INTRODUCTION

This service manual describes the latest service information for the **IC-R8500** COMMUNICATIONS RECEIVER at the time of publication.

MODEL	VERSION	SYMBOL
IC-R8500	U.S.A.	[USA]
	Europe	[EUR]
	France	[FRA]
	Others	[OTH]

To upgrade quality, any electrical or mechanical parts and internal circuits are subject to change without notice or obligation.

CAUTION

NEVER connect the transceiver to an AC outlet or to a DC power supply that uses more than 13.8 V. This will ruin the transceiver.

DO NOT reverse the polarities of the power supply when connecting the transceiver.

DO NOT apply an RF signal of more than 20 dBm (100 mW) to the antenna connector. This could damage the transceiver's front end.

ORDERING PARTS

Be sure to include the following four points when ordering replacement parts:

1. 10-digit order numbers
2. Component part number and name
3. Equipment model name and unit name
4. Quantity required

REPAIR NOTES

1. Make sure a problem is internal before disassembling the transceiver.
2. **DO NOT** open the transceiver until the transceiver is disconnected from its power source.
3. **DO NOT** force any of the variable components. Turn them slowly and smoothly.
4. **DO NOT** short any circuits or electronic parts. An insulated tuning tool **MUST** be used for all adjustments.
5. **DO NOT** keep power ON for a long time when the transceiver is defective.
6. **READ** the instructions of test equipment thoroughly before connecting equipment to the transceiver.

4-1 RECEIVER CIRCUITS

4-1-1 RF CONVERTOR CIRCUIT (CONV UNIT)

The RF convertor circuit converts 1025–1999.99999 MHz RF signals to 200–989.99999 MHz RF signals.

(1) 30.00000–1024.99999 MHz signals

RF signals from the antenna connector (J1) pass through the switching relays (RL1, RL2) to bypass the RF convertor circuit. The bypassed RF signals either bypass or are passed through the RF attenuator circuit (R17–R19, R25–R27) then applied to the RF-B unit via J3.

(2) 1025.00000–1999.99999 MHz signals

RF signals from the antenna connector (J1) are applied to the RF amplifier circuit (IC1, IC3) via the switching relay (RL1) and tunable high-pass filter (D3–D5, D20, D21, L2–L4). The amplified signals are mixed with convertor LO signals at the RF convertor circuit (IC2) to produce 200.00000–989.99999 MHz RF signals. The converted RF signals are applied to the RF-B unit via J3 after bypassing or passing through the attenuator circuit.

The convertor PLL circuit (IC6: VCO, IC7: PLL IC) generates a 1000 or 1010 MHz LO signal and applies them to the convertor circuit directly or divides them by 2 at IC8.

• Convertor LO signals

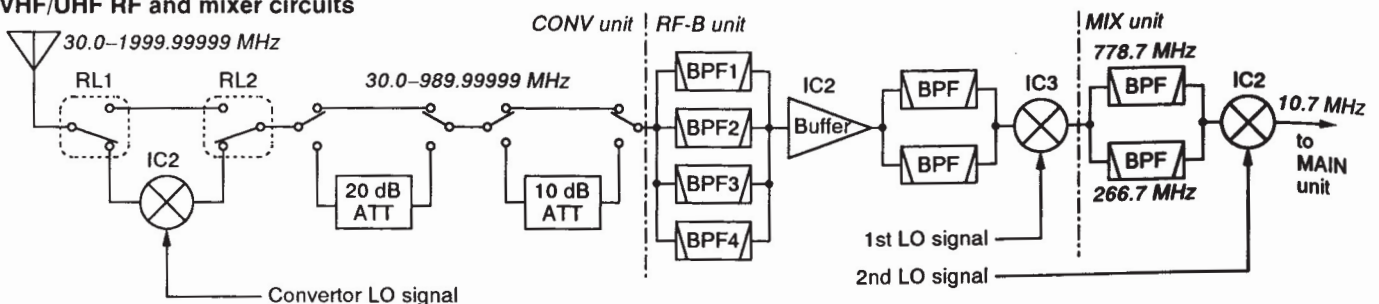

Receive frequency	Convertor LO frequency
1025–1199.99999 MHz	500 MHz
1200–1989.99999 MHz	1000 MHz
1990–1999.99999 MHz	1010 MHz

4-1-2 RF ATTENUATOR CIRCUIT (CONV UNIT)

The attenuator circuit attenuates the signal strength up to 30 dB to protect the RF amplifier from distortion when excessively strong signals are received.

