For Safety Information, Warranties, and Regulatory Information, see the pages at the end of this manual.

HP 1670D-Series Logic Analyzers

HP 1670D-Series Logic Analyzers

The HP 1670D-series logic analyzers are 100-MHz state/250-MHz timing logic analyzers.

Features

- 132 data channels and 4 clock/data channels in the HP 1670D
- 98 data channels and 4 clock/data channels in the HP 1671D
- 64 data channels and 4 clock/data channels in the HP 1672D
- 3.5-inch flexible disk drive
- 540-MB hard disk drive
- HP-IB, RS-232-C, parallel printer, and LAN interfaces
- BNC and UTP LAN ports
- Variable setup/hold time
- 64 K memory on all channels, 128 K in half-channel mode
- Marker measurements
- 12 levels of trigger sequencing for state and 10 levels of trigger sequencing for timing
- 125-MHz time tagging and state tagging
- Full programmability
- DIN mouse
- DIN keyboard support

Options

- Programmer's Guide
- Service Guide
- 1M memory on all channels, 2M in half-channel mode

In This Book

This User's Guide shows you how to use the HP 1670D-series logic analyzers. It contains measurement examples, field and feature definitions, and a basic service guide. Refer to this manual for information on what the menu fields do and how they are used. This manual covers all HP 1670D-series analyzers.

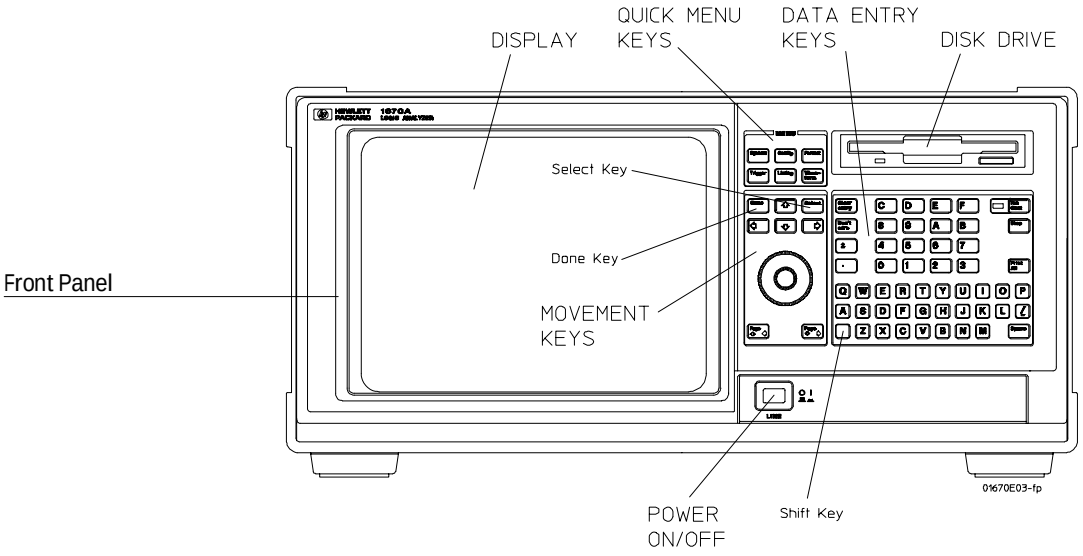
The User's Guide is divided into four parts. The first part, chapters 1 through 4, covers general product information you need to use the logic analyzer. The second part, chapters 5 and 6, contains detailed examples to help you use your analyzer in performing complex measurements. The third part, chapters 7 through 9, contains reference information on the hardware and software, including the analyzer menus and how they are used. There are sections for each analyzer menu and a separate chapter on System Performance Analysis. The fourth part, chapters 10 through 12, provides a basic service guide.

Contents

10 Troubleshooting

Logic Analyzer Overview

HP 1670D-Series Logic Analyzer



Select Key

The Select key action depends on the type of field currently highlighted. If the field is an option field, the Select key brings up an option menu or, if there are only two possible values, toggles the value in the field. If the highlighted field performs a function, the Select key starts the function.

Done Key

The Done key saves assignments and closes pop-up menus. In some fields, its action is the same as the Select key.

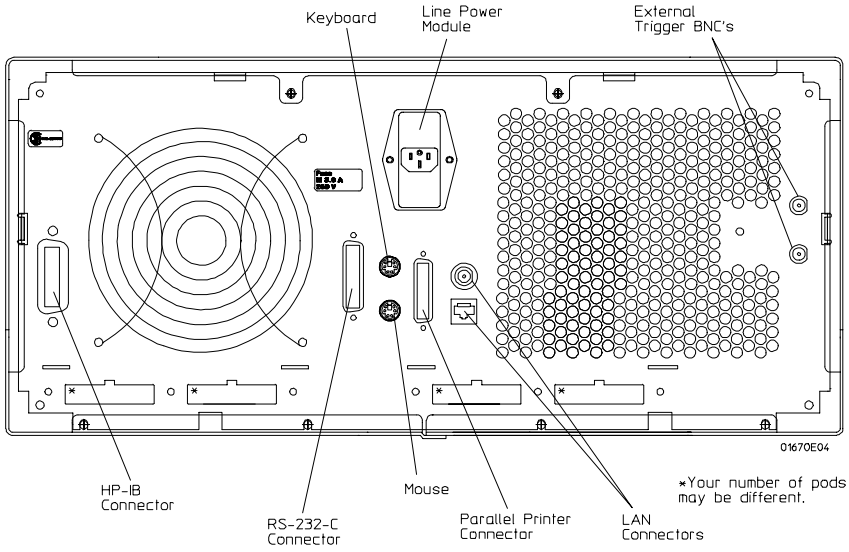
Shift Key

The shift key, which is blue, provides lowercase letters and access to the functions in blue on some of the keys. You do not need to hold the shift key down while pressing the other key — just press the shift key first, and then the function key.

Knob

The knob can be used in some fields to change values. These fields are indicated by a side view of the knob placed on top of the field when it is selected. The knob also scrolls the display and moves the cursor within lists. If you are using a mouse while dragging, you can do the same actions by holding down the right button.

Rear Panel



Line Power Module

Permits selection of 110-120 or 220-240 Vac and contains the fuses for each of these voltage ranges.

External Trigger BNCs

The External Trigger BNCs provide the "Port In" and "Port Out" connections for the Arm In and Arm Out of the Trigger Arming Control menu.

RS-232-C Connector

Standard DB-25 type connector for connecting an RS-232-C printer or controller.

HP-IB Connector

Standard HP-IB connector for connecting an HP-IB printer or controller.

Parallel Printer Connector

Standard Centronics connector for connecting a parallel printer.

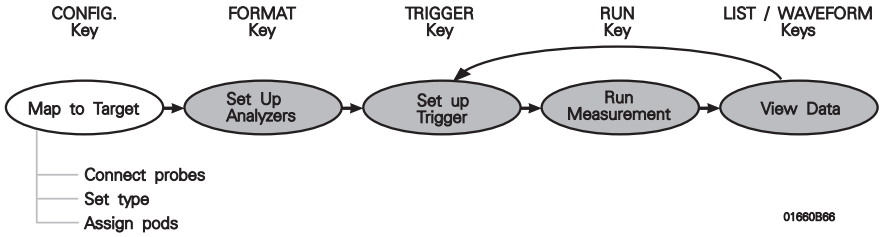
LAN Connectors

Connects the logic analyzer to your local Ethernet network. The BNC connector on top accepts 10Base2 ("thinlan"). The UTP connector below the BNC connector accepts 10Base-T ("ethertwist").

To make a measurement

For more detail on any of the following information, see the referenced chapters. If you are using a preprocessor with the logic analyzer, some of these steps may not apply.

Map to target



Connect probes Connect probes from the target system to the logic analyzer to physically map the target system to the channels in the logic analyzer. Attach probes to a pod in a way that keeps logically-related channels together. Remember to ground each pod.

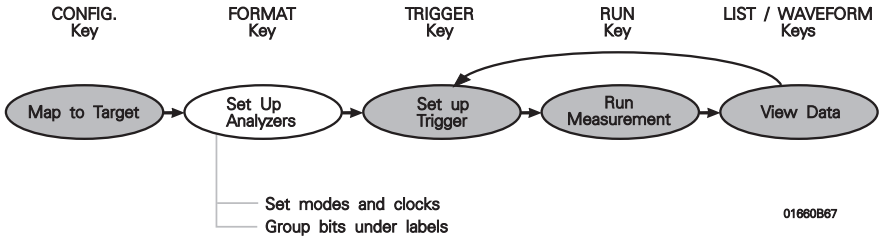
See Also "Probing" in Chapter 7 for more detail on constructing probes.

Set type* When the logic analyzer is turned on, Analyzer 1 is named Machine 1 and is configured as a timing analyzer, and Analyzer 2 is off. To use state analysis, state compare, or software profiling, you must set the type of the analyzer in the Analyzer Configuration menu. You can only use one timing analyzer at a time.

Assign pods* In the Analyzer Configuration menu, assign the connected pods to the analyzer you want to use. The number of pods on your logic analyzer depends on the analyzer model. Pods are paired and are always assigned as a pair to a particular analyzer.

* If you load a configuration file, this step is not necessary.

Set up analyzers*



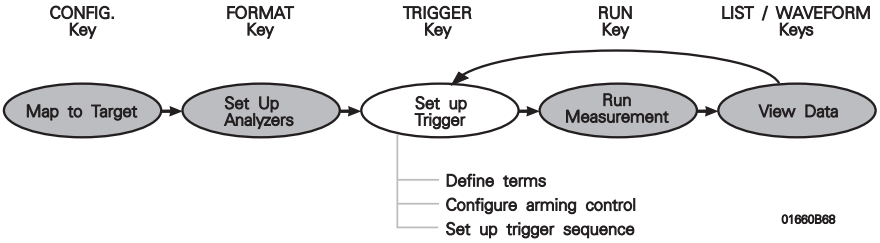
Set modes and clocks Set the state and timing analyzers using the Analyzer Format menu. In general, the timing modes trade channel count for speed. The state analyzer provides for complicated clocking. If your state clock is set incorrectly, the data gathered by the logic analyzer might indicate an error where none exists.

See Also "The Format Menu" in Chapter 7 for more information on modes and clocks.

Group bits under labels The Analyzer Format menu indicates active pod bits. You can create groups of bits across pods or subgroups within pods, and name the groups or subgroups using labels.

* If you load a configuration file, this step is not necessary.

Set up trigger*



Define terms In the Analyzer Trigger menu, define trigger variables called terms to match specific conditions in your target system. Terms can match patterns, ranges, or edges acrossds multiple labels.

Configure Arming Control Use Arming Control if

- you want to correlate the triggers and data of both analyzers
- you want to use the logic analyzer to trigger an external instrument, or
- you want to use an external instrument to trigger the logic analyzer.

Set up trigger sequence Create a sequence of steps that control when the logic analyzer starts and stops storing data, and filters which data it will store. For common tasks, you can use a trigger macro to simplify the process, or use the user-defined macros to loop and jump in sequence.

See Also

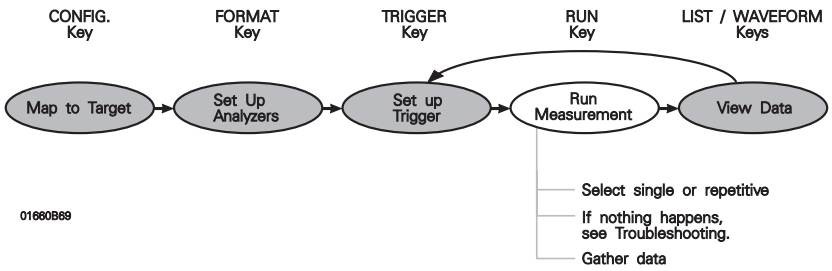
Chapter 4, "Using the Trigger Menu" and Chapter 5, "Triggering Examples" for more information on setting up a trigger.

"The Trigger Sequence" in Chapter 9 for more information about the trigger sequence mechanism.

"To save a configuration" and "To load a configuration" in Chapter 6 for instructions on saving and loading the setup so you don't have to repeat setting up the analyzer and trigger.

* If you load a configuration file, this step is not necessary.

Run measurement



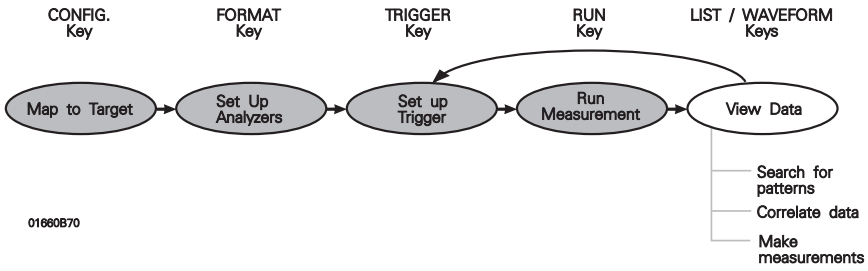
Select single or repetitive From any Analyzer menu, select the field labeled Run in the upper right corner to start measuring, or press the Run key. A single run will run once, until memory is full; a repetitive run will continue until you select Stop or until a stop measurement condition that you set in the markers menu is fulfilled.

If nothing happens, see Troubleshooting. When you start a run, your analyzer menu changes to one of the display menus or a status message pops up. If nothing happens, press the Stop key. If the analyzer still does not display any measurements, see Chapter 10, "Troubleshooting." If memory length is large it will take a noticeable amount of time to fill, and data is not displayed during acquisition.

Gather data You can gather statistics automatically by going to the Waveform, Listing, or Chart menu, turning on markers, and setting patterns for the X and O markers. You can set the analyzer to stop if certain conditions are exceeded, or just use the markers to count valid runs.

See Also "Markers" in Chapter 7 for more information on markers and stop measurement conditions.

View data



Search for patterns In the Waveform, Listing, and Chart menus, you can use symbols and markers to search for patterns in your data. In these menus, toggle the Markers field to turn the pattern markers on, then specify the pattern. When switching views, markers keep their settings.

Correlate data You can correlate data by setting Count Time in your state analyzer's Trigger menu, and then using interleaving and mixed display. Interleaving correlates the listings of two state analyzers. Mixed display correlates a timing analyzer waveform and a state analyzer listing.

You can also correlate data by setting the analyzer type to State Compare, acquiring the data, then using the Compare menu to do a bit-by-bit comparison between the acquired state data and a reference listing.

The System Performance Analysis (SPA) Software does not save a record of actual activity, so it cannot be correlated with timing or state mode.

Make measurements The markers can count occurrences of events, measure durations, and collect statistics. The SPA provides high-level summaries to help you identify bottlenecks. To use the markers, select the appropriate marker type in the display menu and specify the data patterns for the marker. To use SPA, go to the SPA menu, select the most appropriate mode, fill in the parameters, and press Run.

See Also

Chapter 8, "System Performance Analysis (SPA) Software" for more information on using SPA.

"The Waveform Menu", "The Compare Menu", "The Listing Menu", and "The Chart Menu" in Chapter 7 for additional information on the menu features.

Connecting Peripherals

Connecting Peripherals

Your HP 1670D-series logic analyzer comes with a PS2 mouse. It also provides connectors for a LAN, keyboard, Centronics (parallel) printer, HP-IB, and RS-232-C devices. This chapter tells you how to connect peripheral equipment, such as the mouse or a printer, to the logic analyzer.

Mouse and Keyboard

You can use either the supplied mouse and optional keyboard, or another PS2 mouse and keyboard with standard DIN connector. The DIN connector is the type commonly used by personal computer accessories.

Printers

The logic analyzer communicates directly with HP PCL printers supporting the Printer Control Language or with other printers supporting the Epson standard command set. Many non-Epson printers have an Epson-emulation mode. HP PCL printers include the following:

- HP ThinkJet
- HP LaserJet
- HP PaintJet
- HP DeskJet
- HP QuietJet

You can connect your printer to the logic analyzer using HP-IB, RS-232-C, or the parallel printer port. The logic analyzer can only print to printers directly connected to it. It cannot print to a networked printer on the LAN.

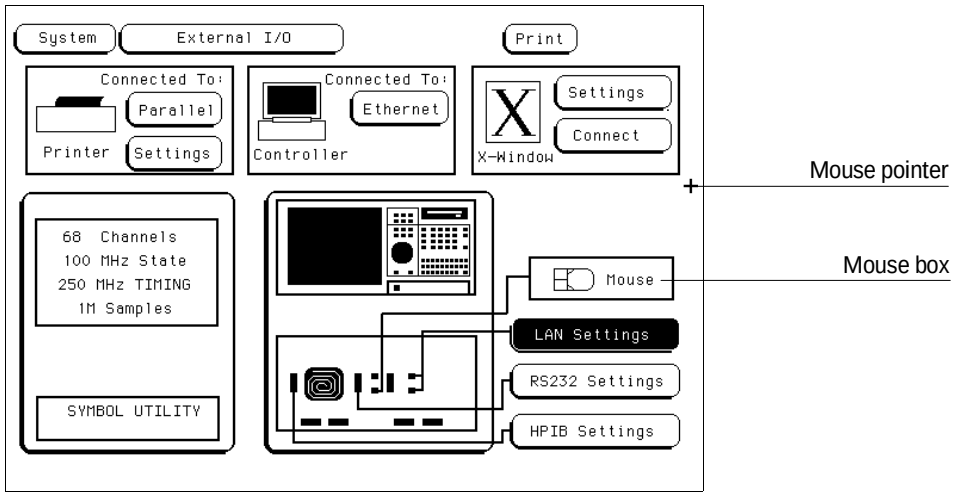
To connect a mouse

Hewlett-Packard supplies a mouse with the logic analyzer. If you prefer a different style of mouse you can use any PS2 mouse with a standard PS2 DIN interface.

1. **Plug the mouse into the mouse connector on the back panel. Make sure the plug shows the arrow on top.**
2. **To verify the connection, check the System External I/O menu for a mouse box.**

   The mouse box is on the right side above the Settings fields. If the logic analyzer was displaying the System External I/O menu when you plugged in the mouse, the menu won't update until you exit and then return to it.

   The mouse pointer looks like a plus sign (+). To select a field, move the pointer over it and press the left button. To duplicate the front-panel knob, hold down the right button while moving the mouse. Moving the mouse up or to the right duplicates turning the knob clockwise. Moving the mouse down or to the left duplicates turning the knob counterclockwise.



System External I/O Menu Showing Mouse Installed

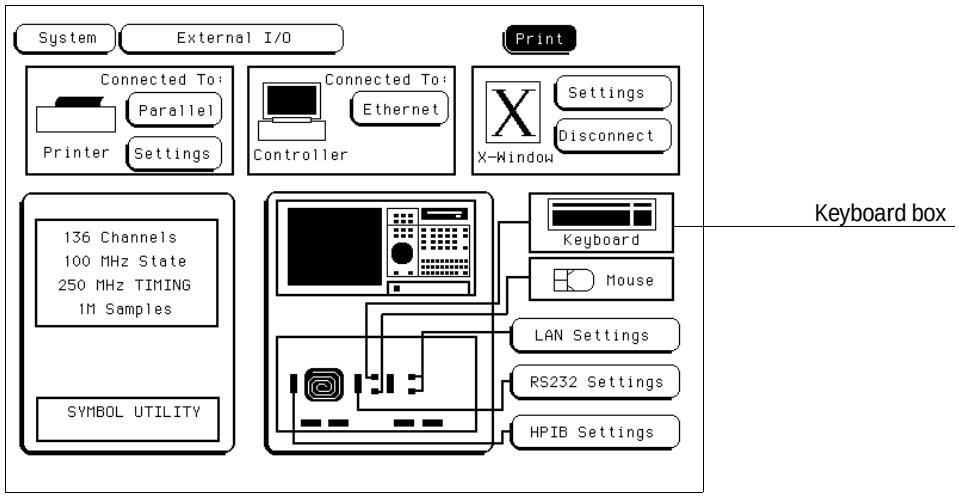
To connect a keyboard

You can use either the HP-recommended keyboard, HP E2427B, or any other keyboard with a standard DIN connector.

1. **Plug the keyboard into the keyboard connector on the back panel.**
2. **To verify the connection, check the System External I/O menu for a keyboard box.**

   The keyboard box is on the right side, below the X Window field. If the logic analyzer was displaying the System External I/O menu while you plugged the keyboard in, the menu won't update until you exit and then return to it.

   The keyboard cursor is the location on the screen highlighted in inverse video. To move the cursor, use the arrow keys. Pressing Enter selects the highlighted field. The primary keyboard keys act like the analyzer's front-panel data entry keys.



System External I/O Menu Showing Keyboard Installed

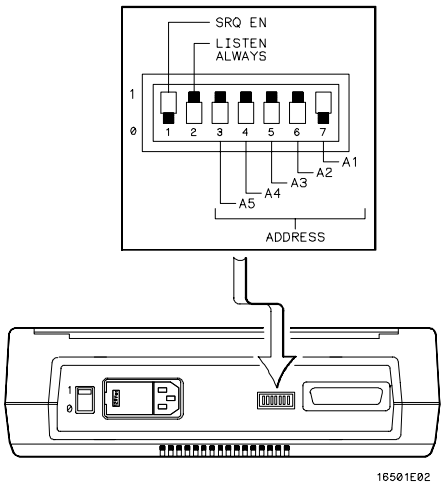
See Also "Keyboard Shortcuts" in Chapter 7 for complete key mappings.

To connect to an HP-IB printer

Printers connected to the logic analyzer over HP-IB must support HP-IB and Listen Always. When controlling a printer, the analyzer's HP-IB port does not respond to service requests (SRQ), so the SRQ enable setting does not have any effect on printer operation.

1. Turn off the analyzer and the printer, and connect an HP-IB cable from the printer to the HP-IB connector on the analyzer rear panel.
2. Turn on the analyzer and printer.
3. Make sure the printer is set to **Listen Always** or **Listen Only**.

   For example, the figure below shows the HP-IB configuration switches for an HP-IB ThinkJet printer. For the **Listen Always** mode, move the second switch from the left to the 1 position. Because the instrument doesn't respond to SRQ EN (Service Request Enable), the position of the first switch doesn't matter.



Listen Always Switch Setting

4 Go to the System External I/O menu and configure the analyzer's printer settings.

a If the analyzer is not already set to HP-IB, select the field under Connected To: in the Printer box and choose HP-IB from the menu.

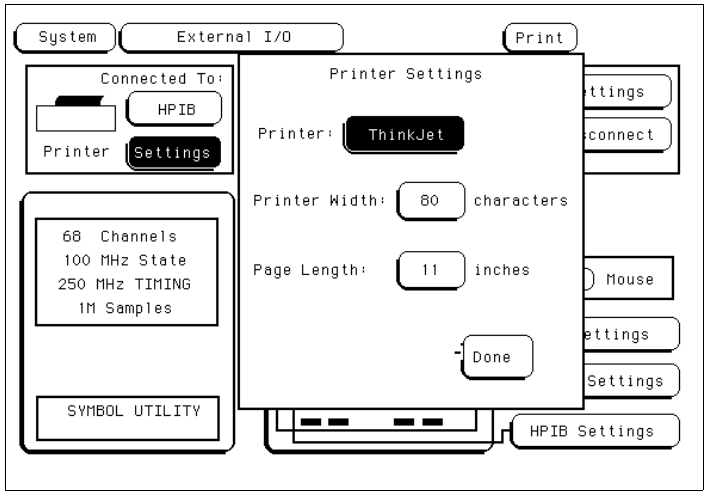
b Select the Printer Settings field.

c In the top field of the pop-up menu, select the type of printer you are using. If you are using an Epson graphics printer or an Epson-compatible printer, select Alternate.

d If the default print width and page length are not what you want, select the fields to toggle them.

If you select 132 characters per line when using a printer other than QuietJet, the listings are printed in a compressed mode. QuietJet printers can print 132 characters per line without using compressed mode, but require wider paper.

e Press done.



Printer Settings Menu

To connect to an RS-232-C printer

1. Turn off the analyzer and the printer, and connect a null-modem RS-232-C cable, such as HP 13242G, from the printer to the RS-232-C connector on the analyzer rear panel.
2. Before turning on the printer, locate the mode configuration switches on the printer and set them as follows:
   - For the HP QuietJet series printers, there are two banks of mode function switches inside the front cover. Set all the switches down to the 0 position.
   - For the HP ThinkJet printer, the mode switches are on the rear panel of the printer. Push all the switches down to the 0 position.
   - For the HP LaserJet printer, the factory default switch settings will work.
3. Turn on the analyzer and printer.
4. Go to the System External I/O menu and configure the analyzer's printer settings.
   a. If the analyzer is not already set to RS-232-C, select the field under Connected To: in the Printer box and choose RS-232C from the menu.
   b. Select the Printer Settings field.
   c. In the top field of the pop-up menu, select the type of printer you are using. If you are using an Epson graphics printer or an Epson-compatible printer, select Alternate.
   d. If the default print width and page length are not what you want, select the fields to toggle them.

      If you select 132 characters per line when using a printer other than a QuietJet, the listings are printed in a compressed mode. QuietJet printers can print 132 characters per line without using compressed mode, but require wider paper.
   e. Press Done.
5. Select the RS232 Settings field and check that the current settings are compatible with your printer.

See Also "The RS-232-C Interface" in Chapter 7 for more information on RS-232-C settings.

To connect to a parallel printer

1. Turn off the analyzer and the printer, and connect a parallel printer cable from the printer to the parallel printer connector on the analyzer rear panel.
2. Before turning on the printer, configure the printer for parallel operation.

   The printer's documentation will tell you what switches or menus need to be configured.
3. Turn on the analyzer and printer.
4. Go to the System External I/O menu and configure the analyzer's printer settings.
   a. If the analyzer is not already set to Parallel, select the field under Connected To: in the Printer box and choose Parallel from the menu.
   b. Select the Printer Settings field.
   c. In the top field of the pop-up menu, select the type of printer you are using. If you are using an Epson graphics printer or an Epson-compatible printer, select Alternate.
   d. If the default print width and page length are not what you want, select the fields to toggle them.

      If you select 132 characters per line when using a printer other than a QuietJet, the listings are printed in a compressed mode. QuietJet printers can print 132 characters per line without using compressed mode, but require wider paper.
   e. Press Done.

There are no settings specific to the parallel printer connector.

To connect to a controller by HP-IB or RS-232-C

You can control the HP 1670D-series logic analyzer with another instrument, such as a computer running a program with embedded analyzer commands. The steps below outline the general procedure for connecting to a controller using HP-IB or RS-232-C.

1. **Turn off both instruments, and connect the cable.**

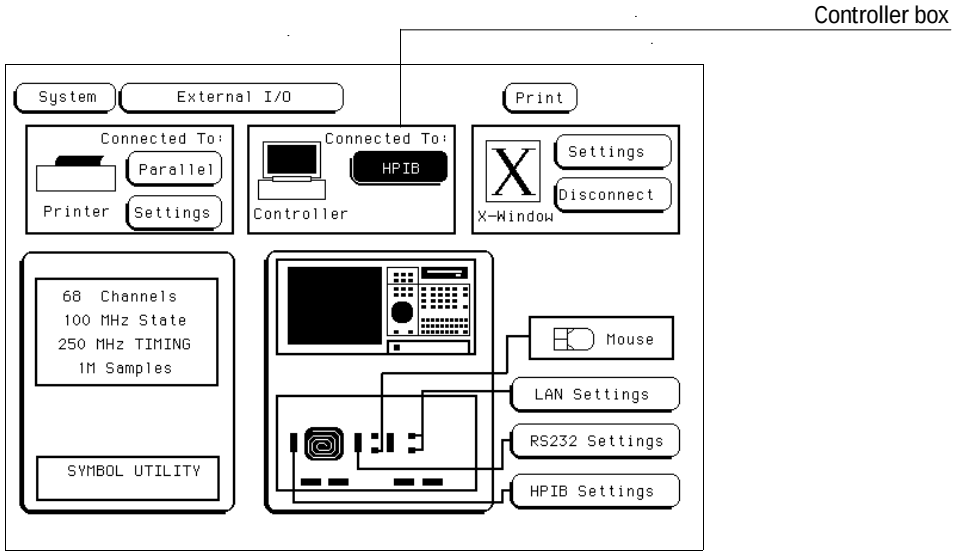
   If you are using RS-232-C, the cable must be a null-modem cable. If you do not have a null-modem cable, you can purchase an adapter at any electronics supply store.

2. **Turn on the logic analyzer, then the controller.**

3. **In the System External I/O menu, select the field under Connected To: in the Controller box and set it appropriately.**

   The figure below is for HP-IB.

4. **Select the appropriate Settings field and configure the values in the pop-up menu to be compatible with the controller.**



See Also

HP 1670D-Series Logic Analyzers Programmer's Guide for more information on connecting and using controllers with RS-232-C and HP-IB.

To connect to a controller by LAN

You can control the HP 1670D-series logic analyzer using LAN. These instructions are only a general guide for controlling a logic analyzer already on the LAN.

Each type of LAN is slightly different. For information on connecting the logic analyzer to your specific LAN, see the *LAN User's Guide*.

1. In the System External I/O menu, check that the LAN settings are correct and set Controller Connected To: to Ethernet.
2. Start up your preferred means of communication.
   - X Window: After enabling client-initiated windows, select Connect in the X-Window box.
   - NFS: Contact your network administrator.
   - Telnet or ftp: Initiate a session from the controlling computer. If you are using telnet, be sure to specify port 5025. If you are using ftp, log in as control.
3. Control the logic analyzer as appropriate to your connection type.
   - X Window: Use the mouse and keyboard with X Window display to control the logic analyzer as though from the front panel.
   - Telnet: Type analyzer programming commands in directly.
   - NFS or ftp: Prepare a file containing commands, and copy it to the logic analyzer's `\system\program` file. The analyzer must be connected as control.

LAN Session

Remember to disconnect your LAN session before turning off the logic analyzer

See Also

HP1670D-Series Logic Analyzer Programmer's Guide for more information on logic analyzer programming commands.

The *LAN User's Guide* for details on connecting the logic analyzer to the LAN and examples of controlling the logic analyzer over LAN.

Using the Analyzer

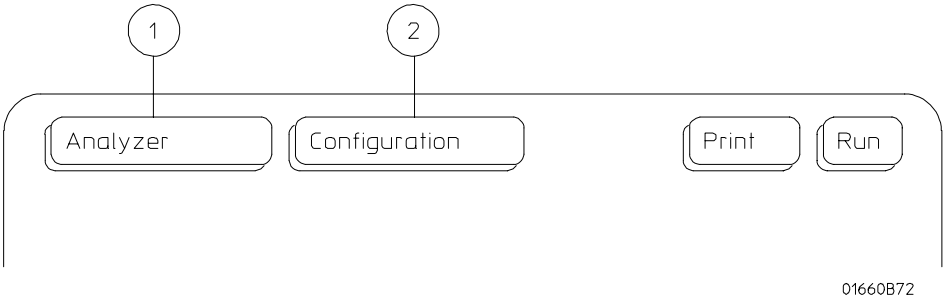
Using the Analyzer

This chapter shows you how to perform the basic tasks necessary to make a measurement. Each section uses an example to show how the task fits into the overall goal of making a measurement.

Accessing the Menus

When you power up the logic analyzer, the first screen after the system tests is the Analyzer Configuration menu. Menus are identified by two fields in the upper left corner. The leftmost field shows Analyzer. This field is sometimes referred to as the "mode field" or the "module field" because it controls which other set of menus you can access. The second field, just to the right of the mode field, accesses menus within the mode and so is called the "menu field". Menus are referred to by the titles that appear in the mode and menu fields; for example, the Analyzer Configuration menu.

The figure below shows the top of the first screen. The mode field, item 1, displays "Analyzer." The menu field, item 2, displays "Configuration." Because menus are identified by the titles in these two fields, this menu is referred to as the Analyzer Configuration menu. When there is no risk of confusion, the menu is sometimes referred to just by the title showing in the second field; for example, the Configuration menu.



Logic Analyzer Configuration Menu

To access the System menus

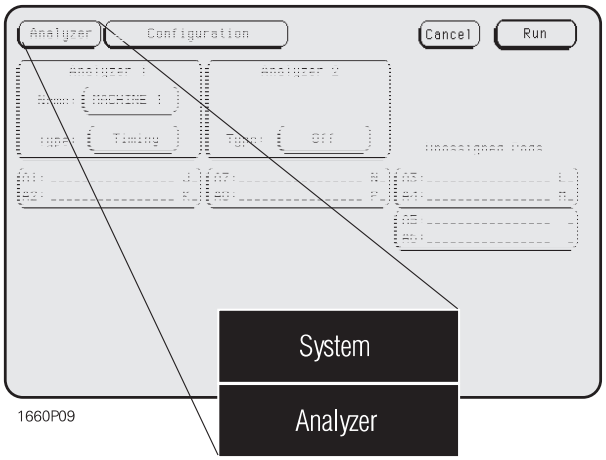
The System menus allow you to load configurations, change colors, and perform system diagnostics.

1 Select the mode field.

Use the arrow keys to highlight the mode field, then press the Select key. Or, if you are using the mouse, click on the field. This operation is referred to as "select".

A pop-up menu appears with the choices System and Analyzer. (If you have installed any optional software, there may be other choices as well.)

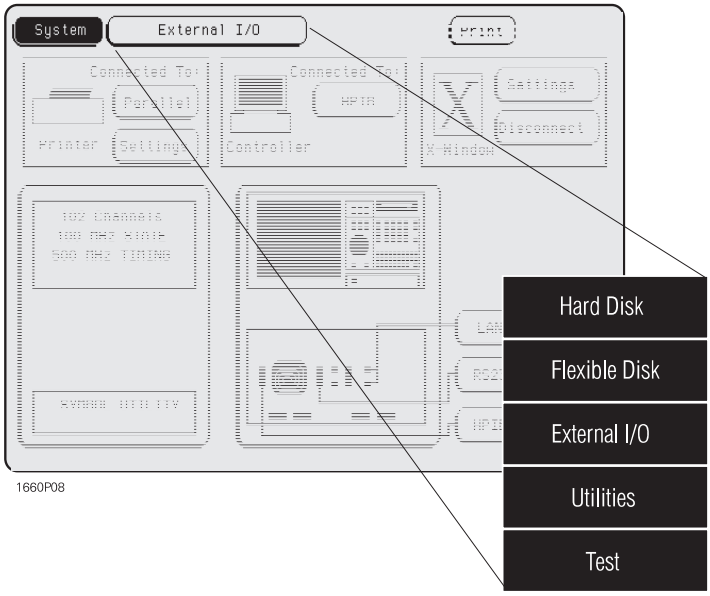
2 Select System.



Mode Pop-Up Menu

3 Select the menu field.

The pop-up menu lists five menus: Hard Disk, Flexible Disk, External I/O, Utilities, and Test.



System Menus

Hard Disk allows you to perform file operations on the hard disk.

- Flexible Disk allows you to perform file operations on the flexible disk.
- External I/O allows you to configure your HP-IB, RS-232-C, and LAN interfaces, and connect to a printer and controller.
- Utilities allows you to set the clock, update the operating system software, and adjust the display.
- Test displays the installed software version number and loads the self-tests.

See Also

For information on the Disk menus, "File Management" in Chapter 6 and "Disk Drive Operations" in Chapter 7.

For information on the External I/O menu, "Connecting Peripherals" Chapter 2, and "The RS-232-C, HP-IB, Centronics, and LAN Interfaces" in Chapter 7.

For information on the Utilities menu, "System Utilities" in Chapter 7.

For how to run the self-tests, "Operator's Service" Chapter 12.

To access the Analyzer menus

The Analyzer menus allow you to control the analyzer to make your measurement, perform operations on the data, and view the results on the display.

1 Select the mode field.

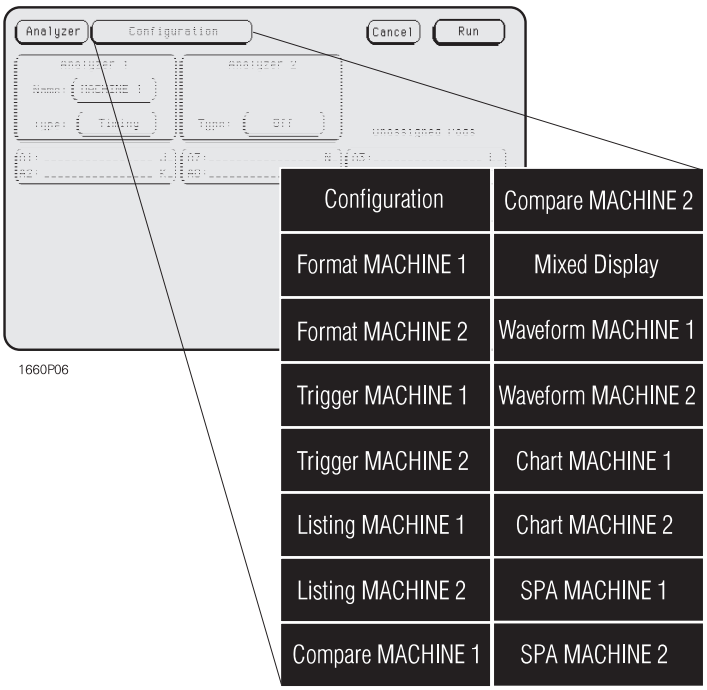
A pop-up menu appears with the choices System and Analyzer. (If you have installed any optional software, there may be other choices as well.)

2 Select Analyzer.

3 Select the menu field.

The figure on the next page shows all possible menus. Your analyzer will never have all of them available at once, because certain menus are only accessible when the analyzer is configured in a particular mode. For instance, the Compare menu is only available when you set an analyzer to State Compare mode. The SPA menu requires an analyzer to be set to SPA.

- Configuration is always available in Analyzer mode. Use Configuration to assign pods and set the analyzer type.
- Format is available whenever an analyzer is set to a type other than "Off." Use Format to create data labels and symbols, adjust the pod threshold level, and set modes and clocks.
- Trigger is available when an analyzer is set to State, State Compare, or Timing. Use Trigger to specify a trigger sequence which will filter the raw information into the measurement you want to see.
- Listing is available when an analyzer is set to State, State Compare, or Timing. Use Listing to view your measurement as a list of states. Using an inverse assembler, a state analyzer can display the measurement as though it were assembly code.
- Compare is available only when an analyzer type is set to State Compare. Use Compare to compare two listings and quickly scroll to the sections where they differ. Because State Compare mode uses significantly more memory than State mode, you should use State Compare only when you plan to compare listings, and use State mode the rest of the time.



Analyzer Menus

- Mixed Display always appears in the menu list when an analyzer is set to State, State Compare, or Timing, but it requires a State or State Compare analyzer with time tags enabled.
- Waveform is available when an analyzer is set to State, State Compare, or Timing. Use Waveform to view the data as logic levels on discrete lines.
- Chart is available only when an analyzer is set to State or State Compare. Use Chart to view your measurement as a graph of states versus time.
- SPA is available only when an analyzer is set to SPA. Use SPA to gather and view overall statistics about your system performance.

See Also

Chapter 7, "Reference", for details on the State and Timing menus, and Chapter 8, "System Performance Analysis (SPA) Software" for information on the SPA menu.

"Using the Analyzer Menus" in this chapter for how to use the menus.

Using the Analyzer Menus

The following examples show how to use some of the Analyzer menus to configure the logic analyzer for measurements. In these examples, we assume that you have already determined which signals are of interest, and have connected the logic analyzer to the target system. Some of the examples use data from a Motorola 68360 target system, acquired with an HP E2456A Preprocessor Interface.

To label channel groups

Hewlett-Packard logic analyzers give you the ability to separate or group data channels and label the groups with a name that is meaningful to your measurement. Labels also assist you in triggering only on states of interest.

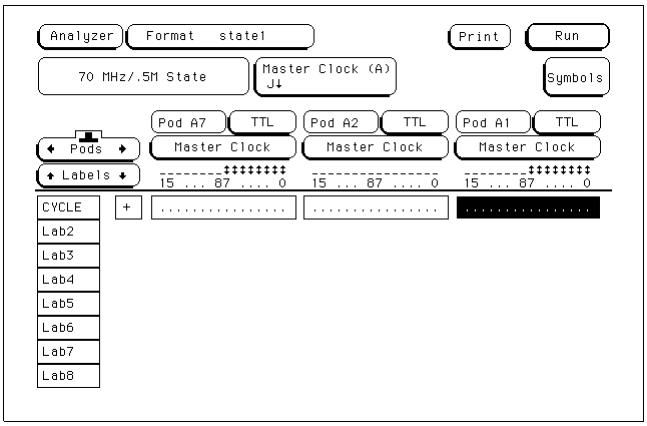
Labels can only be assigned in the Analyzer Format menu. Once assigned, the labels are available in all display menus, where they can be added to or deleted from the display. Use labels when you want to group data channels by function with a name that has meaning to that function.

The default label names are Lab1 through Lab126. You can modify any of these default names to any six-character string. If you are using an HP preprocessor interface, the configuration file has predefined labels for your specific processor which should not be changed.

To create or modify a label and assign channel groups, use the following procedure.

1. **Press the Format key to select the Format menu.**
2. **Select a label under the Labels heading. In the pop-up menu, select Modify Label.**
3. **Use the keyboard to type in a name for the label and press Done.**

   In this example, the label is called CYCLE.



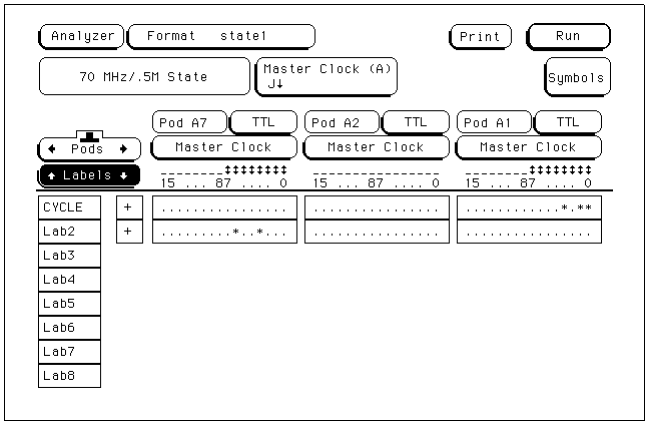
4 Select the pod containing the channels for the label. Use the knob or the arrow keys to position the selector over a channel you want to change.

An asterisk indicates the channel is selected; a dot indicates the channel is not part of the current group.

5 Toggle the channel's group status by pressing Select.

The indicator changes and the selector moves to the next channel.

In this example, the channels 3, 1, and 0 (Pod A1) are assigned to label CYCLE and the channels 6 and 3 (Pod A7) are assigned to the label Lab2.



To create a symbol

Symbols are alphanumeric mnemonics that represent specific data patterns or ranges. Symbols allow you to quickly identify data of interest. When you define a symbol and set the base type to Symbol in the Listing menu, the symbol is displayed in the data listing where the data would normally be displayed. The symbols also appear in the Waveform menu when you view a label in bus form.

To create a symbol, use the following procedure.

1. **In the Analyzer Format menu, select Symbols.**

   The symbol table menu appears. The symbol table is where all user symbols are created and maintained. If you get a message, "No labels specified," check that you have at least one label turned on with channels assigned to it.

2. **In the Symbol menu, select the Label field. In the pop-up menu, select the label that contains the channel groups you want.**

   When you open the symbol table menu, the Label field displays the name of the first active label.

   If the label you want does not appear in the pop-up menu, the label is probably turned off. Return to the Format menu, select the label you want, and select Turn Label On. Another possibility is that the label is on the other analyzer. The two analyzers manage resources separately.

3. **Select the Base field. In the pop-up menu, select the base for the pattern.**

   In this example, binary is used instead of CYCLE because CYCLE only contains three channels.

4. **Select the field below Symbol. Select Add a Symbol, type in the symbol name, then press Done.**

5 If you need additional Symbols, repeat step 4 until you have added all symbols.

   In this example, three symbols are added: MEM RD, MEM WR, and DATA RD.

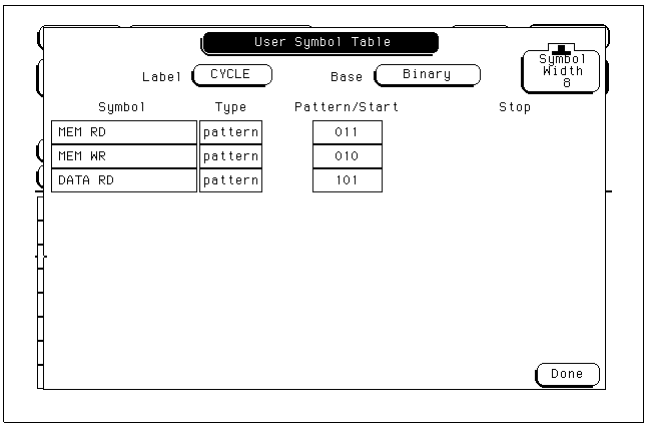
6 Toggle the Type field to "range" or "pattern".

   When Type is range, a third field appears under the Stop column. To specify a full range, you need to enter a value for it, too.

7 Select the Pattern/Start field and use the keypad to enter an appropriate value in the selected base. Use X for "don't care."

8 When the pattern is specified, press Done. If you created additional Symbols, repeat steps 6 and 7 until you have specified all symbols.

9 To close the symbol table menu, select Done.



Symbol Table Menu Showing Three Symbols

You can also download symbol tables created by your programming environment using HP E2450A Symbol Utility. The Symbol Utility is shipped with the HP 1670D-series logic analyzers.

See Also

HP E2450A Symbol Utility User's Guide for more information on the Symbol Utility.

To examine an analyzer waveform

The Analyzer Waveform menu allows you to view state or timing data in a format similar to an oscilloscope display. The horizontal axis represents states (in state mode) or time (in timing mode) and the vertical axis represents logic highs and lows.

1. **In Analyzer mode, press the Run key to acquire data.**

   In any mode other than Analyzer, pressing the Run key has no effect. The menus which ignore Run lack the Run field onscreen. In Analyzer mode with Run available, the menu changes to a display menu.

