/uucp/L_stat system status file
/usr/lib/uucp/R_stat request status file
```

## SEE ALSO

uucp(1C).

UUTO(1C) UUTO(1C)

#### NAME

uuto, uupick - public HP-UX-to-HP-UX system file copy

#### SYNOPSIS

uuto [ options ] source-files destination
uupick [ -s system ]

## HP-UX COMPATIBILITY

Level: HP-U

HP-UX/STANDARD

Origin: System V

# DESCRIPTION

Uuto sends source-files to destination. Uuto uses the uucp(1C) facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the form:

system!user

where system is taken from a list of system names that uucp knows about (see uuname(1C)). Logname is the login name of someone on the specified system.

Two options are available:

-p Copy the source file into the spool directory immediately, and send the copy.

-m Send mail to the requester when the copy is complete.

The files (or sub-trees if directories are specified) are sent to PUBDIR on *system*, where PUBDIR is the *uucp* public directory (/usr/spool/uucppublic). Specifically the files are sent to

PUBDIR/receive/user/mysystem/files.

The recipient is notified by mail(1) of the arrival of files.

*Uupick* accepts or rejects the files transmitted to the recipient. Specifically, *uupick* searches PUBDIR for files destined for the user. For each entry (file or directory) found, the following message is printed on the standard output:

from system: [file file-name] [dir dirname]?

Uupick then reads a line from the standard input to determine the disposition of the file:

<new-line> Go on to next entry.

d Delete the entry.

 $\mathbf{m} \; [\; dir \; ]$  Move the entry to named directory dir (current directory is default). Note

that, if the current working directory is desired for dir, you should **not** specify any parameter with **m**. A construction like **m**. is erroneous, and results in loss

of data.

a [ dir ] Same as m except move all the files sent from system.

Print the contents of the file.

q Stop.

EOT (control-d) Same as q.

!command Escape to the shell to do command.

\* Print a command summary.

Uupick invoked with the -ssystem option will only search the PUBDIR for files sent from system.

#### FILES

PUBDIR/usr/spool/uucppublic public directory

# NOTES

In order to send files that begin with a dot (e.g., .profile) the files must by qualified with a dot. For example: .profile, .prof\*, .profil? are correct; whereas \*prof\*, ?profile are incorrect.

# SEE ALSO

UUX(1C) UUX(1C)

#### NAME

uux - HP-UX-to-HP-UX system command execution

#### SYNOPSIS

uux [ options ] command-string

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

*Uux* will gather zero or more files from various systems, execute a command on a specified system and then send standard output to a file on a specified system. Note that, for security reasons, many installations will limit the list of commands executable on behalf of an incoming request from *uux*. Many sites will permit little more than the receipt of mail (see *mail*(1)) via *uux*.

The *command-string* is made up of one or more arguments that look like a Shell command line, except that the command and file names may be prefixed by *system-name*!. A null *system-name* is interpreted as the local system.

File names may be one of

- (1) a full path name;
- (2) a path name preceded by ~xxx where xxx is a login name on the specified system and is replaced by that user's login directory;
- (3) anything else is prefixed by the current directory.

As an example, the command

```
uux "!diff usg!/usr/dan/f1 pwba!/a4/dan/f1 > !f1.diff"
```

will get the f1 files from the "usg" and "pwba" machines, execute a diff command and put the results in f1.diff in the local directory.

Any special shell characters such as <>;| should be quoted either by quoting the entire command-string, or quoting the special characters as individual arguments.

*Uux* will attempt to get all files to the execution system. For files which are output files, the file name must be escaped using parentheses. For example, the command

```
uux a!uucp b!/usr/file \(c!/usr/file\)
```

will send a uucp command to system "a" to get /usr/file from system "b" and send it to system "c".

Uux will notify you if the requested command on the remote system was disallowed. The response comes by remote mail from the remote machine. The amount of mail notification can be reduced with the -z option, which notifies the remote system only if the command failed. Notification can be disabled totally with the -n option. Executable commands are listed in /usr/lib/uucp/L.cmds on the remote system. The format of the L.cmds file is:

```
cmd,machine1,machine2,...
```

If no machines are specified, then any machine can execute **cmd**. If machines are specified, only the listed machines can execute **cmd**. If the desired command is not listed in **L.sys** then no machine can execute that command.

Redirection of standard input and output is usually restricted to files in PUBDIR. Directories into which redirection is allowed must be specified in /usr/lib/uucp/USERFILE by the system administrator. See the HP-UX System Administrator Guide for details.

The following options are interpreted by uux:

UUX(1C)

- The standard input to *uux* is made the standard input to the *command-string*.
- Send no notification to user.
- -z Send notification only of failures to user.
- -mfile Report status of the transfer in file. If file is omitted, send mail to the requester when the copy is completed.
- -j Control writing of the *uucp* job number to standard output.
- -r Queue job but do not start the file transfer process. By default a file transfer process is started each time uux is evoked.

*Uux* associates a job number with each request. This job number can be used by *uustat* to obtain status or terminate the job.

The environment variable JOBNO and the -j option are used to control the listing of the *uux* job number on standard output. If the environment variable JOBNO is undefined of set to OFF, the job number will not be listed (default). If *uuco* is then invoked with the -j option, the job number will be listed. If the environment variable JOBNO is set to ON and is exported, a job number will be written to standard output each time *uux* is invoked. In this case, the -j option will suppress output of the job number.

### FILES

```
/usr/spool/uucp
/usr/spool/uucppublic
/usr/lib/uucp/*

spool directory
public directory (PUBDIR)
other data and programs
```

#### SEE ALSO

mail(1), uuclean(1M), uucp(1C).

## BUGS

Only the first command of a shell pipeline may have a *system-name!*. All other commands are executed on the system of the first command.