The RF attenuator circuit consists of 2 separate attenuator circuits connected in series. The 1st stage of the RF attenuator circuit (R17–R19) provides 20 dB attenuation; the 2nd stage (R25–R27) provides 10 dB attenuation via a “π” type attenuator.

• VHF/UHF RF and mixer circuits

4-1-3 VHF/UHF RF CIRCUIT (RF-B UNIT)

The RF circuit amplifies the received signals within the range of frequency coverage and filters out-of-band signals.

The RF circuit consists of 4 bandpass filter circuits with an RF amplifier for each.

The received signals from the CONV unit are passed through to the tunable bandpass filter via the switching relay (RL1), then amplified at the RF amplifier circuit. The amplified RF signals are again passed through another bandpass filter to suppress out-of-band signals. The filtered signals are amplified at the other RF amplifier circuit (IC3), then applied to the 1st mixer circuit after passing through the low-pass or bandpass with tuned notch circuit.

The tunable bandpass filters employ varactor diodes to tune the center frequency of the RF passband for wide bandwidth receiving and good image response rejection. These diodes are controlled by the CPU (MAIN unit, IC33) via the voltage amplifier circuit (IC2).

A Ga-As FET is used for the RF amplifiers (Q1–Q4) to provide high sensitivity within wide-band coverage, and also to provide 10 dB amplifying gain.

4-1-4 TUNED NOTCH CIRCUIT (RF-B UNIT)

The tuned notch circuit activates while RF signals higher than 500 MHz are received. The circuit prevents the 1st LO signal from entering the antenna connector and also reduces IF disturbance.

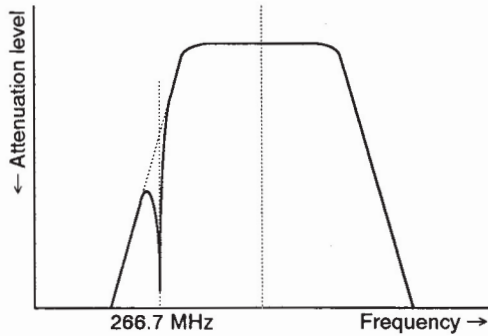

The tuned notch circuit (D29–D32, L51–L54, L74) is designed between the high-pass (L82, C166–C168) and low-pass filter (L55, L56, C96–C98, C100). The high-pass filter reduces IF disturbance (266.7 MHz), and the tuned notch and low-pass filter circuits prevent the 1st LO signal from entering the antenna connector.

4-1-5 VHF/UHF 1ST MIXER CIRCUIT (RF-B UNIT)

The 1st mixer circuit converts the received RF signals to a fixed frequency of the 1st IF signal with a PLL output frequency. By changing the PLL frequency, only the desired frequency will pass through the bandpass filters at the next stage of the 1st mixer.

The filtered RF signals are mixed with 1st LO signals at the 1st mixer circuit (IC4, pin 3) to produce a 778.7 or 266.7 MHz 1st IF signal. The 1st IF signal is output from pin 5, and passed through the low-pass filter circuit (L75-L77, C141-C145) to suppress unwanted harmonic components. The filtered 1st IF signal is applied to the MIX unit via J2.

The 1st LO signals are generated at the VCO-A circuit (VCO-A board, Q1, Q3), and are applied to the 1st mixer (IC4, pin 6) after being amplified at the LO amplifier circuit (IC6) via the V1LO line.

4-1-6 VHF/UHF 1ST IF AND 2ND MIXER CIRCUITS (MIX UNIT)

The 2nd mixer circuit converts the 1st IF signal to a 2nd IF signal.

The 1st IF signal from the RF-B unit is passed through the bandpass filter to suppress unwanted out-of-band signals.

The 778.7 MHz 1st IF signal is passed through the dielectric notch filter (FI2) to obtain good image response rejection for the 21.4 MHz lower frequency from the receiving frequency after passing through the dielectric filter (FI1).

And, the 266.7 MHz 1st IF signal is passed through the helical notch filter (L15) to obtain a good image response rejection for the 21.4 MHz lower frequency from the receiving frequency via the helical bandpass filter (L14).