2. **Go to the Analyzer Waveform menu.**

3. **To adjust the horizontal axis (sec/Div or states/Div) use the knob.**

   If nothing happens when you turn the knob, make sure the Div field has a roll indicator above it, as in the figures on the next page. When you first enter the Waveform menu, the knob adjusts the horizontal axis but if you select another rollable field, the knob will control that field instead.

4. **To adjust the display relative to the trigger, select the Delay field and enter a value or use the knob.**

   The portion of memory being displayed is indicated by a white bar along the bottom of the display area. The position of the trigger in memory is indicated by a white dot on the same line. When the bar includes the dot, then the trigger is visible on the display as indicated by a vertical line with a "t" underneath.

5. **To scroll through waveforms, select the large rectangle below the Div field and use the knob.**

   The roll indicator appears at the top of the rectangle and the name of the first waveform is highlighted. The highlight moves as you turn the knob.

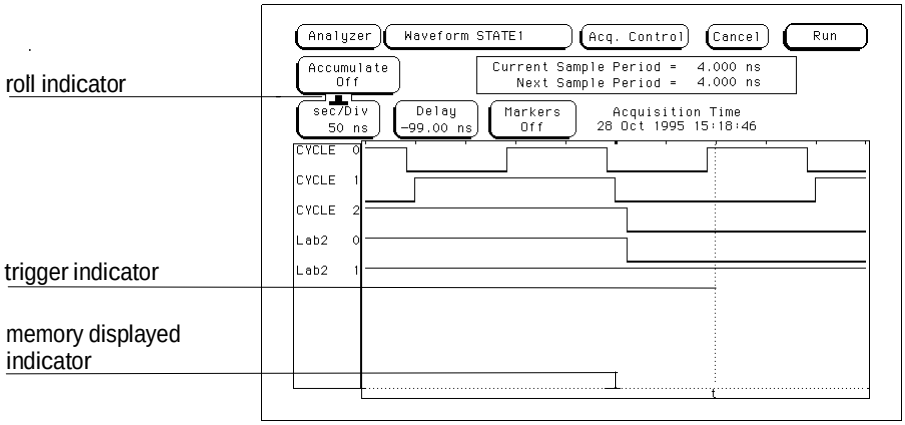
6. **To insert waveforms, select the large rectangle under the Div field. In the pop-up menu select Insert, and then select the labels and channels.**

   The Sequential field inserts all the channels of the label as individual waveforms; the Bus field groups the waveforms; the Bit N field inserts just the Nth bit. Waveforms are inserted after the currently highlighted one.

7 To take measurements, select the Markers field and choose the appropriate marker type.

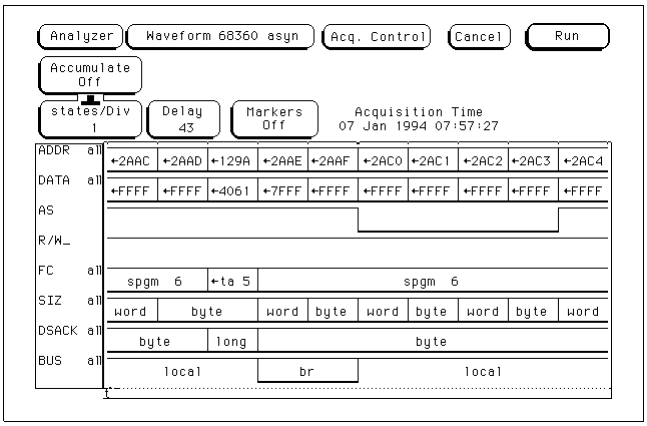
The markers available depend on the type of analyzer and whether or not tagging is enabled. Use markers to locate patterns quickly.

See Also "Count Field" and "Markers Field" in Chapter 7.



Example

The following example shows a state waveform from the Hewlett-Packard preprocessor interface for the Motorola 68360. Notice how the bus waveforms insert symbols or state data.



To examine an analyzer listing

The Analyzer Listing menu displays state or timing data as patterns (states). The Listing menu uses any of several formats to display the data such as binary, ASCII, or symbols. If you are using an inverse assembler and select Invasm, the data is displayed in mnemonics that closely resemble the microprocessor source code.

See Also "The Inverse Assembler" at the end of this chapter for additional information on using an inverse assembler.

1. **In Analyzer mode, press the Run key to acquire data.**

   In any mode other than Analyzer, pressing the Run key has no effect. The menus which ignore Run omit the Run field. In Analyzer mode with Run available, the menu changes to a display menu.

2. **Go to the Analyzer Listing menu.**

   All labels defined in the Analyzer Format menu appear in the listing. If there are more labels than will fit on the screen, the Label/Base field is shaded like a normal field.

3. **To scroll the labels, select the Label/Base field and use the knob, or press the blue Shift key and a Page key.**

   If the Label/Base field is selectable, the roll indicator appears over the field as in the example. To move the labels one full screen at a time, press Shift and a Page key.

4. **To scroll the data, use the Page keys or select the data roll field and use the knob.**

   If you select the data roll field, the roll indicator moves to it. No matter which field is currently controlled by the knob, however, the Page keys page the data up or down.

   The numbers in the data roll column indicate how many samples the data is from the trigger. Negative numbers occurred before the trigger and positive numbers occurred after.

5. **If the labels have symbols associated with them, set the base to Symbol.**

   The symbols you defined appear in the listing.

6 To insert a label, select one of the label fields, then select Insert from the pop-up menu, and select the label you want to insert.

The last label cannot be deleted, so there is always at least one label. You can insert the same label multiple times and display it in different bases.

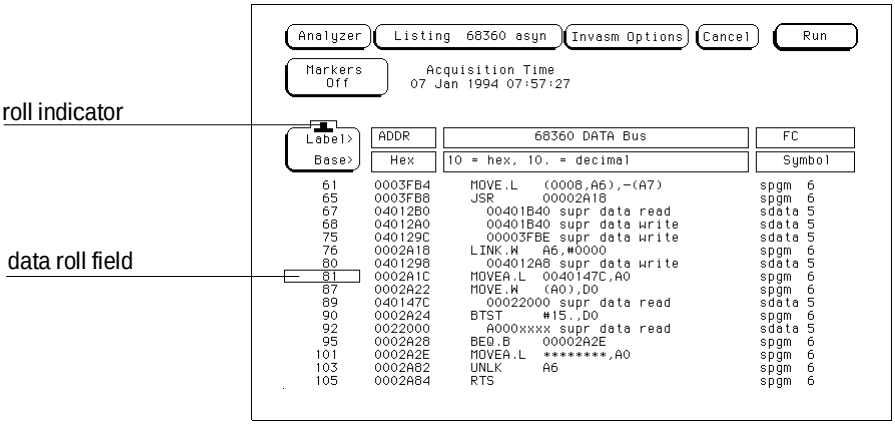
7 To take measurements, select the Markers field and choose the appropriate marker type.

The markers available depend on the type of analyzer and whether or not tagging is enabled. Use markers to locate states quickly.

See Also "Count Field" and "Markers" in Chapter 7.

Example

The following illustration shows a listing from the Hewlett-Packard preprocessor interface for the Motorola 68360. The ADDR label has the base set to Hex to conserve space on the display. The DATA label has the base set to Invasm for inverse assembly. The FC label has the base set to Symbol. Additional labels are located to the right of FC, and can be viewed by highlighting and selecting Label, then using the knob to scroll the display horizontally.



To compare two listings

Compare Menu

The Compare menu is available only if the analyzer type is State Compare.

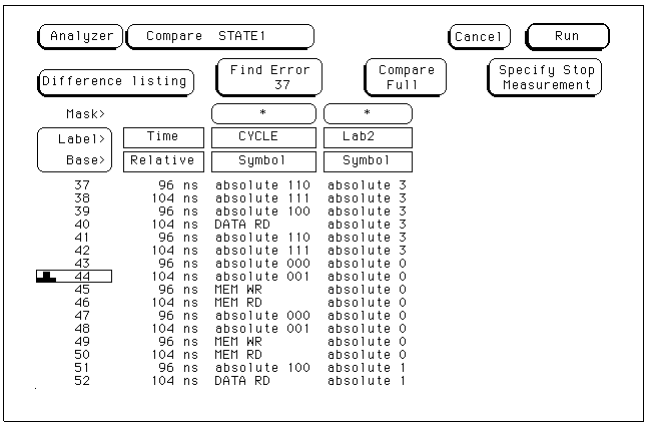
The Compare menu allows you to take two state analyzer acquisitions and compare them to find the differences. You can use this function to quickly find all the effects after changing the target system, or to quickly compare the results of quality tests with results from a working system.

1. In the Configuration menu set Type to State Compare.
2. Set up the rest of the measurement, then press the Run key to acquire data.
3. Go to the Analyzer Compare menu, select Copy Listing to Reference, and then select Execute.

   The Compare menu initially is empty, but when you select Execute, the data appears as the Reference listing. Note that in the Reference listing, time data is not available even if Count Time is turned on in the Trigger menu. The Difference listing does show time data for the currently acquired data.
4. Set up the other test that you want to compare to the first.

   This can be a change to the hardware, or a different system. Do not change the trigger, however, or all the states will be different.
5. Run the test again, then select the Reference listing field to toggle to Difference listing.

   The Difference listing is displayed on the next page.



Difference Listing

The Difference listing displays the states that are identical in dark typeface, and the states that are different in light typeface (indistinguishable in the above illustration). The light typeface shows the data from the current acquisition that is different from the data in the reference file.

6 Select the Find Error field, and use the knob to scroll through the errors.

The display jumps past all states that are identical, and shows the number of errors through the current state in the Find Error field. In the above illustration, there are 37 errors through state 44 of the listing.

The Inverse Assembler

When the analyzer captures a trace, it captures binary information. The analyzer can then present this information in symbol, binary, octal, decimal, hexadecimal, or ASCII. Or, if given information about the meaning of the data captured, the analyzer can inverse assemble the trace. The inverse assembler makes the trace list more readable by presenting the trace results in terms of processor opcodes and data transactions.

To use an inverse assembler

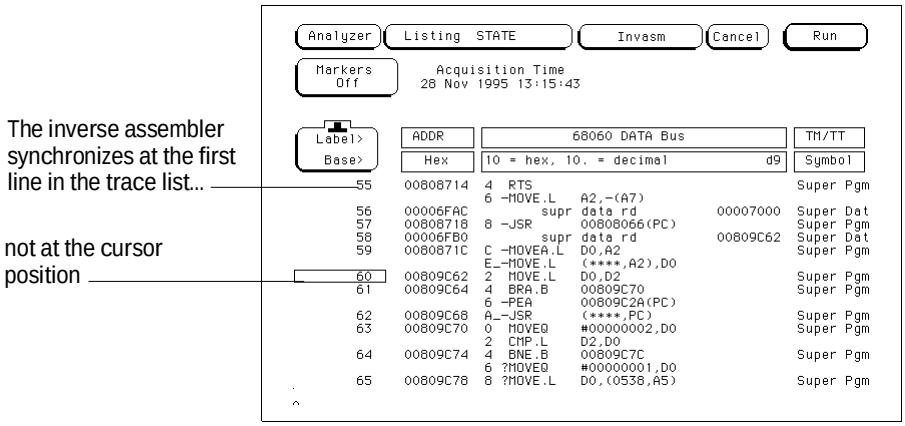
Most preprocessors include an inverse assembler in their software. Loading the configuration file for the preprocessor sets up the logic analyzer to provide certain types of information for the inverse assembler. This section is provided in case you ever have to set up an analyzer for inverse assembly yourself.

The inverse assembly software needs at least these five pieces of information:

- Address bus. The inverse assembler expects to see the label ADDR, with bits ordered in a particular sequence.
- Data bus. The inverse assembler expects to see the label DATA, with bits ordered in a particular sequence.
- Status. The inverse assembler expects to see the label STAT, with bits ordered in a particular sequence.
- Start state for disassembly. This is the first displayed state in the trace list, *not* the cursor position. See the figure on the next page.
- Tables indicating the meaning of particular status and data combinations.

The particular sequences that each label requires depends on the type of chip the inverse assembler was designed for. Because of this, inverse assemblers cannot generally be transferred between platforms.

To run the inverse assembler, you must be sure the labels are spelled correctly as shown here, or as directed in your inverse assembler documentation. Even a minor difference such as not capitalizing each letter will cause the inverse assembler to not work.



Inverse Assembly Synchronization

When you select the Invasm field to begin inverse assembly of a trace, the inverse assembler begins with the first displayed state in the trace list. This is called *synchronization.* It looks at the status bits (STAT) and determines the type of processor operation, which is then displayed under the STAT label. If the operation is an opcode fetch, the inverse assembler uses the information on the data bus to look up the corresponding opcode in a table, which is displayed under the DATA label. If the operation is a data transfer, the data and corresponding operation are displayed under the DATA label. This continues for all subsequent states in the trace list.

If you roll the trace list to a new position and press Invasm again, the inverse assembler repeats the above process. However, it does not reverse the trace list from the starting position. This may cause differences in the trace list above and below the point where you synchronized the inverse assembly. The best way to ensure correct inverse assembly is to synchronize using the first state you know to be the first byte of an opcode fetch.

Chapter 10, "Troubleshooting", if you have problems using the inverse assembler.

Using the Trigger Menu

Using the Trigger Menu

To use the logic analyzer efficiently, you need to be able to set up your own triggers. This book provides examples of triggering in the next chapter. Those examples assume you already know where to find fields in the trigger menu. This chapter explains how to use those fields.

This chapter shows you how to:

- Specify a basic trigger
- Change a trigger sequence
- Set up time correlation between analyzers
- Arm from another instrument, or arm another instrument
- Manage memory

Specifying a Basic Trigger

The default analyzer triggers are

```
While storing "anystate" TRIGGER on "a" 1 time
```

```
Store "anystate"
```

for state analyzers and

```
TRIGGER on "a" > 8 ns
```

for timing analyzers. If you want to simply record data, these will get you started. You can quickly tailor them by specifying a particular pattern to look for instead of the general case.

Customizing a trigger generally requires these steps:

- Assign terms to both analyzers
- Define the terms
- Change the trigger to use the new terms

To assign terms to an analyzer

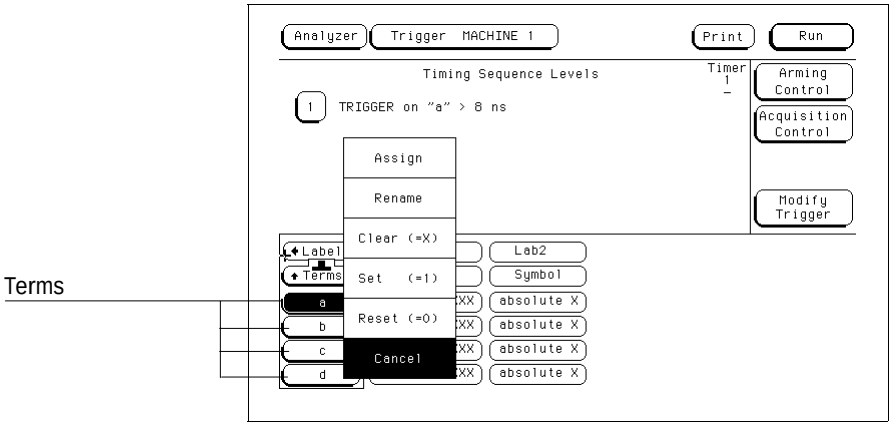
When you turn the logic analyzer on, Analyzer 1 is named Machine 1 and Analyzer 2 is off. Because trigger terms can only be used by one analyzer at a time, all the terms are assigned to Analyzer 1. If you plan to use both analyzers in your measurement, you need to assign some of the terms to Analyzer 2.

1 Go to the Trigger Machine 1 menu.

If you have renamed Machine 1 in the Analyzer Configuration menu, the name you changed it to will appear in the menu instead of Machine 1.

2 Select a term.

The terms are the fields below the roll field "Terms". See the figure below.



Trigger Menu

3 Select Assign from the list that appears.

The Resource Term Assignment menu appears. It is divided into two sections, one for each analyzer. All the terms are listed.

4 To change a term assignment, select a term field.

The term fields toggle from one section to the other. You can get all your terms assigned at once, or just change a few to meet immediate needs.

5 To exit the term assignment menu, select Done.

To define a term

Both default triggers trigger on term "a". If you only need to look for the occurrence of a certain state, such as a write to protected memory, then you only need to define term "a" to make the measurement you want.

1. **In the Trigger menu, select the field at the intersection of the term, and the label whose value you want to trigger on.**

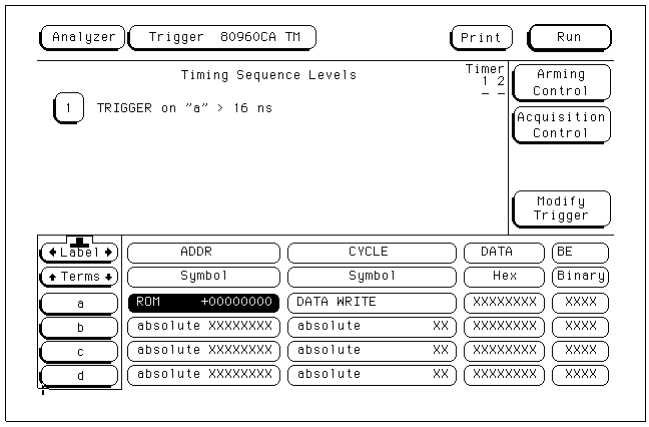
   You set labels in the Analyzer Format menu. If the channels you want to monitor are not attached to a label, they will not appear in the trigger menu.

2. **Enter the value or pattern you want to trigger on.**

   If the label's base is Symbol, a pop-up menu appears offering a choice of symbols. For other bases, use the keypad. An "X" stands for "don't care".

   If there are two conditions that need to be present at the same time, for example a protected address on the address bus and a write on the read/write line, define both values on the same term. See the figure below.

3. **Press Done.**



Term "a" Defined as a Data Write to Read-Only Memory

To change the trigger specification

Most triggers use terms other than "a." Even a simple trigger might use additional terms to set conditions on the actual trigger. To use these terms, you must include them in the trigger sequence specification.

1. **In the Trigger menu, select the number beside the specific level you want to modify.**

   A Sequence Level menu pops up. It shows the current specification for that trigger level.

2. **Select the field you want to change.**

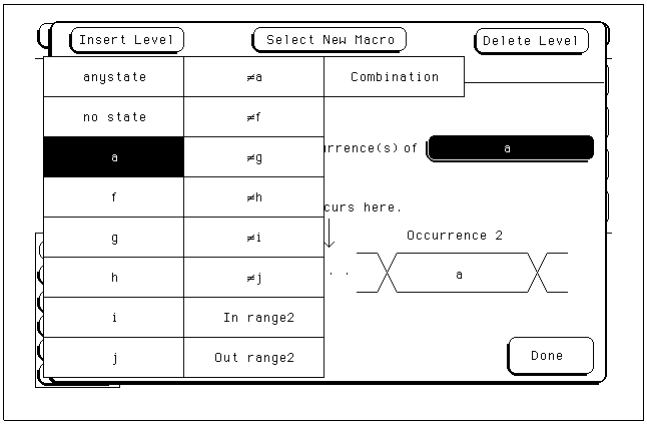
   In the top row of the pop-up menu are three action fields: Insert Level, Select New Macro, and Delete Level. The next section describes the fields in detail. The fields after "While storing," "TRIGGER on," and "Else on" are completed with trigger terms. Selecting these fields pops up a menu of terms.

3. **Select the term you want to use from the pop-up menu, or enter a new value, as appropriate to the field.**

   Selecting "Combination" pops up a menu to define a term combination. The combination mechanism is discussed in "Resource terms" in the Trigger Menu in Chapter 7 and "The Trigger Sequence" in Chapter 9.

   If you have renamed a term, that name is automatically used everywhere the term would appear.

4. **Select Done, repeatedly, until you are back at the Trigger menu.**



Term Selection Pop-up Menu

Changing the Trigger Sequence

Most measurements require more complicated triggers to better filter information. From the basic trigger, you can:

- Add sequence levels
- Change macros

Your logic analyzer provides a macro library to make setting up the trigger easier. There are 12 state macros and 13 timing macros. Most macros take more than one level internally to implement, and can be broken down into their separate levels. You can use the levels to design your own trigger sequences, once they are broken down.

To add sequence levels

You can add sequence levels anywhere except after the final one.

1. **In the Trigger menu, select the number beside the sequence level just after where you want to insert.**

   For example, if you want to insert a sequence level between levels 1 and 2, you would select level 2. To insert levels at the beginning, select level 1.

   A Sequence Level pop-up menu appears. Its exact contents depend on the analyzer configuration and the level specification. However, all Sequence Level pop-up menus have an Insert Level field in the upper left corner.

2. **Select Insert Level.**

   Another pop-up menu offers the choices of Cancel, Before, or After. If the level you started from was the last level, After will not appear.

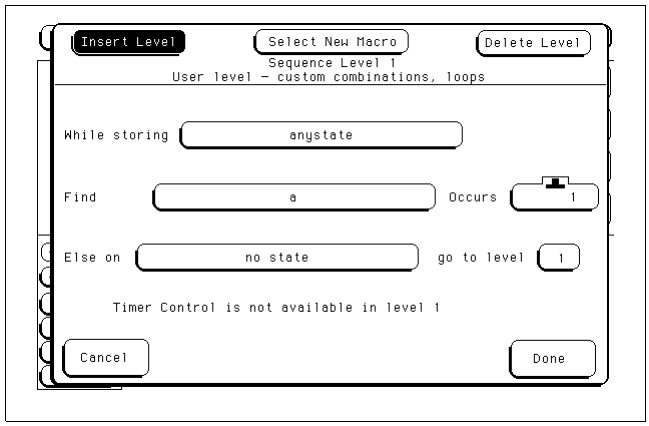
3. **Select Before.**

   The Trigger Macro pop-up menu replaces the Sequence Level one. The macros available depend on whether the analyzer is configured as state or timing.

4. **Use the knob to highlight a macro, and select Done.**

   A new Sequence Level pop-up menu appears. Its contents reflect the macro you just selected. The figure below shows a user macro for a state analyzer.

5. **Fill in the fields and select Done.**



Sequence Level Pop-up Menu

To change macros

You do not need to add and delete levels just to change a level's macro. You can do this from within the Sequence Level pop-up menu.

1. **From the Trigger menu, select the sequence level number of the sequence level you want to modify.**

   A Sequence Level pop-up menu appears. Its contents reflect the current macro.

2. **Choose "Select New Macro".**

   The Trigger Macro pop-up menu replaces the Sequence Level menu. The macros available depend on whether the analyzer is configured as state or timing.

3. **Use the knob to highlight the macro you want, and select Done.**

   A new Sequence Level pop-up menu appears. Its contents reflect the macro you just selected. The wording of this screen is very similar to the macro description, and the line drawing demonstrates what the macro is measuring.

4. **Select the appropriate assignment fields and insert the desired predefined terms, numeric values, and other parameter fields required by the macro. Select Done.**

   For State and State Compare analyzers, the final level must always be a user level.

See Also

"Timing Trigger Macro Library" and "State Trigger Macro Library" in Trigger Menu in Chapter 7 for a complete listing of macros.

Setting Up Time Correlation between Analyzers

There are two possible combinations of analyzers: state and state, and state and timing*. Timing and timing is not possible because the Analyzer Configuration menu only permits one analyzer at a time to be configured as a timing analyzer. For either combination, time correlation is necessary for interleaving and mixed display.

Time correlation is useful when you want to store different sorts of data for each trace, but see how they are related. For instance, you could set up a timing and a correlated state analyzer and see if setup and hold times are being met. Or, you could set up two state analyzers and have one watch normal program execution, and the other watch the control and status lines.

Time correlation requires that state analyzers store time tags. You set the state analyzer to store time tags by turning on Count Time in the Analyzer Trigger menu. The timing analyzer already stores time tags when it samples data.

See Also

"Special Displays" in Chapter 5 for more information on interleaving and mixed display.

* "State" also includes State Compare.

To set up time correlation between two state analyzers

To correlate the data between two state analyzers, both must have Count Time turned on in their Trigger menus. Although both have Count State available, it is not possible to correlate data based on states even when they are identically defined.

1. In the Analyzer Trigger menu, select Count.

   Count may be set to Count Off, Count Time, or Count States. Selecting the field causes a pop-up menu to appear.

2. Select the field after Count and select Time.

   A warning may appear about reduced memory. It will not prevent you from changing Count to Count Time.

3. Select Done.

4. Repeat steps 1 through 3 for the other state analyzer.

   Now when you acquire data you will be able to interleave the listings.

To set up time correlation between a timing and a state analyzer

To set up time correlation between a timing and a state analyzer, only the state analyzer needs to have Count Time turned on. The timing analyzer automatically keeps track of time.

1. In the State Analyzer Trigger menu, select Count.

   Count may be set to Count Off, Count Time, or Count States. Selecting the field causes a pop-up menu to appear.

2. Select the field after Count and select Time.

   A warning may appear about reduced memory. It will not prevent you from changing Count to Count Time.

3. Select Done.

   Now when you acquire data you will be able to set up a mixed display.

Arming and Additional Instruments

Occasionally, you may need to start the analyzer acquiring data when another instrument detects a problem. Or, you may want to have the analyzer itself arm another measuring tool. This is accomplished from the Arming Control field of the Analyzer Trigger menu.

To arm another instrument

1. **Attach a BNC cable from the External Trigger Output port on the back of the logic analyzer to the instrument you want to trigger.**

   The External Trigger Output port is also referred to as "Port Out." It uses standard TTL logic signal levels, and will generate a rising edge when trigger conditions are met.

2. **In the Analyzer Trigger menu, select Arming Control.**

   Arming Control is below the Run button.

3. **Select the field next to Arm Out, and choose PORT OUT from the list.**

4. **If you are using both analyzers, set the "Arm Out sent from" field in the upper right corner.**

   This field does not appear if only one analyzer is configured.

   The selected analyzer will send the arm signal when it finds its trigger. If the OR'd Trigger field is on, the first analyzer that finds its trigger will trigger the other analyzer, which has the effect of sending the Arm Out signal, regardless of whether the intended trigger was seen.

5. **Select Done.**

   When you make a measurement, the analyzer will send an arm signal through the External Trigger Output when the analyzer finds its trigger.

To receive an arm signal from another instrument

When you set the analyzer to wait for an arm signal, it does not react to data that would normally trigger it until after it has received the arm signal. You can send the arm signal to any of the Trigger Sequence levels, but it will go to level 1 unless you change it. Setting up the analyzer to receive an arm signal is more efficient when the sequence levels are already in place.

1. **Connect a BNC cable from the instrument which will be sending the signal to the External Trigger Input port on the back of the logic analyzer.**

CAUTION Do not exceed 5.5 volts on the External Trigger Input.

The External Trigger Input port is also referred to as "Port In." It uses standard TTL logic signal levels, and expects a rising edge as input.

2. **In the Analyzer Trigger menu, select Arming Control.**

   Arming Control is below the Run button.

3. **Select the leftmost field, and choose PORT IN.**

   The field is not unlabeled but shows either Run or PORT IN. It has arrows going from it to the analyzer(s).

4. **To change the default settings, select the analyzer field.**

   A small pop-up menu appears. To change which device the analyzer is receiving its arm signal from, select the Run from field. To change which sequence level is waiting for the arm signal, select the Arm sequence level field.

5. **Select Done until you are back at the Trigger menu.**

Arming a logic analyzer versus OR'd trigger

If one analyzer is set to send the PORT OUT arm, and that analyzer is also set to wait for an arm from the other analyzer, the dependent analyzer does not begin to look for its trigger event until it receives the arm signal. The first analyzer must arm the second analyzer, and then the second analyzer must find its trigger event before the Arm Out is sent.

If OR'd trigger is on, the Arm Out will be sent as soon as the first analyzer triggers.

Managing Memory

Sometimes you will need to manage your memory carefully. There are four simple ways to control memory usage when specifying your trigger:

- Selectively store branch conditions (State only)
- Set memory size
- Place the trigger relative to memory
- Set the sampling rates (Timing only)

To selectively store branch conditions (State only)

In addition to setting up your trigger levels to store anystate, no state, or some subset of states, you can also choose whether or not to store branch conditions. Branch conditions are always stored by default, and can make tracing the analyzer's path through a complicated trigger easier. If you really need extra memory, however, you don't have to store the branch conditions.

You cannot set the analyzer to store only some branches in a trigger sequence specification.

1. **In the Analyzer Trigger menu, select Acquisition Control.**

   The Acquisition Control menu pops up. If the acquisition mode is set to Automatic, the menu contains two fields and an explanation. If Acquisition has been customized, it has four or five fields and a picture showing the amount of memory and where the trigger is currently placed in memory.

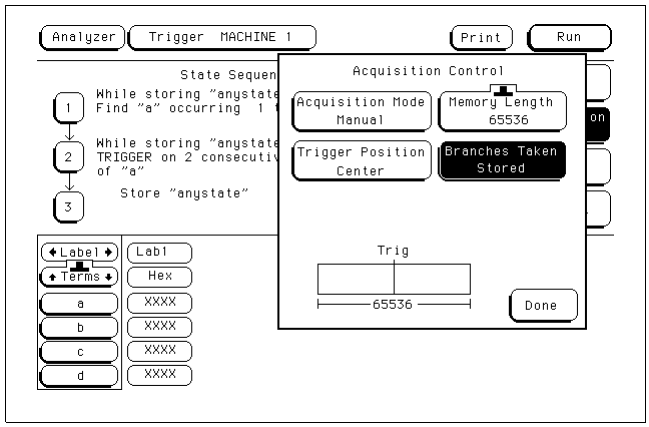
2. **If the mode is Automatic, select the field to toggle it to Manual.**

   The menu now shows four fields and a picture.

3. **Select the Branches Taken Stored field.**

   It toggles to Branches Taken Not Stored.

4. **Select Done.**



Acquisition Control Pop-up Menu with Branches Field Highlighted

To set the memory length

The HP 1670D-series logic analyzers provide 64K memory standard and 1M with the deep memory option. The table below shows the amount of memory available for different modes of operation.

Typically, you will want to use small amounts of memory when you start to troubleshoot, when you are first looking for a problem, and use deep memory when you are searching for the root cause. Shallower memory provides faster acquisitions, but might not have sufficient context. Deep memory provides more context, but takes longer to fill, more time to display, and more time for you to analyze. The Memory Length field allows you to configure the acquisition memory to suit your needs.

1. In the Analyzer Trigger menu, select Acquisition Control.

   The Acquisition Control menu pops up. If the acquisition mode is set to Automatic, the menu contains two fields and an explanation. If Acquisition has been customized, it has four or five fields and a picture showing the amount of memory and where the trigger is currently placed in memory.

2. Select the Memory Length field.

   Use the knob to select the memory length. Memory size can be set in powers of 2 from 4096 to the maximum. The table below shows the maximum memory for various modes of operation.

3. Select Done to exit the Acquisition Control menu.

Table 4-1 Maximum Memory Size

Mode	Standard Memory	1M Option
Full-channel timing	65,536 (64K)	1,032,192
Half-channel timing	131,072 (128K)	2,080,768
State [1]	65,536 (64K)	1,032,192
State [2]	32,768 (32K)	507,904
State Compare [1]	32,768 (32K)	245,760
State Compare [2]	32,768 (32K)	114,688

[1] With tags turned off or non-interleaved tags. Tags are non-interleaved if there is an unassigned pod pair or a pod pair assigned to an analyzer that is turned off.
[2] With interleaved tags.

To place the trigger in memory

In Automatic Acquisition Mode, the exact location of the trigger depends on the trigger specification but usually falls around the center. You can manually place it at the beginning, end, or somewhere else.

1 In the Analyzer Trigger menu, select Acquisition Control.

The Acquisition Control menu pops up. If the acquisition mode is set to Automatic, the menu contains two fields and an explanation. If Acquisition has been customized, it has four or five fields and a picture showing the amount of memory and where the trigger is currently placed in memory.

2 If the mode is Automatic, select the field to toggle it to Manual.

The menu now shows four fields and a picture.

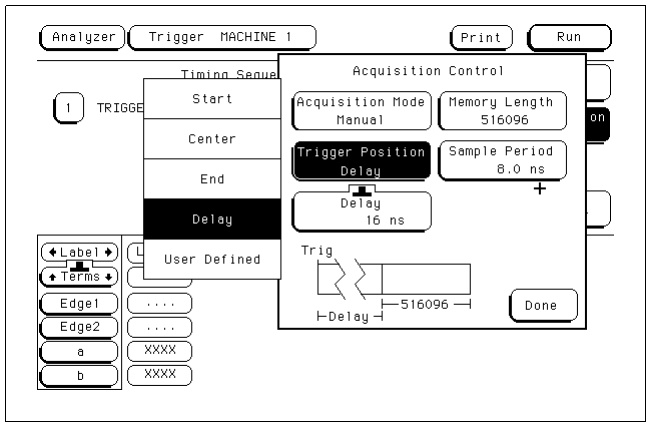
3 Select the Trigger Position field.

A list of choices appears, as shown in the timing trigger example below.

4 Select the appropriate entry for your needs.

Start, Center, and End place the trigger respectively at the beginning, middle, and end of the memory. Delay, available in timing analyzers only, causes the analyzer to not save any data before the time delay has elapsed. User Defined calls up a fifth field where you specify exactly where you want the trigger.

5 Select Done.



Acquisition Control Menu with Trigger Position Pop-up for a Timing Analyzer

To set the sampling rates (Timing only)

A timing analyzer samples the data based on its own internal clock. A short sample period provides more detail about the device under test; a long sample period allows more time before memory is full. However, if the sample period is too large, some information may be missed.

1. **In the Analyzer Trigger menu, select Acquisition Control.**

   The Acquisition Control menu pops up. If the acquisition mode is set to Automatic, the menu contains two fields and an explanation. If Acquisition has been customized, it has four or five fields and a picture showing the amount of memory and where the trigger is currently placed in memory.

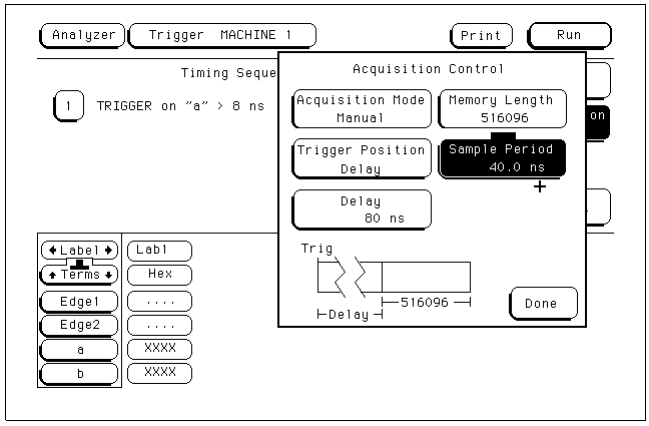
2. **If the mode is Automatic, select the field to toggle it to Manual.**

   The menu now shows four fields and a picture.

3. **Set the Sample Period field using the knob.**

4. **Select Done.**

   Next time you take a measurement, the analyzer will sample at the rate you entered.



Acquisition Control Menu with Sample Period Selected

Triggering Examples

Triggering Examples

As you begin to understand a problem in your system, you may realize that certain conditions must occur before the problem occurs. You can use sequential triggering to ensure that those conditions have occurred before the analyzer recognizes its trigger and captures information.

If you are not familiar with the trigger menus, read through the previous chapter,"Using the Trigger Menu."

Single-Machine Trigger Examples

The following examples require only a single analyzer to make measurements. Sequence specifications are given in the form you see within the sequence levels, but the illustrations show the complete, multi-level sequence specification.

Although all the examples are case-specific, terms are named in a way that highlights their roles in solving the trigger problem. You can easily apply the examples to your specific instance by changing the specific values assigned to the trigger terms.

To store and time the execution of a subroutine

Most system software is composed of a hierarchy of functions and procedures. During integration, testing, and performance evaluation, you want to look at specific procedures to verify that they are executing correctly and that the implementation is efficient. The analyzer allows you to do this by triggering on entry to the address range of the subroutine, and counting the elapsed time since the trigger state.

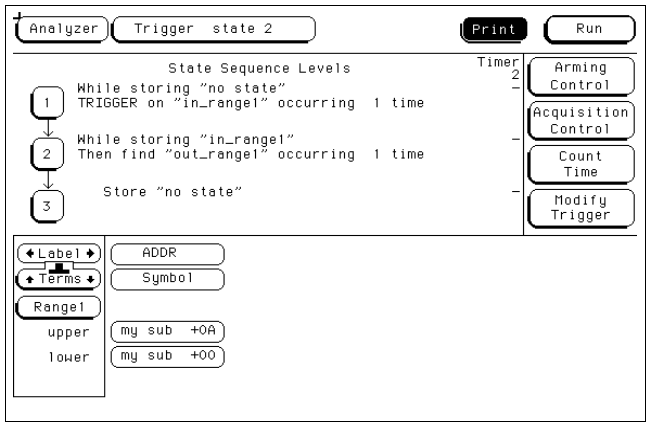
1. Go to the state analyzer's Trigger menu.
2. Set Count to Time.
3. Define a range term, such as Range1, to represent the address range of the particular subroutine.

   You may need to examine the structure of your code to help determine this. If your subroutine calls are really procedure calls, there is likely to be some code at the beginning of the routine that adjusts the stack for local variable allocation. This will precede the address of the first statement in the procedure. If your subroutine has no local storage and is called by a jump or branch, the first statement will also be the entry address.
4. Under State Sequence Levels, enter the following sequence specification:
   - While storing "no state" TRIGGER on "In_Range1" Occurs 1 Else on "no state" go to level 1
   - While storing "In_Range1" Then find "Out_Range1" Occurs 1 Else on "no state" go to level 2
   - Store "no state" on "no state" go to level 1

Prefetch Instructions

For processors that prefetch instructions or have pipelined architectures, you may want to add part or all of the depth of the pipeline to the start address for In_Range1 to ensure that the analyzer does not trigger on a prefetched but unexecuted state.

The figure below shows what you would see on your analyzer screen after entering the sequence specification in step 4.



Trigger Setup for Storing and Timing Execution of a Subroutine

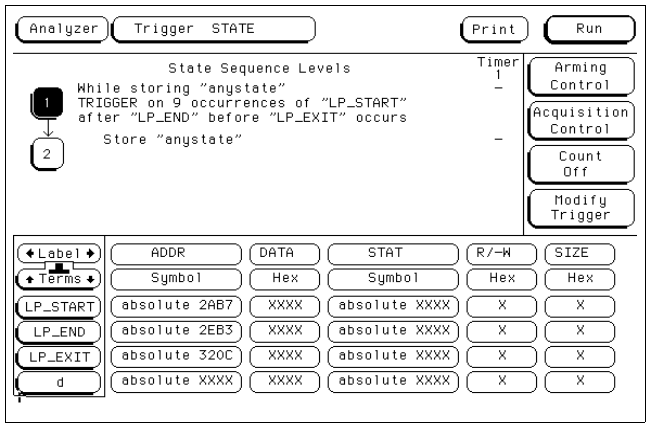
Suppose you want to trigger on entry to a routine called MY_SUB. You can create a symbol from the address of MY_SUB in the Format menu, allowing you to reference the symbol name when setting up the trace specification. Assume that MY_SUB extends for 0A hex locations. You can set up the trigger sequence as shown in the display above.

To trigger on the nth iteration of a loop

Traditional debugging requires print statements around the area of interest. This is not possible in most embedded systems designs, but the analyzer allows you to view the system's behavior when a particular event occurs. Suppose that your system behaves incorrectly on the last iteration of a loop, which, in this instance, happens to be the 10th iteration. You can use the analyzer's triggering capabilities to capture that iteration and subsequent processor activity.

1. Go to the state analyzer's Trigger menu.
2. Define the terms LP_START and LP_END to represent the start and end addresses of statements in the loop, and LP_EXIT to represent the first statement executed after the loop terminates.
3. Change State Sequence Level 1's macro to "Find event2 n times after event1 before event3 occurs."
4. In the pop-up menu, enter the following sequence specification:
   - While storing anystate Find "LP_START" "9" times after "LP_END" before "LP_EXIT" occurs.

   You should use your value for n-1 instead of "9" in the sequence specification above.



Trigger Setup for Triggering on the 10th Iteration of a Loop

The specification has some advantages and a potential problem.

- The advantages are that a pipelined processor won't trigger until it has executed the loop 10 times. Requiring LP_END to be seen at least once first ensures that the processor actually entered the loop; then, 9 more iterations of LP_STARTare really the 10th iteration of the loop. Also, no trigger occurs if the loop executes less than 10 times — the analyzer sees LP_EXIT and restarts the trigger sequence.
- The potential problem is that LP_EXIT may be too near LP_END, and thus appears on the bus during a prefetch. The analyzer will constantly restart the sequence and will never trigger. The solution to this problem depends on the structure of your code. You may need to experiment with different trigger sequences to find one that captures only the data you want to view.

To trigger on the nth recursive call of a recursive function

1. Go to the state analyzer's Trigger menu.
2. Define the terms CALL_ADD, F_START, and F_END to represent the called address of the recursive function, and the start and end addresses of the function. Define F_EXIT to represent the address of the first program statement executed after the original recursive call has terminated.

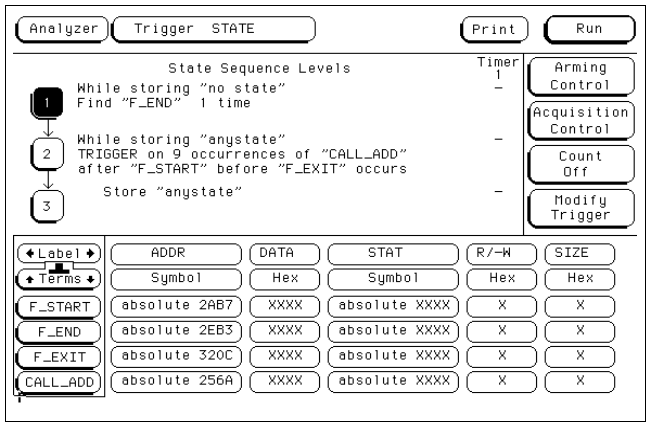
   Typically, CALL_ADD is the address of the code that sets up the activation record on the stack, F_START is the address of the first statement in the function, and F_END is the address of the last instruction of the function, which does not necessarily correspond to the address of the last statement. If the start of the function and the address called by recursive calls are the same, or you are not interested in the function initialization code, you can use F_START for both CALL_ADD and F_START.
3. Change State Sequence Level 1's macro to "Find event2 n times after event1 before event3 occurs."
4. In the pop-up menu, enter the following sequence specification:

   - While storing anystate Find "**CALL_ADD" "9" times after "F_START" before "F_EXIT" occurs.**

   You should use your value for n-1 instead of "**9" in the specification.**
5. Insert another sequence level before the current one. Select the User Level macro and enter the following specification:

   - While storing "**no state" Find "F_END" occurs "1" Else on "no state" go to level 1.**

   As with the trigger specification for "**To trigger on the nth iteration of a loop," this specification helps avoid potential problems on pipelined processors by requiring that the processor already be in the first recursive call before advancing the trigger sequence. Depending on the exact code used for the calls, you may need to experiment with different trigger sequences to find one that captures only the data you want to view.**



Triggering on the 10th Call of a Recursive Function

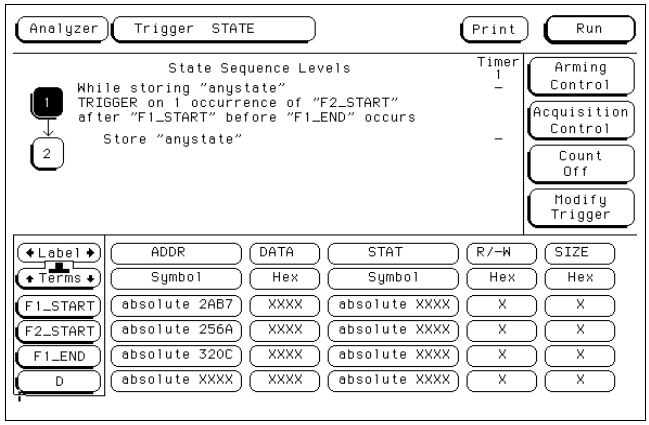
To trigger on entry to a function

This sequence triggers on entry to a function only when it is called by one particular function.

1. Go to the state analyzer's Trigger menu.
2. Define the terms F1_START and F1_END to represent the start and end addresses of the calling function. Define F2_START to represent the start address of the called function.
3. Change State Sequence Level 1's macro to "Find event2 n times after event1 before event3 occurs."
4. In the pop-up menu, enter the following sequence specification:
   - While storing anystate Find "**F2_START" "1" times after "F1_START" before "F1_END" occurs.**

   This sequence specification assumes there is some conditional logic in function F1 that chooses whether or not to call function F2. Thus, if F1 ends without the analyzer having seen F2, the sequence restarts.

   The specification also stores all execution inside function F1, whether or not F2 was called. If you are interested only in the execution of F1, without the code that led to its invocation, you can change the storage specification from "anystate" to "no state" for the second sequence term.

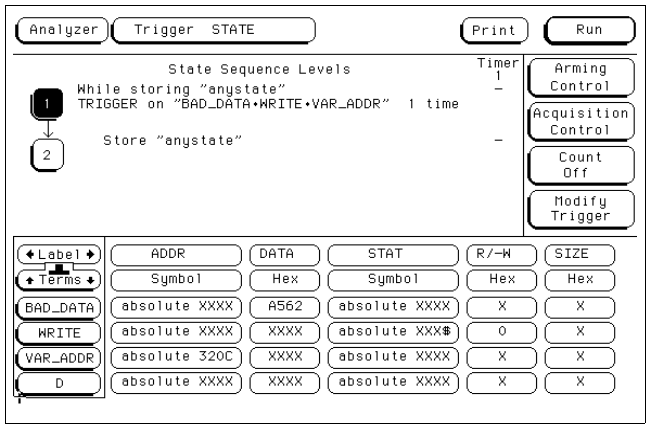


Triggering on Entry to a Function

To capture a write of known bad data to a particular variable

The trigger specification ANDs the bad data on the data bus, the write transaction on the status bus, and the address of the variable on the address bus.

