IBM

Release Notes
IBM Nways Multiprotocol Switched Services (MSS) Family
Client
Version 2.2

IBM Corporation
Part Number 31L3706, EC F53920
February 5, 1999

This document is for use with the IBM Nways Multiprotocol Switched Services (MSS) Client and the IBM MSS Domain Client. In this document, the term *MSS Family Client* is used to refer to both. Where there are differences between the two, they are uniquely identified.

The purpose of this document is to provide the reader with information that might not be in the documentation shipped with MSS Family Client. This document is not to be used as a replacement for that documentation, but as an addition which might add details that were not available at the time of that documentation's production. This document details restrictions, limitations, and procedures that might be needed to operate the MSS Family Client. It is strongly recommended that this document be read completely before the use of the MSS Family Client.

Chapter 1. Overview

MSS Family Client

The IBM MSS Family Client is a Universal Feature Card (UFC) that can be installed into several different models of the 8272, 8270, and some LAN switch features of the IBM 826X switch. It contains a 133-Mhz 603e Processor, 32 MB of memory, 1-MB LAN switch packet memory, and 8 MB of flash. The MSS Client also has a PCI-attached ATM Fiber Interface with 8 MB of packet memory that can be used for ATM or FasTR communication.

The MSS Domain Client is a UFC that provides for high-speed routing between domains on the LAN switch in Ethernet and Token-Ring LAN switches. Protocols that it supports are IP, IPX, Banyan Vines, and Appletalk routing. In the Token-Ring LAN switches, it also provides enhanced source route bridging support. The MSS Domain Client can enhance bridge performance by processing the All Route Explorer (ARE) and Spanning Tree Explorer (STE) packets using the MSS Domain Client's processor. This permits the LAN switch processor to be more available for use on layer 2 switching and management tasks. The enhanced bridging support also supports LAN Network Manager (LNM) agents, Virtual LANs (VLANs), and other Source Route Bridge (SRB) features not currently available on the Token-Ring LAN switch without the MSS Domain Client.

The MSS Client in a Token-Ring LAN switch provides all of the functions of the MSS Domain Client, plus additional ATM functions. It provides for enhanced routing to Classical IP over ATM, Next Hop Routing Protocol (NHRP), and Multiprotocol Over ATM (MPOA). Its bridging support is capable of bridging to Token-Ring Emulated LANs (ELANs) using a high-performance hardware path that allows steady-state packets to be bridged from the LAN switch Token-Ring interface to the ATM ELAN entirely in hardware. The MSS Client also supports FasTR for use in communicating to other FasTR devices that can be directly attached to the MSS Client.

Please see the *MSS Family Clients Interface Configuration and Software User's Guide* for more details on the functions available.

Attention!!!

The operational image and firmware that is preloaded on the MSS Family Client might not be latest available. Please check for fixes (PTFs) to the MSS Family Client operational code and firmware at **http://www.networking.ibm.com/netsupt**.

Chapter 2. General Information, Procedures, and Restrictions

Getting the Latest Information, Code and Fixes

You can get the latest MSS Family Client information, operational image, firmware, configuration program and fixes on the World Wide Web at the following URL:

```
http://www.networking.ibm.com/netsupt
```

From this URL, you can register for e-mail bulletins containing notification of code updates and the latest MSS Family Client information.

It is highly recommended that the user check this site prior to installation of the MSS Family Client into a user production network for later versions of software that might be available. The current level of the operational image can be determined by accessing the MSS Family Client console, entering **talk 5** and then **config**.