The use of the shell metacharacter \* will probably not do what you want it to do. The shell tokens << and >> are not implemented.

Any excess characters are ignored.

NAME

val - validate SCCS file

SYNOPSIS

val -

val [-s] [-rSID] [-mname] [-ytype] files

HP-UX COMPATIBILITY

Level: HP-

HP-UX/STANDARD

Origin:

System III

## DESCRIPTION

Val determines if the specified file is an SCCS file meeting the characteristics specified by the optional argument list. Arguments to val may appear in any order. The arguments consist of keyletter arguments, which begin with a -, and named files.

Val has a special argument, -, which causes reading of the standard input until an end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.

Val generates diagnostic messages on the standard output for each command line and file processed, and also returns a single 8-bit code upon exit as described below.

The keyletter arguments are defined as follows. The effects of any keyletter argument apply independently to each named file on the command line.

-8

The presence of this argument silences the diagnostic message normally generated on the standard output for any error that is detected while processing each named file on a given command line.

-rSID

The argument value SID (SCCS IDentification String) is an SCCS delta number. A check is made to determine if the SID is ambiguous (e. g., r1 is ambiguous because it physically does not exist but implies 1.1, 1.2, etc., which may exist) or invalid (e. g., r1.0 or r1.1.0 are invalid because neither case can exist as a valid delta number). If the SID is valid and not ambiguous, a check is made to determine if it actually exists.

-mname

The argument value name is compared with the SCCS %M% keyword in file.

-ytype

The argument value type is compared with the SCCS %Y% keyword in file.

The 8-bit code returned by val is a disjunction of the possible errors, i. e., can be interpreted as a bit string where (moving from left to right) set bits are interpreted as follows:

bit 0 = missing file argument;

bit 1 = unknown or duplicate keyletter argument;

bit 2 =corrupted SCCS file:

bit 3 = cannot open file or file not SCCS;

bit 4 = SID is invalid or ambiguous:

bit 5 = SID does not exist:

bit 6 = %Y%, **-y** mismatch;

bit 7 = %M%, -m mismatch;

Note that *val* can process two or more files on a given command line and in turn can process multiple command lines (when reading the standard input). In these cases an aggregate code is

VAL(1) VAL(1)

returned - a logical  $\mathbf{OR}$  of the codes generated for each command line and file processed.

# SEE ALSO

admin(1), delta(1), get(1), help(1), prs(1).

# DIAGNOSTICS

Use help(1) for explanations.

# BUGS

Val can process up to 50 files on a single command line. Any number above 50 will produce a fatal error.

### NAME

vi - screen-oriented (visual) display editor based on ex

## SYNOPSIS

```
vi [-t tag] [-r file] [-l] [-wn] [-R] [+command] name ...
view [-t tag ] [-r file ] [-l ] [-wn ] [-R ] [+command ] name ...
vedit [-t tag ] [-r file ] [-l ] [-wn ] [-R ] [+command] name ...
```

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Remarks:

The decryption facilities provided by this software are under control by the United States Government and cannot be exported without special licenses. These capabilities are considered an HP-UX/OPTIONAL feature, and can be sold only to domestic customers at this time.

#### DESCRIPTION

Vi (visual) is a display-oriented text editor based on an underlying line editor ex(1). It is possible to use the command mode of ex from within vi and vice-versa.

When using vi, changes you make to the file are reflected in what you see on your terminal screen. The position of the cursor on the screen indicates the position within the file. The Vi Quick Reference card, the Introduction to Display Editing with Vi and the Ex Reference Manual provide full details on using vi.

## INVOCATION

The following invocation options are interpreted by vi:

<b>-t</b> tag Edit the file containing the tag and posi	sition the editor at its definition.
---	--------------------------------------

$$vi$$
 and  $open$  are modified to have meaning for  $lisp$ .

speed line.

 $-\mathbf{R}$ Read only mode; the **readonly** flag is set, preventing accidental overwriting of

the file.

The specified ex command is interpreted before editing begins.

The name argument indicates files to be edited.

The view invocation is the same as vi except that the **readonly** flag is set.

The vedit invocation is intended for beginners. The report flag is set to 1, and the showmode and **novice** flags are set. These defaults make it easier to get started learning the editor.

### "VI MODES"

Command Normal and initial mode. Other modes return to command mode upon comple-

tion. ESC (escape) is used to cancel a partial command.

Input Entered by a i A I o O c C s S R. Arbitrary text may then be entered. Input mode is normally terminated with ESC character, or abnormally with interrupt.

Last line Reading input for: /? or!; terminate with CR to execute, interrupt to cancel.

## COMMAND SUMMARY

### Sample commands

+command

 $\leftarrow \downarrow \uparrow \rightarrow$ arrow keys move the cursor hjkl same as arrow keys

$\mathbf{i}abc$ ESC	insert text $abc$
$\mathbf{cw}\mathit{new}\mathrm{ESC}$	change word to new
easESC	pluralize word
x	delete a character
dw	delete a word
dd	delete a line
3dd	delete 3 lines
u	undo previous change
$\mathbf{Z}\mathbf{Z}$	exit vi, saving changes
:q!CR	quit, discarding changes
/textCR	search for text
^U ^D	scroll up or down
:ex cmdCR	any ex or ed command

## Counts before vi commands

Numbers may be typed as a prefix to some commands. They are interpreted in one of these ways.