1. Go to the state analyzer's Trigger menu.
2. Define the terms BAD_DATA, WRITE, and VAR_ADDR to represent the bad data value, write status, and the address of the variable.
3. Under State Sequence Level 1, enter the following sequence specification (use the Combination trigger term):
   - While storing "anystate" TRIGGER on "BAD_DATA • WRITE • VAR_ADDR" Occurs "1" Else on "no state" go to level "1"



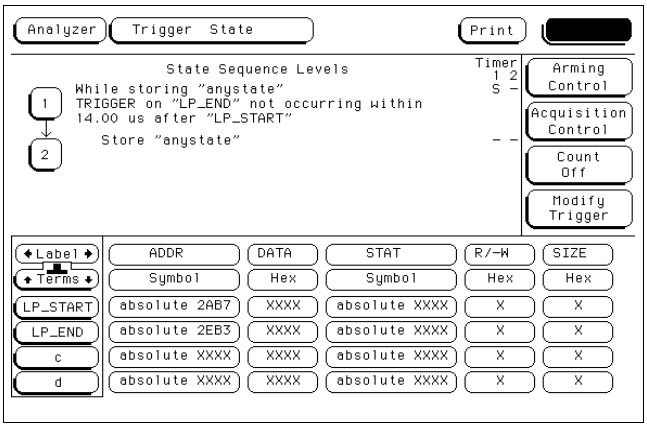
Capturing a Bad Write to a Variable

To trigger on a loop that occasionally runs too long

This example assumes the loop normally executes in 14 µs.

1. Go to the state analyzer's Trigger menu.
2. Define terms LP_START and LP_END to represent the start and end addresses of the loop, and set Timer1 to the normal duration of the loop.
3. Change State Sequence Level 1's macro to "Find event2 occurring too late after event1."
4. In the pop-up menu, enter the following sequence specification:
   - While storing anystate Find "LP_END" occurring too late after "LP_START" Use Timer: "Timer1" Time="14 µs"

   Of course, you use your normal loop duration in place of "14 µs." The macro will automatically start Timer1 for you.



Triggering on a Loop Overrun

To verify correct return from a function call

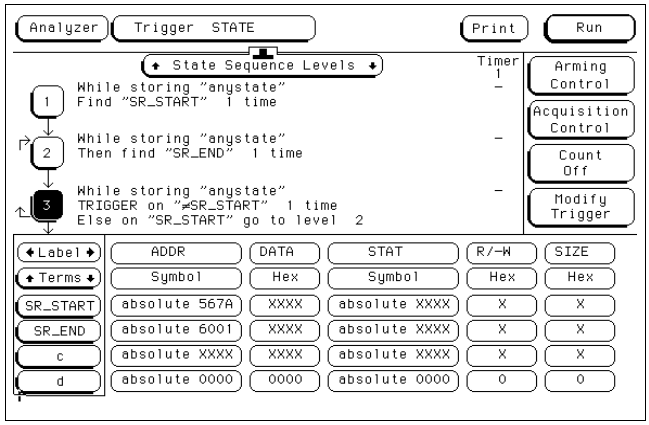
The exit code for a function will often contain instructions for de-allocating stack storage for local variables and restoring registers that were saved during the function call. Some language implementations vary on these points, with the calling function doing some of this work, so you may need to adapt the procedure to suit your system.

1 Go to the state analyzer's Trigger menu.

2 Define terms SR_START and SR_END to represent the start and end addresses of the subroutine.

3 Under State Sequence Levels, insert 2 more sequence levels and enter the following sequence specification:

- While storing "anystate" Find "SR_START" Occurs "1" Else on "no state" go to level "1"
- While storing "anystate" Then find "SR_END" Occurs "1" Else on "no state" go to level "2"
- While storing "anystate" TRIGGER on "≠ SR_START" Occurs "1" Else on "SR_START" go to level "2"

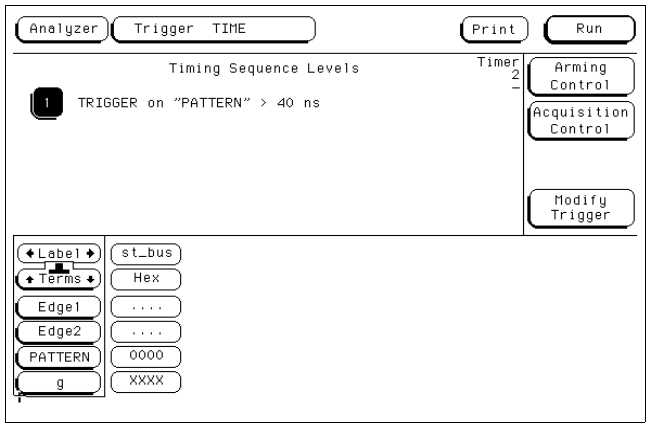


Verifying Correct Return from a Function Call

To trigger after all status bus lines finish transitioning

In some applications, you will want to trigger a measurement when a particular pattern has become stable. For example, you might want to trigger the analyzer when a microprocessor's status bus has become stable during the bus cycle.

1. Go to the timing analyzer's Trigger menu.
2. Define a term called PATTERN to represent the value to be found on the status bus lines.
3. Under Timing Sequence Levels, enter the following sequence specification:
   - TRIGGER on "PATTERN" > 40 ns



Triggering After Lines Have Finished Transitioning

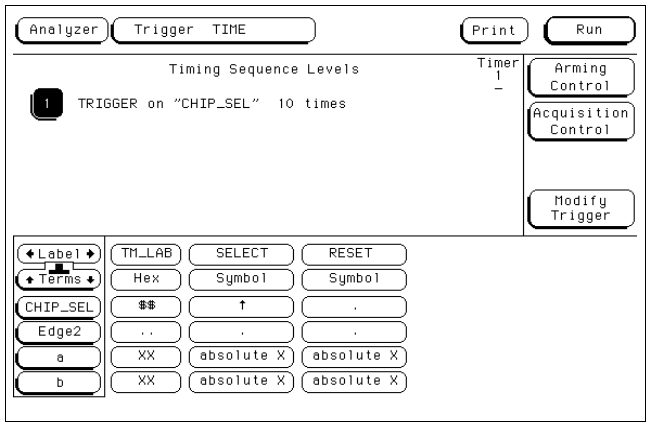
To find the nth assertion of a chip select line

1. Go to the timing analyzer's Trigger menu.
2. Define the Edge1 term to represent the asserting transition on the chip select line.

   You can rename the Edge1 term to make it correspond more closely to the problem domain, for example, to CHIP_SEL.
3. Under Timing Sequence Levels, enter the following sequence specification:

   - TRIGGER on "**CHIP_SEL" Occurs "10" Else on "no state" go to level "1"**

   You should use your value for "**n" in place of "10" in the specification above.**

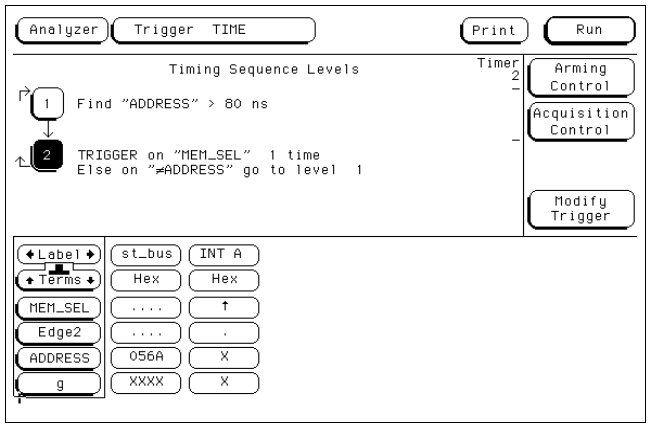


Triggering on the 10th Assertion of a Chip Select Line

To verify that the chip select line is strobed after the address is stable

1. Go to the timing analyzer's Trigger menu.
2. Define a term called ADDRESS to represent the address in question, and the Edge1 term to represent the asserting transition on the chip select line.

   You can rename the Edge1 term to suit the problem, for example, to MEM_SEL.
3. Under Timing Sequence Levels, enter the following sequence specification:
   - Find "ADDRESS" > 80 ns
   - TRIGGER on "MEM_SEL" Occurs "1" Else on "≠ ADDRESS" go to level "1"



Verifying SetupTime for Memory Address

To trigger when expected data does not appear when requested

1 Go to the timing analyzer's Trigger menu.

2 Define a term called DATA to represent the expected data, the Edge1 term to represent the chip select line of the remote device, and the Timer1 term to identify the time limit for receiving expected data.

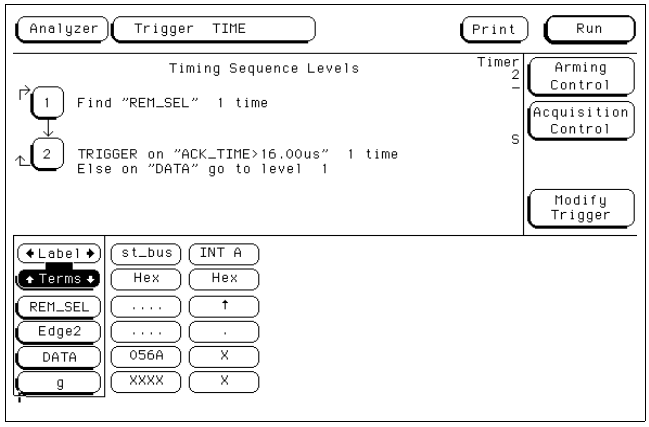
You can rename the Edge1 and Timer1 terms to match the problem domain, for example, to REM_SEL and ACK_TIME.

3 Under Timing Sequence Levels, enter the following sequence specification:

- Find "REM_SEL" Occurs "1" Else on "no state" go to level "1"
- TRIGGER on "ACK_TIME > 16.00 µs" Occurs "1" Else on "DATA" go to level "1"

You will need to start ACK_TIME timer (Timer1) upon entering this state. You do this using the Timer Control field in the menu for sequence level 2.

This sequence specification causes the analyzer to trigger when the data does not occur in 16 µs or less. If it does occur within 16 µs, the sequence restarts. Specifications of this type are useful in finding intermittent problems. You can set up and run the trace, then cycle the system through temperature and voltage variations, using automatic equipment if necessary. The failure will be captured and saved for later review.



Triggering When Data Not Returned

To test minimum and maximum pulse limits

1. Go to the timing analyzer's Trigger menu.
2. Define the Edge1 term to represent the positive-going transition, and define the Edge2 term to represent the negative-going transition on the line with the pulse to be tested.

   You can rename these terms to POS_EDGE and NEG_EDGE.
3. Define the Timer1 term to represent the minimum pulse width, and the Timer2 term to represent the maximum pulse width.

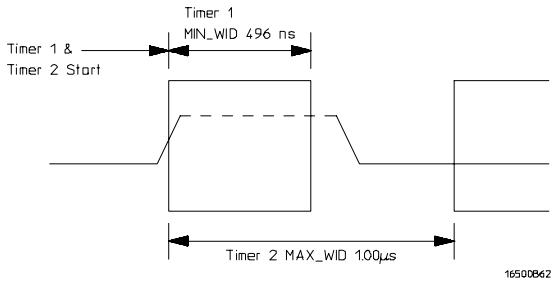
   You can rename these terms to MIN_WID and MAX_WID. In this example, Timer1 was set to 496 ns and Timer2 was set to 1 µs. Both timers start when sequence level 2 is active.
4. Under Timing Sequence Levels, enter the following sequence specification:

   - Find "**POS_EDGE" Occurs "1" Else on "no state" go to level "1"**
   - Then find "**NEG_EDGE" Occurs "1" Else on "no state" go to level "2"**

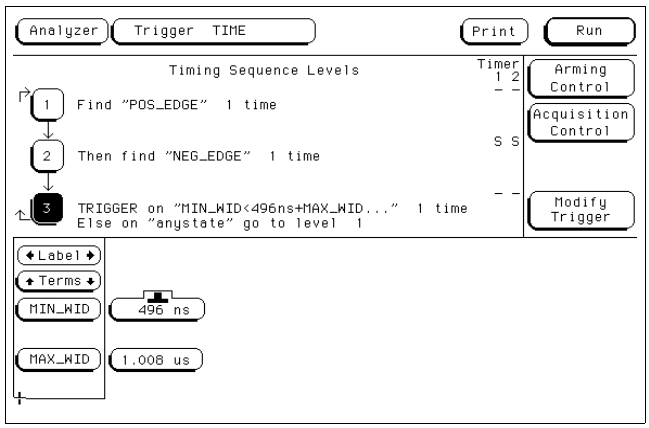
   You will need to start both timers upon entering this second state. You do this using the Timer Control field in the menu for sequence level 2.

   - TRIGGER on "**MIN_WID 496 ns + MAX_WID 1.00 µs" Occurs "1" Else on "anystate" go to level "1"**

   Because both timers start when entering sequence level 2, they start as soon as the positive edge of the pulse occurs. Once the negative edge occurs, the sequencer transitions to level 3. If at that point, the MIN_WID timer is less than 496 ns, or the MAX_WID timer is greater than 1 µs, the pulse width has been violated and the analyzer triggers. Otherwise, the sequence is restarted.



Measurement of Minimum and Maximum Pulse Width Limits

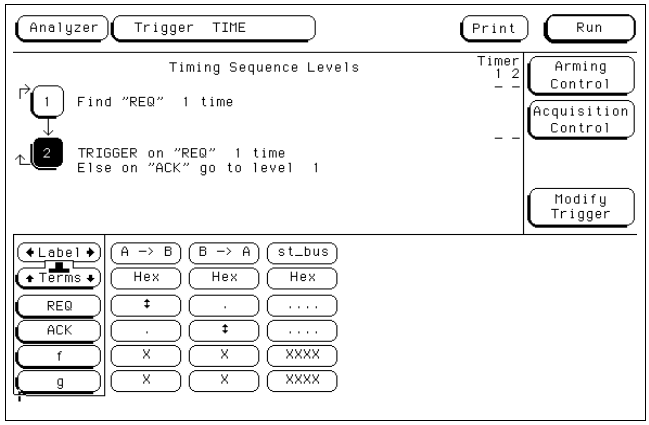


Triggering When a Pulse Exceeds Minimum or Maximum Limits

To detect a handshake violation

1. Go to the timing analyzer's Trigger menu.
2. Define the Edge1 term to represent either transition on the first handshake line, and the Edge2 term to represent either transition on the second handshake line.

   You can rename these terms to match your problem, for example, to REQ and ACK.
3. Under Timing Sequence Levels, enter the following sequence specification:
   - Find "**REQ" Occurs "1" Else on "no state"** go to level "1"
   - TRIGGER on "**REQ" Occurs "1" Else on "ACK"** go to level "1"

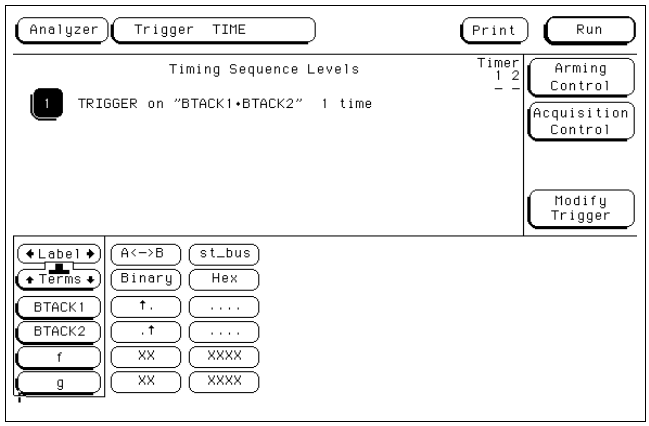


Triggering on a Handshake Violation

To detect bus contention

In this setup, the trigger occurs only if both devices assert their bus transfer acknowledge lines at the same time.

1. Go to the timing analyzer's Trigger menu.
2. Define the Edge1 term to represent assertion of the bus transfer acknowledge line of one device, and the Edge2 term to represent assertion of the bus transfer acknowledge line of the other device.
   You can rename these to BTACK1 and BTACK2.
3. Under Timing Sequence Levels, enter the following sequence specification:
   - TRIGGER on "BTACK1 • BTACK2" Occurs "1" Else on "no state" go to level "1"



Triggering on Bus Contention

Cross-Arming Trigger Examples

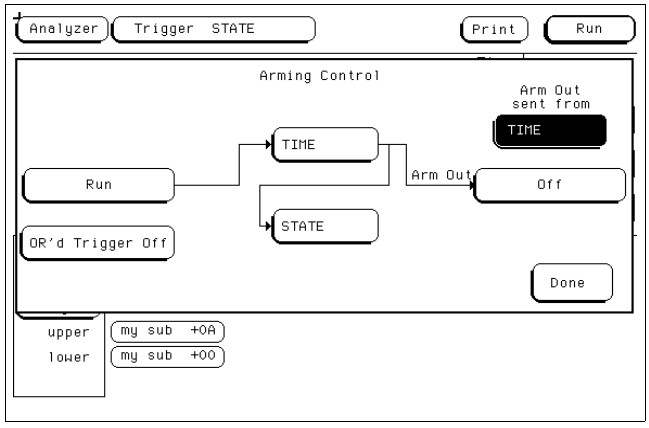
The following examples use cross arming to coordinate measurements between two separate machines within the logic analyzer. The machines can be configured as either a state* analyzer and timing analyzer, or two state analyzers. It is not possible to set both machines to time. Set up cross arming in the Arming Control menu (obtained by selecting Arming Control in the Trigger menu). When coordinating measurements between two machines, you also need to select Count Time to correlate the measurements.

* "State" includes State Compare mode.

To examine software execution when a timing violation occurs

The timing analyzer triggers when the timing violation occurs. When it triggers, it also sets its "arm" level to true. When the state analyzer receives the arm signal, it triggers immediately on the present state.

1. Set up one state analyzer and one timing analyzer.
2. Go to the timing analyzer's Trigger menu.
3. Define Edge1 to represent the control line where the timing violation occurs.
4. Under Timing Sequence Levels, enter the following sequence specification:
   - TRIGGER on "Edge1" Occurs "1" Else on "no state" go to level "1"
5. Go to the state analyzer's Trigger menu and check that term "a" is set to "don't care". In the Arming Control menu, set the state analyzer to be run by the timing analyzer.



Arming the State Analyzer from theTiming Analyzer

6. Under State Sequence Levels, enter the following sequence specification:
   - While storing "anystate" TRIGGER on "arm • a" Occurs "1" Else on "no state" go to level "1"

To look at control and status signals during execution of a routine

The state analyzer will trigger on the start of the routine whose control and status signals are to be examined more frequently than once per bus cycle. When the state analyzer triggers, it sends out an arm signal. The timing analyzer triggers when it receives the true arm level and detects the transition represented by Edge1.

1. Set up one state analyzer and one timing analyzer.
2. Go to the state analyzer's Trigger menu and define term R_START to represent the starting address of the routine.
3. Under State Sequence Levels, enter the following sequence specification:
   - While storing "anystate" TRIGGER on "R_START" Occurs "1" Else on "no state" go to level "1"
4. Go to the timing analyzer's Trigger menu.
5. Define the Edge1 term to represent a transition on one of the control signals.
6. Set the timing analyzer to be run by the state analyzer. Under Timing Sequence Levels, enter the following sequence specification:
   - TRIGGER on "arm • Edge1" 1 time

   You do not need to use a combination trigger when one analyzer is armed from the other analyzer — the arm term is ANDed automatically with the term already in use.

To trigger timing analysis of a count-down on a set of data lines

Your target system may include various state machines that are started by system events such as interrupt processing or I/O activity. The state analyzer is ideal for recognizing the system events; the timing analyzer is ideal for examining the step-by-step operation of the state machines.

1. Set up a timing analyzer and a state analyzer.
2. Go to the state analyzer's Trigger menu.
3. Set the timing analyzer to be run from the state analyzer.
4. Set the state analyzer to trigger on the label and term that identify the start of the count-down routine.
5. Go to the timing analyzer's Trigger Menu.
6. Set the timing analyzer to trigger on any state and store any state.

To monitor two coprocessors in a target system

Debugging coprocessor systems can be a complex task. Replicated systems and contention for shared resources increase the potential problems. Using two state analyzers with preprocessors can make it much easier to discover the source of such problems. For example, you may want to set up one analyzer to trigger only when a certain problem occurs, and set up the other analyzer to be armed by the first analyzer so that it takes its trace only when the first analyzer recognizes its trigger. This will let you observe the behavior of both coprocessors during the occurrence of a problem.

1. Set up both analyzers as state analyzers.
2. Go to the first analyzer's Trigger menu.
3. Set the second analyzer to be run from the first analyzer.
4. Turn on "Count Time".
5. Set the first analyzer to trigger on the problem condition.

   Some problems may involve complex sequences of conditions. See earlier examples in this chapter for more information on defining a trigger sequence.
6. Go to the Trigger menu of the second analyzer.
7. Check that the second analyzer is triggering on arm and that Count Time is set.

   After the measurement is complete, you can interleave the trace lists of both state analyzers to see the activity executed by both coprocessors during related clock cycles.

   You can use a similar procedure if you have only one processor, but want to monitor its activity with that of other system nodes, such as chip-select lines, I/O activity, or behavior of a watchdog timer. In some instances it may be easier to look at related activity with a timing analyzer.

See Also

"Special Displays" in this chapter for information on interleaving.

"To trigger timing analysis of a count-down on a set of data lines" in Cross-Timing Trigger Examples in this chapter.

Interleaved trace lists

Interleaved trace lists allow you to view data captured by two or more analyzers in a single display. When you interleave the traces, you see each state that was captured by each analyzer. These states are shown on consecutive lines.

You can interleave state listings from state analyzers when two are used together in a run. Interleaved state listings are useful when you are using multiple analyzers to look at interaction between two or more processors.

Mixed Display menu

The Mixed Display menu allows you to show state listings and timing waveforms together on screen. State listings are shown at the top of the screen and waveform displays are shown at the bottom. You can interleave state listings from two analyzers at the top of the screen, if desired. You can display waveforms from the timing analyzer at the bottom of the screen.

To interleave trace lists

1. Set up both analyzers as state analyzers.
2. Go to the Trigger menu of the first analyzer.
3. Set Count to Time, and set up the trigger.

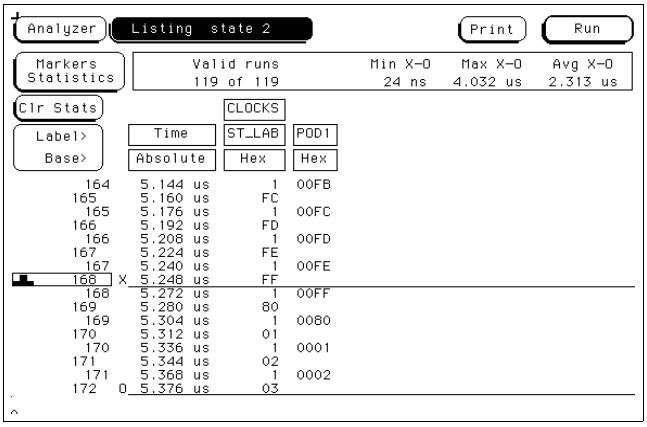
   The logic analyzer uses the time tags stored with each state to determine the ordering of states shown in an interleaved trace list.
4. Set Count to Time, and set up the trigger on the second analyzer.

   The second analyzer does not need to be run from the first analyzer, but both analyzers must have "Count Time" turned on in order to correlate the data.
5. Make the measurement run.
6. Go to one of the Listing menus.
7. Select one of the label fields in the trace list display, then select Interleave.
8. Select the name of the other analyzer and the label to interleave.

   Interleaved data is displayed in a light shade. The line numbers of interleaved data are indented in the data roll field. The labels identifying the interleaved data are shown above the labels for the current analyzer.

In the picture below, the interleaved data are shown in the same font as the current analyzer's data.

If you have problems interleaving, check that each analyzer has a independent clock from the target system, and that both analyzers are configured as state or state compare analyzers.



Interleaved Trace Lists on the HP 1671D

To view trace lists and waveforms on the same display

1. Set up a timing and a state analyzer.
2. Go to the state analyzer's Trigger menu.
3. Set Count to Time, and set up the trigger as appropriate.

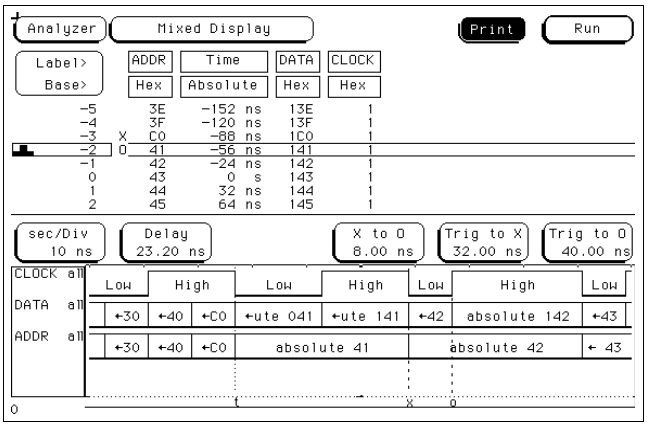
   You do not need to have one instrument arming the other to display the information jointly, but you do need to turn on Count Time so that the information may be correlated.
4. Set up the timing analyzer trigger.

   Timing analyzers implicitly count time because their sampling is driven by an internal clock, rather than an external state clock.
5. Make a measurement run.
6. Go to the Mixed Display menu.
7. Insert labels into the listing as you would in the listing menu.
8. Insert waveforms into the waveform display as you would in the waveform menu.

   You can also position X and O Time markers on the waveform display to be displayed in both the listing and the waveform areas. You must set Time Markers in the Mixed Display even if you set markers in another display.

Mixed Display

You can use Mixed Display to show both waveforms and lists in the same display, making it easier to correlate the events of interest.



Mixed Display Using Timing and State in the HP 1671D

File Management

File Management

Being able to transfer data to a host computer, such as a PC or UNIX workstation, can enhance the logic analyzer in many ways. You can use the host to store configuration files or measurement results for later review. You can save screen images from the logic analyzer in bitmap files to include in reports developed using word processors or desktop publishing tools. Or, you can develop programs on the PC that manipulate measurement results to satisfy your problem-solving needs.

This chapter shows you how to save the different types of information. The examples store files on the flexible disk drive, but you can move the same files to your host computer using a network interface. The HP 1670D family of logic analyzers have HP-IB, RS-232-C, and LAN interfaces. If you need help setting up the LAN interface, see the *LAN User's Guide*.

Transferring Files Using the Flexible Disk Drive

Because the flexible disk drive on the HP 1670D-series logic analyzer will read and write double-sided, double-density or high-density disks in MS-DOS format, it is a useful tool for transferring data to and from IBM PC-compatible computers, as well as transferring data to and from other systems that can read and write MS-DOS format. You can save configuration files, measurement results, and even menu and measurement images from the screen.

This section shows you how to use the flexible disk drive to:

- Save a configuration
- Load a configuration
- Save a trace list in ASCII format
- Save a screen image (such as a display or menu)
- Load system software

To save a configuration

You can save configurations on a 3.5-inch flexible disk or on the internal hard disk for later use. This is especially useful for automating repetitive measurements for production testing.

1. Go to the System Hard Disk or System Flexible Disk menu.
2. Set the field under System to Store.
3. Select the type of configuration you want to save in the field to the right of Store.

   You can save the analyzer configuration, the system configuration, or both.

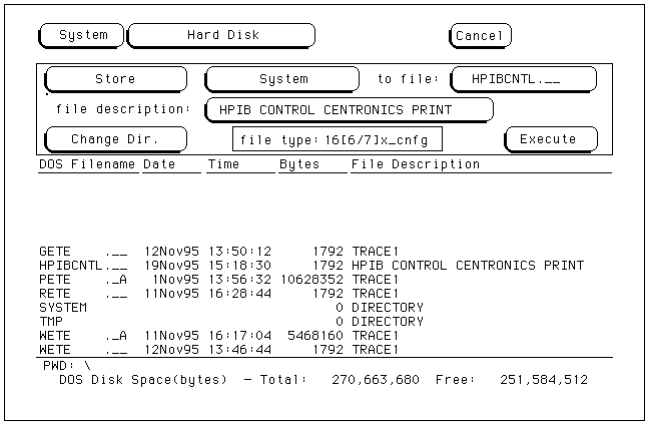
See Also Analyzer and System subheads of "Load and Store" in Disk Drive Operations in Chapter 7 for details of what is stored in a configuration file.

4. Specify a file name into which you will save the configuration using the to file field.
5. Enter a description for the file using the file description field.
6. Select Execute.

   A pop-up menu will appear for you to select Setup Only or Setup and Data. The data files are typically very large, so if you are only interested in the setup, select Setup Only.

Change Directory

If you want to save your file in a directory other than the root, you can select Change Directory from the disk operations field, then type the name of the desired directory in the directory name field, or select it from the list of visible directories using the knob



Saving the System Configuration for Programmatic Control

To load a configuration

You can quickly load a previously saved configuration, saving the trouble of manually setting up the measurement parameters.

1. **Go to the System Hard Disk or System Flexible Disk menu.**

   Your choice here depends on where you saved the configuration.

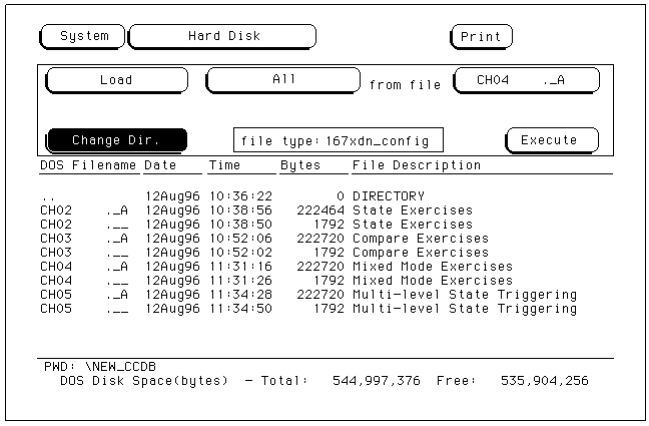
2. **Select the field below System and select Load from the pop-up menu.**
3. **Select the destination from the module list.**

   "System" loads only settings available under the System menus. "Analyzer" loads data and settings for the analyzer. "All" loads both the system and analyzer configurations.

   You can only load files to the area from which they were taken. For instance, you cannot load an analyzer configuration file to the system. Thus, if you select System, then select a file that contains only an analyzer configuration, the configuration will fail. The file type field tells you what type of information is in a file. Analyzer configuration files show "**167xan_config**", and system configurations show "16[6/7]x_cnfg" in the file type field.

4. **Specify a file name from which to load the configuration using the from file field or scrolling with the knob.**
5. **Select Execute.**

   If the configuration file includes measurement data, a status message appears. The analyzer will not respond to input until it is done loading.



Loading Configuration

To save a listing in ASCII format to a flexible disk

Some screens, such as file lists and trace lists, contain columns of ASCII data that you may want to move to a computer for further manipulation or analysis. You can save these displays as ASCII files. While a screen capture saves only the data shown onscreen, saving the display as an ASCII file captures all data in the list, even if it is offscreen.

1. Insert a DOS-formatted 3.5-inch disk in the flexible disk drive.
2. Set up the menu you want to capture, or run a measurement from which you want to save data.

   Only screens that present lists of textual data can be captured as ASCII files.The current display contents cannot be saved as an ASCII file, this option will not be present in the Output Format field.
3. Select Print and choose Print Disk from the pop-up menu.
4. Select the Filename field and specify a file name to which the data will be saved.
5. Select ASCII (ALL) from the Output Format field.
6. Select Flexible Disk from the Output Disk menu, then select Execute.

```
 68332EVS   -  State Listing

Label     ADDR        CPU32 Mnemonic                          STAT
_________ _____ ____________________________________ ________________

      0    406F4    ANDI.L   #********,(A6)+           Opcode Fetch
      1    0FF7A      0004 data write                  Data Write
      2    0FF7C      06F6 data write                  Data Write
      3    40992    BSR.B    0004093E                  Opcode Fetch
      4    40994 nu MOVE.B   ********,(****,A7)        Opcode Fetch
      5    0FF76      0004 data write                  Data Write
      6    0FF78      0994 data write                  Data Write
      7    4093E    MOVE.W   #03FF,00FFFA46           Opcode Fetch
      8    40940      03FF  pgm read                   Opcode Fetch
      9    40942      00FF  pgm read                   Opcode Fetch
     10    40944      FA46  pgm read                   Opcode Fetch
```

Part of a Trace Listing Saved as an ASCII File

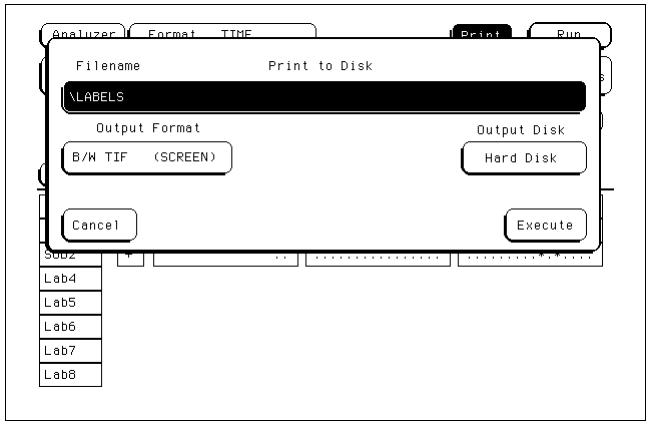
See Also "Retrieving and Storing Data" in the *LAN User's Guide*.

To save a screen's image

You can save displays to disk in one of four different graphical formats.

1. Insert a formatted flexible disk in the flexible disk drive.
2. Set up the menu whose image you want to capture, or run a measurement from which you want to save data.
3. Select Print and choose Print Disk from the pop-up menu.

   If the screen contains a pop-up menu, the Print field is not available You must use a controller to save pop-up menus to files.
4. Select the Filename field and specify a file name to save to.
5. Select the Output Format field and choose one of the following output formats for the graphics file from the pop-up menu.
   - B/W TIF is a black-and-white TIFF (Tagged Image File Format), v 5.0.
   - GRAY TIF is a grayscale TIFF, v 5.0.
   - PCX is a grayscale PCX file (PCX is the PC Paintbrush and Publisher's Paintbrush format from ZSoft).
   - EPS is a black-and-white Encapsulated PostScript file.
6. Select Flexible Disk from the Output Disk menu, then select Execute.



Print Disk Menu

See Also "To copy screen images" in the *LAN User's Guide*.

To load additional software

You can enhance the power of your HP 1670D-series logic analyzer by installing software such as symbol utilities. The symbol utilities software comes with installation instructions. In general, however, you can install logic analyzer software, without additional software, by following these instructions.

1. Turn off the logic analyzer.
2. Insert the first disk of the software into the flexible disk drive.
3. Turn on the logic analyzer.

   The analyzer will load the software as it powers up.
4. To permanently install the software, follow the instructions that come with it.

Transferring Files Using the LAN

The HP 1670D-series logic analyzers come equipped with a LAN interface. You can transfer information from the logic analyzer to a computer for processing or storage over the LAN without ever copying a file to disk.

Because there are so many different network software packages, this section does not attempt to explain how to put your logic analyer on the local network, or how to establish a network connection. Those topics are covered in detail and with many examples in the *LAN User's Guide*, which you should have received with the logic analyzer.

There are four basic types of connections you can establish between a computer and the logic analyzer over an Ethernet LAN: NFS, ftp, telnet, and X Window. NFS programs use the Network File System protocol to share file systems, effectively making the logic analyzer a part of your computer. ftp (File Transfer Protocol) is a common UNIX® program for copying files between two computers. It is also available on many PCs. A telnet or X Window connection is better suited than ftp or NFS for controlling the logic analyzer, but those connections cannot transfer files.

See Also

LAN User's Guide for information on setting up these connections.

To transfer files using NFS

1. **Check that your network software supports NFS, and connect your logic analyzer to the LAN.**

   See the *LAN User's Guide* for instructions.

2. **Mount the logic analyzer.**

   Different NFS packages have different commands for mounting. See the *LAN User's Guide* or your local network documentation. You may require a network administrator to mount the logic analyzer.

3. **Copy files from the logic analyzer to wherever you need them on your computer using your computer's commands. The various files you will see are explained in "The File System" in Chapter 9.**

   If your computer is a SUN workstation, you may have trouble with certain types of files. If you find you are receiving only 1 byte of a file, try using the `dd` command for copying. These files are dynamic files, and the file sizes are computed after they are built. The unknown file size confuses some utilities.

4. **Be sure to unmount the logic analyzer before turning it off.**

   If you do not unmount the logic analyzer before turning it off, you may have trouble later in remounting it.

See Also "The File System" and "Dynamic Files" in Chapter 9 for more details.

To transfer files using ftp

1. Check that your network package includes ftp, and connect your logic analyzer to the LAN.

   See the *LAN User's Guide* for instructions.

2. From the computer you want to transfer the files to or from, establish an ftp connection.
3. At the login prompt, log in as `data` or `control`.

   If you want to load files into the logic analyzer, log in as control. Otherwise, log in as data.

4. If you will be transferring screen images or configuration files, set type to `BIN`.
5. Locate the file you want, and transfer it.

   "The File System" in Chapter 9 explains the different types of files in the file system. Most ftp software lets you use your regular computer commands for moving around the remote file system and listing files. To copy files, most ftp software have `get` and `put` commands.

See Also

"The File System" in Chapter 9 for a description of files and the *LAN User's Guide* for how to establish an ftp connection.

Reference

Logic Analyzer Description

The HP 1670D-series logic analyzers are part of a family of general-purpose logic analyzers. The HP 1670D-series consists of three models ranging in channel width from 68 channels to 136 channels, with 100-MHz state and 250-MHz timing speeds. The HP 1670D-series logic analyzers are designed as full-featured standalone or network-configurable instruments for use by digital and microprocessor hardware and software designers. All models have HP-IB, RS-232-C, Centronics, and Ethernet LAN interfaces for hardcopy printouts and control by a host computer.

Memory depth is 64K per channel in all pod pair groupings, or 128K per channel on one pod of a pod pair (half-channel mode). With the extended memory, option memory depth is 1M per channel in all pod pair groupings, or 2M per channel on one pod of a pod pair in half-channel mode.

Measurement data is displayed as data listings and waveforms, and can also be plotted on a chart or compared to a reference image. Profiled data is displayed as histograms of activity by time, state, or address range.

The 100-MHz state analyzer has master, master/slave, and demultiplexed clocking modes available. Measurement data can be stamped with state or time tags. For triggering and data storage, the state analyzer uses 12 sequence levels with two-way branching, 10 pattern resource terms, 2 range terms, and 2 timers.

The state analyzer has a separate mode for State Compare, which allows you to quickly compare listings. State Compare reduces available memory, but in all other respects functions like State mode.

The 250-MHz timing analyzer has two timing modes with variable width, depth, and speed selections. Sequential triggering uses 10 sequence levels with two-way branching, 8 pattern resource terms, 2 range terms, 2 edge terms, and 2 timers.

The three analyzer models in the HP 1670D-series offer a variety of channel widths and memory depth combinations. The number of data channels ranges from 68 channels with the HP 1672D, and up to 136 channels with the HP 1670D. In addition, a half-channel timing mode is available which doubles acquisition rate from 125 MHz to 250 MHz, doubles memory depth from 64 K to 128 K per channel, and reduces channel width by half.

The optional memory package offers 1M memory on all channels in full-channel mode and 2M memory in half-channel mode (timing only).

The table on the following page illustrates the memory depth and channel width combinations in all acquisition modes with all analyzer models.

State Analyzer Configuration Considerations

- Unused clock channels can be used as data channels.
- With Time or State tags turned on, maximum available memory depth may be reduced. However, full depth is retained if you leave one pod pair unassigned.

State Compare Configuration Considerations

- With standard memory, memory depth is reduced by half whether tags are turned on or off. With the extended memory option, memory depth is one half with tags turned off, and one fourth with tags turned on.

Timing Analyzer Configuration Considerations

- Clock channels can be used as data channels.
- Edge terms can detect glitches.

Table 7-1

Analyzer Memory Depth and Channel Configurations

Mode	Memory Depth		Channel Configuration		
	Standard Memory	1M Option	HP 1670D	HP 1671D	HP 1672D
state 100 MHz [1]	65,536	1,032,192	136 chan. 132 data + 4 data or clock	102 chan. 98 data + 4 data or clock	68 chan. 64 data + 4 data or clock
state 100 MHz [2]	32,768	507,904			
state compare 100 MHz [1]	32,768	245,760	136 chan. 132 data + 4 data or clock	102 chan. 98 data + 4 data or clock	68 chan. 64 data + 4 data or clock
state compare 100 MHz [2]	32,768	114,688			
timing, half-channel 250 MHz	131,072	2,080,768	68 chan. 66 data + 2 data or clock	51 chan. 49 data + 2 data or clock	34 chan. 32 data + 2 data or clock
timing, full-channel 125 MHz	65,536	1,032,192	136 chan. 132 data + 4 data or clock	102 chan. 98 data + 4 data or clock	68 chan. 64 data + 4 data or clock

[1] With tags turned off or non-interleaved tags. Tags are non-interleaved if there is an unassigned pod pair or a pod pair assigned to an anlyzer that is turned off.

[2] With interleaved tags.

Probing

This section discusses the probing system for the logic analyzer. It also contains the information you need for connecting the probe system components to each other, to the logic analyzer, and to the system under test.

Probing Options

You can connect the logic analyzer to your system under test in one of the following ways:

- Microprocessor- and bus-specific interfaces (optional).
- Standard general-purpose probing (provided).
- Direct connection to a 20-pin, 3M-Series type header connector using the optional termination adapter.

See Also *Accessories for HP Logic Analyzers* for additional information about the microprocessor interface kits and for any new probing solutions.

Microprocessor-and Bus-Specific Interfaces

There are a number of microprocessor- and bus-specific interfaces available as optional accessories. Microprocessors are supported by Universal Interfaces or Preprocessor Interfaces, or in some cases, both.

Universal Interfaces are manufactured by other vendors. Universal Interfaces are aimed at initial hardware turn-on, and provide fast, reliable, and convenient connections to the microprocessor system. Many use passive probing and do not support inverse assembly.

Preprocessor interfaces are aimed at hardware turn-on and hardware/software integration, and provide the following:

- All clocking and demultiplexing circuits needed to capture the system's operation.
- Additional status lines to further decode the operation of the CPU.
- Inverse assembly software to translate logic levels captured by the logic analyzer into microprocessor mnemonics.

Bus interfaces will support bus analysis for the following:

- Bus support for HP-IB, RS-232-C, RS-449, SCSI, VME, VXI, ISA, EISA, MCA, FDDI, Futurebus+, JTAG, SBus, PCI, and PCMIA.

General-Purpose Probing

General-purpose probing connects the logic analyzer probes directly to your target system without using any interface. General-purpose probing does not limit you to specific hookup schemes.

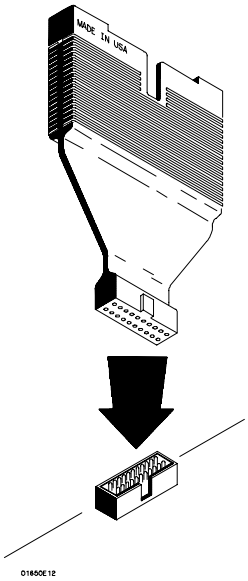
General-purpose probing uses grabbers that connect to both through-hole and surface-mount components. General-purpose probing comes as the standard probing option. You will find a full description of its components and use later in this section.

The Termination Adapter

The logic analyzer must be properly terminated to operate correctly. Most HP preprocessor interfaces have properly terminated state connectors; however, many of them require termination adapters for the timing connectors.

The optional termination adapter allows you to connect the logic analyzer probe cables directly to test ports on your target system without the probes.

The termination adapter is designed to connect to a 20-pin (2x10), 4-wall, low-profile, header connector which is a 3M-Series 3592 or equivalent.



TerminationAdapter

General-purpose probing system description

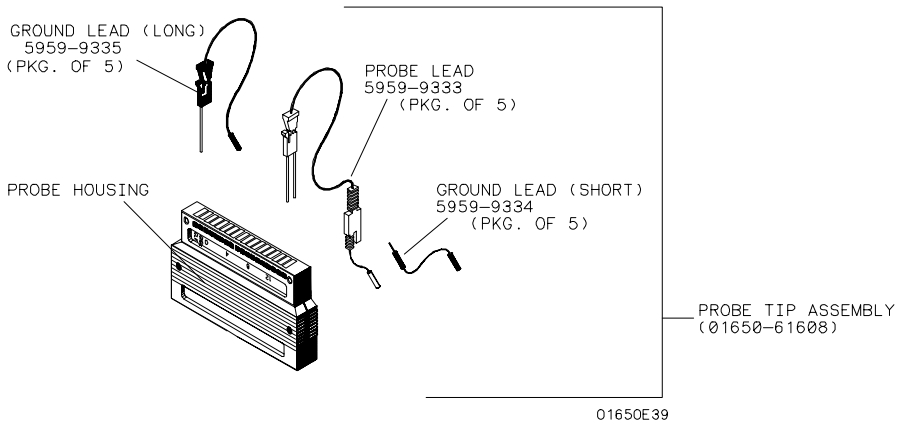
The rest of this chapter is dedicated to general-purpose probing. The standard probing system provided with the logic analyzer consists of a probe tip assembly, probe cable, and grabbers. Because of the passive design of the probes, there are no active circuits at the outer end of the cable.

