# SECTION 4 CIRCUIT DESCRIPTION

## 4-1 RECEIVER CIRCUITS

### 4-1-1 RF ATTENUATOR CIRCUIT (RF UNIT)

The attenuator circuit attenuates the signal strength to approx. 20 dB to protect the RF amplifier from distortion when excessively strong signals are received.

The RF signals from the antenna connector are passed through or bypass the "L" type attenuator (R1, R3). The signals are then applied to the RF filter circuit.

### 4-1-2 RF FILTER CIRCUIT (RF UNIT)

The applied signals pass through either the low-pass filter or the high-pass filter circuits via the band switching diodes.

#### • RF signals below 50 MHz

The RF signals below 50 MHz are passed through the low-pass filter (L1, L2, C7–C11) via the band switching diode (D2). The filtered signals are applied to the HF RF circuit.

#### • RF signals above 50 MHz

The RF signals above 50 MHz are applied to the high-pass filter (L172, C651, C652) after passing through the band switching diode (D84). The filtered signals are then applied to the VHF/UHF RF circuit.

### 4-1-3 HF RF CIRCUIT (RF UNIT)

The HF RF circuit amplifies the received signals within the range 0.01–50 MHz and filters out-of-band signals.

The HF RF circuit consists of three low-pass filters, three high-pass filters and one RF amplifier.

The filtered signals below 1.8 MHz from the RF filter circuit are passed through the low-pass filter (L3, L4, C14–C16) between the band switching diodes (D6, D36), and are then applied to the 1st mixer circuit (IC4).

The 1.8–14.999999 MHz signals pass through the low-pass filter (L6, L7, C21–C25) and high-pass filter (L8, L9, C26–C30) between the band switching diodes (D3, D7), and are then applied to the 1st mixer circuit after being amplified at the RF amplifier (Q12).

The 15–29.999999 MHz signals pass through the low-pass filter (L10, L11, C33–C37) and high-pass filter (L11, L12, C38–C42) between the band switching diodes (D3, D7), and are then applied to the 1st mixer circuit via the RF amplifier circuit (Q12).

The 30–49.999999 MHz signals pass through the high-pass filter (L14, L15, C45–C49) between the band switching diodes (D8, D5), and are then applied to the 1st mixer circuit via the RF amplifier circuit (Q12).

#### • Filters

Receive freq. (MHz)	SW diode	Filter select signal	Components
0.01–1.799999	D6, D36	B0	L3–L5, C14–C17
1.8–14.999999	D3, D7	B1	L6–L9, C21–C30
15.0–29.999999	D3, D7	B2	L10–L13, C33–C42
30.0–49.999999	D8, D5	B3	L14, L15, C45–C49

### 4-1-4 VHF/UHF RF CIRCUIT (RF UNIT)

The VHF/UHF RF circuit amplifies the received signals within the range 50–1300 MHz and filters out-of-band signals.

The VHF/UHF RF circuit consists of 4 bands of filter circuits with an RF amplifier for each.

The 50–149.999999 MHz signals from the RF filter pass through high-pass filter (D11, L17, C53–C55, D12, D82, D83, L18, C57) via the band switching diode (D10), and are then amplified at the RF amplifier (Q8) between the tunable bandpass filters (D13, D80, L19–L21, D14, D81, L23–L25). The filtered signals are applied to the 1st mixer circuit (IC4) via the band switching diode (D15).

For improving the characteristic of the bandpass filter circuit, the shift switch (Q84) shifts the cut off frequency of the high-pass filter (D12, D82, D83, L18, C57). The shift switch (Q84) is controlled by the VCO 1 signal from the DDS IC (IC18).

#### • RF filter and amplifier circuits

The 150–349.999999 MHz signals from the band switching diode (D16) pass through the high-pass filter (L27–L29, C69–C74) and tunable bandpass filter (D18, L31–L33), and are then amplified at the RF amplifier (Q9) and pass through another tunable bandpass filter (D19, L35–L37). The filtered signals are applied to the 1st mixer circuit (IC4) via the band switching diode (D20).