 $\begin{array}{ccc} \text{line/column number} & & \mathbf{z} & \mathbf{G} & | \\ \text{scroll amount} & & \hat{}^{\mathbf{D}} & \hat{}^{\mathbf{U}} \end{array}$ 

repeat effect most of the rest

# Interrupting, canceling

ESC	end insert or incomplete cmd
^?	(delete or rubout) interrupts
$\hat{L}$	reprint screen if ^? scrambles it
$\hat{R}$	reprint screen if $^{}L$ is $\rightarrow$ key

## File manipulation

```
:wCR
                  write back changes
:qCR
                   quit
:q!CR
                  quit, discard changes
:e nameCR
                  edit file name
:e!CR
                  reedit, discard changes
:e + nameCR
                  edit, starting at end
:e + nCR
                  edit starting at line n
:e #CR
                  edit alternate file
                  synonym for :e #
:w nameCR
                  write file name
:w! nameCR
                  overwrite file name
:shCR
                  run shell, then return
:!cmdCR
                  run cmd, then return
:nCR

      O
                       open above
```

 $\mathbf{r}x$ 

replace single char with x

## RtextESC

replace characters

## Operators

Operators are followed by a cursor motion, and affect all text that would have been moved over. For example, since **w** moves over a word, **dw** deletes the word that would be moved over. Double the operator, e.g. **dd** to affect whole lines.

- d delete
- c change
- y yank lines to buffer
- < left shift
- > right shift
- ! filter through command
- = indent for LISP

## Miscellaneous Operations

C	change rest of line (cs
$\mathbf{D}$	delete rest of line $(d\$)$
s	substitute chars $(cl)$
$\mathbf{S}$	substitute lines $(cc)$
J	join lines
$\mathbf{x}$	delete characters (dl)
$\mathbf{X}$	before cursor (dh)
$\mathbf{Y}$	yank lines (yy)

#### Yank and Put

Put inserts the text most recently deleted or yanked. However, if a buffer is named, the text in that buffer is put instead.

$\mathbf{p}$	put	back	text	after	${\it cursor}$
D		1 - C			

Pput before cursor" $x\mathbf{p}$ put from buffer x" $x\mathbf{y}$ yank to buffer x" $x\mathbf{d}$ delete into buffer x

## Undo, Redo, Retrieve

u undo last change
U restore current line
repeat last change
"dp retrieve d'th last delete

## AUTHOR

Vi and ex were developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

## WARNINGS AND BUGS

Software tabs using **^T** work only immediately after the *autoindent*.

Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.

### NAME

vis, inv - make unprintable characters in a file visible or invisible

#### SYNOPSIS

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

HP

Native Language Support:

8-bit and 16-bit data, customs, messages.

## DESCRIPTION

Vis reads characters from each file in sequence and writes them to the standard output, converting those which are not printable into a visible form. Inv performs the inverse function, reading printable characters from each file and writing them, returned if appropriate to non-printable form, to standard out.

Non-printable characters are represented using C-like escape conventions:

- backslash
- \b backspace
- \e escape
- form-feed
- new-line \n
- carriage return \r
  - space
- horizontal tab
- vertical tab
- the 8-bit character whose ASCII code is the 3-digit octal number n.  $\setminus n$
- the 8-bit character whose ASCII code is the 2-digit hexidecimal number n.

Space, horizontal tab, and new line may be treated as printable (and therefore passed unscathed to the output) or non-printable dependent on the options selected. Backslash, although printable, is expanded by vis, to a pair of backslashes so that when passed back through inv, it can be mapped back to a single backslash.

If no input file is given, or if the argument - is encountered, vis and inv read from the standard input file.

## The options are:

- causes new-line, space, and horizontal tab to be treated as non-printable charac--n ters. Thus vis expands them visibly as n, s, and t, rather passing them directly to the output. Inv discards these character, expecting only the printable expansions. New-line characters are inserted by vis every 16 characters so that the output will be in form acceptable for most editors.
- makes vis and inv silent about non-existent files, identical input and output, and -s write errors. Normally, no input file may be the same as the output file unless it is a special file.
- -t treats horizontal tab and space as non-printable characters, in the same manner in which -n options treats them.
- -u causes output to be unbuffered (character-by-character); normally, output is buffered.
- -x causes vis output to be in hexidecimal form rather than the default octal form. Either form is accepted to inv as input.

VIS(1)

# EXAMPLE

If you encounter a file whose contents are unknown–perhaps binary or text–you can take a quick peek into it without jeopordizing your terminal:

vis -n file | head

This will safely show the first 160 bytes of the file.

# SEE ALSO

cat(1), echo(1), od(1).

## WARNING

Command formats such as

vis file1 file2 >file1

will cause the original data in file1 to be lost.

WAIT(1) WAIT(1)

## NAME

wait - await completion of process

## SYNOPSIS

wait

## HP-UX COMPATIBILITY

Level:

HP-UX/NUCLEUS

Origin: System III

# DESCRIPTION

Wait until all processes started with & have completed, and report on abnormal terminations.

Because the wait(2) system call must be executed in the parent process, the shell itself executes wait, without creating a new process.

## SEE ALSO

sh(1), wait(2)

## BUGS

Not all the processes of a 3- or more–stage pipeline are children of the shell, and thus cannot be waited for.

- 1 -

WC(1)

#### NAME

wc - word, line, and character count

## SYNOPSIS

wc [ -lwc ] [ names ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Native Language Support:

8-bit data, customs, messages.

## DESCRIPTION

Wc counts lines, words, and characters in the named files, or in the standard input if no names appear. It also keeps a total count for all named files. A word is a maximal string of characters delimited by spaces, tabs, or new-lines.

The options  $l,\,\mathbf{w},\,$  and  $\mathbf{c}$  may be used in any combination to specify that a subset of lines, words, and characters are to be reported. The default is  $-l\mathbf{w}\mathbf{c}$ .

When names are specified on the command line, they will be printed along with the counts.