The filtered 1st IF signal is mixed with 2nd LO signals at the 2nd mixer circuit (IC1) to produce a 10.7 MHz 2nd IF signal. The 2nd IF signal is applied to the MAIN unit via J4 after suppressing unwanted higher harmonic components at the low-pass filter (L9, L22, C25, C27).

The 2nd LO signals are generated at the VCO-B circuit (VCO-B board, Q1, Q3), and are applied to the 2nd mixer circuit after being amplified at the LO amplifier circuit (IC2).

4-1-7 HF RF FILTER CIRCUIT (RF-A UNIT)

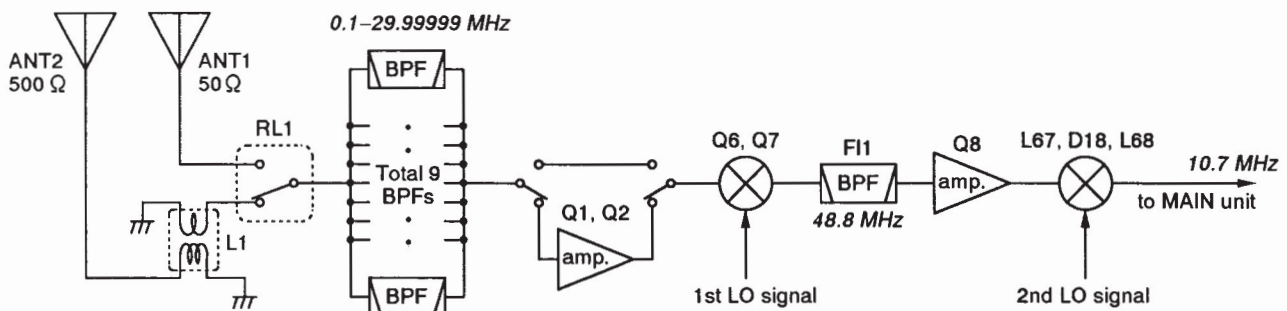

The RF filter circuit consists of an antenna switching circuit, 9 bandpass filters and an RF amplifier circuit.

IC-R8500 has 2 antenna connectors for the HF bands (ANT1 and ANT2); ANT1 employs an SO-239 connector with 50 Ω impedance and ANT2 employs a phono/RCA connector with 500 Ω impedance.

The RF signals from ANT1 (J2) are applied to the bandpass filter to suppress out-of-band signals via the antenna switching relay (RL1). However, the RF signals from ANT2 (J1) are passed through the step-down transformer (L1) to be converted into 50 Ω impedance when ANT2 is selected. Then the RF signals are applied to the bandpass filter.

The filtered RF signals are bypassed or applied to the RF amplifier circuit (Q1, Q2), depending on the status of the 10 dB attenuator. The RF amplifier circuit (Q1, Q2) provides 10 dB gain, therefore, the bypassed RF signal strength seems attenuated when the 10 dB attenuator is turned ON.

4-1-8 HF 1ST MIXER CIRCUIT (RF-A UNIT)

The 1st mixer circuit converts the RF signals to a desired 48.8 MHz 1st IF signal. In this way, the VCO-A circuit output frequencies are used for 1st LO signals after being amplified at the LO amplifier (IC2).

The received RF signals from the bandpass filter circuit are mixed with 1st LO signals at the 1st mixer circuit (Q6, Q7) after passing through the low-pass filter circuit (L59, C98-C100). The mixed 1st IF signal is passed through the crystal filter (FI1) to suppress out-of-band signals then amplified at the IF amplifier circuit (Q8).

The amplified 1st IF signal is applied to the 2nd mixer circuit.

The 2nd mixer circuit converts the 1st IF signal to the desired 10.7 MHz 2nd IF frequency. The 2nd LO signal is used in the mixer circuit to produce a 2nd IF frequency, and the signal is generated at the VCO-B circuit (VCO-B board, Q1, Q3) after being amplified at the LO amplifier (IC1).

The 1st IF signal from the IF amplifier (Q8) is applied to the double balanced mixer circuit (D18, L67, L68) to produce a 10.7 MHz 2nd IF signal. The 2nd IF signal is then passed through the low-pass filter circuit (L84, C145, C146), and is then applied to the MAIN unit via J5.