The following is an example of displaying the operational software version. The software version is highlighted.

```
          Please press the space bar once to obtain the console.
          Console granted to this interface.
          Please type "return" at the MOS Operator Control
          prompt (*) or enter Ctrl-b to exit console.

Publication Corrections

1. Support has been withdrawn for the HTML format help files that are used with the MSS Client Web Console. These files are accessed from links on the Web Pages presented by the MSS Family Client in response to HTML commands. The HTML format help files from previous releases will continue to work with the MSS Family Client. However, the content of those pages might be inaccurate, and links from Web Console pages for new function might be unresolved.

2. The parameter to set Persistent Data Direct VCC mode was omitted from chapter 23 of the *Interface Configuration and Software User's Guide*. When Persistent Data Direct VCC mode is enabled, if the LEC loses its connection to the LES/BUS, the LEC does not immediately drop any Data Direct VCCs. The LEC continues to try to reconnect to the LES/BUS. If the LEC cannot reconnect to the LES/BUS before the reconnect time-out expires, all data direct VCCs is disconnected. The default for Persistent Data Direct VCC mode is disabled.

3. The parameter to set Persistent Data Direct VCC Time-Out was omitted from chapter 23 of the *Interface Configuration and Software User's Guide*. When Persistent Data Direct VCC mode is enabled, if the LEC loses its connection to the LES/BUS, the

LEC does not immediately drop any Data Direct VCCs. The LEC continues to try to reconnect to the LES/BUS. If the LEC cannot reconnect to the LES/BUS before the reconnect time-out specified by this parameter expires, all data direct VCCs are disconnected. The default for Persistent Data Direct VCC Time-Out is 30 seconds.

4. In the *MSS Domain Client UFC Planning and Installation Guide* and the *MSS Client UFC Planning and Installation Guide* the **LED Indicators** section omits the following LED indication: **Yellow-On, Green-Blinking** indicates that the image is being saved to flash memory.

5. The ATM Port LED status indicators do not currently function as stated in the *MSS Client UFC Planning and Installation Guide*.

6. In chapter 1 of the *MSS Family Clients Interface Configuration and Software User's Guide*, under the **Multiple MSS Family Clients** section, it states the possible combinations of MSS Clients, MSS Domain Clients, and ATM UFCs. These combinations are valid only if the LAN switch that they are to be put in does not have slot restrictions concerning the physical placement of the adapters. For example, in the 8272 LAN Switch Module, FN 6308, the MSS Family Clients and ATM UFC are only supported in slots 2 and 4. If the MSS Client is placed in slot 2, it also occupies slot 4, since it is 2 slots wide. This prevents an MSS Domain Client or an ATM UFC from being placed in the 8272 LAN Switch Module when the MSS Client is inserted.

7. In chapter 17 of the *MSS Family Clients Interface Configuration and Software User's Guide*, the example shown for the **list lnm ports** does not accurately show the LNM settings. The following is a more accurate example:

```
ASRT>list lnm ports
Port 1
LNM Agents Enabled: RPS CRS REM
Reporting Link          State            LNM Station Address
     0                  AVAILABLE
     1                  AVAILABLE
     2                  AVAILABLE
     3                  AVAILABLE
MAC Addresses to use when configuring LNM Manager:
     00:04:AC:C4:02:40
     00:04:AC:C4:02:41
Port 2
LNM Agents Enabled: RPS CRS REM
Reporting Link          State            LNM Station Address
     0                  AVAILABLE
     1                  AVAILABLE
     2                  AVAILABLE
     3                  AVAILABLE
MAC Addresses to use when configuring LNM Manager:
     00:04:AC:C4:02:41
     00:04:AC:C4:02:40
```

MSS Family Client CD-ROM

The MSS Family Client CD-ROM contains all of the MSS Family Client publications and the Configuration Program. Please read the readme files that are on the CD for details about installing and accessing the MSS Family Client publications and the Configuration Program.

Please see Appendix A, "Backing Up the MSS Family Client Image" on page A-1 for instructions about creating the backup image.

LAN Switch Image Compatibility

Before installing the MSS Family Client into a LAN switch, it might be necessary to update the LAN switch with an image that supports the MSS Family Client. Depending on the LAN switch and the features that it contains, one or more files might need to be obtained from the **http://www.networking.ibm.com/netsupt** Web site. The minimum version of each image that can be used are listed. If later versions are available, they should be used instead of the listed versions.

8272 Model 216 & 8260 FC 6208/6308
Version 4.0

8270-800 TR LAN Switch
Version 4.0

Token-Ring Port Solo Code
Version: KS30
This code is included with the LAN switch images.

8271 8260 FC 6212 & 6312 Ethernet LAN Switch
Version 4.0

ATM UFC for 8270-800, 8272, 8271 LAN Switches
Version 1.14.0

Please read the associated documentation that is included with the LAN switch images. They contain important instructions, that if not followed, might prevent the MSS Family Client from functioning correctly. In particular, please follow the instructions on updating the boot code on the ATM UFC.

Configuration Program

The configuration program installation instructions are contained in the README file in the **config** subdirectory of the CD-ROM. Please read this information before installing the IBM MSS Client Configuration Program.

Default Configurations

The MSS Family Client is preloaded with default configurations that facilitate the use of the IBM MSS Client Configuration Program. In order to have the IBM MSS Client Configuration Program communicate through the network with the MSS Family Client, it is necessary to configure a workstation with compatible network parameters.

MSS Domain Client Default Configuration

The MSS Domain Client has two preloaded configurations. The first (the default) is for use in a Token-Ring LAN switch. The second is for use in an Ethernet LAN switch. If the MSS Domain Client is to be used in an Ethernet LAN switch, the active configuration of the MSS Client needs to be changed to the second configuration. Please see Appendix C, "Setting the Configuration to the Secondary Configuration" on page C-1 for details.

The default configurations for the MSS Domain Client have a Token-Ring or Ethernet interface preconfigured on domain 0 (default). The interface has an IP address of 10.1.1.5 with a subnet mask of 255.255.255.0. The default gateway is set to 10.1.1.1. SNMP is enabled to read/write for a community string "public". Three spare interfaces are also provided for the user, if dynamic reconfiguration is desired.

MSS Client Default Configuration

The MSS Client has two preloaded configurations. The first, and default, is for use in a Token-Ring LAN switch with the MSS Client to attach to an ATM network. The second is for use in a Token-Ring LAN switch with the MSS Client to be used for FasTR attachment. The MSS Client is not supported on Ethernet LAN switches. If the user wishes to use the MSS Client for FasTR attachment, the active configuration of the MSS Client needs to be changed to the second configuration. Please see Appendix C, "Setting the Configuration to the Secondary Configuration" on page C-1 for details.

The default configuration for the MSS Client has the same configuration as the MSS Domain Client, with several additions. If the MSS Client is to be used for ATM attachment, then there are two LAN Emulation Clients (LECs) predefined, one Token-Ring, and one Ethernet. Both are configured to obtain operating parameters from the LAN Emulation Configuration Server (LECS) using the well known ATM address. The policy to join is on media type. The Token-Ring LEC is preconfigured to use an IP address of 10.1.2.5 with a subnet of 255.255.255.0. The Ethernet LEC is preconfigured to use an IP address of 10.1.3.5 with a subnet mask of 255.255.255.0. If the MSS Client is to be used for FasTR, the FasTR interface is preconfigured with an IP address of 10.1.2.5 with a subnet mask of 255.255.255.0.

Updating the MSS Family Client Operational Image and Firmware

There are several methods for updating the MSS Family Client with newer versions of code.

Updating the MSS Family Client Using the Download UFC Option from the LAN Switch Console

Please see Appendix D, "Updating the MSS Family Client Images" on page D-1 for detailed instructions.

The advantages of this method are:

1. Both operational image and firmware can be updated.

2. Both TFTP and XMODEM are supported.

3. Relatively fast. Download of the operational image should take approximately three minutes through TFTP, with another minute to load the new image.

The disadvantage of this method is:

1. The MSS Family Client is reset and is be able to participate in the network operations until the update is complete.

Updating the Image While the MSS Family Client Is Operational

Please see the *MSS Family Clients Interface Configuration and Software User's Guide* for details on how to use this method.

The advantages of this method are:

1. The act of downloading the image is not destructive to the operation of the MSS Family Client in the network.

2. Using the TIMEDLOAD option, the MSS Family Client can be scheduled to be reloaded at a later time.