## BUGS

Wc counts the number of new-lines to determine the line count. If an ASCII text file has a final line that is not terminated with a new-line character, the count will be off by one.

If there are very many characters, words, and/or lines in an input file, the output may be hard to read. This is because wc reserves a fixed column width for each count.

WHAT(1) WHAT(1)

#### NAME

what - identify files for SCCS information

## SYNOPSIS

what files

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System III

# DESCRIPTION

What searches the given files for all occurrences of the pattern that get(1) substitutes for %Z% (this is @(#) at this printing) and prints out what follows until the first ", >, new-line, \, or null character. For example, if the C program in file **f.c** contains

char ident[] = "@(#)identification information";

and f.c is compiled to yield f.o and a.out, then the command

what f.c f.o a.out

will print

f.c:

identification information

f.o:

identification information

a.out:

identification information

What is intended to be used in conjunction with the SCCS command get(1), which automatically inserts identifying information, but it can also be used where the information is inserted manually.

## SEE ALSO

get(1), help(1).

SCCS User's Guide in HP-UX Concepts and Tutorials.

# DIAGNOSTICS

Use help(1) for explanations.

## **BUGS**

It's possible that an unintended occurrence of the pattern @(#) could be found just by chance, but this causes no harm in nearly all cases.

WHEREIS(1) WHEREIS(1)

#### NAME

whereis - locate source, binary, and/or manual for program

## SYNOPSIS

```
whereis [-sbm] [-u] [-SBM dir ... -f] name ...
```

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: UCB

## DESCRIPTION

Whereis locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form ".ext", e.g. ".c". Prefixes of "s." resulting from use of SCCS are also dealt with. Whereis then attempts to locate the desired program in a list of standard places. If any of the -b, -s or -m flags are given then whereis searches only for binaries, sources or manual sections respectively (or any two thereof). The -u flag may be used to search for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus "whereis -m -u \*" asks for those files in the current directory which have no documentation.

Finally, the **-B -M** and **-S** flags may be used to change or otherwise limit the places where *whereis* searches. The **-f** file flag is used to terminate the last such directory list and signal the start of file names.

#### **EXAMPLE**

The following finds all the files in /usr/bin which are not documented in /usr/man/man1 with source in /usr/src/cmd:

```
cd /usr/bin
whereis -u -M /usr/man/man1 -S /usr/src/cmd -f *
```

## FILES

```
/usr/src/*
/bin, /etc, /lib, /usr/{bin, games, lib}
/usr/man/*
/usr/local/{man/*, bin, games, include, lib}
/usr/contrib/{man/*, bin, games, include, lib}
```

## BUGS

Since the program uses chdir(2) to run faster, pathnames given with the **-M -S** and **-B** must be full; i.e. they must begin with a "/".

Hewlett-Packard - 1 - July 2, 1985

WHO(1) WHO(1)

#### NAME

who - who is on the system

#### SYNOPSIS

who [-uTHlpdbrtasq] [ file ]

who am i

who am I

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Who can list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current HP-UX system user. It examines the /etc/utmp file to obtain its information. If file is given, that file is examined. Usually, file will be /etc/wtmp, which contains a history of all the logins since the file was last created.

Who with the am i or am I option identifies the invoking user.

Except for the default -s option, the general format for output entries is:

name [state] line time activity pid [comment] [exit]

With options, who can list logins, logoffs, reboots, and changes to the system clock, as well as other processes spawned by the *init* process. These options are:

- -u This option lists only those users who are currently logged in. The name is the user's login name. The line is the name of the line as found in the directory /dev. The time is the time that the user logged in. The activity is the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is therefore "current". If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked old. This field is useful when trying to determine whether a person is working at the terminal or not. The pid is the process-ID of the user's shell. The comment is the comment field associated with this line as found in /etc/inittab (see inittab(4)). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, etc.
- -T This option is the same as the -u option, except that the *state* of the terminal line is printed. The *state* describes whether someone else can write to that terminal. A + appears if the terminal is writable by anyone; a appears if it is not. Root can write to all lines having a + or a in the *state* field. If a bad line is encountered, a ? is printed.
- -1 This option lists only those lines on which the system is waiting for someone to login. The name field is LOGIN in such cases. Other fields are the same as for user entries except that the state field does not exist.
- **-H** This option will print column headings above the regular output.
- -q This is a quick who, displaying only the names and the number of users currently logged on. When this option is used, all other options are ignored.
- -p This option lists any other process which is currently active and has been previously spawned by *init*. The *name* field is the name of the program executed by *init* as found in /etc/inittab. The *state*, *line*, and *activity* fields have no meaning. The *comment* field shows the *id* field of the line from /etc/inittab that spawned this process. See *inittab*(4).

WHO(1)

-d This option displays all processes that have expired and not been respawned by init. The exit field appears for dead processes and contains the termination and exit values (as returned by wait(2)), of the dead process. This can be useful in determining why a process terminated.

- -b This option indicates the time and date of the last reboot.
- -r This option indicates the current run-level of the init process. The last three fields contain the current state of init, the number of times that that state has been previously entered, and the previous state. These fields are updated each time init changes to a different run state
- -t This option indicates the last change to the system clock (via the date(1) command) by root. See su(1).
- -a This option processes /etc/utmp or the named file with all options turned on.
- -s This option is the default and lists only the name, line, and time fields.

## FILES

```
/etc/utmp
/etc/wtmp
/etc/inittab
```

## SEE ALSO

date(1), login(1), mesg(1), su(1), init(1M), wait(2), inittab(5), utmp(5).

WHOAMI(1) WHOAMI(1)

NAME

whoami - print effective current user id

SYNOPSIS

whoami

HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: UCB

DESCRIPTION

Whoami prints who you are. It works even if you are su'd, while 'who am i' does not since it uses /etc/utmp.