The 350–699.999999 MHz signals from the band switching diode (D21) pass through the high-pass filter (L40, C92–C94, C619) and tunable bandpass filter (D23, D76, L41, L42). The filtered signals are then amplified at the RF amplifier (Q10) and pass through the tunable bandpass filters (D24, D77, L45–L47). The filtered signals are applied to the 1st mixer circuit (IC4) via the band switching diode (D25).

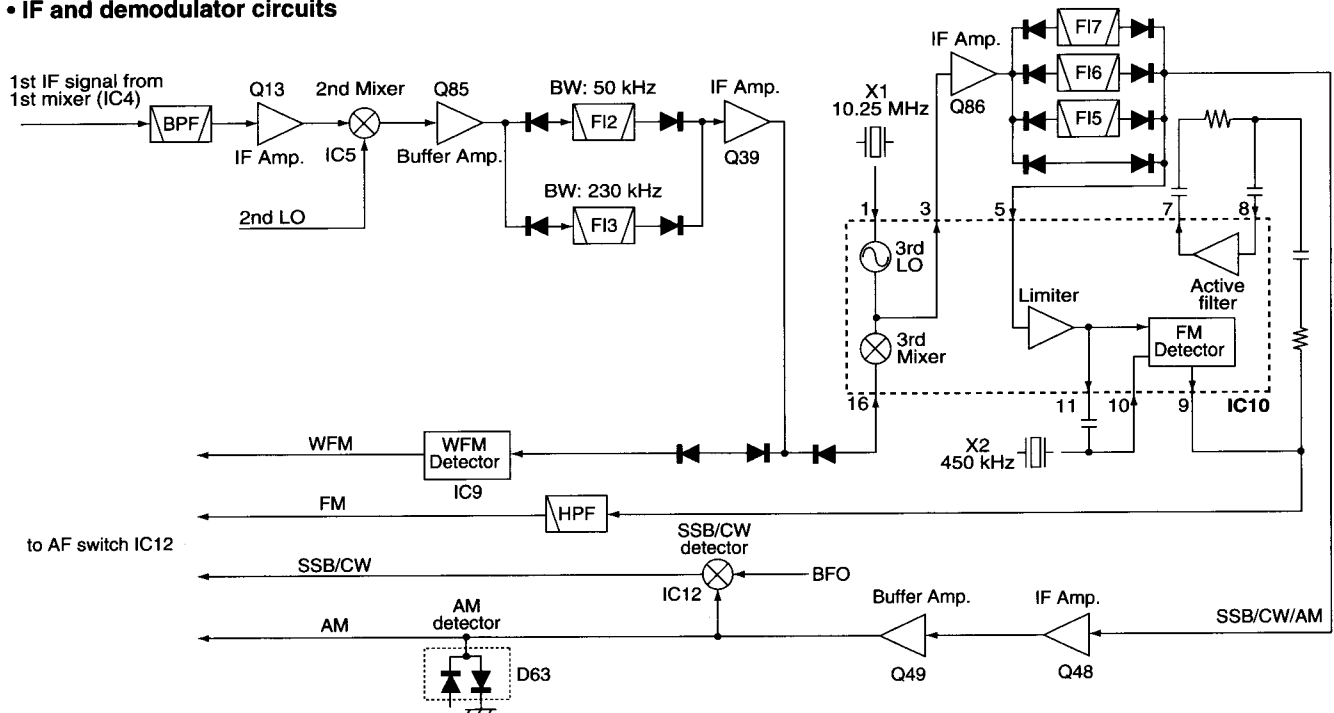

The 700–1300 MHz signals from the band switching diode (D26) pass through the high-pass filter (L141, C110, C606) and 2-stage tunable bandpass filters (D78, D79, L163, D29, D30, L51–L53). The filtered signals are then amplified at the RF amplifier (Q11) and pass through the tunable bandpass filters (D31, D32, L55, L56). The filtered signals are applied to the 1st mixer circuit (IC4) via the band switching diode (D33).