   For example: The user might wish to update the image at 4:00 PM, but schedule the system to reload at 2:00 AM where there is a maintenance window.

The disadvantages of this are:

1. TFTP is the only supported method of loading the image.

2. MSS Family Client firmware cannot be updated using this method.

3. Relatively slow. This method can take up to 16 minutes, during which the MSS Family Client is still operating. It is possible that during this time, the TFTP might encounter network problems that prevent the successful update.

Updating the Image Using the MSS Family Client Firmware

Please see the *MSS Family Clients Interface Configuration and Software User's Guide* for details on how to use this method.

The advantages of this method are:

1. Both operational image and firmware can be updated.

2. Allows for update of the firmware recovery block.

   Note: This should only be done if instructed to do so by IBM Service.

3. Relatively fast. Download of the operational image should take approximately two minutes through TFTP, with another minute to IPL the new image.

The disadvantages of this are:

1. TFTP is the only supported method of loading the image.

2. Interface accesses domain 0 (default) only.

3. The MSS Family Client is reset and is be able to participate in the network operations until the update is complete.

Chapter 3. Restrictions and Common Mistakes

Restrictions

1. The MSS Domain Client on Ethernet LAN switches can be used only for routing. No bridge functions are supported on Ethernet.

2. There are specific HW requirements for activating the SRB function (whether in the base 8270 or 8272, or within the MSS Client/Domain Client UFCs) CONCURRENTLY with the IBM ATM 155-Mbps MMF/Token-Ring UFC. These requirements are detailed in a technical tip documented on the 8270 or 8272 support pages on the Web:

   a. http://www.networking.ibm.com/support/8270

   b. http://www.networking.ibm.com/support/8272

   Your ATM UFC must be at a certain HW level to support source-route bridging function concurrently. The technical tip documents show how to determine whether your particular ATM UFC is at the correct HW level to support concurrent SRB as well as the procedures for remedying the situation if not.

3. If LAN Network Manager (LNM) support is to be used, only one Token-Ring physical port can be in a domain that is to be managed. A domain can contain more than one port and still be bridged, but an LNM agent cannot be initialized for that ring segment.

4. The MSS Family Client's LNM support requires the Token-Ring physical ports be at MPC 3.1. The ARI/FCI Bit Options setting must be set to "Always Set." Please see Appendix B, "Determining the Level of MPC Hardware and Setting the ARI/FCI Bit Options" on page B-1 about how to determine hardware levels and set the ARI/FCI Bit Options. Also, the LNM support works only on those Token-Ring physical ports which are operating in Half Duplex mode. Full Duplex mode is not supported.

5. LNM can not manage any Emulated LANs. This does not restrict the use of an ELAN to connect to the LNM Agent in the MSS Family Client. If LNM is configured on a domain that has an ATM UFC LEC interface, the agent might show it enabled on that segment, but querying status will report an error.

6. A maximum combination of 2 MSS Clients, MSS Domain Clients, or ATM UFCs can be installed in one LAN switch. If there are 2 MSS Clients or MSS Domain Clients in the LAN switch, only one can do the SRB function. This does not prevent a second MSS Client from being used for routing.

7. In the 8270-800, the MSS Family Client should be placed in a slot number lower than the Token-Ring UFCs. Please see the *MSS Client UFC Planning and Installation Guide*, or *MSS Domain Client UFC Planning and Installation Guide* for more detailed restrictions on other platforms.

8. IP-Host on the MSS Family Client is active only if no other IP interface has been configured on the MSS Family Client and bridging is enabled.

9. Although the MSS Family Client firmware is capable of accessing a network through the LAN switch, it is only able to communicate on the default domain (0).

10. The MSS Family Client has the ability to filter frames that are processed through software, but is not able to filter frames that are forwarded entirely by the hardware.

11. The MSS Family Client configuration tool and publications provide options and instructions for the configuration of IP Multicast Dynamic Protocol Filters (DPF) which are not currently available. This limitation will be addressed in a future PTF.

12. The MSS Family Client, when configured for SRB on a Token-Ring LAN switch, is responsible for processing of All Route Explorers and Spanning Tree Explorers for the LAN switch. Filters that might have been configured on the LAN switch for these frames are not active while the MSS Family Client is running.

13. The MSS Family Client, when configured for SRB on a Token-Ring LAN switch, might require the configuration of a internal segment number. This internal segment number is used for network management only. The internal segment is not added to the Routing Information Field (RIF) of frames that are passed through the bridge.

Common Mistakes

There are some common mistakes that might be encountered with the MSS Family Client configuration in the LAN switch.

1. **Configuring Bridging and a Routed Protocol on the same interface in the MSS Family Client when the subnet of the Routed Protocol spans across the bridge.**

   By configuring the routed protocol and SRB on the same interface, the MSS Family Client will filter the protocol traffic, and prevent it from being SR bridged. If the subnet of the routed protocol spans the SR bridge, communication within the subnet will not be reliable. This can be resolved by having two network interfaces in a domain or ELAN that is to be SR bridged. One interface should be configured for SRB (without the routed protocol) and the other interface should be configured for the routed protocol.

2. **Configuring the LAN Switch IP address to the same IP address of the MSS Family Client.**

   Although the MSS Family Client and the LAN switch functions are closely integrated, they both have separate IP interfaces into the network. If this error is made, one or both interfaces might not be able to communicate with the network.