**FILES** 

/etc/passwd Name data base

SEE ALSO

who (1)

WRITE(1) WRITE(1)

## NAME

write - interactively write (talk) to another user

#### SYNOPSIS

write user [ line ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

Native Language Support:

8-bit data, customs, messages.

Remarks: Not supported on the Integral Personal Computer.

## DESCRIPTION

Write copies lines from your terminal to that of another user. When first called, it sends the message:

```
Message from yourname (tty??) [ date ]...
```

to the person you want to talk to. When it has successfully completed the connection, it also sends two bells to your own terminal to indicate that what you are typing is being sent.

The recipient of the message should *write* back at this point. Communication continues until an end of file is read from the terminal, an interrupt is sent, or the recipient has executed "mesg n". At that point *write* writes **EOT** on the other terminal and exits.

If you want to write to a user who is logged in more than once, the *line* argument may be used to indicate which line or terminal to send to (e.g., **tty00**); otherwise, the first writable instance of the user found in **/etc/utmp** is assumed and the following message posted:

user is logged on more than one place.

You are connected to "terminal".

Other locations are:

terminal

Permission to write may be denied or granted by use of the mesg(1) command. Writing to others is normally allowed by default. Certain commands, in particular nroff(1) and pr(1) disallow messages in order to prevent interference with their output. However, if the user has super-user permissions, messages can be forced onto a write-inhibited terminal.

If the character ! is found at the beginning of a line, write calls the shell to execute the rest of the line as a command.

The following protocol is suggested for using *write*: when you first *write* to another user, wait for them to *write* back before starting to send. Each person should end a message with a distinctive signal (i.e., (o) for "over") so that the other person knows when to reply. The signal (oo) (for "over and out") is suggested when conversation is to be terminated.

## FILES

/etc/utmp to find user /bin/sh to execute!

### SEE ALSO

mail(1), mesg(1), nroff(1), pr(1), sh(1), who(1).

## DIAGNOSTICS

- "user is not logged on" if the person you are trying to write to is not logged on.
- "Permission denied" if the person you are trying to write to denies that permission (with mesg).
- "Warning: cannot respond, set mesg -y" if your terminal is set to mesg n and the recipient cannot respond to you.

WRITE(1) WRITE(1)

"Can no longer write to user" if the recipient has denied permission (mesg n) after you had started writing.

XARGS(1) XARGS(1)

### NAME

xargs - construct argument list(s) and execute command

#### SYNOPSIS

xargs [flags] [ command [initial-arguments] ]

## HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin:

System V

Remarks: Not supported on the Integral Personal Computer.

## DESCRIPTION

Xargs combines the fixed *initial-arguments* with arguments read from standard input to execute the specified *command* one or more times. The number of arguments read for each *command* invocation and the manner in which they are combined are determined by the flags specified.

Command, which may be a shell file, is searched for, using one's \$PATH. If command is omitted, /bin/echo is used.

Arguments read in from standard input are defined to be contiguous strings of characters delimited by one or more blanks, tabs, or new-lines; empty lines are always discarded. Blanks and tabs may be embedded as part of an argument if escaped or quoted. Characters enclosed in quotes (single or double) are taken literally, and the delimiting quotes are removed. Outside of quoted strings a backslash (\) will escape the next character.

Each argument list is constructed starting with the *initial-arguments*, followed by some number of arguments read from standard input (Exception: see -i flag). Flags -i, -l, and -n determine how arguments are selected for each command invocation. When none of these flags are coded, the *initial-arguments* are followed by arguments read continuously from standard input until an internal buffer is full, and then *command* is executed with the accumulated args. This process is repeated until there are no more args. When there are flag conflicts (e.g., -l vs. -n), the last flag has precedence. *Flag* values are:

-lnumber

Command is executed for each non-empty number lines of arguments from standard input. The last invocation of command will be with fewer lines of arguments if fewer than number remain. A line is considered to end with the first new-line unless the last character of the line is a blank or a tab; a trailing blank/tab signals continuation through the next non-empty line. If number is omitted, 1 is assumed. Option -x is forced.

-ireplstr

Insert mode: command is executed for each line from standard input, taking the entire line as a single arg, inserting it in initial-arguments for each occurrence of replstr. A maximum of 5 arguments in initial-arguments may each contain one or more instances of replstr. Blanks and tabs at the beginning of each line are thrown away. Constructed arguments may not grow larger than 255 characters, and option -x is also forced. {} is assumed for replstr if not specified.

 $-\mathbf{n} \textit{number}$ 

Execute command using as many standard input arguments as possible, up to number arguments maximum. Fewer arguments will be used if their total size is greater than size characters, and for the last invocation if there are fewer than number arguments remaining. If option -x is also coded, each number arguments must fit in the size limitation, else xargs ter-

-x

-ssize

-eeofstr

minates execution.

-t Trace mode: The *command* and each constructed argument list are echoed to file descriptor 2 just prior to their execution.

-p Prompt mode: The user is asked whether to execute *command* each invocation. Trace mode (-t) is turned on to print the command instance to be executed, followed by a ?... prompt. A reply of y (optionally followed by anything) will execute the command; anything else, including just a carriage return, skips that particular invocation of *command*.

Causes *xargs* to terminate if any argument list would be greater than *size* characters; -x is forced by the options -i and -1. When neither of the options -i, -l, or -n are coded, the total length of all arguments must be within the *size* limit.

The maximum total size of each argument list is set to *size* characters; *size* must be a positive integer less than or equal to 470. If -s is not coded, 470 is taken as the default. Note that the character count for *size* includes one extra character for each argument and the count of characters in the command name.