The tunable bandpass filters employ varactor diodes to tune the center frequency of the RF passband for wide bandwidth receiving and good image response rejection. These diodes are controlled by TUNV signal from the CPU (LOGIC unit; IC1, pin 37) via the tune controller (LOGIC unit; IC11b).

• IF and demodulator circuits

4-1-5 1ST MIXER CIRCUIT (RF UNIT)

The 1st mixer circuit converts the received RF signals to a fixed frequency of the 1st IF signal with a PLL output frequency. By changing the PLL frequency, only the desired frequency will pass through the bandpass filters at the next stage of the 1st mixer.

The filtered RF signals are mixed with 1st LO signals at the 1st mixer circuit (IC4) to produce a 266.7 MHz 1st IF signal. The 1st IF signal is output from pin 5, and passed through the bandpass filter (F11) to suppress unwanted harmonic components. The filtered 1st IF signal is applied to the IF circuit.

The 1st LO signals are generated at the VCO-1 (Q14, Q15) or VCO-2 (Q18, Q19) circuit (according to the receiving frequency band) and are amplified at the buffer amplifier (IC26). The amplified signals are then applied to the 1st mixer (IC4, pin 2) directly or passed through the divider circuit (IC6).

4-1-6 1ST IF AND 2ND MIXER CIRCUITS (RF UNIT)

The 2nd mixer circuit converts the 1st IF signal to a 2nd IF signal.

The filtered 266.7 MHz 1st IF signal from the bandpass filter (F11) is amplified at the 1st IF amplifier (Q13) then mixed with the 2nd LO signal at the 2nd mixer circuit (IC5) to produce a 10.7 MHz 2nd IF signal. The 2nd IF signal is passed through one of 2 bandpass filters (F12 or F13; depending on the selected mode and bandwidth) after being amplified at the IF amplifier (Q85). The filtered 2nd IF signal is amplified at the buffer amplifier (Q39), then applied to the WFM demodulator or 3rd IF circuit.

4-1-7 3RD MIXER CIRCUIT (RF UNIT)

The 3rd mixer circuit mixes the 2nd IF signal and 3rd LO signal to produce a 450 kHz 3rd IF signal (except WFM mode).

The 10.7 MHz 2nd IF signal from the buffer amplifier (Q39) is applied to the 3rd mixer section in the FM IF IC (IC10, pin 16). The applied signal is mixed with a 3rd LO signal generated by X1 (10.25 MHz) to produce a 450 kHz 3rd IF signal.

The 3rd IF signal is output from pin 3, and passed through one of 3 bandpass filters (F15, F16 or F17) or bypassed, according to the selected mode and bandwidth after being amplified at the IF amplifier (Q86). The filtered or bypassed signal is applied to the each demodulator circuit (except WFM mode).

• **Bandpass filter selection**

Modes	Bandpass filter	Passband width
AM, SSB, CW	F15	2.8 kHz
FM, AM, SSB, CW	F16	6 kHz
FM, AM	F17	15 kHz

**4-1-8 DEMODULATOR CIRCUITS (RF UNIT)**

The demodulator circuit converts the 2nd IF signal into AF signals. 4 separate demodulator circuits are employed for each mode.

**(1) WFM mode**

The 10.7 MHz 2nd IF signal from the buffer amplifier (Q39) is applied to the WFM demodulator circuit (IC9, pin 2).

The applied IF signal is amplified at the IF amplifier section in the IC9 and then output from pin 10. The output signal is applied to the quadrature detector section (pin 11) to demodulate AF signals. The demodulated AF signals are applied to the AF switch circuit via the de-emphasis circuit (R179, C285).

**(2) FM mode**

The filtered or bypassed 3rd IF signal is applied to the quadrature detector section in the FM IF IC (IC10, pin 10) then mixed with the signal generated by the discriminator (X2) to demodulate AF signals. The AF signals are output from pin 9 and applied to the AF switch circuit via the high-pass filter circuit (IC11).