3. **Configuring SRB only through LAN switch configuration options without configuring the MSS Family Client.**

   To use the MSS Family Client's SRB function, it must be first configured on the MSS Client. When the MSS Family Client SRB function becomes active, its configuration will take precedence over any previous LAN switch SRB Configuration.

4. **Using the ctrl-b key to exit a MSS Family Client console when in a telnet session.**

   A user can access the MSS Family Client's Console through the LAN switch console. If the user is accessing the LAN switch through the communication port located on the LAN switch, the **ctrl-b** key sequence, or the **return** command, can be used to exit the MSS Family Client's console and return to the LAN switch console.

   If a user telnets to the LAN switch, the **ctrl-b** key sequence will end the telnet session. When telneted to the LAN switch, if the user wishes to exit the MSS

Family Client's console, without terminating the telnet session, the **return** command should be used from the ***** prompt of the MSS Family Client.

5. **The MSS Family Client is configured for SRB in a LAN switch with an ATM UFC not at the proper HW level.**

   If this is the case, the MSS Family Client console will show the SRB function to be operational, but there will be no SRB options from the LAN switch console. Please see the restrictions for more details.

6. **Configuring IP-Host in the MSS Family Client when IP is already configured.**

   This problem will result in the IP-Host being configured, but the user will not be able to get into the HST submenu of the "talk 5" console. This can occur even if there is no IP address configured. The solution is to enter the "clear ip" command from the "talk 6" menu, write the configuration, and then reset. This will remove IP from the configuration and allow the IP-Host support to work.

7. **Configuring SRB on two interfaces in the same domain.**

   This results in one of the two interfaces being disabled. Because a domain can represent one and only one ring number, having two interfaces bridged on one domain is incorrect.

8. **Configuring two or more LAN Emulation Clients (LECs) on the same MSS Client, to the same Emulated LAN (ELAN) without specifying a locally administered MAC address on one of them.**

   The default MAC address of the LEC is the burned-in address of the ATM interface of the MSS Client. If two LECs attempt to join into an ELAN with the same MAC address, the ELAN will reject the registration. The solution is to assign a locally administered MAC address on all but the first LEC.

9. **Attempting to access the MSS Family Client console by telneting to the LAN switch, while a console to the MSS Client is active either from the LAN switch com port or other telnet session.**

   Only one session is permitted through the LAN switch to the MSS Family Client at a time.

10. **Attempting to place a port in a domain that is used for bridging to a MSS Client LEC or a FasTR interface.**

    The MSS Client supports SRB to LECs and the FasTR interface. It does NOT support transparent bridging to these interfaces. The MSS Client obtains a domain for each bridged FasTR or each bridged LEC. Domains will be reserved starting from the maximum domain index (15) to the lowest domain index (0). Once these domains have been allocated, they cannot be used by other ports. This does not apply to LECs or FasTR interfaces that are not being bridged.

    Example: The MSS Client is configured for 3 bridged LECs, 2 routed LECs, and two Token-Ring interfaces on domain 0, one bridged, one routed.

    The three bridged LECs will reserve domain indexes 15, 14, and 13. The Token-Ring interfaces will be a member of domain 0, which can have other ports as members. The routed LECs are not associated with any domains.

11. **Attempting to configure more than one physical port in a domain that is to be managed by LNM.**

    Although the bridging function will continue to work, LNM will not be able to manage the ring. If a domain is currently being managed by LNM and the domain

configuration is changed, then the MSS Family Client should be reset. Failure to do so can cause LNM information to be unreliable.

12. **Attempting to use the MSS Server Configuration Program to configure an MSS Family Client.**

    The MSS Family Client must be configured using its version of the IBM MSS Client Configuration Program that is included on the CD or obtained from the Web. It is not compatible with the MSS Server version of the configuration program.

13. **Attempting to use SNMP to manage the LAN switch and the MSS Family Client without enabling SNMP on both the LAN switch and the MSS Family Client.**

    The LAN switch and the MSS Family Client have separate SNMP agents. In order to manage the combined functions of the LAN switch and the MSS Family Client, both agents must be configured.

Chapter 4. Hints/Recommendations

In order to take full advantage of the Source Route Bridge function of the MSS Family Client, specific configuration changes in the LAN switch are strongly recommended. These settings will reduce the processing load on the LAN switch CPU.

1. Configure the LAN switch IP interface in **only** one Source Route Bridge domain.

   LAN switch IP interfaces on each bridged domain are no longer required because the MSS Family Client SR Bridge function allows communication with a LAN switch IP interface from any domain in the SR bridge.

2. Set the **IP State** to **IP Disabled** for domains that are not needed for IP communication. (This is not the default setting.)

   This will prevent unnecessary traffic from flooding the LAN switch CPU.

Appendix A. Backing Up the MSS Family Client Image

Make sure that there exists a workstation that has a TFTP daemon running that the MSS Family Client can communicate with. At the MSS Family Client console, do the following:

1. At the * prompt, type **talk 6**.

2. At the Config> prompt, type **boot**.

3. At the Boot config> prompt, type **tftp put load**.

Answer the questions to specify the server address, remote path and file name that the image is to be copied to, and the bank to copy from.

The following example shows the dialog when using this procedure to back up the MSS Family Client image.