Eofstr is taken as the logical end-of-file string. Underbar (\_) is assumed for the logical EOF string if -e is not coded. The value -e with no eofstr coded turns off the logical EOF string capability (underbar is taken literally). Xargs reads standard input until either end-of-file or the logical EOF string is encountered.

Xargs will terminate if either it receives a return code of -1 from, or if it cannot execute, com-mand. When command is a shell program, it should explicitly exit (see sh(1)) with an appropriate value to avoid accidentally returning with -1.

### EXAMPLES

The following will move all files from directory \$1 to directory \$2, and echo each move command just before doing it:

The following will combine the output of the parenthesized commands onto one line, which is then echoed to the end of file log:

(logname; date; echo \$0 \$\*) | xargs >>log

The user is asked which files in the current directory are to be archived and archives them into arch (1.) one at a time, or (2.) many at a time.

- 1. ls | xargs -p -l ar r arch
- 2. ls | xargs -p -l | xargs ar r. arch

The following will execute diff(1) with successive pairs of arguments originally typed as shell arguments:

echo \$\* | xargs -n2 diff

### SEE ALSO

sh(1).

## DIAGNOSTICS

Self-explanatory.

YACC(1) YACC(1)

#### NAME

vacc - vet another compiler-compiler

#### SYNOPSIS

yacc [ -vdlt ] grammar

#### HP-UX COMPATIBILITY

Level:

HP-UX/STANDARD

Origin: System V

#### DESCRIPTION

Yacc converts a context–free grammar into a set of tables for a simple automaton which executes an LR(1) parsing algorithm. The grammar may be ambiguous; specified precedence rules are used to break ambiguities.

The output file, **y.tab.c**, must be compiled by the C compiler to produce a program yyparse. This program must be loaded with the lexical analyzer program, yylex, as well as main and yyer-ror, an error handling routine. These routines must be supplied by the user; lex(1) is useful for creating lexical analyzers usable by yacc.

If the -v flag is given, the file y.output is prepared, which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.

If the -d flag is used, the file **y.tab.h** is generated with the **#define** statements that associate the *yacc*-assigned "token codes" with the user-declared "token names". This allows source files other than **y.tab.c** to access the token codes.

If the -l flag is given, the code produced in **y.tab.c** will *not* contain any #line constructs. This should only be used after the grammar and the associated actions are fully debugged. This is useful when you intend to compile y.tab.c with the -g option for cdb, since #line constructs should not be used in file compiled with -g. (See cc(1), cdb(1)).

Runtime debugging code is always generated in y.tab.c under conditional compilation control. By default, this code is not included when y.tab.c is compiled. However, when yacc's -t option is used, this debugging code will be compiled by default. Independent of whether the -t option was used, the runtime debugging code is under the control of YYDEBUG, a pre-processor symbol. If YYDEBUG has a non-zero value, then the debugging code is included. If its value is zero, then the code will not be included. The size and execution time of a program produced without the runtime debugging code will be smaller and slightly faster.

#### FILES

y.output

v.tab.c

v.tab.h

defines for token names

yacc.tmp,

yacc.debug, yacc.acts

temporary files

/usr/lib/yaccpar

parser prototype for C programs

#### SEE ALSO

lex(1), malloc(3X).

LR Parsing by A. V. Aho and S. C. Johnson, Computing Surveys, June, 1974.

YACC - Yet Another Compiler Compiler in HP-UX: Selected Articles.

#### DIAGNOSTICS

The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output; a more detailed report is found in the **y.output** file. Similarly, if some rules are not reachable from the start symbol, this is also reported.

#### **BUGS**

Because file names are fixed, at most one yacc process can be active in a given directory at a time.

error message generator from C programs	
etext	\ /
eval	
evaluate arguments as an expression	
ex	
examine text, facilitate on soft-copy terminals	
exec	
execl	` '
execle	
execlp	
executable file, extract symbol table (name list) entries from	
executable file, get size of	
executable linker/assembler output file, description of	a.out(5)
execute a file in current process	
execute command at lower or higher priority	
execute command immune to hangups, logouts, and quits	nohup(1)
execute command on another system	
execute command using different root directory	
execute commands at specified date(s) and time(s)	
execute commands from file	$sh(1)$

execute new program in existing process	$sh(1)$ , $exec(2)$
execute process with real-time priority	rtprio(1)
execute HALGOL programs	
execute uucp commands on local system	uuxqt(1M)
execute work requests on remote system	
execution profile, create for program	
execution, suspend process execution for time interval	
execv	1 ( ) (
execve	
execvp	` ,
_exit	` ,
exit	. ,
exit from enclosing for or while loop	
exp	
expand	
expand tabs to spaces, and vice versa	
exponent, raise 2 to a power	
exponential function	
-	- ' '
export	
expr	
expreserve	. ,
expression, evaluate arguments as	
exrecover	( )
Extended Memory System description	
external symbols, examine execution profile for	
extract entries from symbol table (name list) of executable file	
extract error messages from C source into a file	
extract files from 5.25" flexible discs	
extract files from Command Set 80 cartridge tape archives	
extract files from media	cpio(1)
extract portions of path names	basename(1)
f77	fc(1)
f77	see fc(1)
fabs	floor(3M)
false	true(1)
fc	
fclose	. ,
fentl	` ,
fcntl(2), description of requests and arguments for	
fentl.h, description of	fentl(7)
fevt	
fdopen	
feof	
ferror	
flush	
fgetc	
fgets	
fgrep	0 - ( )
fifo special file, create	
file, assign another file name to already open file	
file, assign buffering to open	
file attributes file, description of	
file, buffered read from	
file, buffered write to	( )
file, change group ID of	chown(1), chown(2)

file, change mode of	chmod(1) chmod(2)
file, change owner	
file, change permission bits	
file, check revision number for	
file, close a buffered open file	
file comparison, three-way differential	
file control	
file control constants, file containing definitions of	
file, copy LIF in or out	
file, copy to tape while performing certain conversions	
file, count words, lines, and characters contained therein	