**(3) AM mode**

The filtered 3rd IF signal from the one of 3 bandpass filters (F15, F16 or F17) is amplified at the IF and buffer amplifiers (Q48, Q49). The amplified IF signal is applied to the AM detector circuit (D63) to be converted into AF signals, and the AF signals are applied to the AF switch circuit.

**(4) SSB and CW modes**

The amplified 3rd IF signal from the buffer amplifier (Q49) is applied to the mixer circuit (IC12, pin 6) and mixed with the BFO signal generated by the BFO circuit for demodulation. The demodulated AF signals are applied to the AF switch circuit.

**4-1-9 AF SWITCH CIRCUIT (RF UNIT)**

The demodulated AF signals from the demodulator circuits are applied to the AF switch (IC14). This consists of 4 analog switches which are selected with a mode signal from the CPU (LOGIC unit; IC1) via the I/O expander (IC3). The switched AF signals are applied to the AF circuit.

**4-1-10 AF CIRCUIT (RF AND LOGIC UNITS)**

The switched AF signals from the AF switch circuit are amplified at the AF amplifier circuit (RF unit; Q56) and then applied to the LOGIC unit.

The AF signals from the RF unit are applied to the electronic volume control circuit (LOGIC unit; IC9a, pin 1). The level controlled AF signals are output from pin 2 and applied to the AF power amplifier (LOGIC unit; IC10, pin 4). The power amplified AF signals are passed through the AF level control switch (LOGIC unit; S1) then applied to the internal speaker via the [EXT SP] jack.

The electronic volume control circuit controls AF gain, therefore, the AF output level varies according to the [VOL] setting and also the squelch conditions.

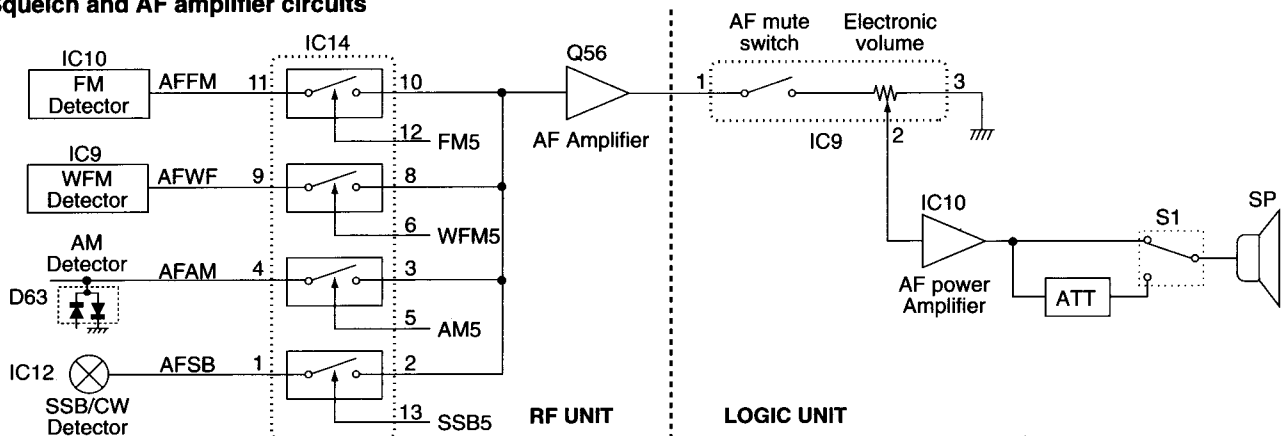

**4-1-11 SQUELCH CIRCUIT (RF AND LOGIC UNITS)**

A squelch circuit cuts out AF signals when no RF signal is received or when the S-meter signal is lower than the [SQUELCH] control setting level. By detecting noise components in the AF signals, the CPU controls the electronic volume control circuit.