The passive probing system is similar to the probing system used with high-frequency oscilloscopes. It consists of a series RC network (90 kΩ in parallel with 8 pF) at the probe tip, and a shielded, resistive transmission line. The advantages of this system include the following:

- 250 Ω in series with 8-pF input capacitance at the probe tip for minimal loading
- Signal ground at the probe tip for high-speed timing signals
- Inexpensive, removable probe tip assemblies

Probe Tip Assemblies

Probe tip assemblies allow you to connect the logic analyzer directly to the target system. This general-purpose probing is useful for discrete digital circuits. Each probe tip assembly contains 16 probe leads (data channels), 1 clock lead, a pod ground lead, and a ground tap for each of the 16 probe leads.



Probe Tip Assembly

Probe and Pod Grounding

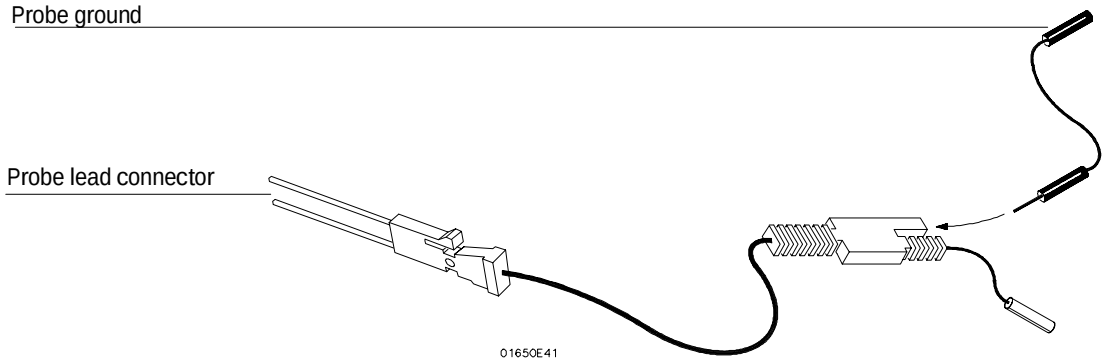
Each pod is grounded by a long, black, pod ground lead. You can connect the ground lead directly to a ground pin on your target system, or use a grabber. To connect the ground lead to grounded pins on your target system, you must use 0.63-mm (0.025-in) square pins, or use round pins with a diameter of 0.66 mm (0.026 in) to 0.84 mm (0.033 in). The pod ground lead must always be used.

Each probe can be individually grounded with a short black extension lead that connects to the probe tip socket. You can then use a grabber or the grounded pins on your target system in the same way you connect the data lines. For extra confidence in your measurements, grounding every third or fourth probe is recommended.

When probing signals with rise and fall times of 1 ns or less, grounding each probe lead with the 2-inch ground lead is recommended. In addition, always use the probe ground on a clock probe.

Probe Leads

The probe leads consists of one 12-inch twisted-pair cable, one ground tap, and one grabber. The probe lead, which connects to the target system, has an integrated RC network with an input impedance of 100 kΩ in parallel with approximately 8 pF, and all in series with 250 Ω. The probe lead has a two-pin connector on one end that snaps into the probe housing.



Probe Ground Lead

Grabbers

The grabbers have a small hook that fits around the IC pins and component leads. The grabbers have been designed to fit on adjacent IC pins on either through-hole or surface-mount components that have lead spacing greater than or equal to 0.050 inches.

Probe Cable

The probe cable contains 18 signal lines, 17 chassis ground lines, and two power lines for preprocessor use. The cables are woven together into a flat ribbon that is 4.5 feet long. The probe cable connects the logic analyzer to the pods, termination adapter, or preprocessor. Each cable is capable of carrying 0.33 amps for preprocessor power.

CAUTION

DO NOT exceed 0.33 amps per cable, or the cable will be damaged.

Preprocessor power is protected by a current limiting circuit. If the current limiting circuit is activated, the fault condition must be removed. After the fault condition is removed, the circuit will reset in one minute.

Minimum Signal Amplitude

Any signal line you intend to probe with the logic analyzer probes must supply a minimum voltage swing of 500 mV to the probe tip. If you measure signal lines with a voltage swing of less than 500 mV, you may not obtain a reliable measurement. Because the minimum input overdrive is the greater of 250 mV or 30% of input amplitude, be sure to correctly set the pod threshold in the Analyzer Format menu.

Maximum Probe Input Voltage

The maximum input voltage of each logic analyzer probe is 40 volts peak.

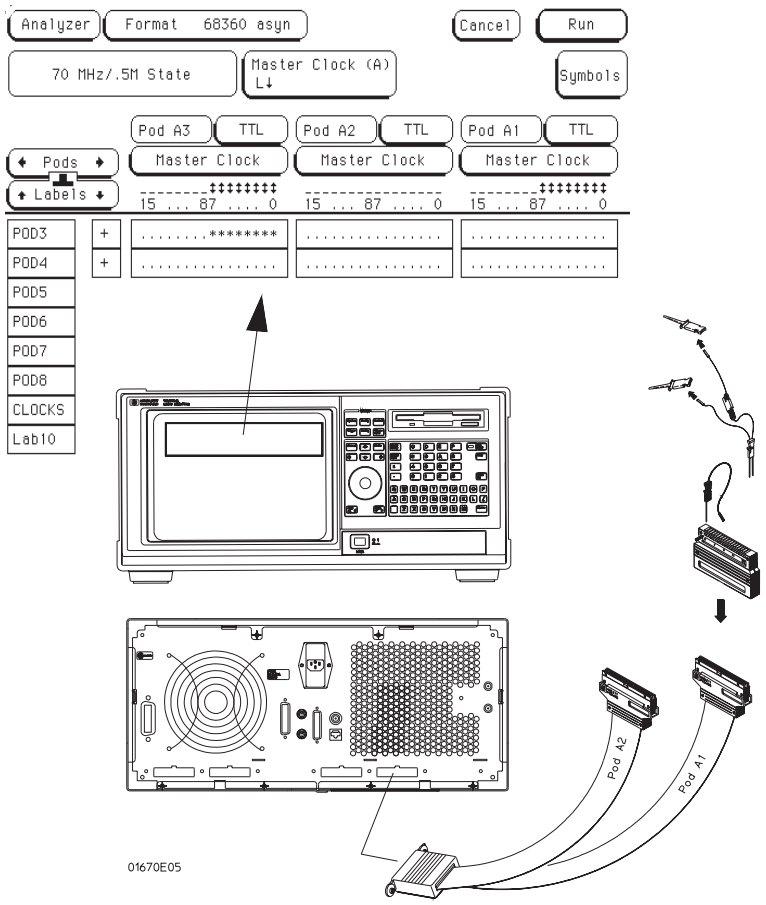
Pod Thresholds

Logic analyzer pods have two preset thresholds and a user-definable pod threshold. The two preset thresholds are ECL (–1.3 V) and TTL (+1.5 V). The user-definable threshold can be set anywhere between –6.0 volts and +6.0 volts in 0.05-volt increments.

All pod thresholds are set independently.

Assembling the probing system

The general-purpose probing system components are assembled as shown to make a connection between the measured signal line and the pods displayed in the Analyzer Format menu.



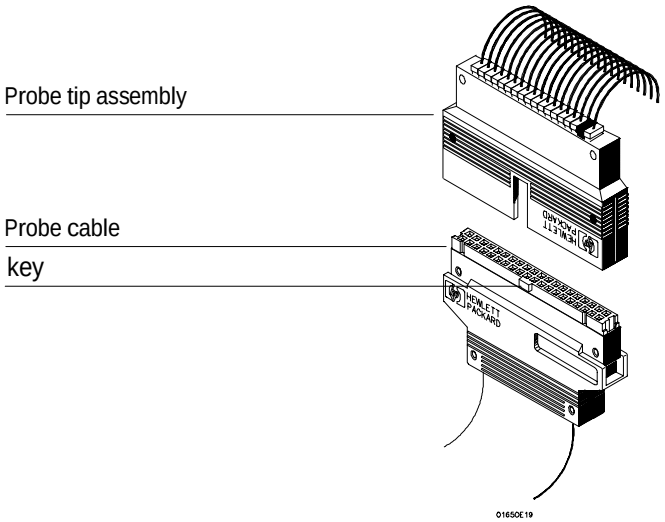
Connecting ProbeCables to the LogicAnalyzer

Connecting Probe Cables to the Logic Analyzer

All probe cables are installed at Hewlett-Packard. If you need to replace a probe cable, refer to the *HP 1670D-Series Logic Analyzers Service Guide*, available from your HP Sales Office.

Connecting the Probe Tip Assembly to the Probe Cable

To connect a probe tip assembly to a cable, align the key on the cable connector with the slot on the probe housing and press them together.



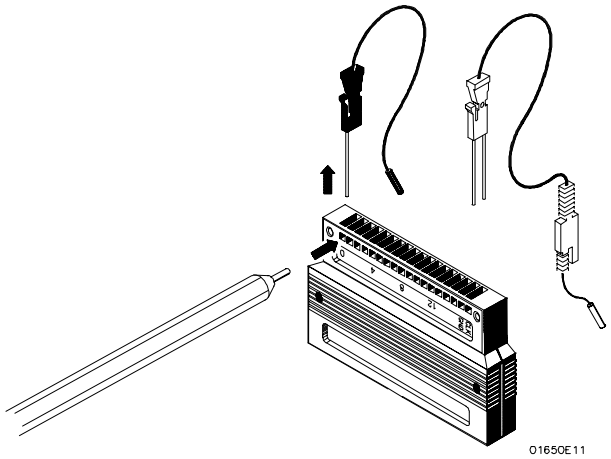
Connecting ProbeTip Assembly

Disconnecting Probe Leads from Probe Tip Assemblies

When you receive the logic analyzer, the probe leads are already installed in the probe tip assemblies. To keep unused probe leads out of your way during a measurement, you can disconnect them from the pod.

To disconnect a probe lead, insert the tip of a ballpoint pen into the latch opening. Push on the latch while gently pulling the probe out of the pod connector as shown in the figure below.

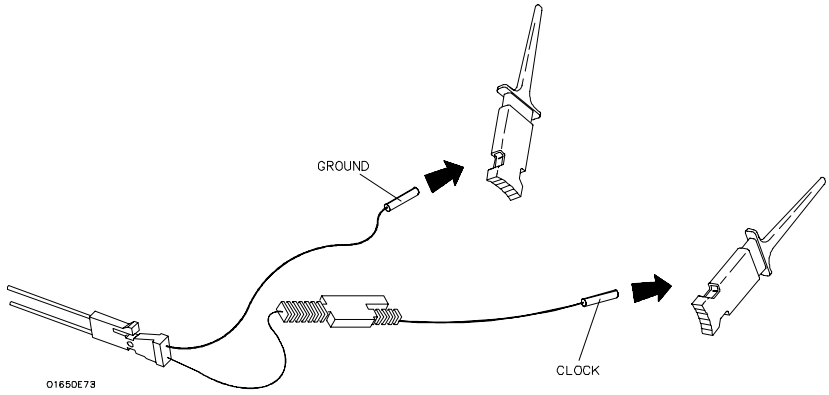
To connect the probes to the pods, insert the double pin end of the probe into the probe housing. Both the double pin end of the probe and the probe housing are keyed so they will fit together only one way.



Installing Probe Leads

Connecting the Grabbers to the Probes

Connect the grabbers to the probe leads by slipping the connector at the end of the probe onto the recessed pin located in the side of the grabber. If you need to use grabbers for either the pod or the probe grounds, connect the grabbers to the ground leads in the same manner.



Connecting Grabbers to Probes

Keyboard Shortcuts

This section explains how to use the optional keyboard interface (HP E2427B Keyboard Kit). You can use the keyboard interchangeably with the knob and front-panel keypad for all menu applications. The keyboard functions fall into the two basic categories of cursor movement and data entry.

Moving the cursor

The keyboard cursor is the location on the screen highlighted in inverse video. Move the cursor using one of the methods described below.

Keyboard cursor movement

There are four cursor keys marked with arrows on the keyboard.

- Up-pointing arrow moves the cursor up.
- Down-pointing arrow moves the cursor down.
- Right-pointing arrow moves the cursor to the right.
- Left-pointing arrow moves the cursor to the left.

The cursor keys do not wrap. This means that pressing the right-pointing arrow when the cursor is already at the rightmost point in a menu will have no effect. The cursor keys do repeat, so holding the key down is the fastest way to continue keyboard cursor movement in a given direction.

Page Up and Page Down keys The Page Up and Page Down keys page through listings. The Page Up key displays the previous page of data. The Page Down key displays the next page of data.

Duplicating front-panel knob The shift-up arrow and the shift-down arrow act like the front-panel knob, and are easier to use than the mouse for fine control.

Selecting a menu item

To select a menu item with the keyboard, position the cursor on the menu item and press the Return or Enter key.

Entering data into a field

When an assignment field is selected, the cursor is displayed under the leftmost character in the field. When you type a character, it is displayed in the cursor position, and the cursor is advanced. Cursor keys move the cursor within the assignment field. Pressing either the Return key or the Enter key will terminate data entry for that item.

Using the keyboard overlays

A keyboard overlay is included in the HP E2427B Keyboard Kit. The table below represents the key mappings.

Key	Functions Like	Key	Functions Like
F1	System Key	S	Select "seconds"
F2	Config Key	M	Select "milliseconds" or "millivolts"
F3	Format Key	U	Select "microseconds"
F4	Trigger Key	N	Select "nanoseconds"
F5	Listing Key	V	Select "volts"
F6	Waveform Key	B	Select "any (both) edge"
F7	Print All Key	R	Select "rising edge"
F8	Run Rep. Key	F	Select "falling edge"
F9	Stop	*	Assign glitch
F10	Done	.	Assign Don't Care (X)
F12	Assign Don't Care (X)		

Common Menu Fields

There are a number of fields having similar operation that appear throughout the different menus. These common fields are listed below:

- Mode (System/Analyzer) field
- Menu field
- Print field
- Run field
- Base field
- Label field
- Roll fields

Because most of these fields are self-explanatory, only the fields with less obvious features are described here.

Print field

The Print field prints what is displayed on the screen at the time you initiate the printout. When you select the Print field, a print selection pop-up menu appears showing you one or more of the following options:

- Print Screen
- Print Disk
- Print All
- Print Partial
- Cancel

While printing, the Print field changes to Cancel and the user interface is not active except for Cancel. When the printout is complete, the user interface becomes active again. The Print field is not available with pop-up menus. The only way to print a pop-up menu is with a controller.

Print Screen

The Print Screen option sends the screen immediately to the printer specified in the System External I/O menu. The option does not create a file; to create a file, use Print Disk.

Print Disk

The Print Disk option copies the screen in graphical form or ASCII, if available, to a file on either drive. Possible output formats are

- ASCII 8-bit standard ASCII text file
- B/W TIF Black-and-white image in TIFF version 5.0 format
- GRAY TIF Grayscale image in TIFF version 5.0 format
- PCX Grayscale image in standard PCX format
- EPS Line image in standard Encapsulated PostScript format

Print All

The Print All option prints not only what is displayed on the screen, but data that is below the screen. This option is only available when an ASCII form of the screen is possible. For example, Print All is never available in Waveform.

When you select Print All with a Listing menu, make sure the first line you want to print is in the state location box (also referred to as the data row field) at the center of the listing area. Lines above this box will not print.

Print Partial

The Print Partial option is identical to the Print All option, except the start and end states are specified. The screen settings and specified data are printed in ASCII form.

Run/Stop field

The Run field starts the analyzer measurement. When you select Run, the screen switches to the display menu last viewed and displays the acquired data. If Stop is selected during a single run, the data acquisition is aborted. If Stop is selected during a repetitive run, the current run cycle is completed before data is displayed.

Repetitive

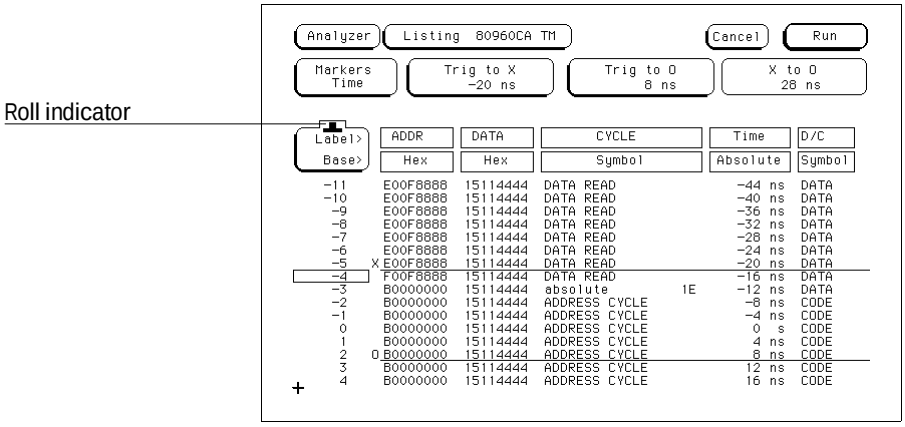
The Repetitive option runs the data acquisition cycle repeatedly until you select Stop or until a pre-assigned stop measurement condition is met. The stop measurement condition is set in the Analyzer Listing or Analyzer Waveform menus when pattern markers are turned on.

Roll fields

Some data may not fit on the screen when there are many pods or labels to display. When this happens, it is indicated by the Label/Base field becoming selectable, and its shade changing to the common field shade. To move through the hidden data, select the field, wait for the roll indicator to appear, then use the knob to move through the data. The field does not need to be selected for the knob to affect it but it does need to be displaying the roll indicator. The figure below shows an active roll field.

If there is more than one rollable field, the roll indicator remains with the last rollable field activated. For example, the Listing menu shown below has both the Label/Base field and the state location field, which are both rollable. However, the only field affected when turning the knob is the field with the roll indicator.

Another way to move through data is by using the Page keys. The Page keys are independent of the knob rolling function and move through data without changing which labels or pods are displayed. Page keys page data one screen at a time. To move the data left or right one screen at a time, press the blue Shift key, then the Page key.



Label and Base Roll Field

Disk Drive Operations

The logic analyzer has a built-in 3.5-inch, double-sided, high-density or double-density, flexible disk drive. The disk drive is compatible with both LIF (Logical Interchange Format) and DOS (Disk Operating System) formats. It also has an internal hard disk drive, which performs the same operations as the flexible disk drive.

Disk operations

Ten disk operations are available:

- Autoload

Designates a set of configuration files to be loaded automatically the next time the analyzer is turned on, and creates an autoload file.

- Copy

Copies files. Any file can be copied from one drive to another, from one directory to another, or to different flexible disks.

- Duplicate Disk

Copies one flexible disk to another flexible disk. You cannot copy the hard disk to a flexible disk in a single operation. All volume labels, directories, and file positions from one disk are copied exactly to another disk. The new disk is formatted to match the source disk if it is required. All files on the destination disk will be destroyed with this operation.

- Format Disk

Formats a flexible disk or the internal hard disk. Either can be formatted in LIF or DOS format. All files on the disk will be destroyed with this operation.

- Load

Loads a file into the logic analyzer, overwriting the current settings or information. You can load system configurations, analyzer measurement setups including measurement data, and inverse assembler files.

- Make Directory

Creates a new directory on a DOS disk. You can save or copy files to the new directory using the store and copy commands. This is not available with LIF disks.

- Pack Disk

Removes all empty or unused sectors between files on a LIF disk so that more space is available. If you select Pack Disk while a DOS disk is in the drive, nothing happens.

- Purge

Purges (deletes) the file you indicate. Deleted files cannot be recovered.

- Rename

Changes the name of the file you select.

- Store

Saves system and analyzer measurement setups. When you store an analyzer setup, you can choose whether or not to also store the data.

Disk operation safeguards

If there is a problem or additional information is needed to execute an operation, a pop-up menu appears near the center of the screen displaying the status of the operation.

If executing a disk operation could destroy or damage a file, a pop-up menu appears when you select Execute. If you do not want to complete the operation, select Cancel to cancel the operation. Otherwise, select Continue.

Autoload

The Autoload operation allows you to designate a set of configuration files to be loaded automatically the next time the analyzer is turned on. This allows you to change the default configuration of certain features to one that better fits your needs. If both the hard drive and flexible drive have autoload setups, only the setup on the flexible drive will be used.

Autoload creates a file that loads all of the files for a given base file name. If you want to load only one type of file, rename that file, or copy it to a separate name and enable it in the current Autoload file. Autoload will remain enabled when you turn on the instrument and load the configuration files, as long as Autoload is enabled before the instrument is shut off.

Format

CAUTION

Executing Format Disk permanently erases all existing information from the disk. After formatting, there is no way to retrieve the original information.

The logic analyzer recognizes a variety of sector sizes for LIF disks. However, it only creates 1024-byte sectors when formatting a LIF disk. DOS disks always have 512-byte sectors.

The logic analyzer does not support track sparing during formatting. If a bad track is found, the disk is considered bad. If a disk has been formatted elsewhere with track sparing, it will be read successfully.

When formatting a disk, the DISK ERROR message appears if the disk is unformatted. This is normal, and you can safely continue the format process.

Load and Store

When you choose Load or Store, you next need to set the field immediately to the right. This field presents at least three choices: All, System, and Analyzer. If you have other software loaded, it might add to the choices.

All

The logic analyzer lets you specify whether you want to store setup and data, or setup only. Choose All to store or load both system and analyzer information. If you are storing, two files (one for the system and one for the analyzer) are created. The system file ends in "._ _" (two underscores) and the analyzer file in "._A".

System

System files store system configurations. System information for the HP 1670D-series consists of settings for printer, controller, RS-232-C, HP-IB, shade, and sound. LAN settings are not saved. System configuration files end in two underscores and have a file type of 16[6/7]x_cnfg.

Analyzer

Analyzer configuration files store measurement setups, which may include data. If you are storing the current measurement and an inverse assembler is already loaded, when you reload the file you are now creating, it will try to pull in the inverse assembler. Other attributes stored in analyzer configuration files include labels, trigger sequence, arming configuration, markers, analyzer names, and pod assignments. Analyzer configuration files end in "._A" and have a file type of 167xdn_config.

Pack Disk

By purging files from the disk and adding other files, you may end up with blank areas on the disk (between files) that are too small for the new files you are creating. On LIF disks, the Pack Disk operation packs the current files together, removing unused areas from between the files so that more space is available for files at the end of the disk. On DOS disks, the Pack Disk operation is not available. If you do select Pack Disk while a DOS disk is in the drive, the disk is not affected.

The RS-232-C, HP-IB, Centronics, and LAN Interfaces

This section describes the controller and printer interfaces and their configurations found in the System External I/O menu. It defines the HP-IB interface and describes how to select a different HP-IB address. It also defines the RS-232-C interface and tells you how to select a baud rate, how to change the stop bits, how to set the parity and data bits, and how to change the protocol. The Centronics (parallel) interface (printer only) and LAN interface (controller only) are also described.

Because there are so many types of Ethernet network software, this section describes only the LAN settings on the logic analyzer. See the *LAN User's Guide* for detailed instructions on connecting the logic analyzer to your LAN.

Controller interface

The logic analyzer is equipped with standard RS-232-C, HP-IB, and Ethernet LAN interfaces that allow you to connect to a controller. All of the interfaces give you remote access for running measurements and uploading and downloading configurations and data.

Printer interface

The logic analyzer can output its screen to various HP-IB, RS-232-C, and Centronics graphics printers. Configured menus, as well as waveforms and other data, can be printed for complete measurement documentation. The analyzer cannot use a networked or shared printer.

See Also

Chapter 2, "Connecting Peripherals" for details on physically connecting equipment.

HP 1670D-Series Logic Analyzers Programmer's Guide for more information on the controller interface.

The *LAN User's Guide* for more information on the setting up the LAN interface to work with your specific network.

The HP-IB interface

The Hewlett-Packard Interface Bus (HP-IB) is Hewlett-Packard's implementation of IEEE Standard 488-1978, "Standard Digital Interface for Programmable Instrumentation." HP-IB is a carefully defined interface that simplifies the integration of various instruments and computers into systems.

The HP-IB interface uses an addressing technique to ensure that each device on the bus (interconnected by HP-IB cables) receives only the data intended for it. To accomplish this, each device is set to a different address, and this address is used to communicate with other devices on the bus. The HP-IB address is the only HP-IB interface setting that is configurable from the logic analyzer.

The HP-IB address can be set to 31 different HP-IB addresses, from 0 to 30. Simply choose a compatible address for your device and software. The default address for all HP-IB logic analyzers is 7. In the System External I/O menu, select HP-IB Settings, then set the Address field to your address.

The RS-232-C interface

The RS-232-C interface is Hewlett-Packard's implementation of EIA Recommended Standard RS-232-C, "Interface Between Data Terminal Equipment and Data Communications Equipment Employing Serial Binary Data Interchange."

With this interface, data is sent one bit at a time and characters are not synchronized with preceding or subsequent data characters. Each character is sent as a complete entity independent of other events.

The following paragraphs describe the settings for RS-232-C. You can change these settings by accessing the System External I/O menu and selecting RS232 Settings. Each field in the Settings pop-up menu presents a list of valid choices.

Baud rate

The baud rate is the rate at which bits are transferred between the interface and the peripheral. The baud rate must be set to transmit and receive at the same rate as the peripheral.

Stop Bits

Stop Bits are used to identify the end of a character. The number of Stop Bits must be the same for the controller as for the logic analyzer.

Parity

The parity bit detects errors as incoming characters are received. If the parity bit does not match the expected value, the character was incorrectly received. The action taken when an error is detected depends on the interface and the device program configuration.

Parity is determined by the requirements of the system. The parity bit may be included or omitted from each character by enabling or disabling the parity function.

Data Bits

Data Bits are the number of bits used to represent the binary code of a character. The HP 1670D-series logic analyzers support 8-bit binary code.

Protocol

Protocol governs the flow of data between the instrument and the external device. It can be controlled either by the hardware, in which case you select None in the RS-232 Settings pop-up menu, or by the software, in which case you select Xon/Xoff. Xon/Xoff stands for Transmit On/Transmit Off.

With less than a 5-wire interface, selecting None does not allow the sending or receiving device to control how fast the data is being sent, which increases the possibility of missing data. With a full 5-wire interface, selecting None allows a hardware handshake to occur. With a hardware handshake, hardware signals control data flow. The HP 13242G cable allows the logic analyzer to support hardware handshake.

The Centronics interface

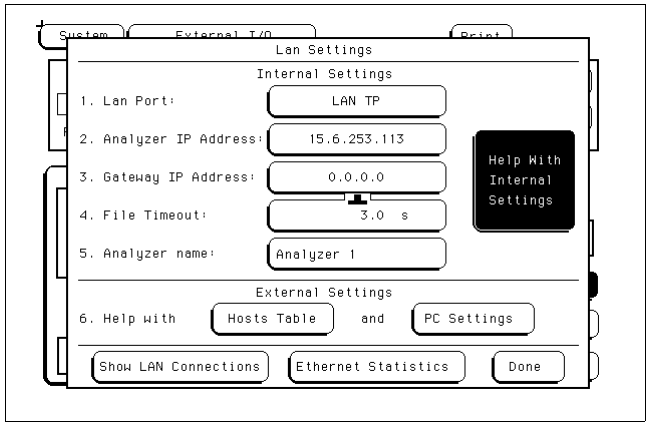
The Centronics interface is an industry-standard parallel printer interface. It can only be used as a printer interface, and is not available to the controller. There are no Centronics-specific settings; page and line length are set in the Printer Settings menu.

See Also

Chapter 2, "Connecting Peripherals," for more information on setting up the parallel printer port.

The Ethernet LAN interface

The LAN interface is Hewlett-Packard's implementation of IEEE standard 802.3 (ISO 8802-3), "Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications." This network protocol is commonly referred to as Ethernet. To access the LAN menus, go to the System External I/O menu and select the LAN Settings field.



LAN Settings Menu

Lan Network

If you are uncertain as to your local network configuration, or have questions concerning addresses, contact your network system administrator

LAN Port

There are two ports for connecting the logic analyzer to a LAN. The LAN TP port is for a twisted pair network, sometimes known as ethertwist or 10Base-T. The LAN BNC port is for a coaxial cable network, sometimes known as thinlan or 10Base2. The LAN Port field toggles between these two ports. Select the field that matches your LAN network and the back-panel connector you are using.

Analyzer IP Address

This is the IP address that the logic analyzer will respond to, and must be unique on the network. If you need to create an IP address, contact your system administrator. Enter the analyzer address in this field.

Gateway IP Address

The gateway IP address is only necessary if the host computer and logic analyzer are on different subnets. Use the address of the gateway nearest the logic analyzer between the analyzer and the host. Your system administrator should be able to provide this information.

File Timeout

The file timeout is the amount of time the logic analyzer will keep a file in memory. If you are transferring 1M of data, the file timeout must be larger than if you are transferring 4K of data. The file timeout can also affect the network timeout. Generally, 1.5 seconds is a good value.

Analyzer name

You can assign an analyzer name to the logic analyzer. It does not have to be the same as the IP alias, although you could set it to the same. This name shows up in the X Window title bar and in ASCII files created by the analyzer.

Help with . . .

These buttons provide additional information on the LAN settings screen, hosts table, and PC settings.

Show LAN Connections

This field pops up a list of all connections to the logic analyzer, and some information as to the type of connection. An IP address followed by "0.0" is an X Window connection. A line beginning with FTP is an ftp connection. PARSER SOCKET is a telnet connection. A straight IP address or computer name is an NFS client.

Ethernet Statistics

This field pops up a display showing the analyzer's ethernet address, the subnet mask, and transmit and receive statistics on the current session, which may be helpful for troubleshooting. These fields are not configurable.

See Also

The *LAN User's Guide* for more details.

System Utilities

The System Utilities menu is used for setting system level parameters such as the system clock, display intensity for each shade, and the sound. In this menu, you can also rewrite the analyzer's memory with any new revisions of the operating system.

Real Time Clock Adjustments field

A real-time clock is displayed in the Waveform and Listing menus. When you store an acquisition, or print a screen, the clock and date at the time of acquisition appear on the copy. To change the clock, go to the System Utilities menu and select Real Time Clock Adjustments. Set the values to the desired date and time. Default Time sets the real-time clock to January 1, 1992 at 12 noon.

The Time Zone field changes the logic analyzer's apparent file times when viewed over NFS. It does not affect the real-time clock. Set the Time Zone to the same Time Zone used by your LAN. This value is usually the same as the difference in hours between your local time and Greenwich Mean Time.

Update FLASH ROM field

The logic analyzer uses flash ROMs to store the operating system. The analyzer you received should have an operating system in place and should also include the operating system files on a flexible disk, but you may occasionally need to update the operating system. Selecting Update FLASH ROM updates the analyzer's operating system.

CAUTION

Updating flash ROM without the proper files will damage the logic analyzer operating system.

1. Go to the System Utilities menu.
2. Insert the flexible disk containing the operating system files into the disk drive.
3. Select Update FLASH ROM.

The analyzer warns, "Selecting Continue Will Erase & Update Flash ROMs." and waits for you to select Cancel or Continue. If you select Continue, the analyzer will be reset. If you need to save the measurement data, select Cancel.

4 Select Continue.

The screen goes black and the analyzer performs its power-up self tests. It then displays a message listing the required files and provides further instructions.

5 Insert the update disk into the flexible disk drive.

6 To search only the flexible disk drive, press the Done key. To search the flexible disk drive, then the hard drive, press any other key.

If you press a key other than Done, the logic analyzer will not pause for you to insert the second disk when it finishes copying files from the first disk. Instead, it will look on the hard drive under the /SYSTEM directory. If it finds copies of the operating system files on the hard drive, those are used instead. This could result in incorrect installation of the updated operating system.

The logic analyzer warns, "We are about to erase flash ROM memory." This is the last point at which you can cancel the operation. Any loss of power between the time the analyzer starts to erase flash ROM and the time it finishes copying the update will destroy the operating system.

CAUTION

If you do not have the required files, turn off the analyzer immediately. Pressing any key will destroy the operating system.

7 If you are sure you are ready to continue, press any key.

8 When the analyzer has completed the update, press any key.

The screen goes black and the analyzer reboots. You have finished updating the flash ROM and the new operating system is in place. It is now safe to turn off the logic analyzer.

Shade adjustments

You can adjust the greys of the display to different levels of intensity. Select the shade number, then select luminosity and adjust it with the knob. Default Shades restores all shade intensity levels to the original factory settings. Changing the shade does not affect the X Window colors.

Type field

The Type field allows you to configure the logic analyzer with either an internal clock (Timing mode) or an external clock (State, State Compare, and SPA). When the Type field is selected, the following choices are available.

Timing When Timing is selected, the analyzer uses its own internal clock to store measurement data into the acquisition memory. This clock is asynchronous to the signals in the target system. Fields relating to external clocks, such as the Analyzer Format menu's Master Clock, do not appear, and certain menus are not available.

The analyzer can only be configured with one timing analyzer. If two are selected, the first will be turned off.

State When State is selected, the analyzer uses a clock from the system under test to clock measurement data into acquisition memory. This clock is synchronous to the signals in the target system. State mode does not allow you to access the Compare menu.

State Compare When State Compare is selected, the Compare menu is available in the main menu selection. For more details on Compare, see "The Compare Menu." State Compare mode functions much like State mode, except that total memory is reduced.

SPA SPA stands for System Performance Analysis. It uses an external clock like a state analyzer, but measures overall system performance rather than recording discrete activity. For more details, see Chapter 8.

Illegal configuration

When both analyzers are turned on and both analyzers have pods assigned to them, the first pod pair, 1/2, and the second pod pair, 3/4, cannot be assigned to the same analyzer. If this configuration is set, the logic analyzer will display a re-assignment menu when you try to leave the configuration screen. Use this re-assignment menu to configure the pod assignment automatically to a legal configuration.

Pod threshold field

The pod threshold field sets the voltage level that the analyzer uses to recognize a change in logic levels. Threshold levels are pod-specific, and cover data and clock channels. If you are working with small voltage swings, ensure that the threshold is set such that the minimun overdrive specification (250 mV or 30% of amplitude) is satisfied.

TTL When the threshold level is TTL, the signals must reach +1.5 volts.

ECL When the threshold level is ECL, the signals must reach –1.3 volts.

User When the threshold level is User, the signals must reach a user-defined value between –6.0 volts to +6.0 volts, definable in 50-mV steps.

Acquisition modes

The Acquisition mode field identifies the channel width and sampling speed of the present acquisition mode. There are two timing acquisition modes. State analyzers only have one acquisition mode.

Full-channel 125MHz The total memory depth is 64K, with data being sampled and stored as often as every 8 ns. With the extended memory option, 1M of memory is available.

Half-channel 250MHz The total memory depth is 128K, with data being sampled and stored as often as every 4 ns, but only one of the pods in each pod pair is active. With the extended memory option, 2M of memory is available.

100-MHz State The total memory depth is 64K per channel. Turning on time tags, or Compare, or both, decreases memory to 32K. With extended memory option, 1M of memory is available.

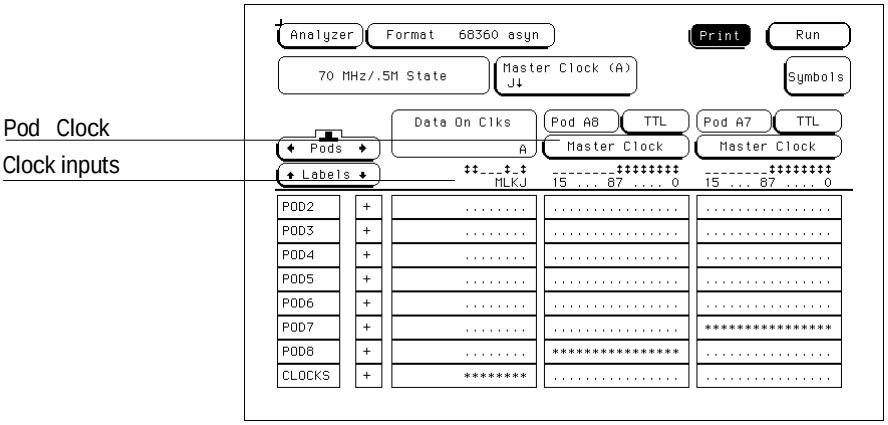
See Also

"Configuration Capabilities" in this chapter and "To set the memory" in Managing Memory in Chapter 4 for additional information on memory configurations.

Data on Clocks display

Beneath the Data on Clocks display, and next to the activity indicators, is a group of all clock inputs available in the present configuration. The number of available clocks depends on the model. The J and K clocks appear with pod pair 1/2, and the L and M with pod pair 3/4. In a model with more than two pod pairs, all other clock lines are displayed to the left of the displayed master clocks, and are used only as data channels.

With the exception of the Range resource, all unused clock bits can be used as data channels in the trigger terms. Activity indicators above the clock identifier show clock or data signal activity.



Pod Clocks

Pod clock field (State only)

The pod clock field identifies the type of clock arrangement assigned to each pod. When the pod clock field is selected, a clock arrangement menu appears with the choices of Master, Slave, or Demultiplex. Once a pod clock is assigned a clock arrangement, its identity and function follow what is configured in the Master and Slave Clock fields.

Master

This option specifies that data on all pods designated "Master Clock" in the same analyzer, are strobed into memory when the status of the clock lines match the clocking arrangement specified under the Master Clock.

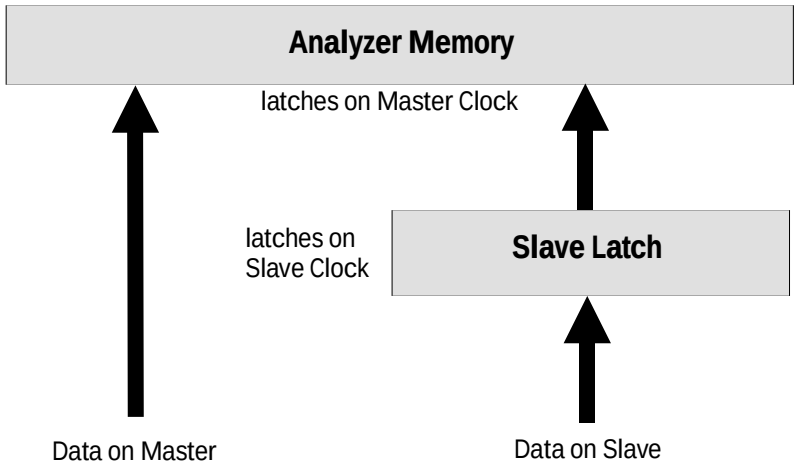
See Also

"Master and Slave Clock fields" in the Format Menu later in this section for information about configuring a clocking arrangement.

Slave

This option specifies that data on a pod designated "Slave Clock" is latched when the status of the slave clock meets the requirements of the slave clocking arrangement. Then, followed by a match of the master clock and the master clock arrangement, the slave data is strobed into analyzer memory along with the master data. See the figure below.

If multiple slave clocks occur between master clocks, only the data latched by the last slave clock prior to the master clock is strobed into analyzer memory.

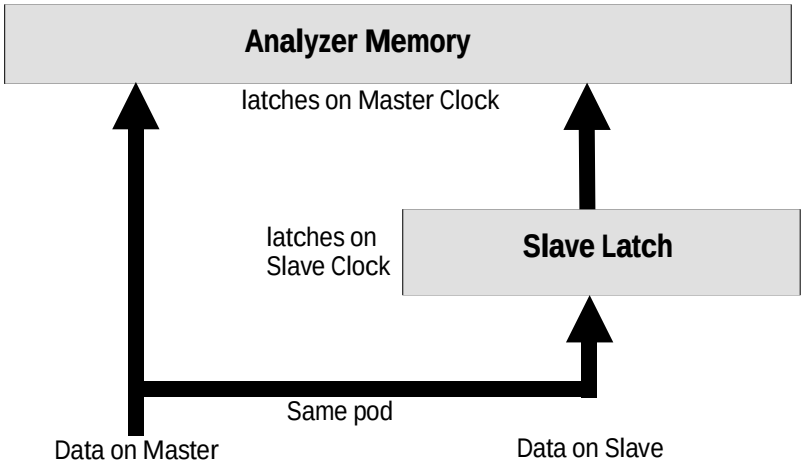


Latching Slave Data

Demultiplex

The Demultiplex mode is used to store two different sets of data that occur at different times on the same channels. In Demultiplex mode, both the master and slave clocks are used, but only one pod of the pod pair is sampled. Channel assignments are displayed as Demux Master and Demux Slave. For easy recognition of the two sets of data, assign slave and master data to separate labels.

When the analyzer sees a match between the slave clock input and the Slave Clock arrangement, Demux Slave data is latched. Then, followed by a match of the master clock and the master clock arrangement, the slave data is strobed into analyzer memory along with the master data. If multiple slave clocks occur between master clocks, only the most recently latched data is strobed into analyzer memory.



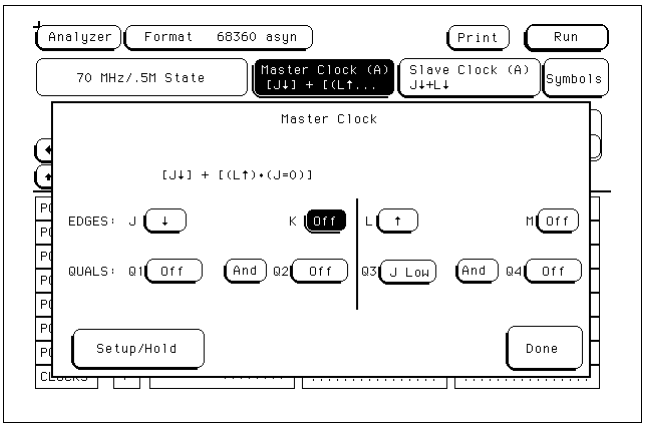
Latching Slave Data in Demultiplex Mode

Master and Slave Clock fields (State only)

The Master and Slave Clock fields are used to construct a clocking arrangement. A clocking arrangement is the assignment of appropriate clocks, clock edges, and clock qualifier levels which allow the analyzer to synchronize itself on valid data.

Clock selections

When the Master or Slave Clock field is selected, a clock/qualifier selection menu appears showing the available clocks and qualifiers for a clocking arrangement. There are four clocks available (J, K, L, M), and four clock qualifiers available (Q1 through Q4).

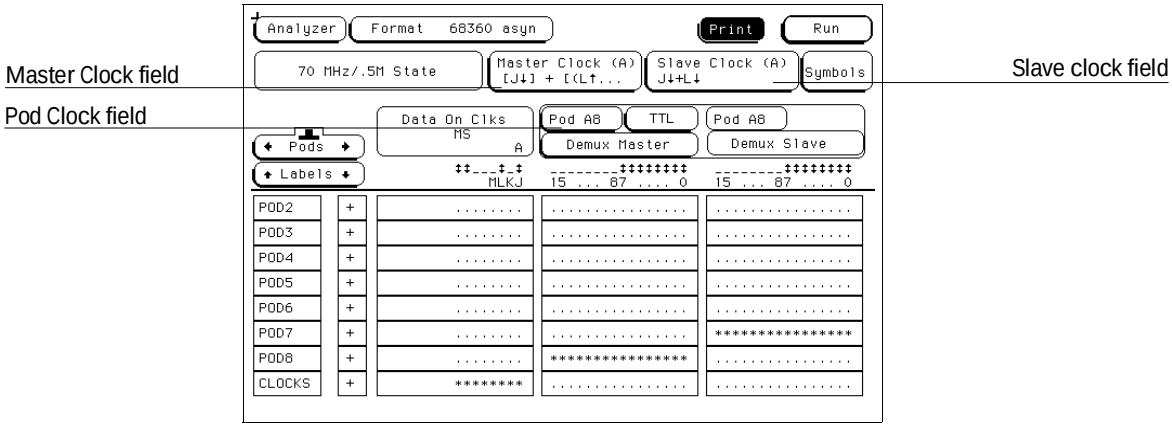


Clock Qualifiers

Clock edges are ORed to clock edges, clock qualifiers are ANDed to clock edges, and clock qualifiers can be either ANDed or ORed together. All clock and qualifier combinations on the left side of the graphic line are ORed to all combinations on the right side of the line. For example, all combinations of the J and K clocks with Q1 and Q2 qualifiers, are ORed to the clock combinations of the L and M clocks with Q3 and Q4 qualifiers.

See Also

"Pod Clock Field" found earlier in the Format Menu in this chapter on selecting clocking arrangement types, such as Master, Slave, or Demultiplex.



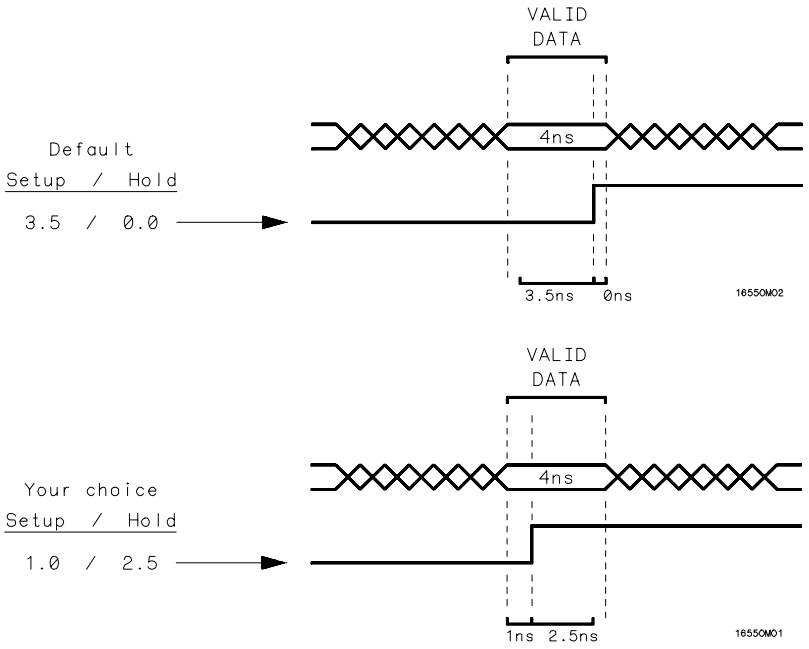
Clock Fields

Setup/Hold field

Setup/Hold, in the Master and Slave clock fields, adjusts the relative position of the clock edge with respect to the time period that data is valid. When the Setup/Hold field is selected, a configuration menu appears. Use this Setup/Hold configuration menu to select each pod pair in the analyzer and assign a Setup/Hold selection from the selection list.