```
*talk 6
Gateway user configuration
Config>boot
Boot configuration
Boot config>tftp put load
+------ BankF -----------+--------- Description ----------+------ Date -------+
| IMAGE - ACTIVE         |                                | 23 Mar 1998 17:09 |
| CONFIG 1 - ACTIVE  *   |  MSS Client ATM Config         | 01 May 1998 16:44 |
| CONFIG 2 - AVAL        |  MSS Client FasTR Config       | 01 May 1998 16:44 |
| CONFIG 3 - NONE        |                                |                   |
| CONFIG 4 - NONE        |                                |                   |
+-----------------------+--------------------------------+-------------------+
   * - Last Used Config      L - Config File is Locked
Specify the server IP address (dotted decimal): : [1.2.3.4] 10.1.1.1
Specify the remote file name: : (load.img) /local/MSSC21/msscopcd.ufc
Select the source bank:  (F): [F]
TFTP SW load image
  put:   /local/MSSC21/msscopcd.ufc
  to:  10.1.1.1
  from:    bank F.
TFTP transfer complete, status: OK

Operation completed successfully.
Config>
```

Appendix B. Determining the Level of MPC Hardware and Setting the ARI/FCI Bit Options

The MPC chips used on the Token-Ring ports must be at a certain level for the MSS Family Client LNM function to work. To check the level, do the following:

1. From the LAN switch console **Main Menu**, select **Configuration...**.

2. From the **Configuration Menu**, select **Token-Ring Port Configuration...**.

3. From **Token-Ring Port Configuration** menu, enter **<Ctrl-f>**.

On the **ARI/FCI Bit Options** screen, the user should see the level of the MPC hardware, as well as the current setting. The user should modify the ARI/FCI Bit Options setting if they are not set to "Always set".

The following panels show an example of the dialog when following this procedure. The selections are in bold.