• **NOISE SQUELCH**

Some noise components in the AF signals from pin 9 of the FM IF IC (IC10) are applied to the noise amplifier section in the IC (IC10, pin 8). The amplified signals are output from pin 7, and applied to the electronic volume control circuit (LOGIC unit; IC9b, pin 8) and level controlled noise components are output from pin 7. The output signals are applied to the noise amplifiers (LOGIC unit; Q6, Q7) to be converted into pulse-type signals, then applied to the CPU (LOGIC unit; IC1, pin 39) as an NOIN signal.

• **Squelch and AF amplifier circuits**

#### • S-METER SQUELCH

The S-meter signal is applied to the CPU from the meter amplifier circuit (RF unit; IC13a) via the SMAD line, and also the S-meter squelch setting level is applied to the CPU. The CPU compares these signals, then outputs a control signal to the electronic volume control circuit (RF unit; IC9a) to cut out AF signals.

#### 4-1-12 NOISE BLANKER CIRCUIT (RF UNIT)

The noise blanker circuit detects pulse-type noise, and stops IF amplifier operation during detection. The noise blanker function activates only when SSB, CW or AM mode is selected.

A portion of the filtered 2nd IF signal from one of 2 bandpass filters (FI2 or FI3) is amplified at the NB amplifier (Q41) then applied to the WFM IF IC (IC9, pin 2). The applied signal is amplified at the IF amplifier section in the IC, then output from pin 10. The output signal is rectified at the NB detector circuit (D53) to be converted into DC voltage after being amplified at the noise amplifier (Q35). The DC voltage is applied to the NB gate control circuit (Q37, Q38) to control the NB gate (Q40).

Some DC voltage is fed back to the IF amplifier section in the WFM IF IC (IC9, pin 3). The IF amplifier functions as an AGC circuit to reduce average noise. Therefore, the noise blanker function shuts off pulse-type noise only.

#### 4-1-13 AGC CIRCUIT (RF UNIT)

The AGC (Auto Gain Control) circuit reduces IF amplifier gain to keep the audio output at a constant level.

An RSSI signal is used for AGC function from the WFM IF IC (IC9, pin 17) while in WFM mode, or used from the FM IF IC (IC10, pin 12) while in FM, AM, SSB or CW (except WFM) mode.

The RSSI output signal is applied to the IF amplifiers (Q13, Q39) after being amplified at the AGC amplifier (Q33) during WFM operation. In other modes, the RSSI signal is amplified at the AGC amplifier (Q51), passes through the time constant circuit (Q52, Q53, R284, R290, R291, C371–C373) and is then applied to the IF amplifiers (Q13, Q39). The AGC control signal is applied to the VHF/UHF tunable bandpass filters after being amplified at the VHF/UHF AGC amplifier (IC13b).

AGC speed is controlled by changing the time constant at the AGC control line with resistors (R284, R290, R291) and capacitors (C371–C373). R290 and C372 are used for AGC slow, and R284 and C371 are used for AGC fast mode's time constant. However, R291 and C373 are connected to the AGC control line while scanning to obtain the fastest AGC response.

#### 4-1-14 VSC CIRCUIT (LOGIC UNIT)

The VSC (Voice Scan Control) detects AF signals and mutes undesired signals such as unmodulated, beat and noise component signals. When the VSC function is ON and an unmodulated signal is received, squelch functions the same as closed (no signal condition) even when it's open, or the scan function resumes for a short period on any scan setting during scanning.

A portion of the AF signals from the AF amplifier (RF unit; Q56) is applied to the VSC control circuit (IC15, pin 16) to detect demodulated signals while the VSC function is ON. When audio (voice) component signals are included in the AF signals, the VSC IC (IC15) outputs a low level signal from pin 13 to the CPU (IC1, pin 45) to release the mute switch (IC9).

#### 4-1-15 S-METER CIRCUIT (RF UNIT)

The S-meter circuit indicates the relative received signal strength while receiving and changes depending on the received signal strength.

A portion of the AGC signal is applied to the meter amplifier circuit (IC13a). The amplified signal is then applied to the CPU (LOGIC unit; IC1, pins 31) as an SMAD signal to drive the S-meter.