With a single clock edge assigned, the choices range from 3.5-ns Setup/0.0-ns Hold to 0.0-ns Setup/3.5-ns Hold. With both edges of a single clock assigned, the choices are from 4.0-ns Setup/0.0-ns Hold to 0.0-ns Setup/4.0-ns Hold. If the analyzer has multiple clock edges assigned, the choices range from 4.5-ns Setup/0.0-ns Hold to 0.0-ns Setup/4.5-ns Hold.

The relationship of the clock signal and valid data under the default setup and hold is shown in the previous figure. If the relationship of the clock signal and valid data is such that the data is valid for 1 ns before the clock occurs and 3 ns after the clock occurs, you will want to use the 1.0-ns setup and 2.5-ns hold setting as shown in the lower figure.



Clock Position in Valid Data

Symbols field

The Symbols field is located directly below the Run field in the upper right corner of the Format menu. Use this field to access the symbol tables.

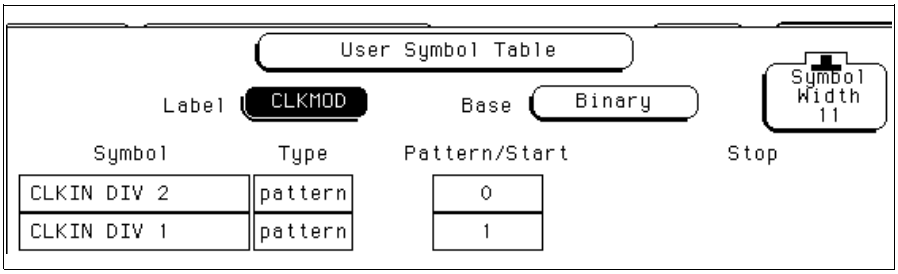
Use symbol tables to define a mnemonic for a specific bit pattern of a label. You can specify up to 1000 total symbols, and use them freely between available analyzers. When measurements are made, the mnemonic is displayed with the selected symbol base where the bit pattern occurs. You can also download compiled symbol tables using HP E2450A Symbol Utility, which is supplied with the logic analyzer.

See Also

HP E2450A Symbol Utility User's Guide for more information on downloading symbols.

Label field

The Label field identifies the label for which you are specifying symbols. When you select this field, a selection menu appears that lists all the labels turned on for that analyzer. Each label has a separate symbol table, so you can give the same name to symbols defined under different labels.



Symbol Pop-Up Menu

Base field

Use the Base field to select the numeric base in which the pattern in the symbols menu is displayed. Binary is not available if more than 20 channels are assigned to a label because there is only enough room for 20 bits to be displayed on the screen.

You cannot specify a pattern or range when the base is ASCII. Define the pattern or range in one of the other bases, then switch to ASCII to see the ASCII characters.

Symbol Width field

Symbol Width specifies how many characters of the symbol name will be displayed when the symbol is referenced in the Trigger, Waveform, and Listing menus. You can display from 1 to 16 characters of the symbol name.

Symbol Name field

When you first access the symbol table, there are no symbols specified. The symbol name field reads "New symbol." Select this field to enter a symbol name. When you are done, a symbol Type field becomes active.

Type field

The symbol Type field toggles between pattern and range. When the symbol is defined as a pattern, a Pattern/Start field appears to the right of the Type field. To assign a pattern, select the Pattern/Start field and type in the desired pattern.

If the symbol is defined as a range, a Pattern/Start field and a Stop field appear. Use these fields to specify the upper and lower boundaries of the range. To assign values to the boundaries, select the fields and enter the pattern. You can specify ranges that overlap or are nested within each other.

See Also "To Create a Symbol" in Chapter 3.

Label fields

The label fields are the fields with label names along the left side of the display below the field captioned Labels. The default label names are Lab1 through Lab126. Selecting the label fields pops up a choice of Turn Label On, Turn Label Off, and Modify Label.

The Turn Label Off option turns off the label. When a label is turned off, the label name and the bit assignments are saved so that you can turn the label back on and not have to retype the bit assignments and name. With labels off, the label names remain displayed for identification and searching purposes.

Labels may have from 1 to 32 channels assigned to them. If you try to assign more than 32 channels to a label, the logic analyzer will beep, indicating an error. A message will appear at the top of the screen telling you that 32 channels per label is the maximum. A pod pair's channel assignments are not preserved when it is reassigned to the other analyzer.

Channels assigned to a label are numbered from right to left by the logic analyzer. The least significant assigned channel on the far right is numbered 0, the next assigned channel is numbered 1, and all other channels assigned sequentially up to the maximum of 16 per pod. Since 32 channels can be assigned to one label at most, the highest number that can be given to a channel is 31.

Although labels can contain split fields, assigned channels are always numbered consecutively within a label.

Label polarity fields

The label polarity fields, which are located just after the label, are used to assign a polarity to each label. The default polarity for all labels is positive (+). You change the label polarity by toggling the polarity field.

When the polarity is positive, 1 is high and 0 is low. When the polarity is negative, 1 is low and 0 is high. All data as well as bit-pattern specific configurations used for identifying, triggering, or storing data reflect the change of polarity. Numbers use the appropriate logical encoding, but waveforms and edges are still shown as logic levels, either low or high. In a timing analyzer with the data inverted, the waveform display remains positive true.

As an example, setting the logic analyzer to trigger on 0A hex with positive polarity is the same as setting it to trigger on F5 hex with negative polarity. The listing would show 0A with + polarity, F5 with – polarity. In the waveform menu, if the waveform is defined as bus, waveform values displayed inside the waveform invert with a change. The waveform values shown as symbols inverts with a change of polarity. If the waveform is defined as individual channels or is not using symbols, it is not affected by changing polarity.

Trigger sequence levels

Sequence levels are the definable stages of the total trigger specification. Individual sequence levels are assigned using either a predefined trigger macro or a user-level trigger macro. The total trigger specification can contain both kinds of macro.

See Also Chapter 4, "Using the Trigger Menu," for more on setting up a trigger.

Sequence level usage

Generally, using one macro in one sequence level uses up one of the available sequence levels, but this may not always be the case. Some of the more complex predefined macros require multiple sequence levels. Keep this point in mind if you are near the limit on remaining sequence levels. The exact number of internal levels required per macro, and the remaining available levels, are shown within the macro library list. User macros, however, use only one level almost all the time. The only instance where multiple levels are used with the User macro is when the "<" duration is assigned.

Modify trigger field

The Modify Trigger field allows you to modify the statements of any single sequence level, as well as perform other high-level actions like global clearing of existing trigger statements, and adding or deleting sequence levels. Break Down Macros/Restore Macros acts a bit differently than the others.

Break Down Macros / Restore Macros

When a predefined macro is broken down, the contents of that macro are displayed in the same long form used in the User macro. If the macro uses multiple internal levels, all levels are separated out and displayed in the sequence levels of the Trigger menu. Once the macros in your trigger specification are broken down, Break Down Macros changes to Restore Macros. Use Restore Macros to restore all macros to their original structure.

When the macro is in a broken-down form, you can change the structure. However, when the macros are restored, all changes are lost and any branching that is part of the original structure is restored.

Use Break Down Macros if you want to view a particular macro part in its long form to see the exact sequence flow. Breaking down macros can also help in creating a custom trigger specification.

When a macro is broken down, you have all the assignment fields and branching options available as though they were a set of User macros. For information on the assignment fields, branching, occurrence counters, and time duration function, refer to the Chapter 4 on the mechanics of creating a trigger level.

Timing trigger macro library

The following list contains all the macros in the library of timing trigger macros. They are listed in the same order as they appear onscreen.

User Mode

1. User level - custom combinations, loops

The User level is a user-definable level. This level offers low-level configuration and uses one to five internal sequence levels. If the "<" duration is used, four or five levels are required.

Basic Macros

1. Find anystate "n" times

This macro becomes true when the first state it sees occurs "n" number of times. It uses one internal sequence level.

2. Find pattern present/absent for > duration

This macro becomes true when it finds a designated pattern that has been present or absent for greater than or equal to the set duration. It uses one internal sequence level.

3. Find pattern present/absent for < duration

This macro becomes true when it finds a designated pattern that has been present or absent for less than the set duration. It uses four or five internal sequence levels.

4. Find edge

This macro becomes true when the designated edge is seen. It uses one internal sequence level.

5. Find Nth occurrence of an edge

This macro becomes true when it finds the designated occurrence of a designated edge. It uses one internal sequence level.

Pattern/Edge Combinations

1. Find edge within a valid pattern

This macro becomes true when a selected edge type is seen at the same time as a designated pattern. It uses one internal sequence level.

2. Find pattern occurring too soon after edge

This macro becomes true when a designated pattern is seen occurring within a set duration after a selected edge type is seen. It uses three or four internal sequence levels.

3. Find pattern occurring too late after edge

This macro becomes true when one selected edge type occurs, and for a designated period of time after that first edge is seen, a pattern is not seen. It uses two internal sequence levels.

Time Violations

1. Find 2 edges too close together

This macro becomes true when a second selected edge is seen occurring within a designated period of time after the occurrence of a first selected edge. It uses three or four internal sequence levels.

2. Find 2 edges too far apart

This macro becomes true when a second selected edge occurs beyond a designated period of time after the first selected edge. It uses two internal sequence levels.

3. Find width violation on a pattern/pulse

This macro becomes true when the width of a pattern violates designated minimum and maximum width settings. It uses four or five internal sequence levels.

Delay

1. Wait "t" seconds

This macro becomes true after a designated time period has expired. It uses one internal sequence level.

State trigger macro library

The following list contains all the macros in the library of state trigger macros. These macros are available to both State and State Compare analyzers. They are listed in the same order as they appear onscreen.

User Mode

1. User level - custom combinations, loops

The User level is a user-definable level. This level offers low-level configuration and uses one internal sequence level.

Basic Macros

1. Find anystate "n" times

This macro becomes true when the first state it sees occurs "n" number of times. It uses one internal sequence level.

2. Find event "n" times

This macro becomes true when it sees a designated pattern occurring a designated number of times consecutively or nonconsecutively. It uses one internal sequence level.

3. Find event "n" consecutive times

This macro becomes true when it sees a designated pattern occurring a designated number of consecutive times. It uses one internal sequence level.

4. Find event 2 immediately after event 1

This macro becomes true when the first designated pattern is seen immediately followed by a second designated pattern. It uses two internal sequence levels.

Sequence Dependent macros

1. Find event 2 "n" times after event 1 before event 3 occurs

This macro becomes true when it first finds a designated pattern 1, followed by a selected number of occurrences of a designated pattern 2. In addition, if a designated pattern 3 is seen anytime while the sequence is not yet true, the sequence starts over. If pattern 2's "nth" occurrence is coincident with pattern 3, the sequence starts over. It uses two internal sequence levels.

2. Find too few states between event 1 and event 2

This macro becomes true when a designated pattern 1 is seen, followed by a designated pattern 2, and with less than a selected number of states occurring between the two patterns. It uses three or four internal sequence levels.

3. Find too many states between event 1 and event 2

This macro becomes true when a designated pattern 1 is seen, followed by at least a selected number of states, then followed by a designated pattern 2. It uses two internal sequence levels.

4. Find n-bit serial pattern

This macro finds an "n" bit serial pattern on a designated channel and a designated label. It uses "n" internal sequence levels.

Time Violations

1. Find event 2 occurring too soon after event 1

This macro becomes true when a designated pattern 1 is seen, followed by a designated pattern 2, and with less than a selected time period occurring between the two patterns. It uses two internal sequence levels.

2. Find event 2 occurring too late after event 1

This macro becomes true when a designated pattern 1 is seen, followed by at least a selected time period, before a designated pattern 2 occurs. It uses two internal sequence levels.

Delay

1. Wait "n" external clock states

This macro becomes true after a designated number of user clock states have occurred. It uses one internal sequence level.

Modifying the user macro

Before you begin building a trigger specification using the user macro, in most cases, one of the predefined trigger macros will work.

If you need to accommodate a specific trigger condition, or you prefer to construct a trigger specification from scratch, use the User macro as a starting point. This macro appears in long form, which means it has the analyzer's total flexibility available in terms of resource terms, global timers, occurrence counters, duration counters, and two-way branching.

The User macro has a "fill-in-the-blanks" type statement. You have the following elements to use:

- Bit Patterns, Ranges, and Edges
- Storage Qualification
- < and > Durations
- Occurrence Counters
- Timers
- Branching

A typical method used during a debug operation is to first trigger on a known pattern, edge or range. From that point, it becomes an iterative process of adding more levels to further filter the data. It is important for you to know how to use elements such as occurrence counters, timers, and branching, to zero in and trigger at the desired point.

As the analyzer executes the trigger specification, it searches for a match between the resource term value and the data. When a match is found, that part of the sequence statement becomes true and the sequencing continues to the next part of the statement or the next sequence level.

Eventually a path of "true" resource terms leads to your trigger command. If timers or occurrence counters are used, the analyzer waits or counts occurrences of a specified value before continuing.

Using bit patterns, ranges, and edges

Bit patterns are set to match specific data values, and ranges are set to match a range of bit patterns. In the Timing Acquisition mode, edges are set to match specific edges of a timing pulse.

Using storage qualification

Storage qualification enables you to store all data, no data, or just selected data.

Setting < and > durations (Timing only)

When a resource term is found during a timing sequence evaluation, you can dictate how long the term must remain before the term actually becomes true. When less than (<) or greater than (>) duration is assigned, the secondary branching (Else on) is not available.

> field When greater than (>) is used, the analyzer continues sequence level evaluation only after the resource term has been true for greater than or equal to the amount of duration specified.

< field When less than (<) is used, the analyzer continues sequence level evaluation only after the resource term has been true for less than or equal to the amount of duration specified. Using less than requires four or five sequence levels.

Using the Occurrence Counters

Occurs field When "Occurs" is selected, the < and > duration functions change to an occurrence counter. Use the occurrence counter to delay sequence evaluation until the resource term has occurred a designated number of times. If the "else on" branch becomes true before all specified occurrences of the primary "Trigger on" branch, the secondary "else on" branch is taken.

Using the timer

Timers are like other resource terms — they are either true or false. Timers can be set to Start, Stop, Pause, or Continue as the analyzer enters a sequence level. The two timers are global, so each sequence level can control the same timer. The default timer condition in all sequence levels is Off.

Timers start as you enter the sequence level, and when the timer count expires, the timer becomes true. If a timer is paused in one level, it must be continued in another level before it can count through.

As more sequence levels are added, the timer status in the new levels defaults to Off. Timers must be continued or started in each new level as appropriate. When a timer expires or stops, its count resets to zero.

Branching

If either the less-than or greater-than duration is used, only the primary branch is available. Otherwise, each sequence level except for the last has two-way branching.

If the primary branch is taken, the analyzer goes to the next level. If the primary branch is not found, the analyzer immediately evaluates the "Else on" secondary branching term.

If the "Else on" term is found, the secondary branch taken is to the designated sequence level. If the "Else on" term is not found, the analyzer continues to loop within the same sequence level until one of the two branches is found. If the "Else on" branch is taken, the occurrence counter is reset even if the "go to level" branch is back to the same level. If both branches are found true at the same time, the primary branch is taken.

Branching across the trigger level is possible. If this occurs, the sequence level evaluation could loop without ever seeing a trigger term. Be careful in designing your sequence instructions.

Resource terms

Resource terms are user-defined variables that are assigned to sequence levels. They are placed into the sequence statement where their bit pattern or edge type is searched for within the data stream. When a match is found, a branch is initiated and the next statement or sequence level is acted upon. Resource terms take the following forms:

- Bit patterns terms a – j (terms h and j are not available to timing analyzers)
- Range terms 1 and 2
- Edge terms 1 and 2 (Timing only)
- Global timers 1 and 2

All resource terms and timer terms are listed in a scrollable Terms field. To view all offscreen terms, select the Terms field, then use the knob to roll the terms list onscreen.

When the logic analyzer is configured as a state analyzer, you can use any of the ten bit pattern terms, range terms, or timers in your trigger specification. When you configure the logic analyzer as a timing analyzer, you can use most of these terms plus the edge terms. Timing analyzers cannot use bit pattern terms h and j.

Bit pattern terms a – j

You can set a bit pattern consisting of any combination of 1s, 0s, or Xs (don't cares) for the 10 terms a – j. Bit pattern terms can also take the NOTed form of a – j.

Range terms 1 and 2

Two range terms are available which can be set to a range of bit pattern values. The first pattern and the last pattern are part of the range which must be matched. Clock channels cannot be used in defining a range.

Range terms take the form of either In Range, or the NOTed form of Out Range.

Edge terms 1 and 2 (Timing only)

The two edge terms are only available in the timing analyzer. Each edge term is assigned positive-going, negative-going, or any-transition edge type.

Global timers 1 and 2

In addition to the resource terms available, there are two global timers available. Each timer can be started, paused, continued, or stopped, from any sequence level except the first.

Assigning resource term names and values

The Terms field identifies the list of available resource terms within the analyzer. A resource term can be assigned to only one machine at a time. The resource term names (a – j, Edge1, Edge2, Range1, Range2) are default names that can be changed. You assign values in the following two ways:

- Using Preset Values
- Assigning Bit by Bit

Changing resource properties When any of the individual term fields are selected, a configuration pop-up menu appears. Use this pop-up menu to quickly set the resource term to a preset value.

Using Preset Values

Assign Assign toggles which machine the term is assigned to. Most of the available resource terms except the Edge terms and terms h and j can be assigned to any analyzer. However, a term can only be assigned to one analyzer at a time.

Rename Rename lets you change the term name. This function works for all terms.

Clear (=X) Clear sets the terms to their broadest possible meaning. For terms a – j, the assignment field is set to all Xs (don't cares). For Ranges 1 and 2, the boundaries are set to the maximum and minimum values. For Timers 1 and 2, the assignment field is set to a minimum time of 400 ns. For Edges 1 and 2, the assignment field is set to don't cares.

Set (=1) In terms a – j, the assignment field is set to its maximum value, with all bits set to 1. This option is not available for the Range, Timer, and Edge terms.

Reset (=0) In terms a – j, the assignment field is set to its minimum value, with all bits set to 0. This option is not available for the Range, Timer, and Edge terms.

Assigning Bit by Bit

Bit pattern terms Just to the right of the bit pattern name fields are the term assignment fields. When any of the individual assignment fields are selected, a keypad appears. Use this keypad to assign real values or Don't Care (X) values.

Edge terms Assign edge terms the same way you do bit pattern terms. Edge terms can be used singularly or in combination with each other across all assigned channels. When you specify an edge on more than one channel, the analyzer ORs the edges.

After the assignment menu closes, you may see "$" indicators in the field display. A "$" indicates the assignment can't be displayed in the selected base because of Don't Cares or Glitch detection. When you display the assignment in binary, however, you can see the actual pattern.

Range terms Range terms require an upper and lower bit pattern boundary. The range is recognized as the data that is numerically between or on the two specified boundaries using unsigned arithmetic. In addition, the range must be contained in a single label across a single pod pair, with no clock bits allowed.

Timer terms Timers are either true or false. Timers start as you enter the sequence level, and when their count expires, they become true. If a timer is paused in one level, it must be continued in another level before it can count through.

The timer status in the new levels defaults to Off, as more sequence levels are added. Timers must be continued or started in each new level as appropriate. A timer's count resets to zero when it expires or stops.

Combination of terms

Combination terms are configured and selected from within trigger sequence levels. All user-defined resource terms can be combined to create complex qualifiers that occupy a single assignment field space.

When you select the term field in a Sequence Level menu, a pop-up selection list appears. If you then select "Combination," a logical assignment menu appears. Use this menu to turn on resource terms and input them into a chain of logical operators.

When the combination is placed in the assignment field, if the term is too long to fit in the assignment field, the display is truncated.

Arming Control field

Arming Control sets up the order of triggering for complicated measurements involving more than one machine. You can set the logic analyzer to begin running when it receives a signal from an external machine, have one analyzer start the other, or have one or both analyzers send a signal to another external machine.

Arming control between analyzers

If both analyzers are on, you can configure one analyzer to arm the other. When you select the analyzer name in the Arming Control menu, a pop-up menu for selecting where the Arm In signal is coming from appears. This pop-up menu also selects the sequence level in which an "arm" flag is placed.

When an analyzer receives an Arm In signal, the arm term in the user-selected sequence level becomes true. If the analyzer was waiting at a sequence level for the arm term, the analyzer begins evaluating the rest of that sequence level. However, if the arm term is not part of the current sequence level, the preceding sequencing could trigger the analyzer before the arm term is seen. Generally, the arm term is evaluated and used in the same way as the other resource terms within the sequence instruction.

If OR'd Trigger is on, when one analyzer triggers it automatically triggers the other analyzer, regardless of the trigger conditions or sequence levels. If the analyzer receiving the trigger is in a selectively-storing sequence level, data can be lost.

Arming control using external BNCs

A more complex arming example involves passing arm signals in and out through the External BNCs on the rear panel. In the Arming Control menu, the External Triggers are called "Port In" and "Port Out". The leftmost field toggles between "Run" and "PORT IN", and the rightmost toggles between "Off" and "PORT OUT".

One possible scenario is to have several test instruments and a logic analyzer connected to a complex target system. The analyzer is armed by an external Arm In signal from another test/measurement entity. After the first analyzer triggers, it arms the second analyzer. After the second analyzer triggers, it sends a Port Out signal through the external BNC. This signal is used to arm another external test/measurement entity.

The Arm Out signal can also be generated by either of the two local analyzers. If the OR'd Trigger field is set to On, then when either analyzer triggers, the Arm Out signal is generated.

Acquisition Control field

Selecting the Acquisition Control field pops up the Acquisition Control menu. The Acquisition Control menu sets the acquisition mode, the memory length, the trigger position within acquisition memory, and the sample period.

Acquisition Mode field The Acquisition Mode field toggles between Manual and Automatic. When set to Automatic, the position of stored data relative to trigger and the sample rate are based on the /Div and delay settings in the Waveform menu.

When Acquisition Mode is set to Manual, additional configuration fields become available. The additional configuration fields work together with the sequence instructions in a prioritized manner to position the memory relative to the trigger point. A small picture at the bottom of the menu displays the sum effect of all the settings on the trigger position within memory.

Memory Length The Memory Length field sets the amount of memory to be used for acquisition. It applies to all acquisition modes. Only discrete sizes are available (see "To set the memory length" in Managing Memory in Chapter 4). If you enter a number with the keyboard, it is rounded to the nearest available discrete size.

Trigger Position field The Trigger Position field sets how much information is stored before and after the trigger. When a run is started, a timing analyzer will not look for a trigger until at least the proper percent of pretrigger data has been stored. In a state analyzer, the analyzer fills the memory with the designated amount of poststore data. Actual prestore data is a function of how many states preceeded the trigger in the data stream up to (memory length – poststore). It is possible for there to be no prestore if the trigger occurs immediately.

In a timing analyzer, even when the trigger position is set to Start or End, there will always be a small portion of pretrigger and posttrigger data stored. Most of the choices designate prestore and poststore percentages, but the Delay setting affects when the memory begins storing data relative to the trigger.

Delay (Timing Only) The Delay field delays the start of acquisition storage after the trigger. The delay time range is affected by the sample period, but could range from 16 ns to 8 ks. As the picture in the pop-up menu shows, any data falling between the trigger and the delay time is not stored.

Branches Taken Stored / Not Stored field (State Only) The Branches Taken field is a toggle field that sets the analyzer to store or not store the resource term that sent the analyzer to a particular branch. This field is not available to timing analyzers.

As the analyzer steps through the sequence instructions, it may take either branch of a sequence level. With Branches Taken set to Stored, the data values that caused the branch are stored. When the analyzer is set to Branches Taken Not Stored, only the data you explicitly designate in the sequence levels is stored. You cannot selectively store branches with this field.

Count field (State only)

The Count field accesses a selection menu which indicates whether acquisition data is stamped with a Time tag or a State Count tag.

Time and State tags

If you have all pod pairs assigned, the state acquisition memory is reduced by half when time or state tags are turned on. You can maintain full memory depth if you leave a specified pod pair unassigned.

States Count States places numbered tags on all data relative to the trigger. Pre-trigger data has negative numbers and post-trigger data has positive. In the display menus, State numbering is either relative to the previous memory location, or absolute from the trigger point. You can set it in the display menus by toggling the Absolute/Relative field.

Time Count Time places time tags on all displayed data. Data stored before triggering has negative time numbers and data stored after triggering has positive time numbers. Time tag numbering is set to be either relative to the previous memory location or absolute from the trigger point. Selecting the Absolute or Relative option is done by toggling the Absolute/Relative field. Time tag resolution is 8 ns.

To retain full memory using time or state tags To retain full memory depth when using time or state tags requires that one pod pair be unassigned. The exact pair to unassign varies. Generally it is best to unassign one of the higher pod pairs. If you have two analyzers configured, the first and second pod pairs must be assigned to different analyzers.

Markers

The Markers field accesses the markers selection menu. When the Markers field is selected, a marker selection menu appears with the marker choices that are appropriate for the present analyzer configuration.

Off

The Off selection turns off marker operations , but does not turn off operations based on the markers. For example, if a stop measurement was previously specified and the stop measurement criteria are met, the measurement will stop even though the markers are off.

Pattern markers

Pattern markers identify and mark unique bit patterns in the data listing. Once the unique bit patterns are marked, you can use them as reference points or as criteria for a stop measurement.

When a marker is positioned in the Listing menu, it is also positioned in the Chart menu and Waveform menu, but not in the Mixed Display menu.

State analyzer markers

In a State or State Compare analyzer with Count Off in the Trigger menu, only Pattern markers are available. With Count Time turned on, Time markers and Statistics markers become available. With Count States turned on, State markers become available.

Timing analyzer markers

Timing analyzers always have marker choices of Pattern, Time, or Statistics. Timing analyzers do not have state markers. The pattern markers, though, can be used to count intervening patterns.

Stop measurement field

The stop measurement function specifies a condition that stops the analyzer measurement during a repetitive run. If two analyzers are configured, both analyzers stop when either specified stop condition is satisfied.

Off The Off selection turns all Stop measurement operations off. If the stop measurement operation is not turned off and the stop measurement criteria is met, the measurement will stop even though the markers are set to other types or are turned off.

X-O The X-O option is available in the Timing analyzer and in the State analyzer when its count is set to Time.

When X-O is selected, a repetitive run is stopped when a comparison of the time period between the X and O markers and one of the time period options is true.

Compare When you select Compare, a repetitive run is stopped when a comparison of data in the Listing menu and data and criteria in the Reference listing of the Compare menu matches an equality selection. The equality selection is set from the Equal/Not Equal selection pop-up menu.

Statistics

After patterns are assigned to the X and O markers, statistical information is available when markers are set to Statistics. Statistics are based on the time between the X and O markers. Both markers must be found before valid statistical information is displayed.

In a State or State Compare analyzer, Statistics markers only become available when the Trigger menu Count field is set to Time.

/Div field

The /Div field is states/Div for state analyzers and sec/Div for timing analyzers. In timing analyzers with acquisition control set to automatic, the sec/Div field affects the sample period. Timing waveforms are reconstructed relative to the sample period. A shorter sample period puts more sample points on the waveform for a more accurate reconstruction, but also fills memory more quickly.

If a changed sec/Div field results in a change in the sample period, you must run the analyzer again before the new sample period takes effect. The sample period is shown in the second row from the top when the markers are turned off.

Accumulate field

The Accumulate field controls whether old data is cleared or displayed along with new data. The Accumulate field toggles On/Off. When Accumulate is on, the analyzer displays the data from a current acquisition on top of the previously acquired data. When Accumulate is off, the display is cleared before each new run cycle.

If you leave the Waveform menu, or pop up a menu over the waveform display, any accumulated display data is lost and the accumulation process starts over.

Delay field

Depending on the analyzer configuration, a positive or negative delay measured in either states (State only) or time (Time only) can be set. The Delay field allows you to scroll the data and place the display window at center screen. Changing the delay will not affect the data acquisition unless it is a timing analyzer and the acquisition mode is automatic. In this case, the sample period may change.

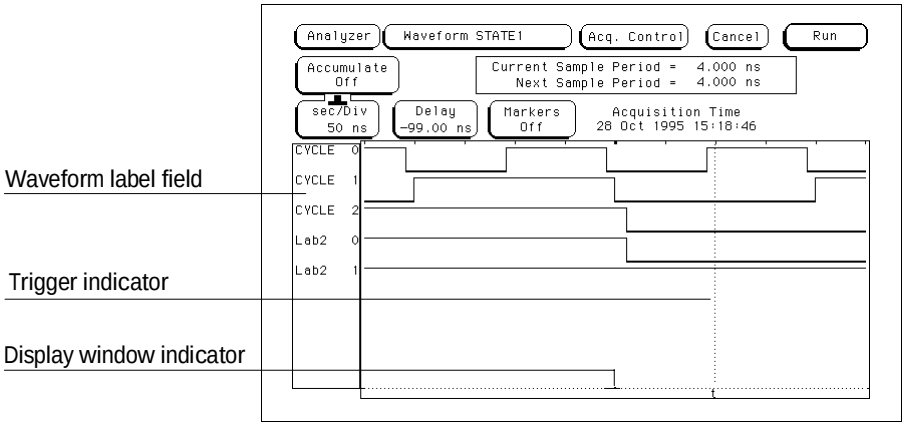
The delay range of a timing analyzer is from –2500 seconds to +2500 seconds. The delay range of a state analyzer is based on the memory length and cannot exceed total memory size.

Waveform display

Display location reference line

At the bottom of the Waveform menu is a reference line which displays the relative location of the display window, the markers, and the trigger point with reference to the total memory.

Total memory is represented by a horizontal dotted line. The display window is represented by an overlaid solid line. The markers and trigger point are represented by small dots above the total memory line, and X, O, and t labels below the total memory line.



Waveform Menu

Waveform label field

The waveform label field, located on the left side of the waveform display (see previous page), is both a display and configuration field. Waveforms are listed in the waveform label field after they are configured for display. If there are more waveforms than can be displayed, you can roll the list by selecting the waveform label field, then after the roll indicator appears, turning the knob.

If the waveform label field is selected a second time, a waveform modification menu appears. Use this menu to configure the waveform display.

When the waveform modification menu appears, select the operation to insert, replace, delete, or scale waveforms into the display. You can display up to 24 waveforms on screen at one time. You can insert a maximum of 96 waveforms in the waveform label field. If you insert more, the new ones replace the currently selected waveform.

Viewing state values in the bus option

When waveforms in a label are overlaid with the Bus option, the value of the data is displayed in the base selected in the Listing menu to the right of each new transition in the waveform display. This happens only when the waveform size is set to large.

If the field is set to view a large amount of data, or the waveform scaling is set to small or medium, the state data readout does not fit between transitions. To display the state data readouts within the waveform, zoom in on the data and use the large waveform setting.

The Mixed Display Menu

The Mixed Display menu combines a state listing display located at the top of the menu and a waveform display located at the bottom of the menu. The Mixed Display menu shows both state and timing data in the same display.

The Mixed Display menu only becomes available when at least one analyzer is configured as a state analyzer, with its Count field in the Trigger menu set to Time. If two state analyzers are configured, both state listing displays can be interleaved as well as shown separately. However, the listing menus are the best display menus for a two-state analyzer configuration.

The waveform display area shows timing analyzer waveforms from the configured timing analyzer.

Interleaving state listings

Interleaved state listings allow you to view two labels and their data from different analyzers in the same column. The process of interleaving state listings can be performed in either the Listing menu or the Mixed Display menu. For example, if data is interleaved in the Listing menu, it will be automatically interleaved in the Mixed Display menu.

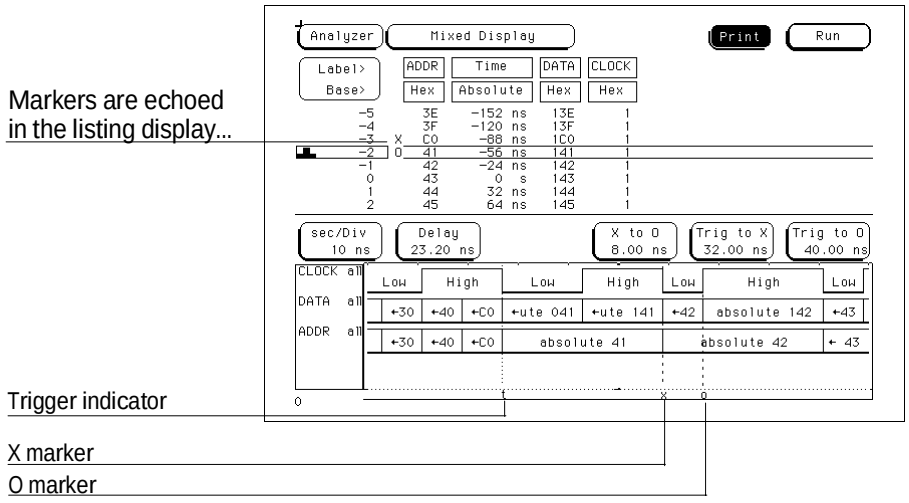
The interleaved label is placed directly above the selected label, and all interleaved data is displayed in white. In addition, the state numbers of the interleaved data are indented. Because of the lack of room available in the listing portion of the Mixed Display menu, the label identifying the interleaved data is not displayed. The listing menus should be used to display interleaved labels when two state analyzers are configured.

Markers

The markers in the Mixed Display menu are not the same as the markers in the individual Listing and Waveform menus. First, Mixed Display markers are set only in the waveform area. The listing area echos but cannot set the markers. Second, markers placed in the Analyzer Waveform and Analyzer Listing menus will not transfer to the Mixed Display menu. You must place new markers in Mixed Display menu.

Time-correlated displays

Once the Time markers are set in the Waveform display area of the Mixed Display menu, time-correlated X and O Time markers will be displayed in both the listing and the waveform display areas.



Mixed Display Menu Showing Markers

State Chart is a software post-processing feature that provides the ability to build X-Y charts of label activity using state data. The Chart menu builds a graphical representation of the system under test. You can plot a label's value against its position in the list against other label values. You can use both horizontal and vertical markers in either mode.

An accumulate mode is available that allows the chart display to build up over several runs.

Label vs. Label charts

When labels are assigned to both axes, the chart shows how the data acquired under one label varies in relation to the other for a particular measurement. Label values are always plotted in ascending order from the bottom to the top of the chart, and in ascending order from left to right across the chart. Plotting a label against itself will result in points falling on a diagonal line from the lower left to upper right corner (there could be only 1 point).

Label vs. State charts

Label versus State is a plot of data values acquired under a label-versus-sample order. Besides the standard horizontal and vertical markers available also to label vs. label charts, label vs. state charts have sample and pattern markers. With Count Time, you can also measure time and gather statistics; with Count States, you can measure states.

Axis Control field

Axis Control pops up a menu that lets you select what will appear on the X and Y axes, what base the measurements display in, and how much of the memory appears onscreen.

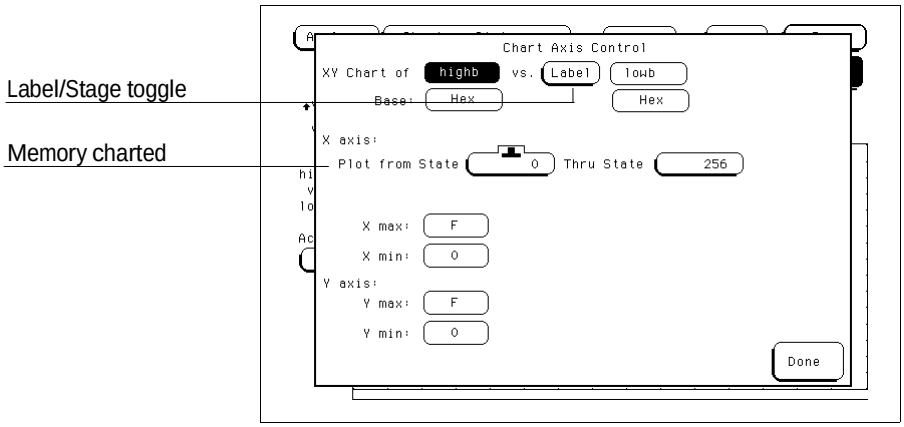


Chart Axis Control menu

Base The base fields control the base that the markers and other onscreen values appear in. If you are charting label versus label, you can set the two labels to use different bases.

Memory Charted The two values in the line "Plot from State thru State" control how much of the memory can be examined. The minimum and maximum values are based on the size of the data in memory. Setting these fields to show only a subset of your data will speed up display.

X max, X min, Y max, and Y min These values are the maximum and minimum values of the axes. Use these to focus in on a particular area. In label versus state charts, the X fields do not appear.

Markers field (label vs state only)

The Markers field is available when you chart a label versus state. The default marker type is Sample. The other marker types are Pattern, State, Time, and Statistics. Sample markers show the Y axis value of the X marker. A dashed line indicates you have gone beyond the charted memory.

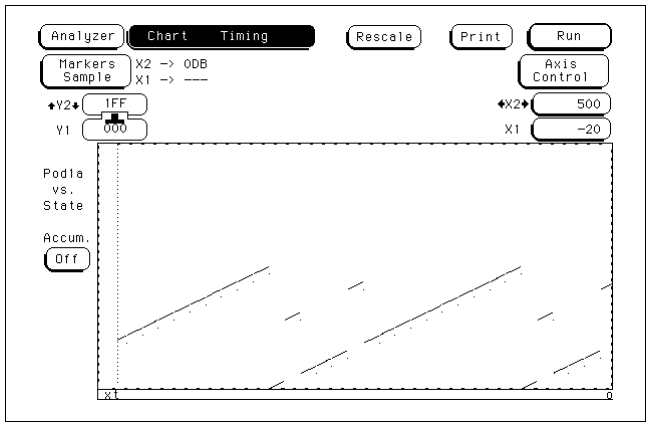

Chart Menu with Sample Markers Active

Pattern markers let you specify the pattern you want to place the marker on. Specify Patterns pops up a menu. Place the markers using Search. The Find X-Pattern field by toggles to Find O-Pattern.

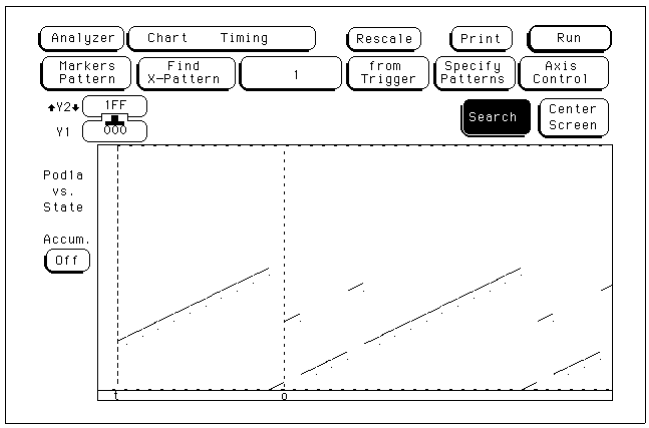

Chart Menu with Pattern Markers Active

To use State markers, you must first turn on Count States in the Analyzer Trigger menu. State markers use the State tags to measure distance between events.

If you turn on Count Time in the Analyzer Trigger menu, Time and Statistics markers become available. Use Time markers to measure time between events. Statistics markers also measure time between events, but the X and O markers are set using Pattern markers first.

Rescale field

The Rescale field allows you to zoom in on a particular area, or move back to viewing the entire chart. To use Rescale, place your markers to box in an area you want to focus on, and then select one of the "between markers" choices. To move back to the big picture, choose Full Scale. You can also display a larger picture by setting the markers outside the current boundaries and choosing one of the "between markers" options.

When more data is available above or below the currently displayed data, "clip" is displayed just to the left of the corner of the display.

If you rescale the area between markers and you do not see your data, check the memory charted fields.

State Compare is a software postprocessing feature that provides the ability to do a bit-by-bit comparison between the acquired state data listing and a reference listing. State Compare is only available for an analyzer configured as a State Compare analyzer.

The comparison between the acquired state listing data and the data in the reference listing is done relative to the trigger points. The two data records are aligned at the trigger points and then compared bit-by-bit. Any bits in the acquired data that do not match the bits in the compare image are treated as unequal.

- You can separately view the acquired data, the reference listing, and a listing that highlights the bits in the acquired data that do not match the corresponding bits in the reference listing.
- You can edit the reference listing for unique comparisons.
- You can mask specific bits that you do not want to compare. These "Don't compare" bits can be specified individually for a given label and state row, or specified by channel across all state rows.
- You can select a range of states to compare. When a range is selected, only the bits in states on or between the specified boundaries are compared. Also, you can save the reference listing along with the analyzer configuration to disk.

Reference/Difference listing field

The Reference /Difference listing field is a toggle field that switches the displayed listing between the Reference and the Difference listing.

Reference Listing

The Reference listing is a template that acquired data is compared to during a comparison measurement. The boundaries of the template are controlled by using the channel masking and compare range functions. Any bits in the reference listing displayed as "X" have been set to don't care during bit editing.

When the reference data listing is rolled, the difference data listing and the data listing in the Listing menu are also rolled.

Difference Listing

The Difference listing is a display of the acquired data listing with the data that differs from the Reference listing highlighted with inverse video. If the base is inverse assembled symbols, the entire line is highlighted with inverse video.

The controls that roll the listing in all three menus (the normal State listing, the Reference listing, and the Difference listing) are synchronized. This allows you to view corresponding areas of all lists, cross check alignment, and analyze the bits that do not match.

See Also

"To compare two listings" in Chapter 3.

Copy Listing to Reference field

The initial Reference listing is generated by either copying the data listing from the listing menu or by loading an analyzer configuration file which contains a Reference listing. Be aware that if you load an analyzer configuration, the other menu setups will change.

When the Copy Listing to Reference field is selected, the contents of the acquisition data structure (Listing menu display) are copied to the Reference image buffer. The previous Reference listing is lost if it has not been saved to a disk.

Find Error field

The Find Error field allows you to locate any patterns that do not match in the current comparison. Occurrences of differences, or errors, are found in numerical ascending order from the start of the listing. The first occurrence of an error has the numerical value of one.

You select which error number to find by highlighting the Find Error field and entering a number from the front-panel keypad. If the roll indicator is in the Find Error field, simply turn the knob. The listing is then scanned sequentially until the specified occurrence is found and rolled into view.

Compare Full/Compare Partial field

The Compare Full/Compare Partial field is a toggle field which allows you to compare either the full range of states or define a subset of the total number of states in the Reference image to be used in the comparison.

The Compare mode is accessed by selecting the Compare Full/Compare Partial field in either the Compare or Difference listing menus. A pop-up menu appears in which you select either the Full or Partial option, when selected.

When you select the Partial option, fields appear for setting the start state and stop state values. Only bits in states (lines) on or between the boundaries are compared against the acquired data.

Mask field

The channel masking field is used to specify a bit or bits in each label that you do not want compared. This causes the corresponding bits in all states to be ignored in the comparison. The Reference listing itself remains unchanged on the display.

When you select the Mask field an assignment pop-up menu appears in which you specify the channels to be compared and the channels to be masked. A "." (period) indicates a don't compare mask for that channel, and an "*" (asterisk) indicates that channel is to be compared.

Bit Editing field

The bit editing fields are located above the labels in the Reference listing display. A bit editing field exists for every label in the display unless the label's base is ASCII or inverse assembled symbols. The bit editing fields allow you to modify the values of individual bits in the Reference image or specify them as don't compare bits.

You access data in the Reference listing by rolling the data listing using the knob until the data is located in the bit editing field. To enter a desired pattern or don't compare (X) for a bit, select the field and use the front-panel keypad.

System Performance Analysis (SPA) Software

System Performance Analysis Software

The System Performance Analysis (SPA) software is included as standard software in the HP 1660C/CS and HP 1670D-series logic analyzers. It was originally HP 10390A System Performance Analysis (SPA) Software, a software package for the HP 16550A logic analyzer module and the HP 1660A/AS-series logic analyzers.

SPA provides you with a set of functions for performing statistical analysis on your target system. Its functions include State Overview, State Histogram, and Time Interval modes.

To be successful with this software, you should be familiar with the operation of the logic analyzer.

The screen shots shown in this chapter are HP 16550A screens. If you are using an HP 1660- or HP 1670-series logic analyzer, your screens will be similar. This chapter is organized as follows:

- "What is System Performance Analysis?" outlines typical SPA applications, and describes the operating characteristics for each SPA mode.
- "Getting Started" describes how to access the SPA menus and how to select the SPA modes and set the specifications.
- "SPA Measurement Processes" is a detailed description of the measurement processes used by the SPA package. This theory of operation explains how the SPA software samples and sorts the data from the target system, and how the onscreen measurement values are computed for the State Overview, State Histogram, and Time Interval modes.
- "Using State Overview, State Histogram, and Time Interval" leads you through the State Overview, State Histogram, and Time Interval modes. It also tells how to set up SPA for the three modes, how to interpret the acquired data, and how to make measurements on specific areas of interest.
- "Using SPA with Other Features" tells you how to use SPA with other features.

Error messages and warnings reported by SPA are the same as those reported by the logic analyzer. Refer to "Troubleshooting," Chapter 10, for descriptions of these messages.

If you are just getting started, the first two sections are recommended reading. Part 3 is optional. If you are an experienced user, the last sections will help you with your SPA measurements. Use the first three sections for review when necessary. If you need programming information, refer to the *HP1670D -series Logic Analyzers Programmer's Guide*, available from your HP Sales Office.

