

X.21 Monitoring for Fault Localization

By Paul Blakemore

2843 Digital Communications Analyzer

X.21 is a much used means of data transmission for subscribers to carry data across national networks. X.21 also defines test loops which can be invoked automatically on NTUs (Network Termination Units) from the customer terminal equipment to enable local and remote sections of the connection to be tested.

Occasionally spurious loops can appear on NTUs which disrupt customer data. By monitoring the link between the customer terminal equipment and the NTU it is often possible to isolate the cause of the problem to the customer equipment or the network equipment (NTU).

End-to-End Communication between Local and Remote Terminals

Local Loopback Invoked at NTU by Local Terminal

Remote Loopback Invoked at NTU by Local Terminal

LOOP REQUESTS

Lines Involved in X.21 Loop Protocol

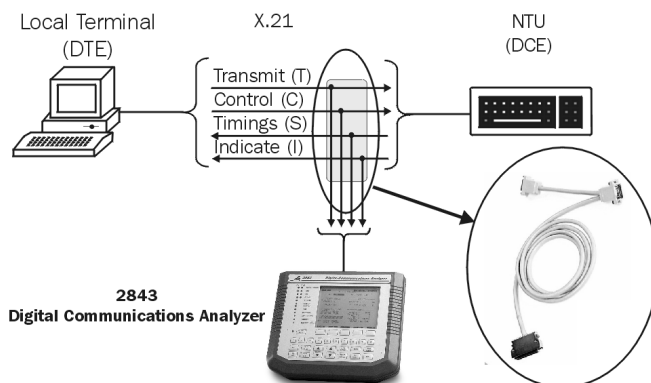

The normal state for the C and I lines is ON (1).
Local Loop command (request) is 11110000.....
Remote Loop command (request) is 1100.....

The DTE (Data Terminal or Termination Equipment) requests a local or remote loop from the DCE (Data Communication Equipment) by transmitting a repeating pattern on the **T** line, at the same time holding the **C** line OFF. The DCE responds by invoking a local or remote loop as appropriate, which causes the looping pattern to be received by the DTE on the **R** line. The DCE also Sets the **I** line OFF to acknowledge the loop. The **C** and **I** lines are now returned to

ON during the loop test phase, following which a loop clear request is made by the DTE setting the **C** line to OFF, which causes the DCE to remove the loop.

X.21 MONITORING

Lines Monitored

The X.21 line is monitored by using a monitor cable which allows all the X.21 lines to pass transparently between the DTE and DCE. The lines monitored are Transmit (T), Control (C), Indicate (I) and Timing (S), the first three of which are involved in the X.21 loop protocol. The Timing line is monitored to allow the data on the Transmit line to be clocked into the 2843 and lack of a clock signal will cause a line alarm.

X.21 Monitor Page

Select 1 to detect loop words on T line when c = 0.
Select 2 to detect loop words on T line when c = 1 or 0.

Control lines display as 1 (ON) or 0 (OFF), or X when HISTORY key pressed if change of status since start of test or since history reset.

Displays as 1 in presence of local or remote loop commands on T line, or X when HISTORY key pressed if change of status since start of test or since history reset.

TX ON
TEST OFF

Detect looping requests when C = 0 : 1
Detect looping requests when C = 0 or 1 : 2

Control

C = 1 I = 1

Loopback

Remote = 0
Local = 0

(1 = Loopback Condition)

< Use HISTORY key to review history >

If spurious loops have been appearing on an NTU then monitoring the link between the terminal and the NTU can isolate the problem.

Detect Loop Commands When C = 0

This is the normal selection since the terminal always sets **C** to 0 (OFF) when requesting a loop from the NTU. If a loop does appear on the NTU and the terminal has requested it, then with the HISTORY key pressed **C** will display X and either REMOTE LOOP or LOCAL LOOP will display X. Also I will display X to show that the NTU has acknowledged the loop. If the display remains unchanged then it is not the terminal that has requested the loop.

Detect Loop Commands When C = 0 or 1

This selection would be used if it were suspected that the NTU is setting a loop in response to loop commands appearing in the data when **C** is set to 1 (ON). If a loop does appear and **C** has remained unchanged, but either REMOTE LOOP or LOCAL LOOP display X with the HISTORY key pressed, this indicates that the NTU is functioning incorrectly. If a loop appears, **C** remains unchanged and neither REMOTE LOOP nor LOCAL LOOP display X with the HISTORY key pressed, then a malfunction of the NTU that does not involve interaction between it and the connected terminal is indicated.

Conclusion

The X.21 monitoring capability in 2843 is a powerful tool for isolating automatic looping problems between terminals and network equipment.