The SMAD signal is also used for noise and S-meter squelch operation by comparison with the [SQUELCH] control setting level and received signal strength at the CPU.

### 4-2 PLL CIRCUITS

#### 4-2-1 1ST LO PLL CIRCUIT (RF UNIT)

The 1st LO circuit generates the 1st LO frequencies, and the signals are applied to the 1st mixer circuit. The 1st LO circuit consists of a VCO-1/2 circuit and PLL IC, etc.

The generated signal from VCO-1 (Q14, Q15) or VCO-2 (Q18, Q19) is applied to the prescaler section in the PLL IC (IC7, pin 11) after being amplified at the buffer amplifiers (IC26, Q27). The applied signal is prescaled in the PLL IC based on the divided ratio (N-data) to produce approx. 50 kHz signals which are applied to the phase detector section.

The generated reference signal from the reference oscillator (X1; 10.25 MHz) is amplified at the buffer amplifiers (Q22, Q42) and is applied to the programmable divider section in the PLL IC (IC7, pin 20). The applied signal is prescaled in the PLL IC based on the divided ratio (1/205) to produce approx. 50 kHz phase signals. The reference phase signals are applied to the phase detector section.

The phase detector section compares 2 of the applied phase signals. The phase detected signals are passed through the charge pump section and then output from pin 6 of the PLL IC. The output signals are applied to the loop filter circuit (Q25, Q26) to be converted into DC voltage as a PLL lock voltage. The lock voltage is applied to the CPU (LOGIC unit; IC1, pin 33) as an L1AD signal to control the VHF/UHF tunable bandpass filter.

#### 4-2-2 2ND LO PLL CIRCUIT (RF UNIT)

The 2nd LO circuit generates the 2nd LO frequencies, and the signals are applied to the 2nd mixer circuit. The 2nd LO circuit consists of a DDS, VCO-3 and loop filter circuit, etc.

The generated signal from VCO-3 (Q76) is divided by 8 at the divider circuit (IC23) after being amplified at the buffer amplifier (Q77). The divided signal is then amplified at IC28, and applied to the DDS circuit (IC18). The DDS circuit generates digital signals using the applied signal as a clock frequency. The phase detector section in the DDS IC compares

its phase with the divided reference frequency (3.41 MHz) which is generated at the reference oscillator (X1).

The D/A converter (R351–R374), bandpass filter (L117, L118, L175, C496–C503) and buffer amplifier (IC19) circuits are connected to the DDS output to convert the digital oscillated signals into smooth analog signals.