What is System Performance Analysis?

The logic analyzer's state or timing analyzer is used to make quantitative measurements on specific events in the target system. For example, a state or timing analyzer can measure a specific time interval on a microprocessor's control lines or can find out how a particular subroutine was called.

System Performance Analysis, on the other hand, is used for qualitative measurements on the target system. SPA provides statistical analysis functions so you can determine how efficiently your target system is operating.

SPA repeatedly samples signals of interest, such as an address bus or the output of a counter. The multiple data sets from the repeated sampling are then used to build histograms and to compile statistics that describe your target system's performance over time.

Some typical examples of SPA applications include:

- Obtain an overview of system activity.
- Identify software problems that lock up the microprocessor.
- Determine the best-case and worst-case execution times for a software module or a state machine.
- Establish standards for software modules or state machines.
- Identify inefficient use of mass storage and other peripherals.
- Evaluate memory utilization, such as illegal access in protected portions of memory, and locality of execution.

Operating characteristics

The following describes the operating characteristics of the System Performance Analysis software for the three SPA measurement modes.

State Overview The State Overview mode displays a bar chart of a label's state value versus the relative number of occurrences of each value in the defined range of the label. State Overview is available on any label defined in the Format Specification.

- The X axis is the defined range for the specified label divided into 256 buckets.
- The range of the specified label is user-definable.

- The Y axis is the relative number of occurrences in each bucket.
- Maximum value of the Y axis is constantly updated to reflect the number of occurrences in the bucket that has the most occurrences, and is displayed as "Max count."
- The total number of states sampled for the selected label is presented as Total count. This includes states that may be outside the user-specified X axis range.
- Two markers are available on the X axis to determine the range of a bucket and number of occurrences in any bucket.
- Choice of base for a specified label is user-definable.

State Histogram The State Histogram mode displays states that occur within user-defined ranges of a label. State Histogram is available on any label defined in the Format Specification.

- Maximum number of ranges is 11.
- Other States included/excluded is available and displays a histogram of all states not covered by the user-defined ranges.
- You can trace All States or patterned Qualified States.
- Total samples displays the total number of occurrences in all displayed ranges.
- Choice of base for specified label is user-definable.

Time Interval The Time Interval mode displays time intervals between user-defined start and end events.

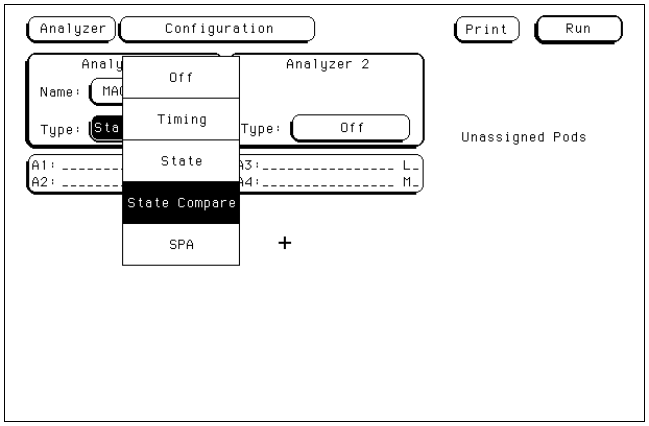
- Start and end events can be defined over all labels defined in the Format Specification.
- 10 ns is the minimum sample period and time interval resolution.
- The maximum number of time interval ranges is 8.
- Time interval range size is 10 ns to 9,999,999 seconds.
- Calculated statistics provides Maximum time, Minimum time, Average time, and Total number of time intervals sampled (one time interval defined to be a paired start/end event).
- Auto-range feature automatically scales the eight time intervals over maximum and minimum times using a logarithmic scale or linear scale.
- Choice of base for labels is user-definable.

Getting Started

This section describes how to access the System Performance Analysis (SPA) menus. Also, it describes selecting the SPA modes and setting the specifications.

Accessing the menus

The SPA menus are accessed through the Analyzer Configuration menu. When the configuration menu is displayed, select the Type field and choose SPA from the pop-up menu.



Configuring an analyzer for SPA

Selecting State Overview, State Histogram, or Time Interval modes

To access one of the three SPA modes, select the analyzer menu field after configuring one of the analyzers as SPA and select SPA.

Once in the SPA menu, you can move from State Overview, State Histogram, or Time Interval Modes by selecting the Trace Mode field. A pop-up menu appears, and you can select one of the three SPA modes in the pop-up menu.

SPA Modes

If you change modes while the logic analyzer is acquiring data, it will stop the acquisition

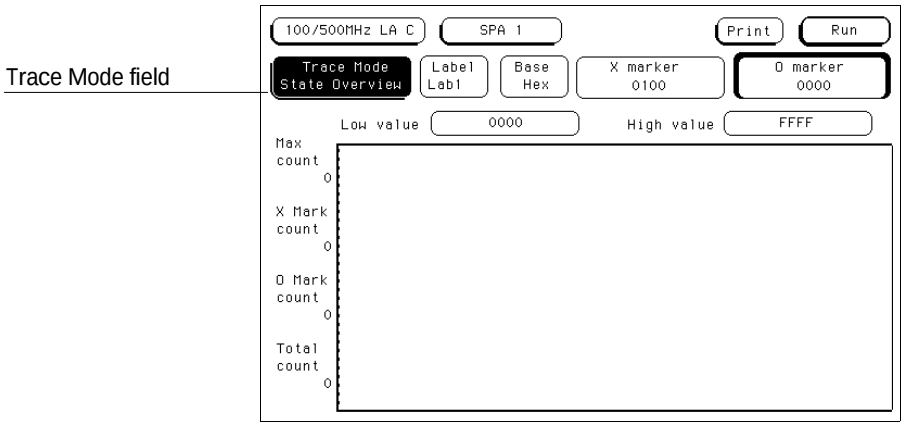
Setting up the State Format specification

When a state or timing analyzer is changed to SPA, SPA will retain the state or timing format specification. For complete details on changing from a state or timing analyzer to SPA, see "Using SPA with Other Features."

The State and Timing format specification menus provide symbol tables. You can use any defined symbols to specify the Low and High values in State Overview, to define the ranges and the qualified states in State Histogram, or to specify the Start and End conditions in Time Interval.

Your ability to use existing state or timing configurations with SPA depends on your application and target system. If your SPA measurement uses the same physical signals from the target system as an existing state or timing configuration, it may be easier to load the state or timing configuration from the disk instead of entering a new one.

This manual assumes you already have a basic understanding of the Analyzer Format menu, and it will not be covered here.



Default SPA menu

SPA Measurement Processes

This section introduces you to the measurement processes of the System Performance Analysis (SPA) software. It tells you how to select the appropriate trace mode and labels. It also explains how SPA samples and sorts data.

Selecting and changing trace modes

SPA has three trace modes: State Overview, State Histogram, and Time Interval. These are selected by the Trace Mode field in the SPA data display.

Only the currently displayed trace mode is affected during an acquisition. While acquiring and viewing data in one trace mode, the other two trace modes are not updated. If the trace mode or any other critical variable is changed during an acquisition, the logic analyzer stops the acquisition and displays "Warning: Run HALTED due to variable change."

Each trace mode only performs statistics on its own database. Therefore, if acquisitions are completed in two different trace modes, the two modes will not contain the same data.

For example, you select the State Overview mode and press the Run key. After the data accumulates for a period, press Stop. You then select the Time Interval mode and the screen is blank since no data has been acquired in this mode. You again press Run and let data accumulate and press Stop. In this example, two separate data sets are acquired, the first for State Overview mode, the second for Time Interval. You can now move between the modes and see the correct data for the associated measurement.

This separate acquisition data applies to all three trace modes. Three separate views of the target system can be acquired and stored in SPA.

Sampling methods and data sorting

SPA provides a statistical summary of target system behavior over time. The greater the number of samples, the more accurate the statistics. Therefore, SPA should always be run in the Repetitive mode. By doing this, the analyzer will continue to sample the data and update the display until Stop is pressed, or until a sampling variable is changed on the display.

After SPA completes an acquisition, each sample in the current acquisition is compared to the ranges or buckets for the current trace mode. If the sample matches a range or bucket, it is sorted into that range or bucket. This process is repeated for every sample in the acquisition. After the entire acquisition

has been sorted, the histograms and displayed statistics are updated, and the analyzer is re-armed for the next acquisition. Refer to the following sections on the three trace modes for details on sorting criteria and statistical computation.

Between each successive acquisition, there is blind time during which the captured data is unloaded and sorted, the display is updated, and the analyzer is restarted. The length of the blind time is a function of the complexity of the SPA measurement.

Selecting and changing labels

Labels are defined in the Format menu. A label is any named group of 32 or fewer data channels.

The State Overview and State Histogram modes monitor one label at a time. Any labels that are defined in the Format menu are available. A typical example is the ADDR (address) label used in many of the Hewlett-Packard inverse assembler configurations. Often, SPA measurements will use the ADDR label to monitor memory activity.

Qualified State Histogram and Time Interval modes use all of the labels in the Format menu to define either the qualified state or the start and stop events, respectively. While State Overview and State Histogram deal with recorded states, Time Interval deals with time.

Label

Changing from one label to another in State Overview or State Histogram mode, or changing the Start or End pattern in Time Interval, erases any configuration information and data for the original label. When returning to the original label, the display returns to its default mode. Loss of configurations and data when changing between labels can be prevented by saving configurations of interest to the disk before making the change, or by printing the results.

State Overview mode

State Overview mode is an X-versus-Y chart of the activity on a specified label. It provides a global view of the distribution of activity of the target system signals grouped under the specified label.

X-axis scaling The X axis represents the defined range of the specified label and is divided into a series of buckets, or smaller ranges. The range

of the X axis is defined by the Low value and High value fields, and is divided equally among 256 buckets. For example, if the range defined by the low and high values is 1100, then 1100 divided by 256 equals 4.29. This value will be rounded up to 5, each bucket will have a range of 5, and only 220 buckets will be used (1100/5 = 220). The display grid will be truncated on the right because only 220 buckets are displayed.

If the full range of the label or the portion of the label defined by the Low value and High value is less than 255, then the number of buckets will be the difference between the Low and High values.

The Low and High values can be specified as discrete values in binary, octal, decimal, or hexadecimal. If Symbols have been defined in the Format menu, they can also be used for the low and high values.

Data sampling and sorting All input channels defined in the Format menu are sampled when Run is pressed. Once acquired, the sampled data is sorted into the buckets of the specified label, and the State Overview display is updated. The acquisition is repeated until Stop is pressed, or until a display variable is changed.

Y-axis scaling The display builds a vertical histogram where the Y axis represents the relative number of occurrences in each of the buckets. As successive acquisitions are acquired and sorted, the display is constantly re-scaled vertically so that the upper limit of the Y axis represents the largest number of occurrences in any bucket.

The Y axis maximum limit is displayed in Max count.

Total count The Total count field is the total number of states sampled over the entire label range since the measurement was started.

X and O markers Markers can be placed on any bucket to determine the number of occurrences in that bucket. The X Mark count and O Mark count fields display the number of occurrences at the markers. The markers move only on the bucket boundaries.

The range of each bucket can be determined by selecting the X marker or O marker fields and noting the change in the marker value in the pop-up menu as the marker is moved slowly across the display.

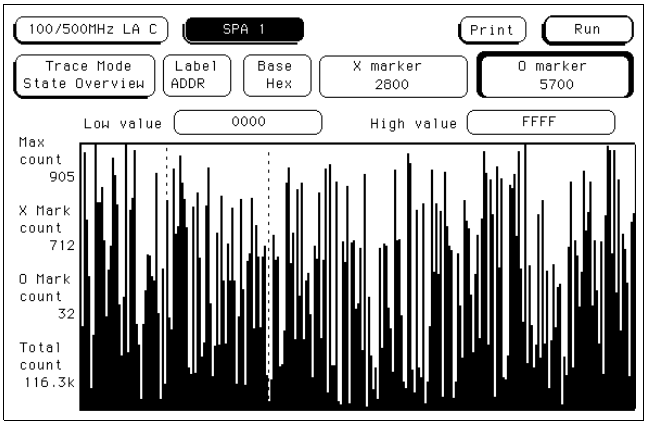
Example

State Overview

An example of a State Overview measurement is testing for access to a reserved area of memory. In this case, the address bus of the target system would need to be grouped under a single label, such as ADDR. Activity over the entire address range can be monitored. by selecting the ADDR label in State Overview mode, and by defining the full range of the label (Low value = 0000, High value = FFFF with a 16-bit ADDR label. Access into reserved memory is easily identified.

The number of address values per bucket is decreased and a more detailed analysis can be performed by selecting only the range of the reserved area of memory with the Low and High values.

The figure below shows a State Overview display.



SPA State Overview menu

State Histogram mode

State Histogram mode displays relative activity of ranges of a specified label. The ranges can also be compared to activity on the rest of the label not defined in the ranges. Data qualification is possible with State Histogram, so data can be filtered during acquisition.

Data sampling and sorting All input channels defined in the Format menu are sampled when run is pressed. Once acquired, each sample in the acquisition is compared to each defined range. If the sample value is inclusively within the range and if the range is on, the count for that range is incremented, then the State Histogram display is updated. The acquisition is repeated until Stop is pressed or until a display variable is changed.

The histogram is displayed on a percentage scale, and each bar represents the fraction of all samples in that range. For example, if a bar reaches the 40% value on the display, then the range for that bar contains 40% of all the samples displayed. If the total of all bars equals greater than 100%, then ranges have been overlapped and data has been counted twice.

State Histogram vs. State Overview State Histogram is similar to State Overview, but there are key differences between the two modes. State Overview shows relative distribution of activity over a single contiguous range of a label. State Histogram also allows several non-contiguous ranges of a label to be defined.

State Overview requires minimal setup, and provides a quick overview of system activity. State Histogram requires more setup, but provides greater resolution and measurement flexibility.

State Overview mode does not display data that falls out of the range of its Low and High values. State Histogram, on the other hand, has an "Other States included/excluded" feature that will present a histogram of any activity that does not fall into the defined ranges (see "Other States included/ excluded," later in this section).

State Overview samples and displays all activity on the specified label. But State Histogram allows data qualification so that only activity of interest is sampled and displayed (see "Trace Type: All States vs. Qualified States," later in this section).

Range specifiers Up to 11 ranges are available. The ranges are defined by specifying a low and high value on the specified label and by a name you define. The ranges need not be contiguous. If two ranges overlap in any manner, acquired data will be counted in both ranges.

If a range has a low and high value and a name defined, and the range is turned off, it will retain the low and high value and name when turned back on.

User-defined ranges vs. symbols When defining low and high values for the State Histogram ranges, you may use symbols instead of entering discrete values. Symbols can only be used for labels selected in the State Histogram mode if the labels are defined in the Format menu, and only if the base in the State Histogram menu is set to Symbol.

Pattern or range symbols defined in the Format menu can be used to set the low or high value of a range.

Total samples The total samples field displays the total number of samples in all the displayed ranges. If Other States included is selected, then total samples is the total of all displayed samples plus the other states. If any ranges are overlapped and samples fall in multiple buckets, these samples are only counted once in total samples.

Number of samples per range Displayed next to each bar is a value representing the number of samples for that range. The ratio of these values to total samples determines the relative size of the histograms. These values are updated as the repeated acquisitions are sorted and displayed.

Other States included/excluded Usually the defined ranges will not cover the entire range of the specified label. The Other States included/ excluded field provides an optional histogram showing all activity on the specified label that does not fall within any of the defined ranges. By selecting excluded, the relative activity of only the defined ranges is displayed. If included is selected, the "other" histogram appears under the ranges.

If a range is turned off, any activity in that range is included in Other States. The activity of a turned off range is included in the other range, whether included or excluded other states is displayed or not.

Trace Type: All States vs. Qualified States State Histogram mode can qualify data as it is sampled. Qualifying data while sampling allows only data of interest to be stored, while the rest is discarded.

When Trace Type is set to Qualified States, a new field appears in the upper row of the display. The new field, Specify States, is where the data qualification is defined. The data qualification is not limited only to the label selected in the State Histogram menu. It is defined over all labels defined in

the Format menu as a combination of values in the current base, and don't cares.

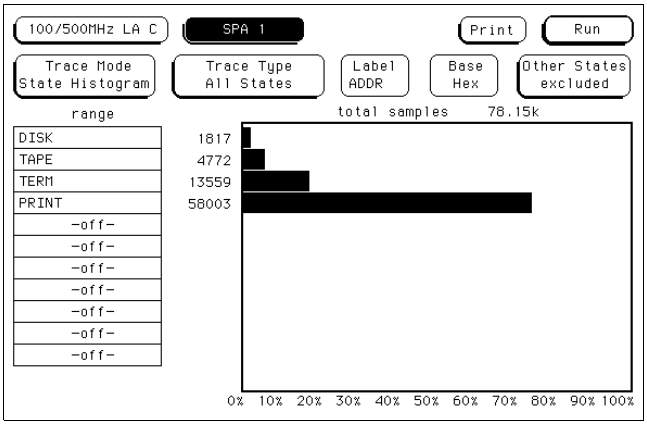
A microprocessor target system memory may contain two arrays. The address ranges of the arrays can be defined and the relative activity in the arrays monitored in State Histograms. But, what if you only want to monitor writes to the array? In this case, you can define the data qualification as "Memory Write" on the STATUS label. States that do not meet the qualification criteria are not stored by the analyzer, so they are not included in Other States.

Example

State Histogram

A computer system has several I/O devices, such as a data terminal, disk drive, tape drive, and printer. Each device has its own service routines stored in memory. The problem is that one or more of the devices is tying up the CPU.

The system address bus is monitored using State Histogram to define the memory blocks with stored service routines. The histograms quickly show that the print spooler is not working because the printer is constantly interrupting the CPU and is consuming 80% of address bus activity. The figure below shows a sample State Histogram display.



SPA State Histogram menu

Time Interval mode

Time Interval mode shows distribution of execution time of a single event. The event is defined by specifying Start and End conditions as patterns across all labels defined in the Format menu.

Data sampling and sorting When you press Run, the analyzer samples the target system using the definitions entered in the Format menu. During acquisition, the state analyzer searches the data for the start and end conditions, and uses the analyzer's time tag feature to time the event. The time durations for each Start/End pair are then sorted into user-definable time interval ranges on the display. The acquisition is repeated until Stop is pressed or until a display variable is changed.

After the data is sampled, timed, and sorted, the histogram for each time interval range is updated.

If two time intervals are adjacent and have a common boundary (the upper limit of one equals the lower limit of the next), and a sampled time interval falls on the common boundary, the sample will be sorted into the higher time interval.

Start/End conditions Start and end conditions for Time Interval are specified on all labels defined in the Format menu as a combination of values in the current base and don't cares.

If a start or end condition is not found during an acquisition, the histogram will not change. The analyzer will only update when a start and stop event are both found.

Start and end conditions need not be adjacent in the data stream. For example, when the state analyzer sees the specified start condition, it starts the timer. If the start condition occurs again before the end condition occurs, the timer will not be reset.

For measurement purposes, the analyzer measures the time between the first occurrence of the start condition and the first occurrence of the stop condition.

Time Interval ranges A maximum of 8 time interval ranges are available. Each range has a lower and upper limit which can be entered manually. The Auto-range feature will automatically scale the eight ranges. The minimum allowable limit is 0 ns, the maximum 9,999,999 seconds.

Ranges do not have to be contiguous. However, gaps between ranges increase the risk of missed data. If two ranges overlap, data will be counted in both ranges. This applies to any number of overlapping ranges, or any portions of overlapping ranges. Common boundaries of adjacent ranges are not considered to be overlapped.

A range can be turned off by setting the lower and upper values to zero.

Auto-range The Time Interval ranges can be scaled quickly by selecting "Auto-range." This option requires a global Minimum time and Maximum time for the eight time interval ranges. The eight ranges are then scaled using either a log scale or linear scale.

All the ranges may be quickly initialized to off by selecting Auto-range, setting Minimum time and Maximum time to zero, and performing a linear scale.

The smallest increment allowable using Auto-scale is 10 ns. If the time interval defined by the minimum and maximum times is too small to allow all 8 ranges to be scaled, Auto-range will scale as many as possible and exclude some upper time interval ranges. The maximum resolution of each time interval is 10 ns.

Min, Max, and Avg Time Statistics The Time Interval mode display shows three statistics: Maximum (Max) time, Minimum (Min) time, and Average (Avg) time. These values are displayed, whether or not they fall into any of the time interval ranges. Therefore, they are helpful in determining if the appropriate time intervals have been chosen.

The maximum resolution of the statistics is 8 ns.

Total samples Total samples is displayed above the histogram. A sample is defined as one Start/End pair. The Total samples field is not updated until the analyzer's memory is full or until Stop is pressed.

Example

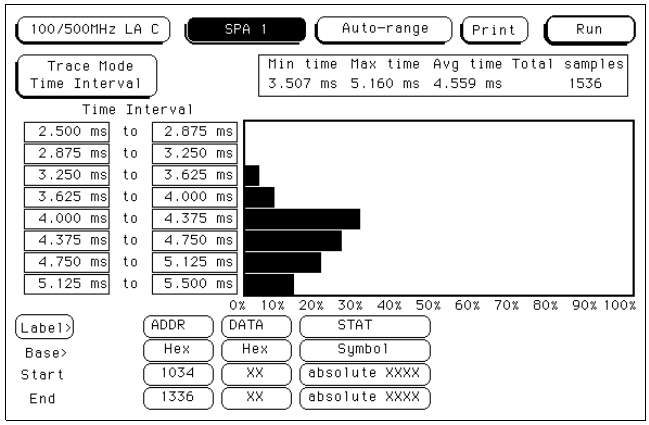
Time Interval

A team of applications programmers is writing a math package for a spreadsheet. They need to develop standards for the various math functions. Using time interval mode, they can test the execution time of each of the math functions.

For each math function, they enter the starting and ending addresses in the Time Interval menu. They run the math function while monitoring its execution time with their logic analyzer in the Time Interval mode. Using Auto-range, they can quickly vary the time interval ranges for either greater time coverage or greater time resolution.

If the programmers wanted to see the details of the time intervals, they could set up a state analyzer measurement (not using SPA) and capture the activity between the start and stop events. The details could then be viewed in the state listing menu.

The figure below shows a sample Time Interval menu and its display.



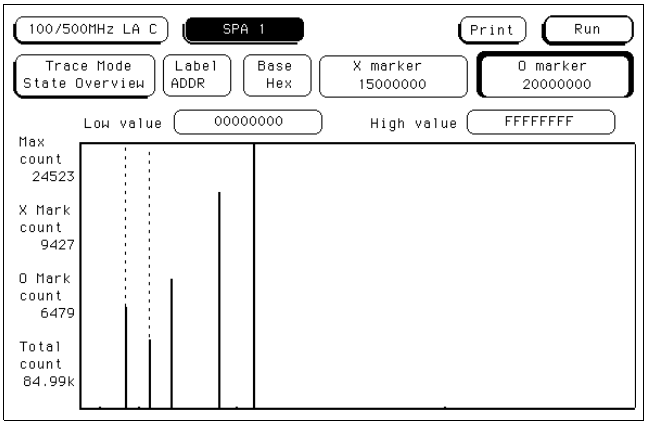
SPA Time Interval menu

Measurement example using all three trace modes

In a 32-bit microprocessor system, you want to determine how efficiently the CPU is being utilized. Critical questions might be: are any processes consuming excessive processing time, are any processes getting stuck in wait loops, and is the system handling service calls and interrupts efficiently?

You connect the HP logic analyzer to the address bus of your system. In the Format menu, you define a 32-bit label called ADDR and the state clocking. In many cases, HP provides preprocessors, inverse assemblers and standard configurations for popular microprocessors, and you need not enter the configuration manually or worry about probing issues.

In the State Overview mode, you select the ADDR label and start the acquisition to monitor the entire memory space. After several acquisitions, five areas of relatively high activity begin to build on the histogram. Using the X and O markers to determine the address boundaries of these five regions, you quickly recognize two programs, a delay routine in the operating system kernel, and a keyboard interrupt routine. The figure below shows the State Overview display.

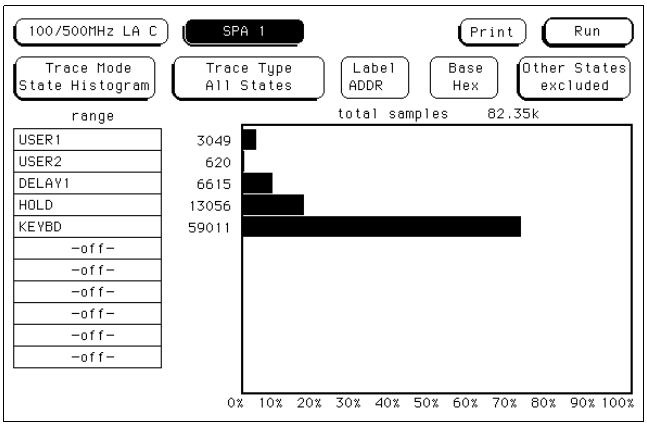


SPA State Overview

Next, you go to the State Histogram menu and enter the names and boundaries of the five routines in the state histogram ranges.

State Histogram then displays the relative activity of the five routines. After several acquisitions, it is apparent that the interrupt routine is being accessed more often than expected.

The figure below shows the State Histogram display for this example.

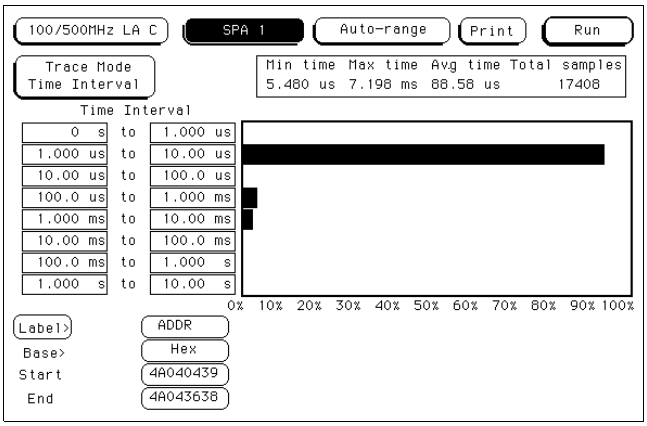


SPA State Histogram

You now go to the Time Interval menu and enter the Start and End conditions for the suspect interrupt routine. Before altering the default Time Interval ranges, you start the acquisition and observe the Maximum (Max), Minimum (Min), and Average (Avg) times. From these values, the typical execution times of the interrupt are apparent, and provide good starting values for the Time Interval ranges using Auto-range. From the Max time, it is apparent that the interrupt routine is having problems.

Running the acquisition again, you discover that the interrupt usually takes the expected 8 microseconds, but occasionally it takes as long as 8 milliseconds. A faulty key on the keyboard is discovered.after experimenting with the target system while monitoring the interrupt with Time Interval mode. The key is bouncing excessively, resulting in an extended interrupt routine call.

The figure on the next page shows the Time Interval display for this example.



SPA Time Interval

Using State Overview, State Histogram, and Time Interval

This section explains how to use the State Overview, State Histogram and Time Interval modes of SPA.

Setting up the logic analyzer

This section assumes you have defined the format and have connected the logic analyzer probes to the target system. For complete details on these topics, refer to the appropriate reference section.

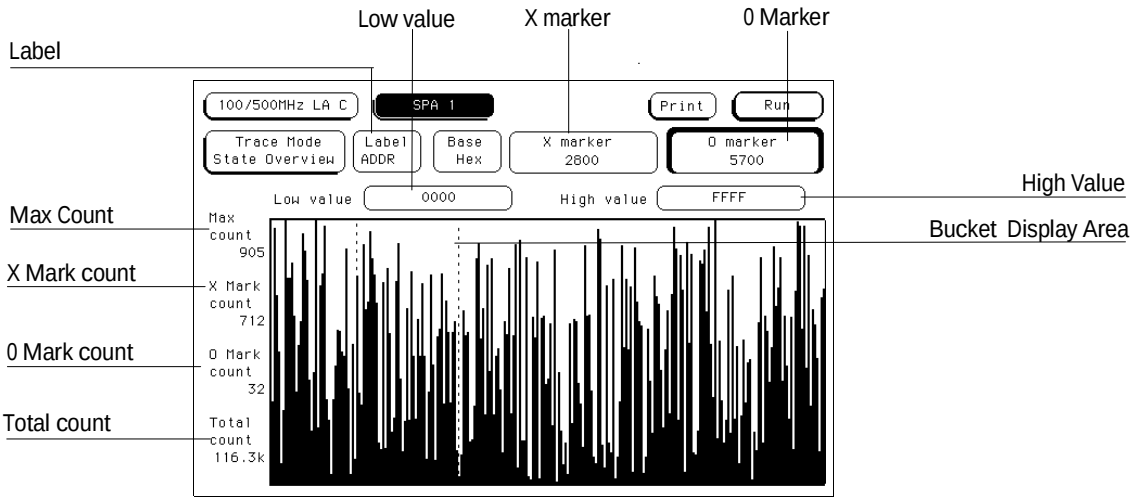
For a detailed description of State Overview, State Histogram, and Time Interval mode measurement processes, refer to the third section, "SPA Measurement Processes."

Using State Overview mode

Choosing a label to monitor To specify a label to monitor, select the Label field in the State Overview menu (see the figure on the next page). The pop-up menu shows a list of all the labels defined in the Format menu. From this list, choose the label you want to monitor.

Changing Labels

Changing from one label to another will erase the display setup for the first label. If you want to change to a different label, but don't want to lose the setup for the current one, first save the current one to disk, or print it.



SPA State Overview menu with fields called out

Specifying Low and High values The range of the X axis is determined by the Low value and High value fields. To change the X axis range, select the Low value and High value fields and enter new limits. The range you specified will then be divided among the 256 available buckets along the X axis (unless the range is less than 256 or the histogram frame is truncated due to bucket range round-off).

For example, you might set the low and high values so that the range is 1100. 1100 divided by 256 is 4.29. This will be rounded up to 5, and each bucket will have a range of 5. Since 1100 divided by 5 is 220, the histogram frame will be truncated at the right because the X axis will show only 220 of the 256 buckets.

The default high and low values represent the full range of the label you chose. Before changing these values, you may want to run the acquisition and acquire some data to view activity over the entire range of the label. You can then zoom in on areas of interest.

You can enter low and high values in binary, octal, decimal, hexadecimal, ASCII, or symbol.

Interpreting the histogram display Press the blue Shift key and Run to start the State Overview acquisition. As the data is sampled and sorted, the buckets along the X axis will accumulate (see the figure on the previous page). The relative height of the vertical bars show the distribution of activity on the label you chose. The analyzer will continue to sample, sort the data, and update the display until you press Stop or until you change a display variable.

Max count represents the current upper limit of the Y axis for the bucket with the greatest number of data samples. Max count for the limit of the Y axis will increase as the buckets fill with samples.

Read Total count to find the total number of samples taken over the specified range of the label. This is not affected by the low and high values.

Using the markers To find the number of data samples in any bucket, select the X marker or O marker field. Turn the knob to move the marker to the area of interest. Read the X Mark count or O Mark count values to determine the number of samples in the current bucket.

As you move either marker across the display, the value in the X Marker or O Marker field will change. The amount of change of the marker's value represents the size of the bucket.

Zooming in on an area of interest When viewing the State Overview display, you may see areas of high activity and areas of little or no activity. To zoom in on one of these areas for more resolution, put the X and O markers on the boundaries of the area, then adjust the low and high values to match the X and O marker positions.

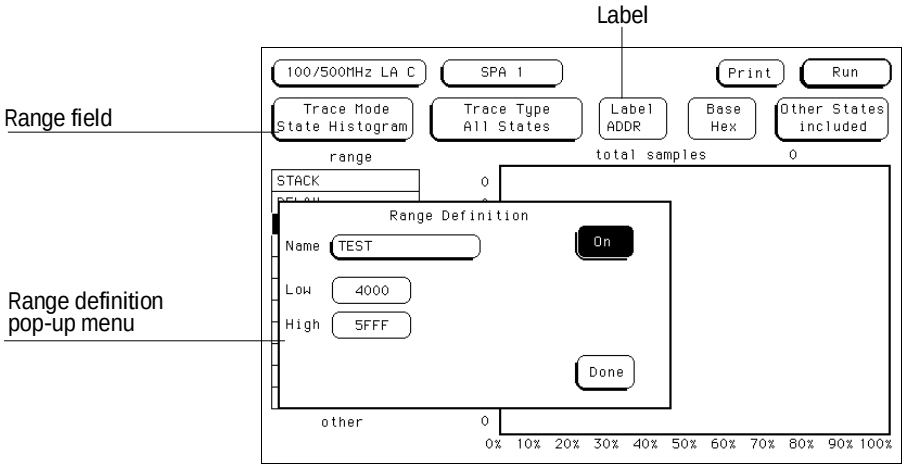
Using State Histogram mode

Choosing a label to monitor To specify a label to monitor, select the Label field in the State Histogram display. In the pop-up menu, you will see a list of all the labels defined in the Format menu. From this list, choose the label you want to monitor.

Changing Labels

Changing from one label to another will erase the display setup for the first label. If you want to change to a different label, but do not want to lose the setup for the current one, save the current one to a disk.

Defining the ranges To define a range on the specified label, select one of the 11 range fields.When you select one of the 11 ranges, you will see the Range Definition pop-up menu. This pop-up menu has fields where you enter the low and high value, a name for the range, and whether the range is on or off.



SPA State Histogram menu with fields called out

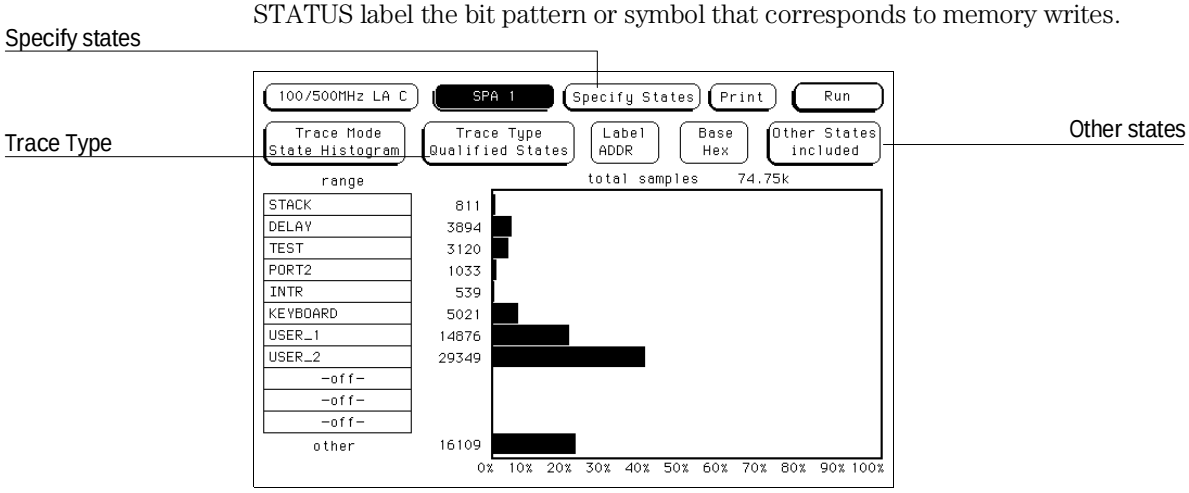
Using symbols for ranges In the Format menu, you can define symbols for any available label. The symbols can be defined as Pattern Symbols or as Range Symbols. For complete information on defining and using symbols, see "Symbols Field" in The Format Menu in Chapter 7.

If you set the base field in the State Histogram display to Symbol, you can use any defined range or pattern symbol to set the lower and upper values of the ranges.

Tracing All States vs. Qualified States You can qualify the data sampled and sorted in the State Histogram by selecting the Trace Type field and setting it to Qualified States. This creates a new field at the top of the display called "Specify States."

Select Specify States and you will see a pop-up menu that contains a pattern field for every label defined in the Format menu. Use the pattern fields to define the data qualification.

For example, in the State Histogram you may want to monitor the address bus of a microprocessor system to examine memory activity. But, you may want to monitor only writes to memory. In the Specify States pop-up menu, you can tell the analyzer to sample only memory writes by entering under the STATUS label the bit pattern or symbol that corresponds to memory writes.



SPA State Histogram menu with fields called out

Interpreting the histogram display Press the blue Shift key and Run to start the State Histogram acquisition. The relative activity over the ranges you defined is displayed as histograms (see the figure on the previous page). The total samples field shows the total number of data samples displayed in all of the ranges. The number of samples for each range is displayed to the left of each histogram.

The percentage amounts of the histograms total 100% (note the scale at the bottom of the display). If they add up to more than 100%, you have overlapped two or more ranges, and the data samples are being counted in multiple ranges.

The analyzer will continue to sample, sort the data, and update the display until you press Stop or until you change a display variable.

Other States included/excluded The histograms show the relative distribution of activity over the ranges you have defined. In most cases, the ranges will not cover the full range of the label you chose to monitor.

To view the activity over the entire range of the label, including activity not covered by the ranges, select the Other States field and change it to included. Another histogram bar called "other" will appear at the bottom of the display. This will show activity not covered by the ranges. You can toggle included/excluded if the analyzer is running since it only affects the display and not the accumulated data that has been acquired.

Note that changing between included and excluded changes the absolute sizes of the histograms. Unless you have defined overlapping ranges, the total percentage size of all the range histograms plus the histogram for other should equal 100%.

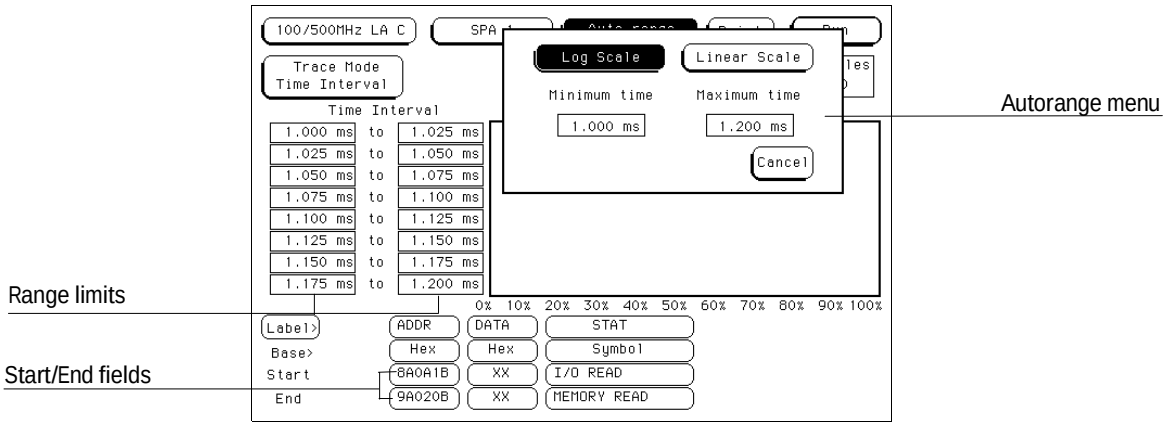
Using Time Interval mode

Use Time Interval mode to determine the distribution of time between two specific events. The state analyzer uses the time tag feature to time the event; thus, in Time Interval mode, the minimum state clock period is 10 ns.

Specifying an event To use Time Interval mode, you must define an event that you want timed. At the bottom of the display, note the Start and End fields. To define an event, select the appropriate labels in the Start and End fields to define the boundaries.

For example, start and end might be the beginning and ending addresses of a subroutine stored in memory. If you are timing a counter period, start and end might be the initial and final count values.

Note that in start and end, you are not limited to a single label. You define the event over all available labels as patterns including don't cares. Be sure that the start and end conditions actually occur in the target system, or the analyzer will not find the timing reference points and will not make the time interval measurement. You may want to use the state analyzer (not SPA) to verify that the Start and Stop events actually occur.



SPA Time Interval menu with fields called out

For measurement purposes, the analyzer measures the time between the first occurrence of the Start condition and the first occurrence of the Stop condition.

Defining the Time Interval ranges Before changing the ranges from their default values, you may want to press Run and acquire some data. From this initial run, the Maximum (Max), Minimum (Min), and Average (Avg) statistics on the display will help you choose the appropriate set of Time Interval ranges.

To define the ranges, select the fields for the lower and upper limits, and enter the limits of the range. The ranges do not need to be contiguous, but if you leave gaps between the ranges, critical data may be missed. Also, if you overlap ranges, data may be counted multiple times and present a misleading histogram.

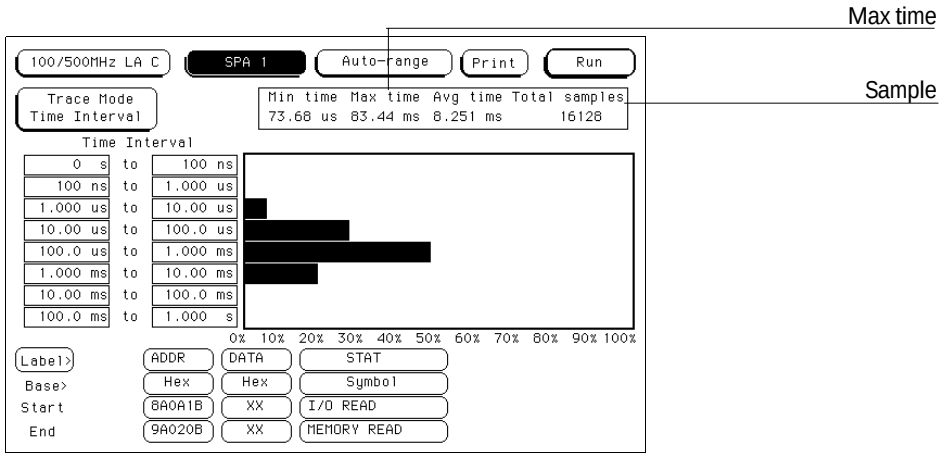
Using Auto-range To quickly set up all 8 time interval ranges, select the Auto-range field. Enter the minimum time and maximum time for all 8 ranges combined. Then, when you select Log Scale or Linear Scale, all 8 ranges will be scaled accordingly between the Minimum and Maximum times. Common boundaries of adjacent ranges are not considered overlapped. Values that fall on the common boundary will be included in the highest range.

A fast way to set up the Time Interval display is to define your Start and End events and select Run using the default ranges. Select Repetitive Run mode. After accumulating some data , press Stop. Then select Auto-range and enter the Min time and Max time display statistics in the Auto-range Minimum time and Maximum time fields. When you select Log Scale or Linear Scale, the ranges will be defined automatically.

Interpreting the histogram display As the analyzer samples the data, it searches for Start/End event pairs. One event pair is considered to be one sample. The time value for each event pair is compared to each defined time interval range. The range's count is incremented if the time value falls within that range.

The analyzer continues to search for Start/End event pairs until you press Stop or until you change a display variable. The distribution of the events' time duration is displayed as histograms.

The Max time, Min time, and Avg time statistics give you useful statistics for the event you defined, regardless of the ranges you've set up.



SPA Time Interval menu with statistics

The Total samples field shows the number of Start/End event pairs found by the analyzer, whether they are covered by the ranges or not.

Using SPA with Other Features

Programming with SPA

SPA is programmable. Refer to the *HP1670D-Series Logic Analyzers Programmer's Guide* for SPA commands. The Programmer's Guide is available as an option with the logic analyzer. Contact your HP Sales Office for more information.

Changing between SPA and a State/Timing Analyzer

If you have configured a state or timing analyzer in the logic analyzer, you can quickly change to SPA, or from SPA to a state or timing analyzer. You can use the same Format menu in your SPA measurements as you did in your state or timing analysis measurements.

To change between a state analyzer and SPA, go to the Analyzer Configuration menu, select the Type field, and select SPA from the list.

When SPA is selected, a separate trace specification definition is used. Even though the Qualified State Histogram and Time Interval modes use the same pattern recognizers as the state and timing analyzers, the SPA definitions are kept separate from those entered in the state or timing analyzer mode. As a result, switching between SPA and state or timing recovers the user's original pattern recognizers for the selected mode. Any Symbols in the Format menu will also carry over to SPA.

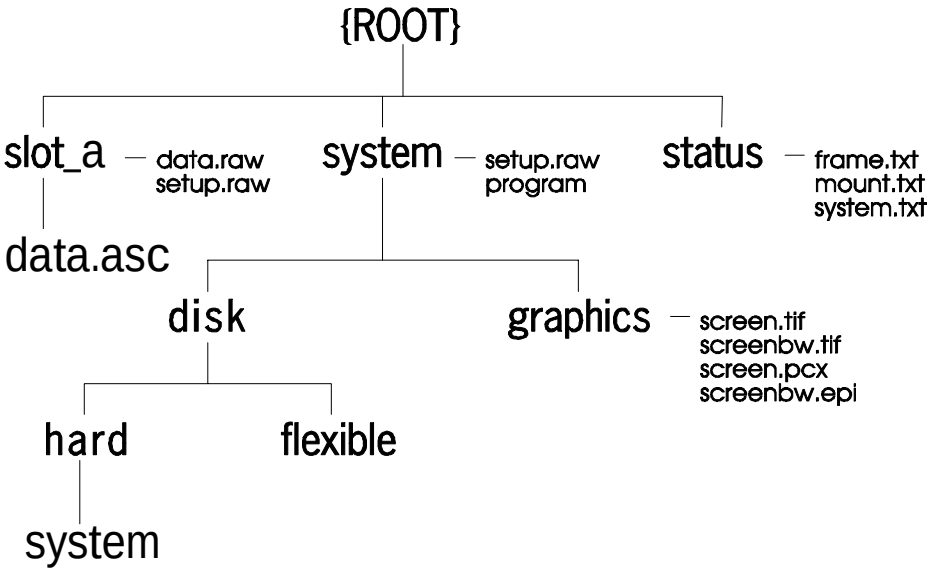
Concepts

Concepts

Understanding how the analyzer does its job will help you use it more effectively and minimize measurement problems. This chapter explains the structure of the file system, the general operation of the trigger sequence, and the details of the hardware.