file, create and open temporary	` ,
file, create device/special	
file, create or overwrite ordinary	
file, create or remove link to/from	
file, create ordinary	
file creation mask, set	
file, description of buffered I/O	
file, description of password file, /etc/passwd	
file, description of SCCS file format	
file descriptor, assign stream to	
file descriptor, close	
file descriptor, copy/duplicate	dup(2), icntl(2)
file descriptor, create file pointer using	
file descriptor, determine if associated with terminal	
file descriptor, get value of	
file, determine accessibility of	
file, error logging file for system	
file, find and/or remove duplicate lines in	
file, find spelling errors in	
file format, per-process accounting	
file, generate name for temporary	
file, get information about	
file, get/set status flags for	
file, indicate the occurrence of an error while reading	
file, indicate when EOF is encountered when reading from	
file, locate in file system	$\dots \qquad \text{find}(1)$
file, move to new position in	
file name, create file name vs. i-node list	
file name, create unique	
file name, extract from path name	
file name, find special file for mounted file system on which file lies	
file name, generate for temporary file	
file name, generate for terminal	
file, open for reading or writing	$\cdots \cdots $
file, open with assigned buffering	fopen(3S)
file owner or group, change	
file pointer, create using file descriptor	
file pointer, move read/write (seek)	lseek(2)
file pointer, obtain for file	fopen(3S)
file pointer, re-assign to another file	fopen(3S)
file, print last part of	
file, put line length specifications in text files	
file, put margin specifications in text files	fspec(5)
file, put tab specifications in text files	
	= ', '

£1 J J	.1 (1)
file, read and execute commands from file, read and format data from	
file, read character from	
file, read from	
file, read word from	getc(35)
file, remove	rm(1)
file, remove extra new-line characters from	
file, remove selected fields from each line in	
file, remove selected table column entries from	
file, rename LIF	
file, rewind before next I/O operation	
file scanner, big	
file, search contents of for specified string(s)	
file, set/clear set-user-ID, set-group-ID, sticky bits	
file size limit, get for process	
file, sort contents of	
file, split into pieces	
file system, backup file system on cpio archive	
file system (Bell) consistency check and interactive repair	
file system (Bell) debugger	
file system consistency check and interactive repair	fsck(1M)
file system, construct on special file	
file system debugger	
file system descriptor file entry	
file system, find special file associated with	
file system hierarchy	hier(7)
file system, install commands in	
file system, list of those to be checked by fsck(1M)	checklist(5)

files, concatenate two or more	cat(1)
files, copy	
files, copy and simultaneously edit	$\dots$ sed(1)
files, copy between two systems uucp	
files, copy out to media	cpio(1)
files, description of /etc/profile and \$HOME/.profile	profile(5)
files, extract from media	
files, format and print	
files, merge lines in one or more	
files, move, link, or copy	
files, print	- ` '
files, unpack/extract from 5.25" flexible discs	
files, unpack/extract from Command Set 80 cartridge tape archives	
filter reverse line-feeds and backspaces	
find	
find current user slot in utmp file	` '
find duplicate lines in file	
find files	- ( )
find files in a BIF system	
find name of a terminal t	
find strings for inclusion in message catalog	
	` '
findmsg	
findstr	
fix manual pages for faster viewing with $man(1)$	
fixman	` '
flag, get/set close-on-exec	
flags, mapping pwb/V6 UNIX terminal flags into current HP-UX	
flags, set shell	
flexible discs, unpack/extract files from	
floating point number, split into integer and fractional parts	
floating point to ASCII conversion	\ /
floor	
flow graph, C, generate	cflow(1)
flush buffers associated with an open file	. fclose(3S)
fmod	
fold long lines for finite-width output device	
fopen	
for loop, exit from enclosing	
for loop, resume the next iteration of	
fork	
format and print files	
format C program	
format, compiled term file	$\dots$ term(5)
format data into string	
format data on buffered open file	. printf(3S)
format data on standard output	. printf(3S)
format, nlist structure	
format of an i-node, description of	inode(5)
format of a out file, description of	$\dots  a.out(5)$
format of core image file, description of	
format of cpio archive, description of	
format of library/archive file, description of	
format of SCCS file, description of	
format, privileged values	
format SDF volume	

format specifications, put in text file	fenec(5)
format tables for nroff or troff	
format text	
formatted output from varargs argument list	( )
formatted output with numbered arguments	- ( )
formatter, text, simple	
formatting text with the man macros	
formatting text with the mm macros	
FORTRAN 77 compiler	
fprintf	
fputc	
fputs	
fread

nm	nm(1)
nodename, get	
nodename, set/print name of current	hostname(1)
nohup	
non-ASCII string collation used by NLS	
nroff	
nroff, format tables for	
nroff, interpret output from nroff for printing	
nroff, troff, tbl, eqn constructs, remove from text	
numbered-argument print output formatting	
object code, locate for program	
object file, debugger for	
object file, extract symbol table (name list) entries from	
object file, get size of	
object file link information utility	linkinfo(1)
object file, print symbol table (name list) of	nm(1)
object file, remove symbol table and relocation bits from	
object library, find ordering relation for	lorder(1)
octal, hexadecimal dump	
od	
on-line manual command	
on-line manual, create preformatted manual pages for	
open	open(2)
open a file and assign buffering to it	fopen(3S)
open file, assign buffering to	
open file descriptor, duplicate	
open file for reading or writing	
operating system, append to an existing operating system	
operating system, change to different OS or different version of same OS	chsys(1M))
operating system, check integrity of OS in SDF boot area(s)	
operating system, copy from one or more SDF boot areas to another	
operating system, create new operating system from ordinary files	
operating system management package description	
operating system, mark as loadable or non-loadable	osmark(1M)
operating system, shut down OS with optional re-boot	
operating system, split into one or more ordinary files	oscp(1M)
optarg	getopt(3C)
opterr	getopt(3C)