**4-2-3 BFO CIRCUIT (RF UNIT)**

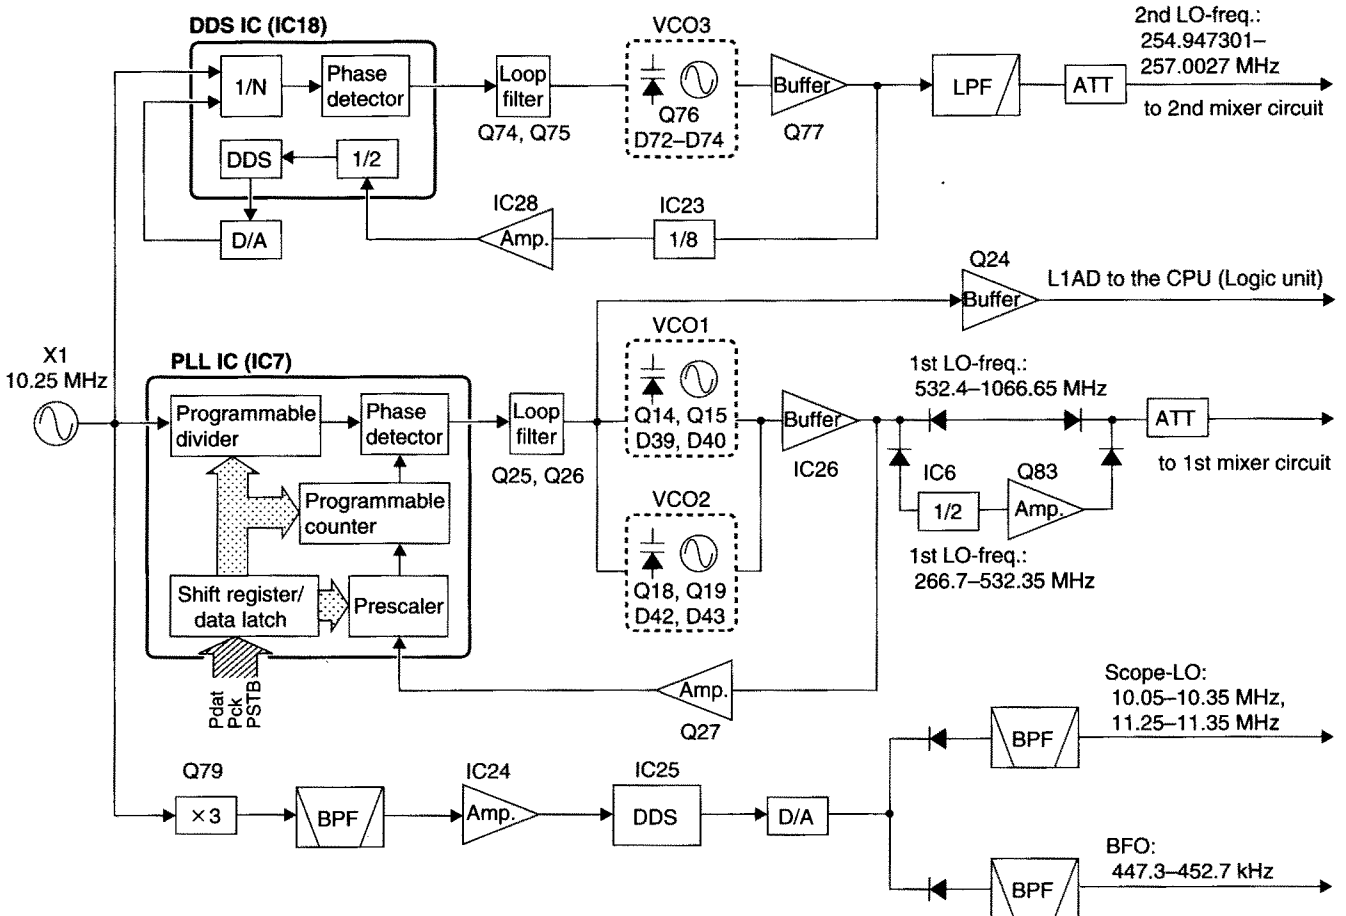

The BFO signals are generated by the DDS circuit (IC25) using the divided reference signal. 10-bit digital signals are converted into 447.3–452.7 kHz analog wave signals at the D/A converter (R423–R442). The converted analog wave signals are passed through the bandpass filter (L99–L101, C269–C274) via the switching diode (D52), then applied to the mixer circuit (IC12).

**4-3 SCOPE CIRCUIT**

**4-3-1 SCOPE RECEIVER CIRCUIT (RF UNIT)**

A portion of the 10.7 MHz 2nd IF signal from the 2nd mixer circuit (IC5) passes through the bandpass filter (F18) to suppress out-of-band signals, and is then mixed with a scope LO signal at the mixer section in the FM IF IC (IC8, pin 15), which includes the RSSI terminal, to produce a 450 kHz scope IF signal. The mixed IF signal is filtered at the ceramic bandpass filter (F14) then applied to the limiter amplifier section in the FM IF IC (IC8, pin 5). The applied IF signal is converted into DC voltages according to the applied IF signal strength at the RSSI section in the IC.

**• PLL circuits**

The converted voltages are applied to the CPU (LOGIC unit; IC1, pin 34) as an SCAD signal.

The sweeping scope LO signals generated by IC25 (10.05–10.35 MHz/11.25–11.35 MHz) are applied to the mixer section in the FM IF IC, when the scope function is activated.