The HP 1670D-series logic analyzers have a complex internal file system. Many of the file attributes are only accessible over a LAN connection. From the logic analyzer's front panel, the only parts of the file system you can examine are the hard disk drive and the flexible disk drive.

The control user can write to the various parts of the logic analyzer file system over a LAN connection. A data user can only write to the `\system\disk\hard` and `\system\disk\flexible` directories.



Logic Analyzer Directory Structure

Standard files

See the diagram on the previous page for the location of these files.

\slot_a Analyzer subdirectory.

\slot_a\data.raw Binary measurement data files. You can save and restore measurement data by copying these files.

\slot_a\setup.raw Binary configuration file. You can save and restore the analyzer configuration by copying this file.

\slot_a\data.asc Directory containing the information for the currently setup analyzers. The subdirectory names are the same as the analyzer names set in the Analyzer Configuration menu.

\system System subdirectory.

\system\setup.raw Binary configuration file. You can save and restore the system configuration by copying this file.

\system\program Port for sending programming commands to the command parser.

\system\disk Subdirectory containing the hard and flexible disk drives.

\system\disk\hard Same directory structure as System Hard Disk menu.

\system\disk\flexible Same directory structure as System Flexible Disk menu.

\system\graphics Image files for the current screen in TIFF, PCX, and Encapsulated PostScript formats.

\status Status information. `frame.txt` shows what software is being used; `system.txt` shows whether or not the analyzer is running; `mount.txt` shows LAN connections.

Hardware–Directory mapping

Analyzer

The analyzer information can be retrieved from the `\slot_a` directory. This directory contains a binary configuration file, a binary data file, and an ASCII subdirectory. Copy the binary files if you want to eventually reload the information to the analyzer.

There are two subdirectories attached to the `data.asc` subdirectory, one for each of the two analyzers in the logic analyzer. These subdirectories are only available when their respective analyzer is turned on in the Configuration menu. The default names are `machine1` and `machine2`.

Each analyzer subdirectory under `data.asc` contains the current measurement data in ASCII form. Each label has a file containing its data. The label files are named `{label}.txt`. Also in the directory are `1st_line.txt`, `line_num.txt`, and `time_abs.txt` or `state_abs.txt` depending on whether state or time tags are turned on. (Timing analyzers always have `time_abs.txt`.)

`{label}.txt` {label} is the label's name. For instance, the ADDR label's data would be contained in `addr.txt`. The data is represented as a column of values in whichever base is currently set in the Listing menu.

`1st_line.txt` Lists the number of the first line of the most recent data acquisition. This number indicates the number of states that occurred before the trigger, which is always state 0. Use this information to align data from different measurements.

`line_num.txt` Contains the line numbers corresponding to the lines of data in a listing.

`time_abs.txt` or `state_abs.txt` Each file contains a column of tag values for the most current measurement.

System

The system directory contains the disk drives, the screen images, the command parser, and a configuration file. The disk drives are described in more detail in the following paragraphs.

The screen images are contained in the `graphics` subdirectory. Each file has the same image, but in a different format. The TIFF files are version 5.0. See "Print field" in Common Menu Fields in Chapter 7 for more information on the formats.

The command parser is the `\system\program` file. To program the logic analyzer, write commands to this file.

See Also

The *LAN User's Guide* for information on controlling the logic analyzer through `\system\program`.

Hard disk drive

When you receive the logic analyzer, the hard disk drive is already DOS-formatted. The factory also creates a directory on the hard disk drive named "/SYSTEM". The /SYSTEM directory is intended to store system software such as backup copies of the operating system files and the performance verification files. When you recieve your logic analyzer, the /SYSTEM directory already contains two X Window font files and several files containing examples.

The files on the hard disk drive are not essential to the logic analyzer's correct operation. However, you can store important files such as optional software, autoload files, configurations, and software backups here. You can configure the logic analyzer to Autoload files from the hard disk at power up.

When the logic analyzer searches for autoload files and software options, it first looks in the flexible disk drive. If the flexible disk drive contains an autoload file and two software options, the analyzer does not check the hard disk drive. If some of these were not found, the analyzer next checks the hard drive's ROOT directory.

You can manually copy files, such as performance verification files, to the /SYSTEM directory, but they will not necessarily be installed when the analyzer powers up. To automatically load software, follow the installation instructions provided with the software. It will change the power-up sequence to include the software option, and will also copy the files to the /SYSTEM directory.

Flexible disk drive

The flexible disk drive reads 3.5-inch flexible disks in both DOS and LIF format. If a disk is in the drive when the analyzer is turned on, the analyzer checks the disk for software and autoload files. If these files are found, they are loaded into the analyzer.

User-Generated file types

In addition to the standard, logic analyzer-created file types described in the last section, there are six file types you might create on the HP 1670D-series logic analyzer.

Standard file types

The file type is shown in a small display box centered on the line above the file listings in the disk menus.

autoload_file indicates the file, almost always named AUTOLOAD, as an autoload file. The file description indicates if the autoload file is enabled or disabled, and the file it autoloads. Autoload files are created by executing "Autoload" in the System Disk menu.

167xdn_config indicates the file contains an analyzer configuration. These files are created by executing "Store Analyzer" or "Store All" in the System Disk menu.

16[6/7]x_cnfg indicates the file contains a system configuration. These files are created by executing "Store System" or "Store All" in the System Disk menu.

DOS indicates the file is in DOS format. It might be a screenshot or a file created on a PC and copied to the disk. These files are not loadable.

directory indicates the file is a directory and that you can change to that directory. Other files are within it.

16[6/7]x_opt indicates the file is software that can be used with either the HP 1660 or HP 1670 family of logic analyzers. These files are either on a flexible disk or have been copied to the hard disk.

Standard filename endings

Filename endings are not restricted to certain types. Because you can change the name of a file, these descriptions are just general guidelines. In addition, other tools you use with the logic analyzer will likely have their own set of filename endings.

[none] Of the common file types you can create using the logic analyzer, only the ASCII listings do not have a default ending. If you supply one in the Print to Disk filename field, that ending will be used, but no ending is automatically appended as with other filenames.

Three other types of files commonly do not have a default ending: directories, software, and autoload files. Check the file type field to be sure what type of file you are selecting.

._A This ending is appended to analyzer configuration files created with the Store operation from the System Disk menu.

._ _ This ending is appended to system configuration files created with the Store operation from the System Disk menu.

.TIF This ending is appended to TIFF version 5.0-format screenshots created with the Print to Disk function.

.EPS This ending is appended to EPS-format screenshots created with the Print to Disk function.

.PCX This ending is appended to PCX-format screenshots created with the Print to Disk function.

Dynamic files

The logic analyzer's file system uses dynamic files for configuration information and data. This means that applications such as File Manager or a spreadsheet cannot determine the size of the files until they are retrieved if they are copied directly from the logic analyzer.

When you view the file statistics for these files over the LAN, you will see file sizes of 0 bytes or 1 byte. The 0-byte size indicates that the file is empty. The 1-byte size indicates that there is information in the file. If you transfer the file of interest to your PC or workstation, you will be able to see the actual file size.

Known Incompatibilities

Some operating systems and applications may exhibit unexpected behavior when working with the dynamic files from the logic analyzer. The "% complete" display may appear incorrect during file transfers. This does not affect the transfer or the contents of the file. Once you have saved the file in your local environment, the correct "% complete" will be displayed during future retrievals.

Your applications might only retrieve one or two characters from a file that you believe has many more characters in it. To work around this problem, copy the file that you want to work with from the logic analyzer to your local computer. Use the local copy as your working copy.

SUN Operating Systems

The file copy commands in the SUN workstation and Solaris operating systems will not work with the dynamic files like those used in the logic analyzer. You can use the **`dd`** command instead of using the **`cp`** or **`cat`** commands.

The Trigger Sequence

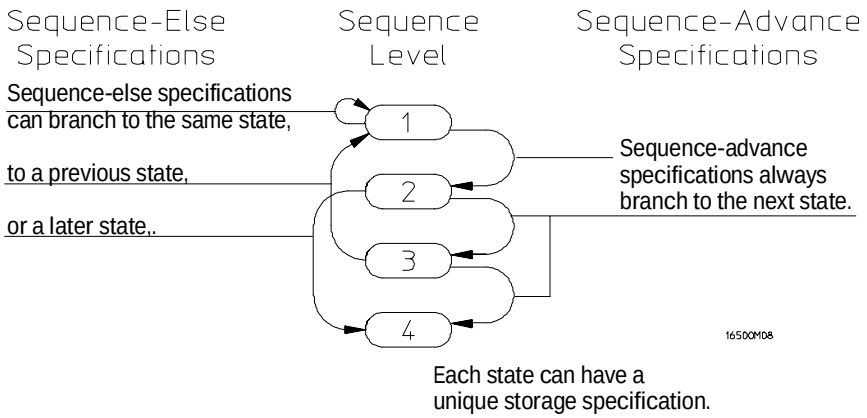
HP 1670D-series logic analyzers have triggering and data storage features that allow you to capture only the system activity of interest. Understanding how these features work will help you set up analyzer trigger specifications that satisfy your measurement needs.

In both the state and timing analyzers, the trigger sequence acts as a filtering mechanism, with a minimum of two steps and a maximum of twelve steps in the state analyzer, and ten steps in the timing analyzer. Some trigger macros may use more than one step. The steps are the sequence level specifications. The analyzer searches for a trigger sequence by matching input values on the pods to branch conditions, which control transitions between sequence levels. You can insert or delete levels to make the trigger sequence as simple or complex as needed for your application.

Trigger sequence specification

The following figure, shows a sequence specification with four levels. To define the trigger sequence, you specify sequence-advance, sequence-else, storage, and trigger-on specifications.

Each level except the last has two branch conditions—the sequence-advance and sequence-else specification. The storage specification indicates whether data should be stored or not while the logic analyzer is at that sequence level. (The trigger-on specification is a special sequence-advance specification that is described in the section "Trigger On Specification.")



State Analyzer Sequence with Four States

Sequence-advance specification The sequence-advance branch, sometimes called the "if" branch or primary branch, always branches to the next level. You can specify the following kinds of sequence-advance specifications:

```
Find (or Then find) "<TERM>" <OCCURS> time(s)

Find (or Then find) "<TERM>" <TIME PERIOD>
```

If the <TERM> is found <OCCURS> number of times or the <TERM> remains stable for <TIME PERIOD>, the analyzer advances to the next sequence level.

Sequence-else specification The sequence-else branch, sometimes called the "else if" branch or secondary branch, may branch to any other state, including the current state, a previous state, or a later state. The sequence-else specification looks like the following:

```
Else on "<TERM>" go to level <sequence level>
```

If the Sequence-Else specification is satisfied before the sequence-advance specification, the sequencer goes to <sequence level>.

The last state may only have a sequence-else branch specification, which may branch to the same state or a prior state.

Storage specification In each state, a storage specification determines the data stored by the analyzer while it is searching for the sequence-advance, sequence-else, and trigger specifications. Storage specifications are defined using the same pattern, range, and timer resources available for defining branching specifications.

```
While storing "anystate", "no state", or "<TERM>"
```

Note that if you specify "no state," the analyzer still stores sequence-advance terms and TRIGGER terms unless you also set Branches Taken Not Stored in Acquisition Control in the Analyzer Trigger menu.

Trigger on specification If there are branch and storage specifications for each sequence level, what does the trigger term mean? The trigger term is a special sequence-advance specification in that, when found, it locks the contents of analyzer acquisition memory. The trigger can be positioned at the beginning, middle, or end of acquisition memory.

The trigger specification can look like the following:

```
TRIGGER on "<TERM>" <OCCURS> times
```

```
TRIGGER on "<TERM>" <TIME PERIOD>
```

If the trigger term is found <OCCURS> times, or if the trigger term remains stable for <TIME PERIOD>, the trigger is captured in memory. Then the analyzer advances to the next sequence level. If you want to capture activity after the trigger is captured, define an additional sequence level and specify the desired storage qualification for post-trigger activity (for example, store anystate).

Analyzer resources

The sequence-advance, sequence-else, storage, and trigger-on specifications are set by a combination of up to 10 pattern terms, 2 range terms, 2 timers, and 2 edge terms (timing analyzer only). A resource can only be assigned to one analyzer at a time.

10 pattern terms The pattern terms, a through j, represent single states to be found on labeled sets of bits. For example, you could have an address on the address bits or a status on the status bits, or both the address and status occurring together. Pattern terms AND conditions occurring on separate labels. The timing analyzer cannot use the h and j terms.

2 timers You can start, stop, continue, or pause the timers upon entry to a sequence state, then compare a current timer value against a preset value to determine whether to branch to another state.

2 range terms The range terms, Range1 and Range2, represent ranges of values to be found on labeled sets of bits. For example, you could have a range of addresses to be found on the address bus or a range of data values to be found on the data bus. Range terms are satisfied by any value within the range for "In_Range," and any value outside the range for "Out_Range."

2 edge terms (timing analyzer only) The edge terms, Edge1 and Edge2, represent edges. The edge terms can be set to catch glitches. When an edge term comprises more than one channel, it ORs the channel conditions together and any of the specified transitions satisfy the term.

You can combine the pattern terms and range terms with logical operators to form complex pattern expressions in the sequence-advance, sequence-else, and TRIGGER on specifications.

For example,

```
Find "(<TERM1>•<TERM2>) + (<TERM3>•<TERM4>)"
```

Where <TERM> can be a single value on a set of labels, any value within a range of values on a set of labels, or a glitch or edge transition on a bit or set of bits.

Limitations affecting use of analyzer resources There are limitations on the way resources can be combined to form complex pattern expressions. Resources are combined in a four-level hierarchy. First, resources are divided into two groups. The groups can be combined with AND or OR. Second, within these groups, resources are combined into pairs. Pairs can also be logically combined using AND or OR. Third, individual resources are combined into pairs using AND, NAND, OR, NOR, XOR, and NXOR. Fourth, individual resources may be included or excluded from participating in a pattern expression. You can also include the logical negation of the resource.

The following table shows how resources are divided in the logic analyzer. Some resources may not be available, depending on the analyzer configuration. For example, if you are using the analyzer as a state analyzer, the Edge1 and Edge2 resources are not available. If the timers are assigned to the other analyzer, the Timer1 and Timer2 resources are not available. The timers are also not available in the first sequence level.

Table 9-1 Resource Combination Hierarchy

Group	Pair	Resource Operation	Resource	Pair Links	Group Link
Group 1	Pair 1	Off, On, Negate	a	Combine resources within pairs using AND, NAND, OR, XNOR	Combine pairs within groups or in group 1 and group 2 using AND or OR
		Off, On, Negate	b		
	Pair 2	Off, On, Negate	c		
		Off, In Range, Out of Range	Range 1		
	Pair 3	Off, On, Negate	d		
		Off, On, Negate	Edge 1		
	Pair 4	Off, On, Negate	e		
		Off, <, >	Timer 1		
Group 2	Pair 1	Off, On, Negate	f	Combine resources within pairs using AND, NAND, OR, NOR, XNOR	
		Off, On, Negate	g		
	Pair 2	Off, On, Negate	h		
		Off, In Range, Out of Range	Range 2		
	Pair 3	Off, On, Negate	i		
		Off, On, Negate	Edge 2		
	Pair 4	Off, On, Negate	j		
		Off, <, >	Timer 2		

For example, the following combinations are valid combinations for the analyzer:

```
(a+b) • (In_Range2 + Timer2 > 400 ns)
```

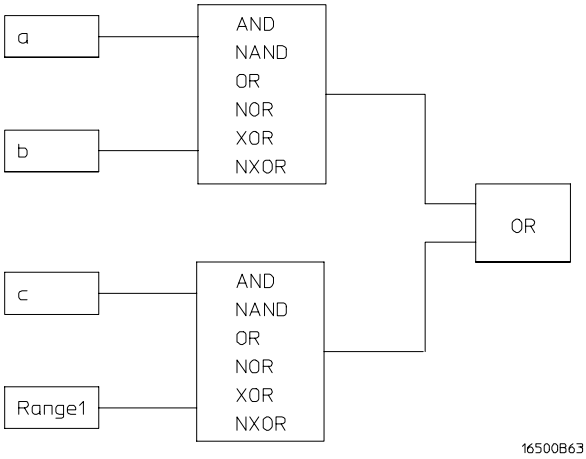
```
(c • Out_Range1) + (f xor g)
```

The following combinations are not valid because resources cross pair boundaries:

```
a xor c
```

```
(d + Timer1 < 400 ns) • Edge1
```

The first example shows that a and c cannot be combined at the first level. The following figure shows the possible combinations of the a, b, c, and Range1 terms:



Combining a, b, c, and Range1Terms

The following combination is not valid because pairs cross group boundaries:

```
((a+b) + (h • In_Range2)) • (j xor Timer2 > 400 ns)
```

Note that although the analyzer interface will not allow you to enter invalid combinations, you need to be aware of what combinations are legal, so that you can make the desired measurement.

Another limitation is that the analyzer cannot handle ranging for input pods that are assigned to different pod pairs. For example, if you need to define a 32-bit range term, you must do it using pods 1/2, 3/4, or 5/6. Trying to define a range across pods 2/3, 4/5, or 1/6 will not work.

Timing analyzer

When you configure a timing analyzer, the trigger sequence follows the general outlines described previously. The trigger sequence of the timing analyzer differs from the state analyzer in the following ways:

- There are 10 levels available to build a trigger.
- The trigger term is always the last step.
- The timing analyzer cannot use pattern terms h and j.
- The timing analyzer has two additional resources, Edge1 and Edge2.
- Edge1 and Edge2 recognize occurrences of a glitch, rising edge, falling edge, either edge, or no edge on a bit or ORed set of bits.

State analyzer

When you configure a state or state compare analyzer, the trigger sequence follows the general outlines described previously. The trigger sequence differs from the timing analyzer in the following ways:

- There are 12 levels available to build a trigger.
- The trigger term is never the last step.
- The state analyzer cannot use Edge1 and Edge2.
- The state analyzer can use patterns terms h and j.

Configuration Translation Between HP Logic Analyzers

Analyzer configuration files cannot be transferred directly from one type of analyzer to another because each analyzer has internal architectural differences, reflected in the number of pods, clock configurations, trigger sequence features, analyzer resources, and so on. To help you move configuration files from one analyzer to another, most HP logic analyzers support automatic translation of analyzer configurations. The HP 1670D-series logic analyzer can translate configuration files from the following common analyzer models:

HP 16510	HP 16550
HP 16511	HP 16554
HP 16540	HP 16555
HP 16541	HP 16556
HP 16542	HP 1660

If you save an analyzer configuration from one model of analyzer, then load that configuration into a model that supports configuration translation and was released after the original analyzer, the translator will adjust the configuration as required to account for differences between the models.

The configuration translator needs to account for many aspects of the analyzer architecture. Some of the considerations are as follows:

- When a range term is split across multiple pods, the term must span adjacent odd/even pairs, starting with 1. Thus, terms could span pods 1 and 2, 3 and 4, 5 and 6, or 7 and 8, but not 2 and 3. Again, the translator may display messages asking you to reconnect cables in a different configuration.
- When loading a configuration into an analyzer with fewer pods than the one on which the configuration was saved, the translator must remove pod assignments. Which pods are removed from the

configuration will depend on the widths of each pod in the original analyzer and in the new analyzer.

The configuration translation also needs to account for many differences in the format and trace menus between the analyzers, including label names, polarities, thresholds, symbols, clocking, number of sequence levels, branch conditions, and patterns, among others.

To ensure that trace measurements act as expected when you move configuration files from one analyzer to another, follow these recommendations:

- Ensure that the analyzer pods are hooked up as required by the configuration translation and the new analyzer. The onscreen messages given by the translator will help you identify which analyzer pods must be swapped. If you are using an HP preprocessor, the preprocessor User's Guide may contain information showing the cable connections for different analyzer models.
- Review all trace format and trigger menu settings to verify that they will meet your measurement requirements. You should check label assignments, channel masks, pattern and range definitions, trigger sequence setup, and general analyzer configuration (which pods are mapped to each analyzer).

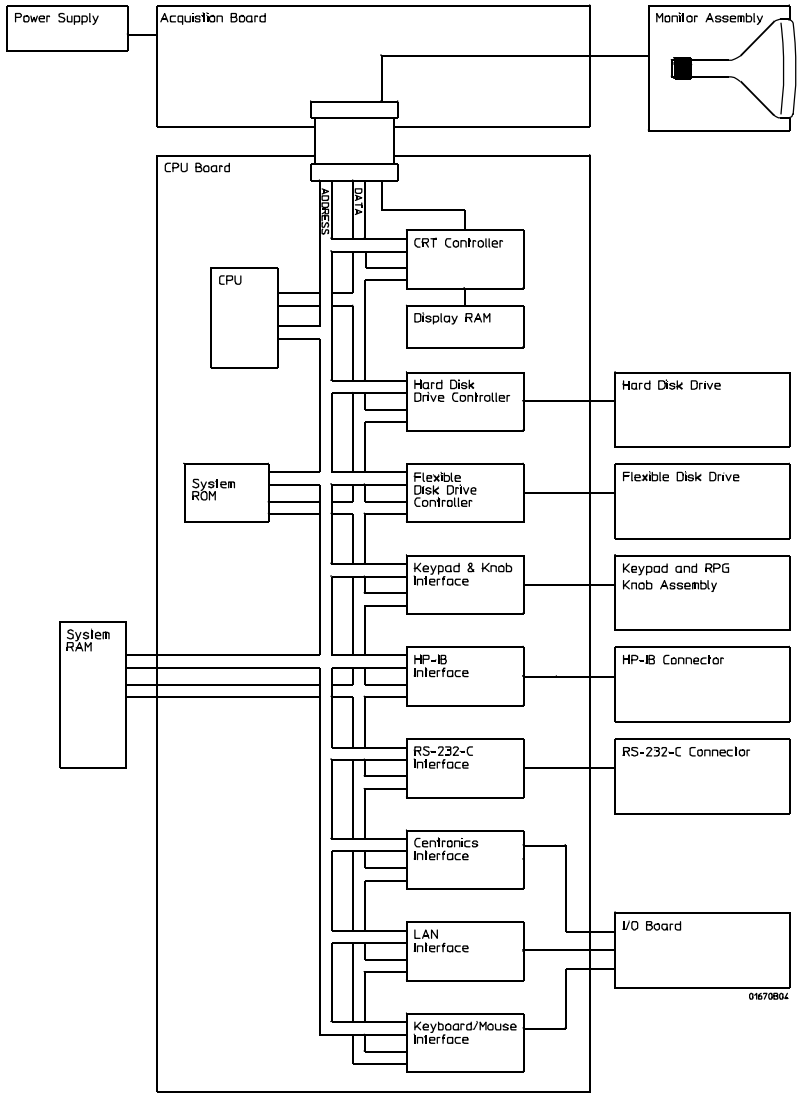
Configuration Files

When you move a configuration file from one analyzer to another, the trace data from previous measurements is not moved. If you need to store trace data for future reference, see "To save a listing in ASCII format" in Chapter 6.

This section describes the theory of operation for the logic analyzer and the self-tests. The information in this section should help you understand how the logic analyzer operates and what the self-tests are testing. This information is not intended for component-level repair.

The block-level theory is divided into two parts: theory for the logic analyzer and theory for the acquisition boards. A block diagram is shown with each theory.

HP 1670D-series analyzer theory



HP 1670D-Series Logic Analyzer

CPU Board

The microprocessor is a Motorola 68EC020 running at 25 MHz. The microprocessor controls all of the functions of the logic analyzer, including processing and storing data, displaying data, and configuring the acquisition ICs to obtain and store data.

System Memory

The system memory is made up of both read-only memory (ROM) and random access memory (RAM). Two types of ROM are used. A single 128Kx8 EPROM is used as a boot ROM, and four 512Kx8 flash ROMS are configured to provide a 256Kx32 flash ROM space. One 1Mx4 byte SIMM provides 4MB RAM space.

On power-up, instructions in the boot ROM command the instrument to execute its boot routine. The boot routine includes power-up operation verification of the instrument subsystems and entering the operating system. The CPU searches for the operating system on flash ROM. Then, if the operating system is in flash ROM, the instrument will be initialized with the default configuration and await front panel instructions from you. If the operating system is not in flash ROM, the CPU accesses the disk drive to see if the operating system is on the disk.

The DRAM stores the instrument configuration, acquired data to be processed, and any inverse assembler loaded in the instrument.

Keypad and Knob Interface

The front-panel keypad is scanned directly from the microprocessor address bus during the video blanking cycle of the CRT. When a front panel key is pressed, the associated address bits are fed to the data bus through the pressed key and read by the microprocessor.

The rotary pulse generator (RPG) knob has its own interface circuit. Pulses and direction of rotation information are directed to the RPG interface. The microprocessor then reads and interprets the RPG signals and performs the desired tasks.

HP-IB Interface

The instrument interfaces to HP-IB as defined by IEEE Standard 488.2. The interface consists of an HP-IB controller and two octal drivers/receivers. The microprocessor routes HP-IB data to the controller. The controller then buffers the 8-bit HP-IB data bits and generates the bus handshaking signals. The data and handshaking signals are then routed to the HP-IB bus through the octal line drivers/receivers. The drivers/receivers provide data and control signal transfer between the bus and controller.

RS-232-C Interface

The instrument RS-232-C interface is compatible with standard RS-232-C protocol. The interface consists of a controller, and drivers/receivers. The controller serializes parallel data from the microprocessor for transmission. At the same time, the controller also receives serial data and converts the data to parallel data characters for the microprocessor.

The controller contains a baud rate generator that can be programmed from the logic analyzer front panel for one of eight baud rates. Other RS-232-C communications parameters can also be programmed from the logic analyzer front panel.

The drivers and receivers interface the instrument with data communications equipment. Slew rate control is provided on the ICs, eliminating the need for external capacitors.

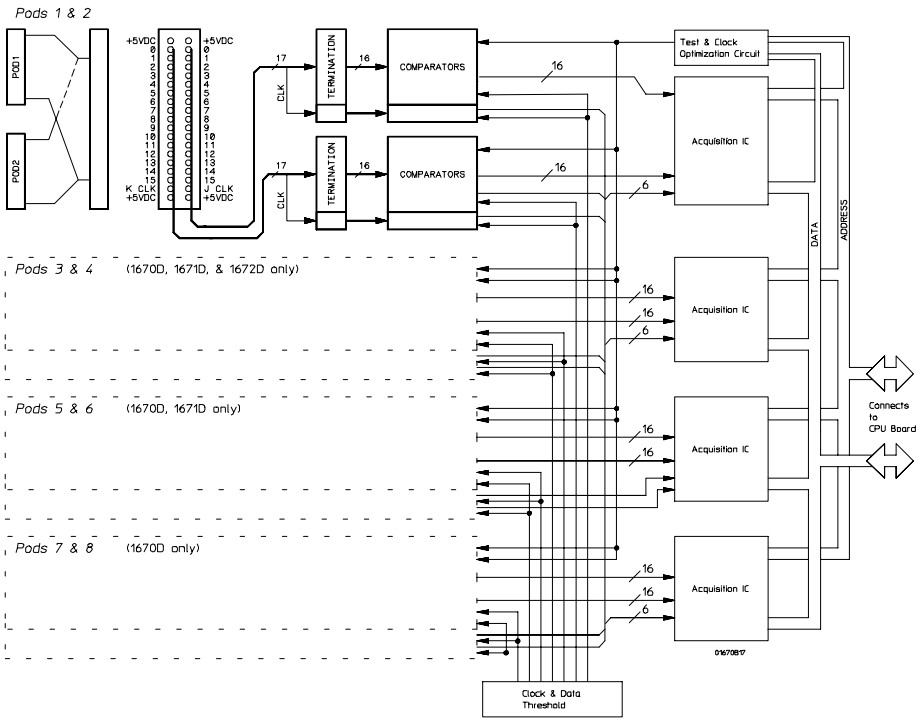
Centronics Interface

The interface to the Centronics port includes latches and buffers. The latches and buffers convert the logic analyzer backplane signals into parallel Centronics signals.

LAN Interface

The LAN Interface is primarily a single LAN integrated circuit with supporting components. Isolation circuitry for the LAN port is included on the I/O board. The LAN interface conforms to IEEE 802.3

Logic acquisition board theory



Logic Acquisition Board

Probing

The probing circuit includes the probe cable and terminations. The probe cable consists of two 17-channel pods which are connected to the circuit board using a high-density connector. Sixteen single-ended data channels and one single-ended clock/data channel are passed to the circuit board per pod.

If the clock/data channel is not used as a state clock in state acquisition mode, it is available as a data channel. The clock/data channel is also available as a data channel in timing acquisition mode. Eight clock/data channels (HP 1670D), six (HP 1671D), or four (HP 1672D) are available as data channels, however only four clock/data channels can be assigned as clock channels in the HP 1670D and HP 1671D. All clock data channels available in the HP 1672D can be assigned as clock channels.

The cables use nichrome wire woven in polyarmid yarn for reliability and durability. The pods also include one ground path per channel in addition to a pod ground. The channel grounds are configured such that their electrical distance is the same as the electrical distance of the channel.

The terminations on the circuit board are resistive terminations that reduce transmission line effects on the cable. The terminations also improve signal integrity to the comparators by matching the impedance of the probe cable channels with the impedance of the signal paths of the circuit board. All 17 channels of each pod are terminated in the same way. The signals are reduced by a factor of 10.

Comparators

Two proprietary 9-channel comparators per pod interpret the incoming data and clock signals as either high or low depending on where the user-programmable threshold is set. The threshold voltage of each pod is individually programmed, and the voltage selected applies to the clock channel as well as the data channels of each pod.

Each of the comparator ICs has a serial test input port used for testing purposes. A test bit pattern is sent from the Test and Clock Synchronization Circuit to the comparator. The comparators then propagate the test signal on each of the nine channels of the comparator. Consequently, all data and clock channel pipelines on the circuit board can be tested by the operating system software from the comparator.

Acquisition

The acquisition circuit is made up of a single HP proprietary ASIC. Each ASIC is a 34-channel state/timing analyzer, and one ASIC is included for every two logic analyzer pods. All of the sequencing, pattern/range recognition, and event counting functions are performed onboard the IC.

In addition to the storage qualification and counting functions, the acquisition ASICs also perform master clocking functions. All four state acquisition clocks are fed to each IC, and the ICs generate their own sample clocks. Every time you select RUN, the ICs individually perform a clock optimization before data is stored.

Clock optimization involves using programmable delays onboard the IC to position the master clock transition where valid data is captured. This procedure greatly reduces the effects of channel-to-channel skew and other propagation delays.

In the timing acquisition mode, an oscillator-driven clock circuit provides a four-phase, 125-MHz clock signal to each of the acquisition ICs. For high-speed timing acquisition (125 MHz and faster), the sample period is determined by the four-phase, 125-MHz clock signal. For slower sample rates, one of the acquisition ICs divides the 125-MHz clock signal to the appropriate sample rate. The sample clock is then fed to all acquisition ICs.

Threshold

A precision octal DAC and precision op amp drivers make up the threshold circuit. Each of the eight DAC channels is individually programmable which allows you to set the thresholds of the individual pods. The 16 data channels and the clock channel of each pod are all set to the same threshold voltage.

Test and clock synchronization circuit

ECLinPS (TM) ICs are used in the Test and Clock Synchronization Circuit for reliability and low channel-to-channel skew. Test patterns are generated and sent to the comparators during software operation verification. The patterns are propagated across all data and clock channels and read by the acquisition ASIC to ensure proper operation of both the data and clock pipelines.

The Test and Clock Synchronization Circuit also generates a four-phase, 125-MHz sample/synchronization signal for the acquisition ICs operating in the timing acquisition mode. The synchronizing signal keeps the internal clocking of the individual acquisition ASICs locked in step with the other ASICs at fast sample rates. At slower sample rates, one of the acquisition ICs divides the 125-MHz clock signal to the appropriate sample rate. The slow speed sample clock is then used by all acquisition ICs.

Self-tests description

The self-tests identify the correct operation of major functional areas in the logic analyzer. The self-tests are not intended for component-level diagnostics.

Three types of tests are performed on the HP 1670D-series logic analyzers: the power-up self-tests, the functional performance verification self-tests, and the parametric performance verification tests.

The power-up self-tests are performed when power is applied to the instrument. The power-up self-tests are divided into two parts. The first part is the system memory tests and the second part is the microprocessor interrupt test. The system memory tests are performed before the logic analyzer actually displays the power-up self-test screen. Both the system ROM and RAM are tested during power-up. The interrupt test is performed after the power-up self-test screen is displayed.

The functional performance verification self-tests are run using a separate operating system, the performance verification (PV) operating system. The PV operating system resides on a separate disk that must be loaded when running the functional performance verification self-tests. The system and analyzer tests are functional performance verification tests.

Parametric performance verification requires the use of external test equipment that generates and monitors test data for the logic analyzer to read. Refer to chapter 3, "Testing Performance," of the *HP 1670D-Series Logic Analyzers Service Guide* for further information about parametric performance verification.

Troubleshooting

Troubleshooting

Occasionally, a measurement may not give the expected results. If you encounter difficulties while making measurements, use this chapter to guide you through some possible solutions. Each heading lists a problem you may encounter, along with some possible solutions. Error messages which may appear on the logic analyzer are listed below in quotes. Symptoms are listed without quotes.

If you still have difficulty using the analyzer after trying the suggestions in this chapter, please contact your nearest Hewlett-Packard Service Center.

CAUTION

When you are working with the analyzer, be sure to power down both the analyzer and the target system before disconnecting or connecting cables, probes, and preprocessors. Otherwise, you may damage circuitry in the analyzer, preprocessor, or target system.

Analyzer Problems

This section lists general problems that you might encounter while using the analyzer.

Intermittent data errors

This problem is usually caused by poor connections, incorrect signal levels, or marginal timing.

- ☐ **With the logic analyzer and all connected equipment turned off, remove and reseat all cables and probes; ensure that there are no bent pins on the preprocessor interface or poor probe connections.**

- ☐ **Adjust the threshold level of the data pod in the Format menu to match the logic levels in the system under test.**

- ☐ **Use an oscilloscope to check the signal integrity of the data lines.**

  Clock signals for the state analyzer must meet particular pulse shape and timing requirements. Data inputs for the analyzer must meet pulse shape and setup and hold time requirements.

See Also See "Capacitive Loading" in this section for information on other sources of intermittent data errors.

Unwanted triggers

Unwanted triggers can be caused by instructions that were fetched but not executed.

- ☐ **Add the prefetch queue or pipeline depth to the trigger address.**

  The depth of the prefetch queue depends on the processor that you are analyzing. Suppose you are analyzing a pipelined processor having fetch, decode, execute, and memory stages. The processor fetches 32-bit words. To ensure that the processor has started executing a particular routine when the trigger occurs, set the trigger to the module entry address plus 08 hex. (This assumes that there is no immediate data in the instruction stream.)

No activity on activity indicators

- ☐ Ensure that the Threshold settings in the Format menu match the logic family being probed.
- ☐ Check for loose cables, board connections, and preprocessor interface connections.
- ☐ Check for bent or damaged pins on the preprocessor probe.

Capacitive loading

Excessive capacitive loading can degrade signals, resulting in incorrect capture by the preprocessor interface, or system lockup in the microprocessor. All preprocessor interfaces include additional capacitive loading, as can custom probe fixtures you design for your application. To reduce loading, remove as many pin protectors, extenders, and adapters as possible.

Careful layout of your target system can minimize loading problems and result in better margins for your design. This is especially important for systems that are running at frequencies greater than 50 MHz.

No trace list display

If there is no trace list display, it may be that your trigger specification is not correct for the data you want to capture, or that the trace memory is only partially filled.

- ☐ Check your trigger specification to ensure that it will capture the events of interest.
- ☐ Try stopping the analyzer; if the trace list is partially filled, this should display the contents of trace memory.

Preprocessor Problems

This section lists problems that you might encounter when using a preprocessor. If the solutions suggested here do not correct the problem, you may have a defective preprocessor. Refer to the User's Guide for your preprocessor for test procedures. Contact your local Hewlett-Packard Sales Office if you need further assistance.

Target system will not boot up

If the target system will not boot up after connecting the preprocessor interface, the microprocessor or the preprocessor interface may not be installed properly, or they may not be making electrical contact.

- ☐ **Ensure that you are following the correct power-on sequence for the preprocessor and target system.**

  1 Power up the analyzer and preprocessor.

  2 Power up the target system.

  If you power up the target system before you power up the preprocessor, interface circuitry in the preprocessor may latch up, preventing proper target system operation.

- ☐ **Verify that the microprocessor and the preprocessor interface are properly rotated and aligned, so that the index pin on the microprocessor (such as pin 1 or A1) matches the index pin on the preprocessor interface.**

- ☐ **Verify that the microprocessor and the preprocessor interface are securely inserted in their respective sockets.**

- ☐ **Verify that the logic analyzer cables are in the proper sockets of the preprocessor interface and are firmly inserted.**

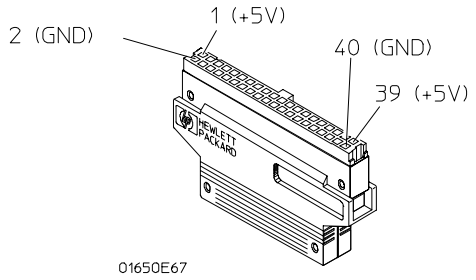
- ☐ **Reduce the number of extender sockets.**

See Also "Capacitive Loading" in the previous section of this chapter.

Slow clock

If you have the preprocessor interface hooked up and running, and observe a slow clock or no activity from the interface board, the +5V supply coming from the analyzer may not be getting to the interface board.

☐ **To check the +5V supply coming from the analyzer, disconnect one of the logic analyzer cables from the preprocessor and measure across pins 1 and 2 or pins 39 and 40.**



- If +5 V is not present, check the internal preprocessor fuse or current limiting circuit on the logic analyzer. For information on checking this fuse or circuit, refer to the *HP 1670D-Series Logic Analyzers Service Guide*.
- If +5 V is present and the cable connection to the preprocessor appears sound, contact your nearest Hewlett-Packard Sales Office for information on servicing the power supply board.

Erratic trace measurements

There are several general problems that can cause erratic variations in trace lists and inverse assembly failures.

- ☐ **Ensure that the preprocessor configuration switches are correctly set for the measurement you are trying to make.**

  Some preprocessors include configuration switches for various features (for example, to allow dequeueing of the trace list). See your *Preprocessor User's Guide* for more information.

- ☐ **Try doing a full reset of the target system before beginning the measurement.**

  Some preprocessor designs require a full reset to ensure correct configuration.

- ☐ **Ensure that your target system meets the timing requirements of the processor with the preprocessor probe installed.**

  See "Capacitive Loading" earlier in this chapter. While preprocessor loading is slight, pin protectors, extenders, and adapters may increase it to unacceptable levels. If the target system design has poor timing margins, such loading may cause incorrect processor functioning, giving erratic trace results.

- ☐ **Ensure that you have sufficient cooling for the preprocessor probe.**

  Current processors such as the i486, Pentium™, and MC68040 generate substantial heat. This is exacerbated by the active circuitry on the preprocessor board. You should ensure that you have ambient temperature conditions and airflow that meet or exceed the requirements of the microprocessor manufacturer.

Inverse Assembler Problems

This section lists problems that you might encounter while using the inverse assembler.

When you obtain incorrect inverse assembly results, it may be unclear whether the problem is in the preprocessor or in your target system. If you follow the suggestions in this section to ensure that you are using the preprocessor and inverse assembler correctly, you can proceed with confidence in debugging your target system.

No inverse assembly or incorrect inverse assembly

This problem is due to incorrect synchronization, modified configuration, incorrect connections, or a hardware problem in the target system. A locked status line can cause incorrect or incomplete inverse assembly.

- ☐ **Verify that the inverse assembler has been synchronized by placing an opcode at the top of the display (not at the input cursor) and pressing the Invasm key.**

  Because the inverse assembler works from the first line of the trace *display*, if you jump to the middle of a trace and select Invasm, prior trace states are not disassembled correctly. If you move to several random places in the trace list and select Invasm each time, the trace disassembly is only guaranteed to be correct from the top of the display forward for each selection.

See Also "The Inverse Assembler" in Chapter 3.

- ☐ **Ensure that each analyzer pod is connected to the correct preprocessor cable.**

  There is not always a one-to-one correspondence between analyzer pod numbers and preprocessor cable numbers. Preprocessors must supply address (ADDR), data (DATA), and status (STAT) information to the analyzer in a predefined order, so the cable connections for each preprocessor are often altered to support that need. Thus, one preprocessor might require that you connect cable 2 to analyzer pod 2, while another will require you to connect cable 5 to analyzer pod 2. See the User's Guide for your preprocessor for further information.

- ☐ **Check the activity indicators for status lines locked in a high or low state.**
- ☐ **Verify that the STAT, DATA, and ADDR format labels have not been modified from their default values.**

  These labels must remain as they are configured by the configuration file. Do not change the names of these labels or the bit assignments within the labels. Some preprocessors also require other data labels; check your Preprocessor User's Guide for more information.
- ☐ **Verify that all microprocessor caches and memory managers have been disabled.**

  In most cases, if the microprocessor caches and memory managers remain enabled you should still get inverse assembly, but it may be incorrect since some of the execution trace was not visible to the logic analyzer.
- ☐ **Verify that storage qualification has not excluded storage of all the needed opcodes and operands.**

Inverse assembler will not load or run

You need to ensure that you have the correct system software loaded on your analyzer.

- ☐ **Ensure that the inverse assembler is on the same disk as the configuration files you are loading.**

  Configuration files for the state analyzer contain a pointer to the location of the corresponding inverse assembler. If you delete the inverse assembler or move it to another location, the configuration process will fail.
- ☐ **Make sure you are using the version of the inverse assembler software that corresponds to the operating system version installed on your analyzer.**

See Also See your *Preprocessor User's Guide* for details.

Error Messages

This section lists some of the messages that the analyzer displays when it encounters problems.

". . . Inverse Assembler Not Found"

This error occurs if you rename or delete the inverse assembler file that is attached to the configuration file. Ensure that the inverse assembler file is not renamed or deleted, and that it is on the same flexible disk or in the same directory as the configuration file.

"No Configuration File Loaded"

This is usually caused by trying to load a configuration file for one type of module or the system into a different type of module.

- ☐ **Verify that the appropriate module has been selected as the target of the Load operation. Selecting Load All will cause incorrect operation when loading most preprocessor interface configuration files.**

See Also "To Load a Configuration" in chapter 6, "File Management."

"Selected File is Incompatible"

This occurs when you try to load a configuration file for the wrong module. Ensure that you are loading a translatable configuration file for your logic analyzer.

"Slow or Missing Clock"

- ☐ This error might occur if the target system is not running properly. Ensure that the target system is on and operating properly.
- ☐ Check your State clock configuration. The proper clocking scheme should be listed in your *Preprocessor Interface User's Guide*.
- ☐ If the error message persists, check that the logic analyzer pods are connected to the proper connectors. See the User's Guide for your preprocessor interface to determine the proper connections.

"Waiting for Trigger"

If a trigger pattern is specified, this message indicates that the specified trigger pattern has not occurred. Verify that the triggering pattern is correctly set.

- ☐ When analyzing microprocessors that fetch only from long-word aligned addresses, if the trigger condition is set to look for an opcode fetch at an address not corresponding to a long-word boundary, the trigger will never be found.

"Must have at least 1 edge specified"

You must assign at least one clock edge to one of the available clocks in the clocking arrangment. The analyzer will not let you close the clock assignment pop-up menu until an edge is specified.

"Time correlation of data is not possible"

To time-correlate the data, it must be stored with time tags.

- ☐ Set the Count field in the Analyzer Trigger menu to Time.

"Maximum of 32 channels per label"

You have tried to assign more than 32 channels to a single label.

- ☐ Unassign some of the channels. If you need more than 32 channels to specify trigger conditions, you can AND terms in the Analyzer Trigger menu.

"Xmin is greater than or equal to Xmax"

The X axis settings are incorrectly set in the Analyzer Chart menu.

- ☐ Select Axis Control and enter different values for Xmin or Xmax. For data to be displayed, the maximum value must be at least one greater than the minimum value.

"Ymin is greater than or equal to Ymax"

See "Xmin is greater than or equal to Xmax".

"Timer is off in sequence level n where it is used"

If you use timers as part of your trigger sequence, you must remember to turn them on using Timer Control in the Sequence Level pop-up menu.

- ☐ Check that your timers are turned on. The timer status is shown in the right side of the Sequence Level display of the Trigger menu. An "S" means "Start", "P" means "Pause", "C" means "Continue", and "-" means "off".

"Timer is specified in sequence, but never started"

This message often appears with "Timer is off in sequence level n where it is used," but is not quite the same. Instead of referring to a particular sequence level, but this message is a general warning that the timer has not been set to Start in any level.

- ☐ Start the timer in one of the levels before it is used.

"Inverse assembler not loaded - bad object code."

The inverse assembler file has been corrupted.

- ☐ Try loading a different copy of the inverse assembler.

"Measurement Initialization Error"

The logic analyzer failed its internal hardware calibration.

- ☐ Run the Performance Verification tests.

See Also Chapter 12, "Operator's Service" or the *HP 1670D-Series Logic Analyzers Service Guide* for information on running the Performance Verification tests.

"Warning: Run HALTED due to variable change"

This message appears when certain analyzer settings are changed during a repetitive run. When this occurs, the analyzer stops.

Specifications

General Information

This chapter lists the accessories, specifications and characteristics for the HP 1670D-series logic analyzers.

Accessories

The following accessories are supplied with the HP 1670D-series logic analyzers. The part numbers are current as of this edition of the User's Guide, but future upgrades may change the part numbers. Do not be concerned if the accessories you receive have different part numbers.