optimization routines: CRT screen and cursor control	curses(3X)
optind	getopt(3C)
option letter, get from argv	
options, parse command line	getopt(1)
options, set for terminal	stty(1)
options, set shell	sh(1)
opx25	opx25(1M)
ordering relation, find for object library or archive file	lorder(1)
ordinary file, create	mknod(2)
ordinary file, create or overwrite	creat(2)
OS, append to an existing operating system	
OS, change to different OS or different version of same OS	
OS, check integrity of operating system in SDF boot area(s)	
OS, copy from one or more SDF boot areas to another	
OS, create new operating system from ordinary files	oscp(1M)
OS management package description	
CC	551161 (1111)

OS, mark as loadable or non-loadable	osmark(1M)
OS, shut down operating system with optional re-boot	
OS, split operating system into one or more ordinary files	
osck	
oscp	
osmark	
osmgr	
output character or word to open file or standard output	
output, description of formatted/unformatted output to printer	
output, description of system handling of terminal output	
output, print formatted data into string	* ` '
output, print formatted data on buffered open file	- \ /
output, print formatted data on standard output	
output string to open file or standard output	
overlay program onto existing process and execute	
overview of accounting commands	
owner, change for file	aboum(1) aboum(2)
page	chown(1), chown(2)
page size, set for paged data	more(1)
paged data, set for program	chatr(1)
paging and swapping enable	swapon(IM)
PAM	
parameter substitution	` '
parameters, environment	
parameters, install in environment	
parameters, mark as readonly	
parameters, perform left-shift on positional	
parameters, set for terminal	
parameters, set for terminal on login	
parent process ID, get for process	
parity, settings for terminal	
parse command line options	
Pascal compiler	
passwd	
password, change login	
password encryption	
password file, close	$\dots$ getpwent(3C)
password file, description of	
password file, get line containing matching user ID	getpw(3C)
password file, output line similar to those contained in	$\dots$ putpwent(3C)
password file, read one line from	$\dots getpwent(3C)$
password file, rewind	
password file, search for matching user ID	
password file, search for matching user name	
password, read from /dev/tty or standard input	$\dots$ getpass(3C)
password/group file checkers	pwck(1M)
paste	
path name, get for terminal	
path name, isolate directory name from	
path name, isolate file name from	$\dots$ basename(1)
pattern, find and process within text	
pattern, search contents of file for	
pause	
pause, suspend process for interval	
pc	$pc(1)$

pipe, create/close between process and command	$\dots$ popen(3S)
pipe, get intermediate data from	tee(1)
pipeline, create	$\dots$ pipe(2)
pipeline, get intermediate data from	tee(1)
place error messages from C source into a file	mkstr(1)
plock	plock(2)
plotter, description of hpib interface to	hpib(4)
popen	$popen(3S)$
port, database listing terminal type connected to each	$\dots$ ttytype(5)
portable code between HP-UX implementations, typedefs for	
position magnetic tape	mt(1)
positional parameters, perform left-shift on	$\sinh(1)$
posters, make using large letters	
pow	
power function	
powerfail	
pr	
prealloc	
preallocate disc storage	
preprocessor for C compiler	cnn(1)
print and format files	pp(1)
print and summarize an SCCS file	
print arguments after shell interpretation	
print, copy, and/or concatenate files	
print, copy, and/or concatenate mes print current SCCS file editing activity	
print documents formatted with mm macros	sact(1)
print decuments formatted with min macros	(1)
print enective current user id	
print formatted data on standard output, open life, or string	
print formatted output from varargs argument list print formatted output with numbered arguments	vpriiii(35)
print last part of file	
print name list (symbol table) of object file	
print name of current working directory	pwa(1)
print news items	news(1)
print time and date	
print user, group IDs and names	
printer, description of formatted/unformatted output	Ip(4)
printer, description of hpib interface to	hpib(4)
printer options, set	$\dots \operatorname{sip}(1)$
printf	
printmsg	printmsg(3C)
priority, run command at lower or higher	
privileged values format	
procedures: shell procedures for accounting	` ,
process accounting	acctprc(1M)

process accounting commands	acctcom(1)
process and system state initialization	
process, change data segment space allocation for	brk(2)
process, change root directory of	
process, create a new	
process, create/close pipe between process and command	popen(3S)
process, enable break-point debugging of child process	
process, format of core image of terminated process	- ` ` `
process, get ID, group ID, and parent process ID of	
process, get real/effective user and real/effective group ID's for	
process, get/set file size limit for	
process group ID, set	
process, lock/unlock address space or segment	
process number, get	· /
process, overlay new program onto existing	0 - ( )
process, print accumulated user and system time elapsed for	
process, send SIGIOT to	
process, send signal to	
process, set group ID for	
process status, report	
process, suspend execution for interval of time	
process, suspend until signal	
process, terminate	
process, time execution of	
process, wait for completion of	
processes, list active	
processes, send signal to all user processes	
processes, specify maximum number of processes per user	
processes, terminate all user processes	
processor type	
prof	
profil	- 1
profile, create for program during execution	
profile data, display	prof(1)
profile files, description of /etc/profile and \$HOME/.profile	
program, add diagnostics to	
program, change internal attributes of	
program, check/verify C	
program, create execution profile for	
program, create from object files	ld(1)
program, debugger for	
program, execute command from	system(3S)
program, force action associated with signal to be taken	ssignal(3C)
program, format C	
program, generate for lexical analysis of text	lex(1)
program, get particular addresses associated with	
program, get size of	
program, locate source, binary, and/or on-line manual page for	whereis (1)
program, maintain, update, and recompile	
program, overlay onto existing process and execute	
program, run immune to hangups, logouts, and quits	
program, set up signal handling for	
program verification	
provide semaphores and record locking on files	
provide truth value about your processor type	* *