4-1-10 IF CIRCUIT (MAIN UNIT)

The 10.7 MHz 2nd IF signal from the MIX unit is applied to the mode switch (D3) after being amplified at the IF amplifier circuit (Q2). However, the 10.7 MHz 2nd IF signal from the RF-A unit is applied to the mode switch (D3) directly. The IF signal from the mode switch is then applied to a different circuit depending on the receiving mode.

(1) WFM mode

The 2nd IF signal from the mode switch (D3) is applied to the IF amplifier circuit (Q4). The amplified IF signal is passed through the bandpass filters (FI1, FI2) to suppress out-of-band signals. The filtered IF signal is then applied to the WFM demodulator circuit.

(2) Other modes

The 2nd IF signal from the mode switch (D3) is passed through the bandpass filter (FI3) to suppress out-of-band signals, and then applied to the IF amplifier circuit (Q15). The amplified IF signal is then applied to the 3rd mixer circuit.

4-1-11 3RD MIXER CIRCUIT (MAIN UNIT)

The 3rd mixer circuit mixes the 2nd IF signal and 3rd LO signal to produce a 455 kHz 3rd IF signal. The 3rd LO signal is generated at the DDS circuit (PLL unit, IC13) and is applied to the 3rd mixer circuit via the buffer-amplifier (Q28).

The 2nd IF signal from the IF amplifier circuit (Q15) is applied to the 3rd mixer circuit (IC6, pin 6), and also the 3rd LO signal (10.245 MHz) is applied to pin 8 of the IC. The mixed 3rd IF signal is output from pin 3, and is passed through different bandpass filters depending on the receiving mode and passband width. The filtered 3rd IF signal is applied to the matched demodulator circuit with the receiving mode via the IF amplifier circuit (Q16).

4-1-12 DEMODULATOR CIRCUIT (MAIN UNIT)

The demodulator circuit converts the 3rd IF signal into AF signals. 4 separate demodulator circuits are employed for each mode.

(1) WFM mode

The filtered 10.7 MHz 2nd IF signal from the bandpass filter (F12) is applied to the WFM demodulator circuit (IC2, pin 7). The applied IF signal is mixed with an LO signal which is generated by X1 to demodulate AF signals. The demodulated AF signals are output from pin 13, and are then applied to the squelch control gate (IC19d).

(2) FM mode

The amplified 3rd IF signal at the IF amplifier (Q16) is again amplified at the other IF amplifier (Q64) and then applied to the FM detector circuit (IC8, pin 5). The applied 3rd IF signal is mixed with the signal generated by discriminator (X2) to demodulate AF signals. The demodulated AF signals are output from pin 9 and passed through the active filter circuit (IC32a) to suppress unwanted subaudible tone audio signals and lower noise components.

The filtered AF signals are applied to the squelch control gate (IC19c).

(3) AM mode

The amplified 3rd IF signal from the IF amplifier (Q16) is again amplified at the other IF amplifiers (Q17, Q18). The amplified 3rd IF signal is then applied to the AM demodulator circuit (D15). The demodulated AF signals are applied to the squelch control gate (IC19b).

(4) SSB and CW modes

The amplified 3rd IF signal from the IF amplifier (Q18) is applied to the balanced mixer circuit (IC7) and mixed with BFO signals to demodulate AF signals. The demodulated AF signals are applied to the squelch control gate (IC19a).

The BFO signals are generated at the BFO circuit (PLL unit, IC15) and are applied to the balanced mixer circuit via the buffer-amplifier (Q31).

4-1-13 SQUELCH CONTROL CIRCUIT (MAIN UNIT)

The demodulated AF signals from the demodulator circuits are applied to the squelch control gate (IC19). This consists of 4 analog switches which are selected with a mode signal and squelch control setting from the CPU (IC33) via the expander IC (IC18). The switched AF signals are applied to the AF circuit.

4-1-14 SQUELCH CIRCUIT (MAIN UNIT)

(1) FM, FM-N, AM and AM-W modes

A squelch circuit cuts out AF signals when no RF signal is received or the S-meter signal is lower than the [SQUELCH] control setting level. By detecting noise components in the AF signals, the CPU switches the squelch control gate.

Some noise components in the AF signals from pin 9 of the FM IF IC (IC8) are applied to the noise filter section in the FM IF IC (pin 10). The filtered noise components are output from pin 11, and then applied to the noise amplifier circuit (IC9b). The amplified signals are rectified at the noise detector circuit (D16) and the detected voltages are applied to the CPU (IC33) via the NOAD line after being current-amplified at the current-amplifier circuit (IC4a).