Accessories supplied	**HP part number**	**Qty**
Probe tip assemblies	01650-61608	Note 1
Probe cables	01660-61605	Note 2
Grabbers (20 per pack)	5090-4356	Note 1
Probe ground (5 per pack)	5959-9334	Note 1
HP 1670D User's Guide	01670-99004	1
LAN User's Guide	01660-97018	1
Symbol Utility (disk and manual)	E2450A	1
Accessories pouch	01660-84501	1
RS-232-C loopback connector	01650-63202	1
PS2 mouse	A2839B	1

Note 1 Quantities: 8 - 1670D
6 - 1671D
4 - 1672D

Note 2 Quantities: 4 - 1670D
3 - 1671D
2 - 1672D

Specifications

The specifications are the performance standards against which the product is tested. For testing procedures, refer to the *HP 1670D-Series Logic Analyzers Service Guide*, available from your HP Sales Office.

Maximum state speed	100 MHz
Minimum state clock pulse width*	3.5 ns
Minimum master to master clock time*	10.0 ns
Minimum glitch width*	3.5 ns
Threshold accuracy	± (100 mV + 3% of threshold setting)

Setup/Hold Time:*

Single clock, single edge	0.0/3.5 ns through 3.5/0.0 ns, adjustable in 500-ps increments
Single clock, multiple edges	0.0/4.0 ns through 4.0/0.0 ns, adjustable in 500-ps increments
Multiple clocks, multiple edges	0.0/4.5 ns through 4.5/0.0 ns, adjustable in 500-ps increments

* Specified for an input signal VH = –0.9 V, VL = –1.7 V, slew rate = 1 V/ns, and threshold = –1.3 V.

Characteristics

These characteristics are not specifications, but are included as additional information.

		Full Channel	**Half Channel**
Maximum state clock rate		100 MHz	not applicable
Maximum conventional timing rate		125 MHz	250 MHz
Memory depth		64K*	128K*
Channel count:			
	HP 1670D	136	68
	HP 1671D	102	51
	HP 1672D	68	34

*Option 030 provides 1016K/2400K memory depth in full/half-channel modes.

Supplemental characteristics

Probes

Input resistance	100 kΩ, ± 2%
Input capacitance	~ 8 pF
Minimum voltage swing	500 mV, peak-to-peak
Threshold range	± 6.0 V, adjustable in 50-mV increments, CAT I

State analysis

State/Clock qualifiers	4
Time tag resolution*	8 ns or 0.1%, whichever is greater
Maximum time count between states	34 seconds
Maximum state tag count*	4.29×10^9

* Maximum state clock rate with time or state tags on is 100 MHz. When all pods are assigned to a state or timing machine and all memory is in use, time or state tags halve the memory depth.

Timing analysis

Sample period accuracy	0.01% of sample period
Channel-to-channel skew	2 ns, typical
Time interval accuracy	± [sample period + channel-to-channel skew +(0.01%)(time reading)]

Triggering

Sequencer speed	125 MHz, maximum
State sequence levels	12
Timing sequence levels	10
Maximum occurrence counter value	1,048,575
Pattern recognizers	10

Maximum pattern width	136 channels in HP 1670D, 102 channels in HP 1671D, 68 channels in HP 1672D
Range recognizers	2
Range width	32 channels
Timers	2
Timer value range	400 ns to 500 seconds
Glitch/Edge recognizers	2 (timing only)
Maximum glitch/edge width	136 channels in HP 1670D, 102 channels in HP 1671D, 68 channels in HP 1672D

Measurement and display functions

Displayed waveforms 24 lines maximum, with scrolling across 96 waveforms.

Measurement functions

Run/Stop functions Run starts acquisition of data in specified trace mode.

Stop Stop halts acquisition and displays the current acquisition data.

Trace mode Single mode acquires data once per trace specification. Repetitive mode repeats single mode acquisitions until Stop is pressed or until the time interval between two specified patterns is less than or greater than a specified value, or either within or not within a specified range.

Indicators

Activity indicators Provided in the Configuration and Format menus for identifying high, low, or changing states on the inputs.

Markers Two markers (X and O) are shown as vertical dashed lines on the display.

Trigger Displayed as a vertical dashed line in the Waveform display and as line 0 in the Listing display.

Data entry/display

Labels Channels may be grouped together and given a 6-character name. You may assign up to 126 labels in each analyzer with up to 32 channels per label.

Display modes State Listing, State Waveforms, Chart, Compare Listing, Compare Difference Listing, Timing Waveforms, and Timing Listings. State Listing and Timing Waveforms can be time-correlated on the same displays.

Timing waveform Pattern readout of timing waveforms at X or O marker.

Bases Binary, octal, decimal, hexadecimal, ASCII (display only), two's complement, and symbols.

Symbols 1,000 maximum. You can download symbols over an RS-232, HP-IB, or LAN.

Marker functions

Time interval The X and O markers measure the time interval between a point on a timing waveform and the trigger, two points on the same timing waveform, two points on different waveforms, or two states (time tagging on).

Delta states (state analyzer only) The X and O markers measure the number of tagged states between one state and trigger or between two states.

Patterns The X and O markers can be used to locate the nth occurrence of a specified pattern from trigger, or from the beginning of data. The O marker can also find the nth occurrence of a pattern from the X marker.

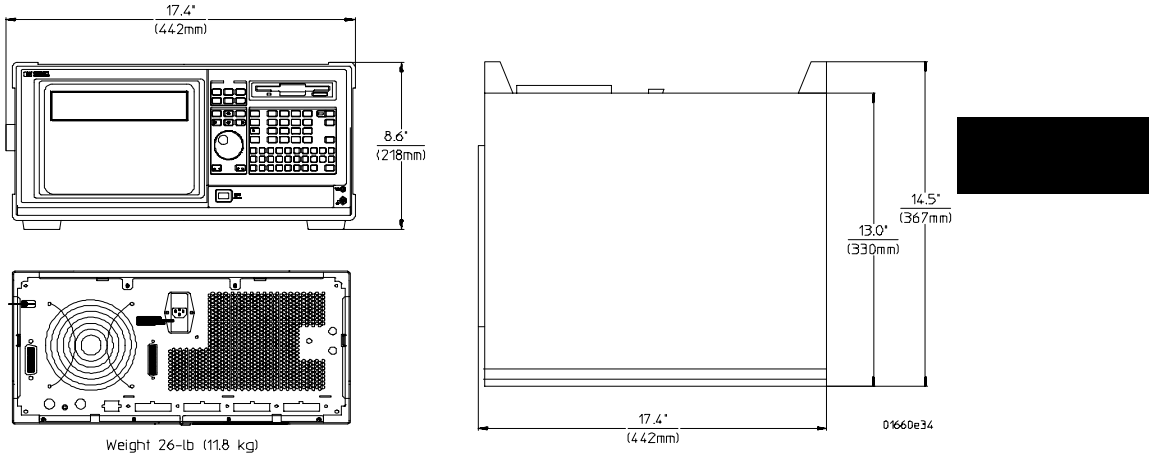
Statistics X and O marker statistics are calculated for repetitive acquisitions. Patterns must be specified for both markers, and statistics are kept only when both patterns can be found in an acquisition. Statistics are minimum X to O time, maximum X to O time, average X to O time, and ratio of valid runs to total runs.

Auxiliary power

Power through cables	1/3 amp at 5 V maximum per cable, CAT 1

Operating environment

Temperature	Instrument, 0 °C to 55 °C (+32 °F to 131 °F). Probe lead sets and cables, 0 °C to 65 °C (+32 °F to 149 °F). Flexible disk media, 10 °C to 40 °C (+50 °F to 104 °F).
Humidity	Instrument, probe lead sets, and cables, up to 80% relative humidity at +40 °C (+122 °F).
Altitude	To 3067 m (10,000 ft).
Vibration	Operating: Random vibration 5 to 500 Hz, 10 minutes per axis, ≈0.3 g (rms). Non-operating: Random vibration 5 to 500 Hz, 10 minutes per axis, ≈ 2.41 g (rms); and swept sine resonant search, 5 to 500 Hz, 0.75 g (0-peak), 5-minute resonant dwell at 4 resonances per axis.



Dimensions

Operator's Service

Operator's Service

This chapter provides the operator with information on how to prepare the logic analyzer for use, and contains self-tests and flow charts used for troubleshooting the logic analyzer.

The *HP 1670D-Series Logic Analyzers Service Guide* contains detailed service procedures. You can order service guides through your HP Sales Office; they are not shipped with the logic analyzer.

This section includes instructions for preparing the logic analyzer for use.

Power requirements

The logic analyzer requires a power source of either 115 Vac or 230 Vac, –22% to +10%, single phase, 48 to 66 Hz, 200 Watts maximum power.

Operating environment

Specifications for the operating environment are listed in chapter 11. The logic analyzer will operate at all specifications within the temperature and humidity range in chapter 11. However, reliability is enhanced when operating the logic analyzer within the following ranges:

- Temperature: +20 °C to +35 °C (+68 °F to +95 °F)
- Humidity: 20% to 80% noncondensing

Note the noncondensing humidity recommendation. Condensation within the instrument can cause poor operation or malfunctions. Provide protection against internal condensation.

Storage

Store or ship the logic analyzer in environments within the following limits:

- Temperature: -40 °C to +75 °C
- Humidity: Up to 90% at 65 °C
- Altitude: Up to 15,300 meters (50,000 feet)

Protect the logic analyzer from temperature extremes which cause condensation on the instrument.

To inspect the logic analyzer

1. **Inspect the shipping container for damage.**

   If the shipping container or cushioning material is damaged, keep them until you have checked the contents of the shipment and checked the instrument mechanically and electrically.

2. **Check the supplied accessories.**

   Accessories supplied with the logic analyzer are listed in "Accessories" in chapter 11.

3. **Inspect the product for physical damage.**

   Check the logic analyzer and supplied accessories for obvious physical or mechanical defects. If you find any defects, contact your nearest Hewlett-Packard Sales Office. Arrangements for repair or replacement are made, at Hewlett-Packard's option, without waiting for a claim settlement.

To apply power

1. **Check that the line voltage selector, located on the rear panel, is on the correct setting and the correct fuse is installed.**

   See also, "To set the line voltage" on the next page.

2. **Connect the power cord to the instrument and to the power source.**

   This instrument is equipped with a three-wire power cable. When connected to an appropriate ac power outlet, this cable grounds the instrument cabinet. The type of power cable plug shipped with the instrument depends on the country of destination.

3. **Turn on the instrument power switch located on the front panel.**

To set the line voltage

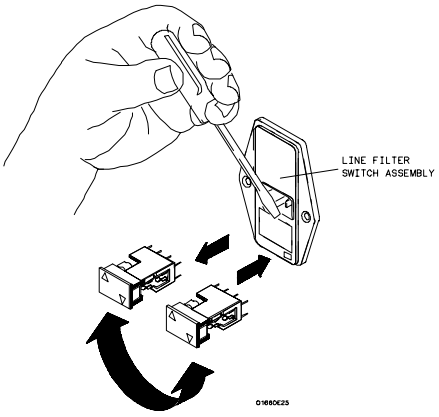
When shipped from HP, the line voltage selector is set and an appropriate fuse is installed for operating the instrument in the country of destination.

CAUTION

Electrostatic discharge can damage electronic components. Use grounded wrist straps and mats when performing any service to the logic analyzer.

1 Turn the power off, then remove the power cord from the instrument.

2 Remove the fuse module by carefully prying at the top center of the fuse module until you can grasp it and pull it out by hand.



Setting Line Voltage

3 Re-insert the fuse module with the arrow for the appropriate line voltage aligned with the arrow on the line filter assembly switch.

4 Reconnect the power cord and turn the instrument on.

To degauss the display

If the logic analyzer has been subjected to strong magnetic fields, the CRT might become magnetized and display data might become distorted. To correct this condition, degauss the CRT with a conventional external television type degaussing coil.

To clean the logic analyzer

With the instrument turned off and unplugged, use mild soap and water to clean the front and cabinet of the logic analyzer. Harsh soap might damage the water-base paint. Do not immerse the logic analyzer in water.

To test the logic analyzer

- If you require a test to verify the specifications, the *HP 1670D-Series Logic Analyzers Service Guide* is required. Start at the beginning of chapter 3, "Testing Performance."
- If you require a test to initially accept the operation, perform the self-tests described in Troubleshooting in this chapter.
- If the logic analyzer does not operate correctly, go to the flow charts provided in Troubleshooting in this chapter.

Troubleshooting

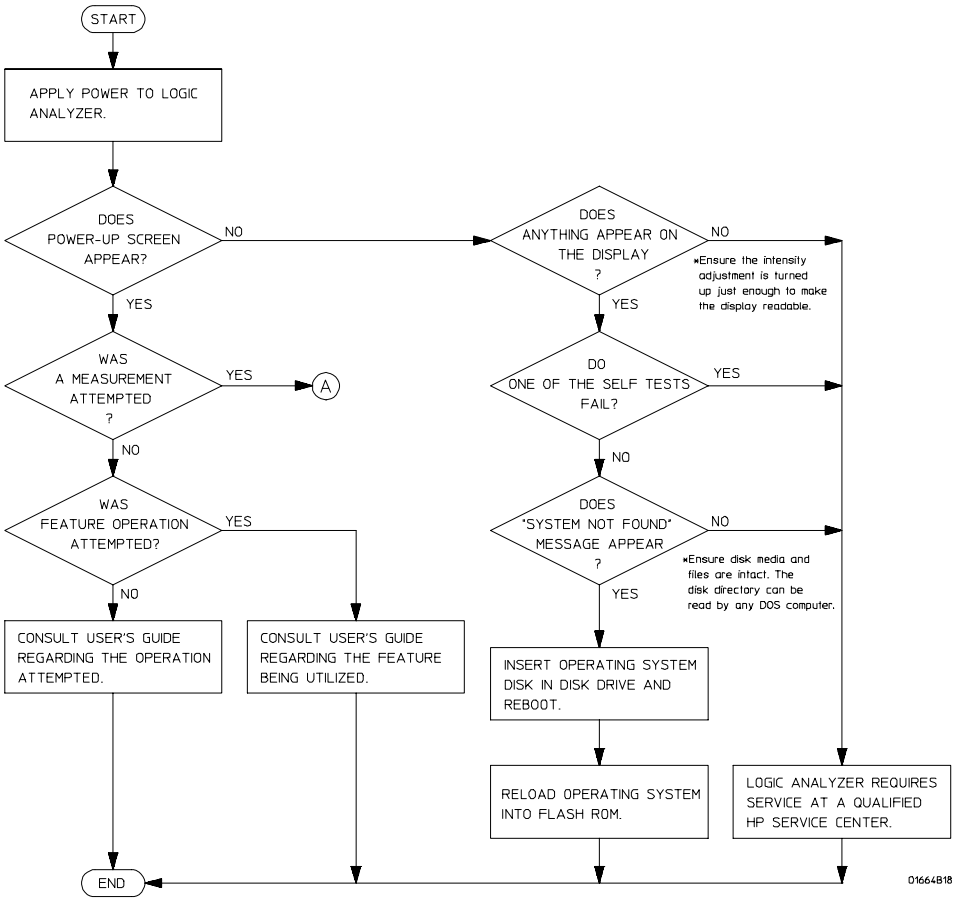
This section helps you troubleshoot the logic analyzer to find the problem. The troubleshooting consists of flowcharts, self-test instructions, and tests.

If you suspect a problem, start at the top of the first flowchart. During the troubleshooting instructions, the flowcharts will direct you to perform other tests.

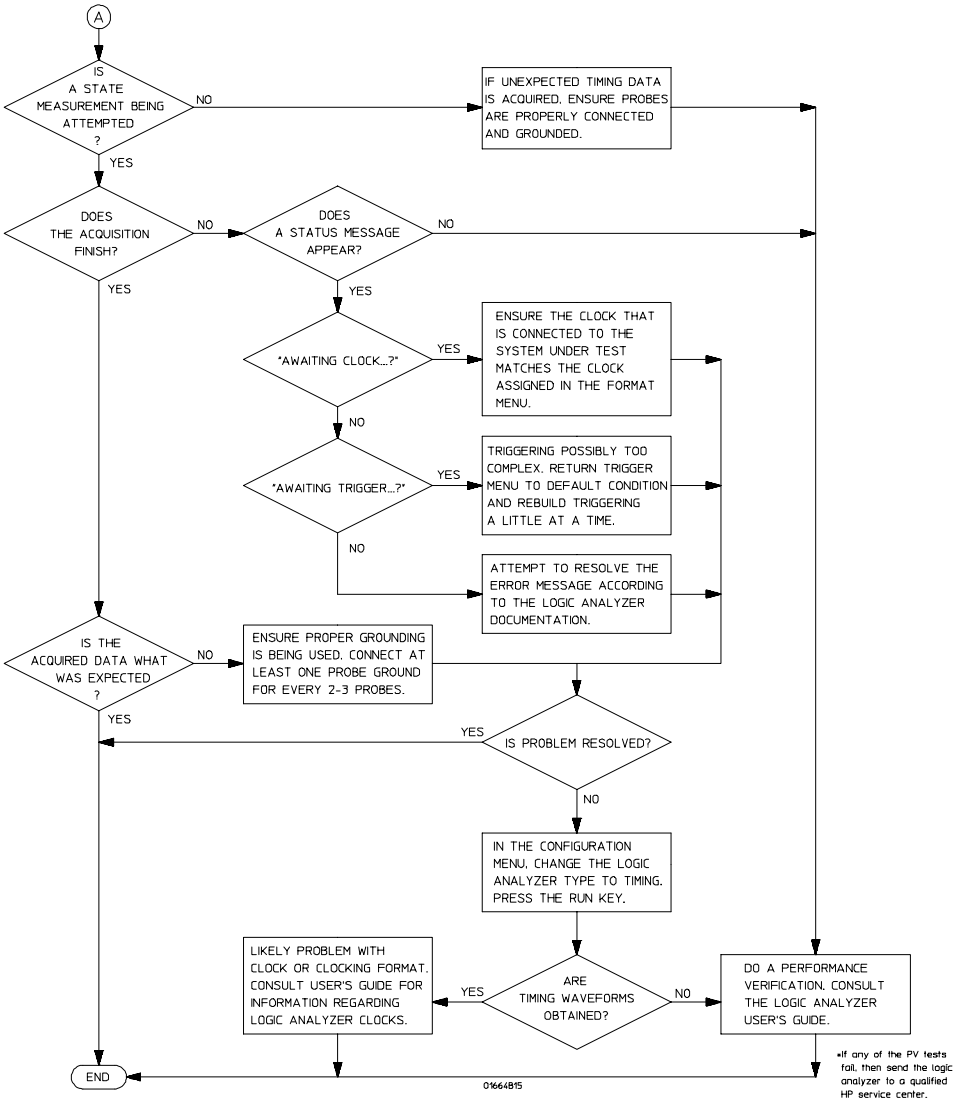
You can return this instrument to Hewlett-Packard for all service work, including troubleshooting. Contact your nearest Hewlett-Packard Sales Office for more details.

To use the flowcharts

Flowcharts are the primary tool used to isolate problems in the logic analyzer. The flowcharts refer to other tests to help isolate the trouble. The circled letters on the charts indicate connections with the other flowcharts. Start your troubleshooting at the top of the first flowchart.



Troubleshooting Flowchart 1



Troubleshooting Flowchart 2

To check the power-up self-tests

The logic analyzer automatically performs power-up self-tests when you apply power to the instrument. The revision number of the operating system shows in the upper-right corner of the screen during these power-up tests. As each test completes, either "passed" or "failed" prints on the screen in front of the name of each test.

1. Disconnect all inputs, then insert a formatted disk into the flexible disk drive.
2. Let the instrument warm up for a few minutes, then cycle power by turning off the power switch and turning it on again.

   If the instrument is not warmed up, the power-up test screen will complete before you can view the screen.
3. As the tests complete, check if they pass or fail.

   The Flexible Disk Test reports No Disk if a disk is not in the disk drive.

Performing Power-Up Self-Tests

passed	ROM text
passed	RAM test
passed	Interrupt test
passed	Display test
passed	PS2 Controller Test
passed	Hard Disk Test
No Disk	Flexible Disk Test

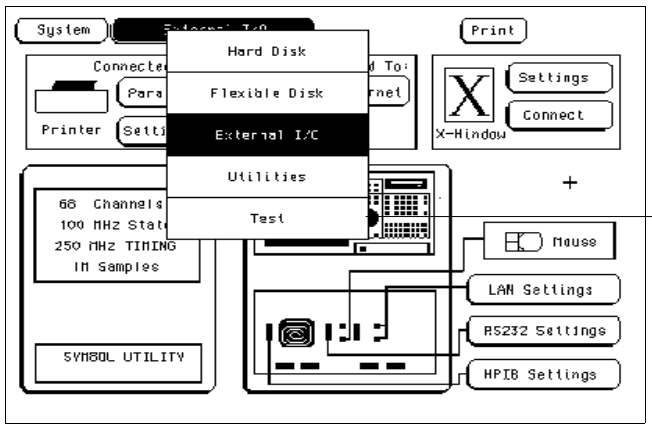
To run the self-tests

Self-tests identify the correct operation of major functional areas of the instrument. You can run all self-tests without accessing the interior of the instrument. If a self-test fails, the troubleshooting flowcharts instruct you to change a part of the instrument.

These procedures assume the files on the PV disk have been copied to the /SYSTEM subdirectory on the hard disk drive. If they have not already been copied, insert the PV disk in the flexible disk drive before starting this procedure.

1. If you just did the power-up self-tests, go to step 2.

   If you did not just do the power-up self-tests, disconnect all inputs, then turn on the power switch. Wait until the power-up tests are complete.
2. Press the System key, and select the field next to System. Then, select Test in the pop-up menu.



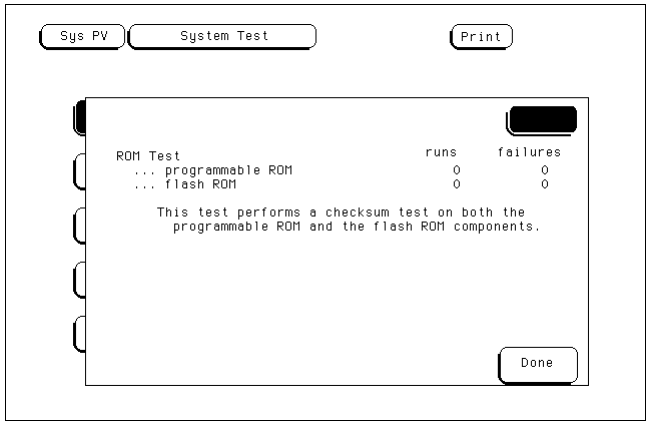
System Menu

3. Select the box labeled Load Test System, then select Continue.

4 Press the System key, then select the field next to Sys PV. Select System Test to access the system tests.

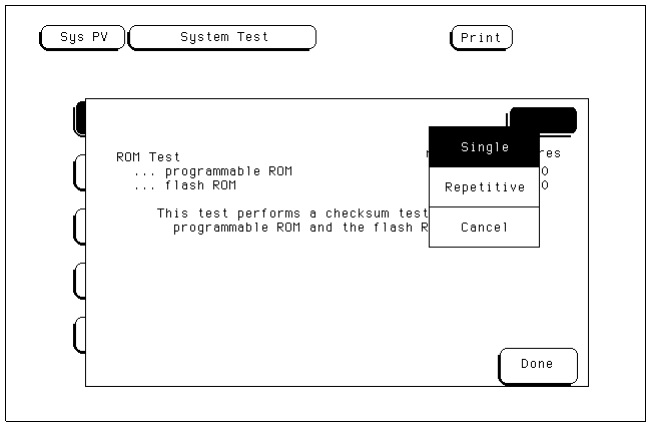
5 Select ROM Test. The ROM Test screen is displayed.

You can run all tests at one time by running All System Tests. To see more details about each test, you can run each test individually. This example shows how to run an individual test.

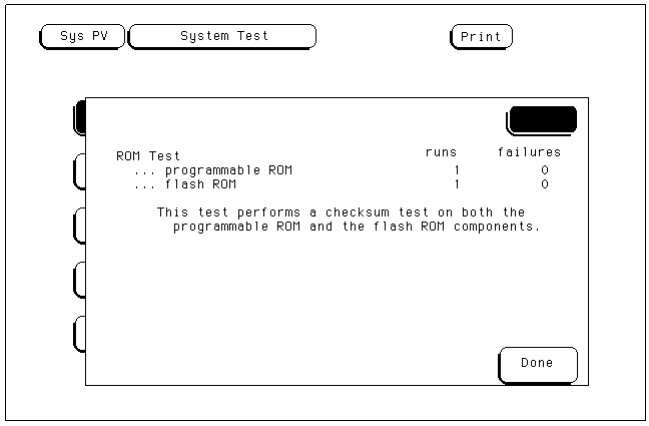


6 Select Run, then select Single.

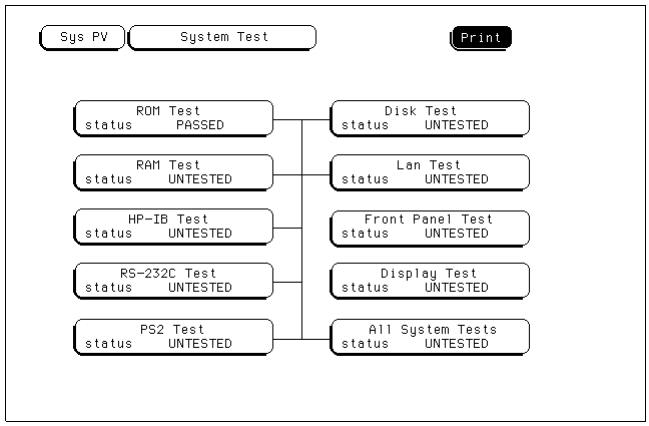
To run a test continuously, select Repetitive. Select Stop to halt a repetitive test.



For a Single run, the test runs one time, and the screen shows the results.



7 To exit the ROM Test, select Done. Note that the status changes to PASSED or FAILED.



8 Install a formatted disk that is not write-protected into the flexible disk drive. Connect an RS-232-C loopback connector onto the RS-232-C port. Run the remaining System Tests in the same manner.

9 Select the Front Panel Test.

A screen duplicating the front-panel appears on the screen.

a Press each key on the front panel. The corresponding key on the screen will change from a light to a dark color.

b Test the knob by turning it in both directions.

c Note any failures, then press the Done key a second time to exit the Front Panel Test. The test screen shows the Front Panel Test status changed to TESTED.

10 Select the Display Test.

A white grid pattern is displayed. These display screens can be used to adjust the display.

a Select Continue and the screen changes to full bright.

b Select Continue and the screen changes to half bright.

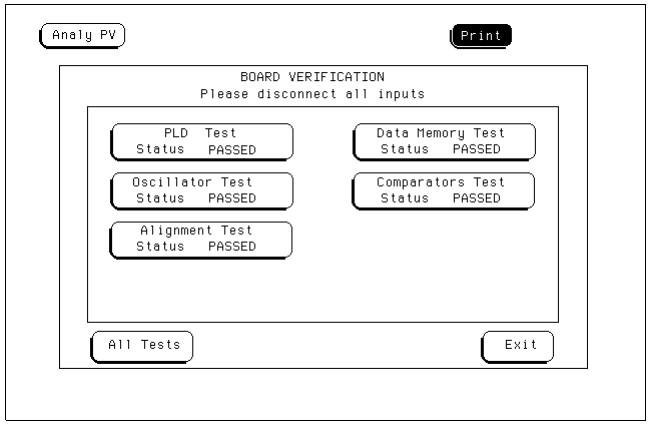
c Select Continue and the test screen shows the Display Test status changed to TESTED.

11 Select Sys PV, then select Analy PV in the pop-up menu.

12 In the Analy PV menu, select Board Verification Tests. In the Board Verification menu, select All Tests.

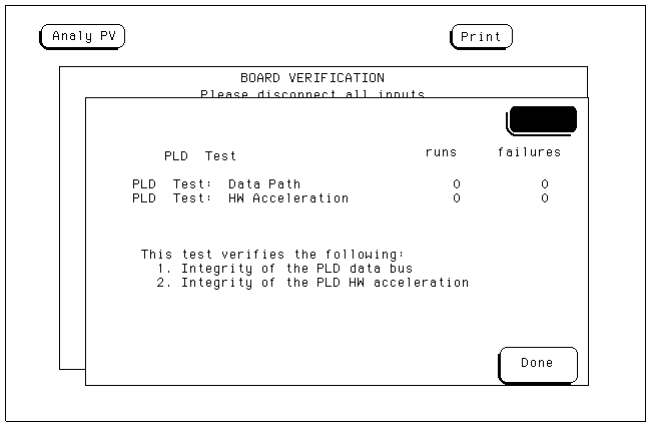
You can run all tests at one time by selecting All Tests. To see more details about each test when troubleshooting failures, you can run each test individually. This example shows how to run all tests at once.

When the tests finish, the status for each test shows PASSED or FAILED, and the status for the All Tests changes from UNTESTED to TESTED.



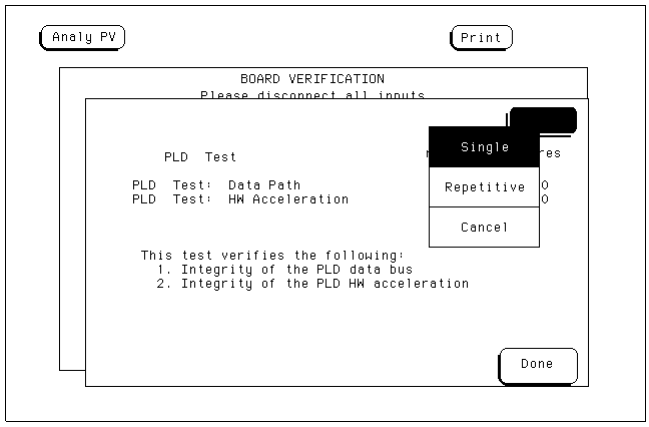
13 Select PLD Test. The PLD Test screen is displayed.

You can run all tests at one time by running All System Tests. To see more details about each test, you can run each test individually. This example shows how to run an individual test.

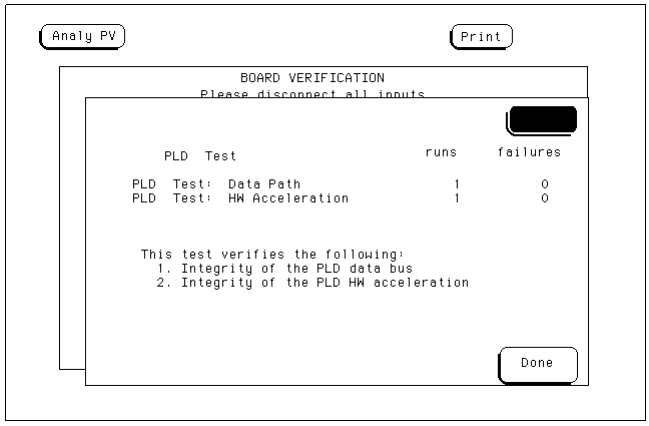


14 Select Run, then select Single.

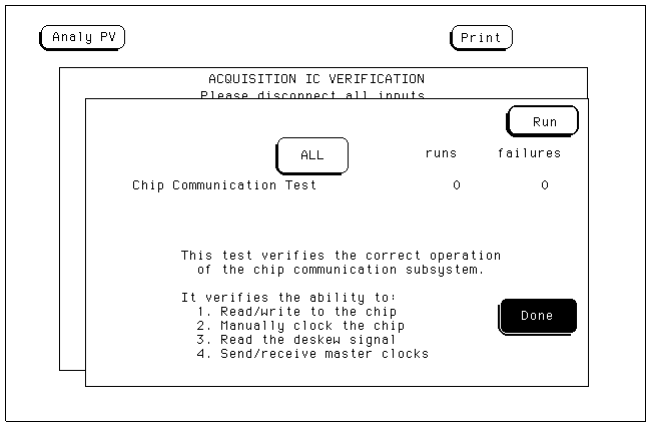
To run a test continuously, select Repetitive. Select Stop to halt a repetitive test.



For a Single run, the test runs one time, and the screen shows the results.



15 Select Exit to exit the Board Verification Test. In the Analy PV menu, select Acquisition IC Verification, then select Communication Test.

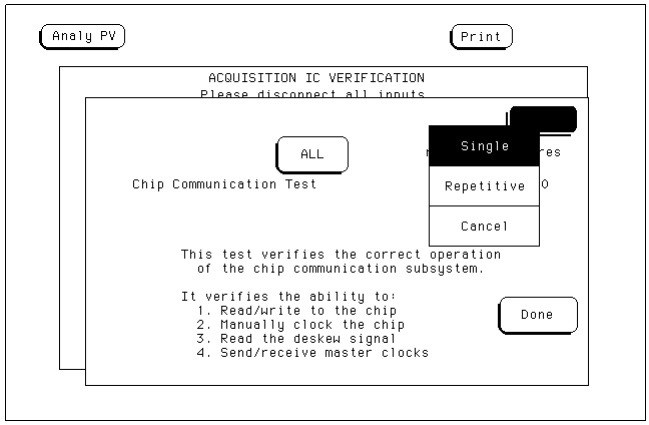


The ALL field provides a pop-up menu to let you select individual pod pairs to test, or to test all pod pairs at once. The individual tests are factory tests used to isolate a defective pod.

16 Select Run, then select Single.

To run a test continuously, select Repetitive. Select Stop to halt a repetitive test.

For a Single run, the test runs one time, and the screen shows the results.



17 Select Done to exit the Communications test.

18 To exit the tests, press the System key. Select the field to the right of the Sys PV field.

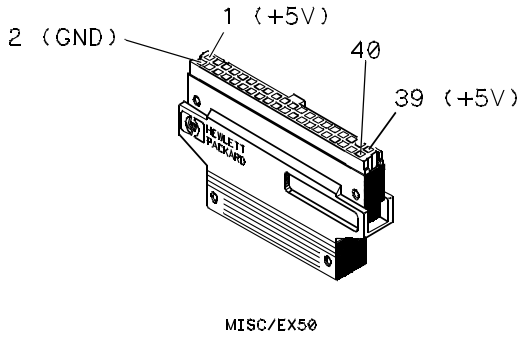
19 Select the Exit Test System.

If you are performing the self-tests as part of the troubleshooting flowchart, return to the flowchart.

To test the auxiliary power

The +5 V auxiliary power is protected by a current overload protection device. If the current on pins 1 and 39 exceed 0.33 amps, the circuit will open. When the short is removed, the circuit will reset in approximately 1 minute. There should be +5 V after the 1 minute reset time.

To test the auxiliary power, use a multimeter and verify the +5 V on pins 1 and 39 of the probe cables.



Testing Auxillary Power

Glossary

benchtop logic analyzer A small, standalone HP logic analyzer that is not part of the HP 16500 Logic Analysis System.

bit The information the logic analyzer stores for one sample of one physical line. Bits are either "low" or "high." See also channel.

bucket In the SPA State Overview mode, an individual subrange of states displayed on the histogram's X axis containing part of the acquisition data.

channel The analyzer's mapping of a single physical line. Channel is often used interchangeably with bit. Channels are grouped into labels in the Analyzer Format menu.

don't care Signifies that the signal state should be ignored. "Don't cares" are represented by "X" in assignment fields.

glitch A pulse of very short duration, usually less than the setup or hold time. To the logic analyzer, a glitch is two or more transitions across the logic threshold between consecutive samples.

label A name for a group of functionally-related channels. Three common labels, which are required by HP preprocessor interface inverse assemblers, are ADDR, DATA , and STAT. If a label is on, it appears in all display menus and the Trigger menu, letting you quickly display, store, or trigger on information of interest. See also symbol and term.

listing An alphanumeric display of state information. See also trace and waveform.

menu field The field to the right of the mode field. The menu field allows you to set up the instrument selected in the mode field.

mode field Also known as module field. The field in the upper-left corner of the logic analyzer. This field selects the mode, such as "Analyzer" or "System."

module field See mode field.

OMF Symbol Table OMF stands for Object Module File. The HP E2450A Symbol Utility uses the OMF to produce a table of symbols in the executeable file.

storage qualification Storage qualification allows you to specify the type of information to be stored in memory. Use storage qualification to prevent memory from being filled with unwanted activity.

symbol An alphanumeric name given to a specified bit-pattern or range for the bits in a particular label (see label). A label can have many symbols, each having a different meaning. For example, if the CYCLE label includes the bits for the Read/Write (R/W) and I/O signals, one symbol might be I/O READ, with I/O and R/W both high, while another symbol might be I/O WRITE, with I/O high and R/W low. Symbols are named and specified in the Format menu. Symbols are available only when the associated label is on. Symbols are also available for defining trigger terms. See also label and term.

term A resource for specifying storage conditions or trigger conditions. A term uses the bits in a label to identify the condition for storage or triggering. If symbols have previously been defined for the label, they can be used as the conditions, or you can specify new patterns or ranges. For example, if the CYCLE label includes the symbols I/O READ and I/O WRITE, term "a" could be I/O READ and term "b" could be I/O WRITE, and the trigger/storage macro could start storing at term "a" and stop storing at term "b."

trace The record of target system activity stored by the state or timing analyzer. This record can be displayed as either a waveform or a listing. See also listing and waveform.

trigger A reference event around which you want to gather information. In the analyzer, you might want to trigger on a glitch in hardware or entry to a subroutine in software. When beginning, you might want to trigger on the first occurrence of any kind (trigger on "anystate"). As you learn more about the problem you are trying to isolate, you may enter more specific trigger conditions. When you want to gather a continuous stream of activity leading up to a system crash, you will want to trigger on "no state." Note that some microprocessors fetch instructions on 32-bit boundaries. If you are tracing activity of one of these processors, and you specify trigger on an address that is not on a 32-bit boundary, that address will never appear on the address bus; therefore, the analyzer will never find its trigger. Make sure you specify triggers that the analyzer will find. The state

analyzer, timing analyzer, and oscilloscope cannot complete their measurement unless they find a trigger.

user symbol table A table containing the symbols that are created, using the Symbols option in the Format menu. This is the standard symbol capability of the HP logic analyzer. See also OMF Symbol Table.

waveform An oscilloscope-like display of a trace. Because analyzers only record whether a line is "low" or "high" at the time of sampling, the waveforms are sharp square waves rather than the rough curves of an oscilloscope. See also listing and trace.

Index

DECLARATION OF CONFORMITY

according to ISO/IEC Guide 22 and EN 45014

Manufacturer's Name: Hewlett-Packard Company

Manufacturer's Address: Colorado Springs Division
1900 Garden of the Gods Road
Colorado Springs, CO 80907 USA

declares, that the product

Product Name: Logic Analyzer

Model Number(s): HP 1670D, HP 1671D, and HP 1672D

Product Option(s): All

conforms to the following Product Specifications:

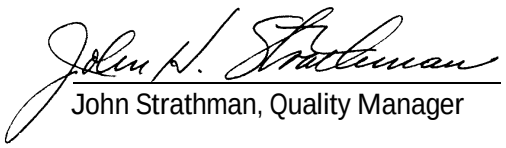
Safety:	IEC 348:1978 / HD 401 S1:1981	
	UL 1244	
	CSA-C22.2 No. 231 (Series M-89)	
EMC:	CISPR 11:1990 / EN 55011:1991	Group 1 Class A
	IEC 555-2:1982 + A1:1985 / EN 60555-2:1987	
	IEC 555-3:1982 + A1:1990 / EN 60555-3:1987 + A1:1991	
	IEC 801-2:1991 / EN 50082-1:1992	4 kV CD, 8 kV AD
	IEC 801-3:1984 / EN 50082-1:1992	3 V/m, {1kHz 80% AM, 27-1000 MHz}
	IEC 801-4:1988 / EN 50082-1:1992	0.5 kV Sig. Lines, 1 kV Power Lines

Supplementary Information:

The product herewith complies with the requirements of the Low Voltage Directive 73/23/EEC and the EMC Directive 89/336/EEC.

This product was tested in a typical configuration with Hewlett-Packard test systems.

Colorado Springs, 6/19/96



John Strathman, Quality Manager

European Contact: Your local Hewlett-Packard Sales and Service Office or Hewlett-Packard GmbH, Department ZQ / Standards Europe, Herrenberger Strasse 130, D-71034 Böblingen Germany (FAX: +49-7031-14-3143)

1 TTL logic threshold, all cables disconnected
2 The HP-IB, Printer, RS232, and LAN cables were temporarily attached for the appropriate EFT Test.

Sound Pressure Level

Less than 60 dBA

Document Warranty

The information contained in this document is subject to change without notice.

Hewlett-Packard makes no warranty of any kind with regard to this material, including, but not limited to, the implied warranties or merchantability and fitness for a particular purpose.

Hewlett-Packard shall not be liable for errors contained herein or for incidental or consequential damages in connection with the furnishing, performance, or use of this material.

Complete product warranty information is given on the last page of this guide.

Safety

This apparatus has been designed and tested in accordance with IEC Publication 348, Safety Requirements for Measuring Apparatus, and has been supplied in a safe condition. This is a Safety Class I instrument (provided with terminal for protective earthing). Before applying power, verify that the correct safety precautions are taken (see the following warnings). In addition, note the external markings on the instrument that are described under "Safety Symbols."

Warning

- Before turning on the instrument, you must connect the protective earth terminal of the instrument to the protective conductor of the (mains) power cord. The mains plug shall only be inserted in a socket outlet provided with a protective earth contact. You must not negate the protective action by using an extension cord (power cable) without a protective conductor (grounding). Grounding one conductor of a two-conductor outlet is not sufficient protection.
- Only fuses with the required rated current, voltage, and specified type (normal blow, time delay, etc.) should be used. Do not use repaired fuses or short-circuited fuseholders. To do so could cause a shock or fire hazard.
- Service instructions are for trained service personnel. To avoid dangerous electric shock, do not perform any service unless qualified to do so. Do not attempt internal service or adjustment unless another person, capable of rendering first aid and resuscitation, is present.
- If you energize this instrument by an auto transformer (for voltage reduction), make sure the common terminal is connected to the earth terminal of the power source.
- Whenever it is likely that the ground protection is impaired, you must make the instrument inoperative and secure it against any unintended operation.
- Do not operate the instrument in the presence of flammable gasses or fumes. Operation of any electrical instrument in such an environment constitutes a definite safety hazard.
- Do not install substitute parts or perform any unauthorized modification to the instrument.
- Capacitors inside the instrument may retain a charge even if the instrument is disconnected from its source of supply.
- Use caution when exposing or handling the CRT. Handling or replacing the CRT shall be done only by qualified maintenance personnel.

Safety Symbols

Instruction manual symbol: the product is marked with this symbol when it is necessary for you to refer to the instruction manual in order to protect against damage to the product.

Hazardous voltage symbol.

Earth terminal symbol: Used to indicate a circuit common connected to grounded chassis.

WARNING

The Warning sign denotes a hazard. It calls attention to a procedure, practice, or the like, which, if not correctly performed or adhered to, could result in personal injury. Do not proceed beyond a Warning sign until the indicated conditions are fully understood and met.

CAUTION

The Caution sign denotes a hazard. It calls attention to an operating procedure, practice, or the like, which, if not correctly performed or adhered to, could result in damage to or destruction of part or all of the product. Do not proceed beyond a Caution symbol until the indicated conditions are fully understood or met.

Hewlett-Packard
P.O. Box 2197
1900 Garden of the Gods Road
Colorado Springs, CO 80901

Product Warranty

This Hewlett-Packard product has a warranty against defects in material and workmanship for a period of one year from date of shipment. During the warranty period, Hewlett-Packard Company will, at its option, either repair or replace products that prove to be defective.

For warranty service or repair, this product must be returned to a service facility designated by Hewlett-Packard.

For products returned to Hewlett-Packard for warranty service, the Buyer shall prepay shipping charges to Hewlett-Packard and Hewlett-Packard shall pay shipping charges to return the product to the Buyer. However, the Buyer shall pay all shipping charges, duties, and taxes for products returned to Hewlett-Packard from another country.

Hewlett-Packard warrants that its software and firmware designated by Hewlett-Packard for use with an instrument will execute its programming instructions when properly installed on that instrument. Hewlett-Packard does not warrant that the operation of the instrument software, or firmware will be uninterrupted or error free.

Limitation of Warranty

The foregoing warranty shall not apply to defects resulting from improper or inadequate maintenance by the Buyer, Buyer-supplied software or interfacing, unauthorized modification or misuse, operation outside of the environmental specifications for the product, or improper site preparation or maintenance.

No other warranty is expressed or implied. Hewlett-Packard specifically disclaims the implied warranties or merchantability and fitness for a particular purpose.

Exclusive Remedies

The remedies provided herein are the buyer's sole and exclusive remedies. Hewlett-Packard shall not be liable for any direct, indirect, special, incidental, or consequential damages, whether based on contract, tort, or any other legal theory.

Assistance

Product maintenance agreements and other customer assistance agreements are available for Hewlett-Packard products.

For any assistance, contact your nearest Hewlett-Packard Sales Office.

Certification

Hewlett-Packard Company certifies that this product met its published specifications at the time of shipment from the factory. Hewlett-Packard further certifies that its calibration measurements are traceable to the United States National Institute of Standards and Technology, to the extent allowed by the Institute's calibration facility, and to the calibration facilities of other International Standards Organization members.

About this edition

This is the first edition of the *HP 1670D-Series Logic Analyzers User's Guide*

Publication number
01670-97004

Printed in USA.

Edition dates are as follows:

First edition, August 1996

New editions are complete revisions of the manual. Update packages, which are issued between editions, contain additional and replacement pages to be merged into the manual by you. The dates on the title page change only when a new edition is published.

A software or firmware code may be printed before the date. This code indicates the version level of the software or firmware of this product at the time the manual or update was issued. Many product updates do not require manual changes; and, conversely, manual corrections may be done without accompanying product changes. Therefore, do not expect a one-to-one correspondence between product updates and manual updates.

The following list of pages gives the date of the current edition and of any changed pages to that edition.

All pages original edition