```
                        Main Menu

                Configuration...

                Status/Statistics...

                Reset/Diagnostics...

                Non-Token-Ring Ports Menu...

                Download...

    Exit
```

```
                    Configuration Menu

  Switch Information...                    TokenPipe...

  Domain Configuration...                  MAC Filter & Port Security...

  IP Configuration...                      Address Aging...

  SNMP Configuration...                    Switching Mode Threshold...

  Spanning Tree...                         Password...

  Token-Ring Port Configuration...         Console Configuration...

  TokenProbe Configuration...              Source Route Configuration...

  Return

Appendix C. Setting the Configuration to the Secondary Configuration

At the MSS Family Client console, do the following:

1. At the ∗ prompt, type **talk 6**.

2. At the `Config>` prompt, type **boot**.

3. At the `Boot config>` prompt, type **set**.

4. When prompted for `source bank`, press **Enter** which will accept the default of **F**.

5. When prompted for `source configuration`, type **2**.

6. When prompted for `duration`, press **Enter**, which will accept the default of **always**.

7. Reset the MSS Family Client.

The following example shows the dialog when using this procedure to setup the MSS Family Client to use the secondary configuration.

```
*talk 6
Gateway user configuration
Config>boot
Boot configuration
Boot config>set
+------ BankF ----------+--------- Description ----------+------ Date -------+
| IMAGE - ACTIVE        |                                | 23 Mar 1998 17:09 |
| CONFIG 1 - ACTIVE  *  | MSS Client ATM Config          | 01 May 1998 16:44 |
| CONFIG 2 - AVAL       | MSS Client FasTR Config        | 01 May 1998 16:44 |
| CONFIG 3 - NONE       |                                |                   |
| CONFIG 4 - NONE       |                                |                   |
+----------------------+--------------------------------+-------------------+
   * - Last Used Config    L - Config File is Locked

Select the source bank:  (F): [F]
Select the source configuration:  (1, 2, 3, 4): [1] 2
Select the duration to use for booting:  (once, always): [always]
Set SW to boot using bank F and configuration 2, always.

Operation completed successfully.
Boot config>
```

Appendix D. Updating the MSS Family Client Images

Before this procedure is attempted, the LAN switch should have its IP configured and enabled in the domain to be used.

1. From the LAN switch console **Main Menu**, select **Download...**.

2. From the **Download** panel, select **TFTP Download...**.

   Note: It is highly recommended that the TFTP option be used if possible. The MSS Family Client's operational image for release 2.1 is almost 5 MB, and as a result will take a long time to download at serial port speeds.

3. From the **TFTP Download** menu, select **Download Image**. When prompted, select **UFC Image**.

4. The LAN switch will then present a menu of all possible UFCs that are available for downloading. Select the one which needs to be updated. If the user presses the escape key from this menu, no UFCs will be selected, and the menu will exit.

5. Once you have selected the UFC you wish to download, the LAN switch will reset the card and bring it to its download state. This will stop the MSS Family Client from running in the network.

6. When prompted please select the server IP address, domain, and path and filename to be used to get the MSS Family Client's operational image or firmware. When these settings are made, select **Execute Network Download**.

7. Once the download is complete, the MSS Family Client will store the image to the flash of the MSS Family Client.

8. To activate the image just downloaded, the MSS Family Client will need to be reset.

The following panels show an example of the dialog when following this procedure. The user options are in bold.

```
                            Main Menu

                    Configuration...

                    Status/Statistics...

                    Reset/Diagnostics...

Appendix E. Setting Up a Token-Ring LAN Switch to Dump the MSS Family Client

The dumping of the MSS Family Client can be useful in situations where IBM service needs to debug a problem. The dumping of an MSS Family Client should only be done if it has been requested by service personnel. It will require a workstation that is reachable from the LAN switch if the MSS Family Client is not operational, has a TFTP daemon running, and has at least 40 MB of free space.

Before this procedure is attempted, the LAN switch should have its IP configured and enabled in the domain to be used.

The MSS Family Client in a Token-Ring LAN switch can be enabled to initiate a dump on a fatal error. After a fatal error in which the MSS Family Client dumps its memory, the MSS Family Client will be reset so that it can resume normal operations. The MSS Family Client can also be manually dumped if the automatic method was not successful.

To enable the MSS Family Client for dumping automatically, follow these steps:

 1. At the * prompt on the MSS Family Client console, type **talk 6**.

 2. At the Config> prompt, type **enable reboot-system** and **enable dump-memory**.

 3. Now the LAN switch needs to be set up to TFTP the dump files to a file server on the LAN. At the login screen of the LAN switch, where prompted for password enter **diag**. At the **Diagnostics Menu** select **Miscellaneous...**.

 4. At **TFTP Upload** menu set the server IP address, domain, and path to be used to hold the MSS Family Client's dump. After these settings are made, select the **Return** option. These settings will be used when a MSS Family Client initiates a dump.

If the MSS Family Client is not operating, and a console cannot be established, the user can select the **Execute Network Upload** option to initiate the dumping of the MSS Family Client. The user must set the file name first for the dump to take place. The file name must be in the following format: ufcXY, where X is the slot number, and Y is the dump image number. The MSS Family Client has 3 dump files, so if the card was in slot one, the file names would be "ufc11", "ufc12", and "ufc13".