The [SQUELCH] control level signal is applied to the CPU (IC33) via the sub-CPU (FRONT unit, IC1) as a reference voltage for comparison with the noise voltages. Also, an S-meter signal is applied to the CPU from the meter amplifier (IC9a). The CPU compares these signals, then outputs a control signal to the squelch control gate.

The FM IF IC detects noise components even in AM and AM-W modes for noise squelch control, and also the IF amplifier (Q18) is activated in FM and FM-N modes for S-meter and S-meter squelch functions.

(2) WFM, SSB, CW and AM-N modes

The squelch circuit mutes AF output when the S-meter signal is lower than the [SQUELCH] control setting level.

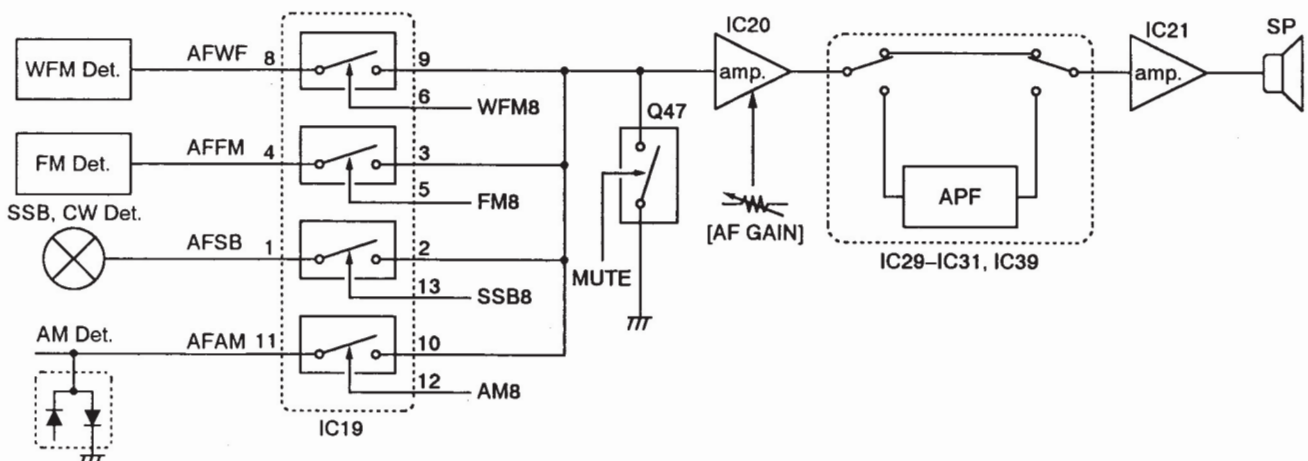

SSB, CW and AM-N modes

A portion of the 3rd IF signal from the IF amplifier (Q18) is converted into DC voltage at the AGC detector (Q27, D20) and the meter amplifier (IC9a). The amplified signal is applied to the CPU (IC33) via the SMAD line. The CPU outputs control signals to the squelch control gate when the S-meter signal is at a low level.

WFM mode

The WFM demodulator (IC2) controls input voltage of the meter amplifier (IC9a, pin 2) via Q6 and the AGC line. The same circuit is used even in WFM mode with SSB, CW and AM-N modes.

UNIT NAME:

[MAIN]→[MAIN-A], [RF-A]→[RF-C], [RF-B]→[RF-D], [MIX]→[MIX-A], [CONV]→[CONV-B], [PLL]→[PLL-B]

4-1-15 AF AMPLIFIER CIRCUIT (MAIN UNIT)

The AF amplifier circuit amplifies the demodulated AF signals to drive a speaker.

AF signals from the squelch control gate are pre-amplified at the AF amplifier (IC20) and are then applied to the AF power amplifier (IC21) after either passing through or bypassing the APF circuit (IC29-IC31, IC39). The power amplified AF signals are applied to the internal speaker via the [EXT SP] and [PHONE] jacks when no plugs are connected to the jacks.

The [AF GAIN] control signal is also applied to the AF pre-amplifier (IC20, pin 8) via the CPU (IC33) to control amplifying gain.

4-1-16 NOISE BLANKER CIRCUIT (MAIN UNIT)

The noise blanker circuit detects pulse-type noises, and stops IF amplifier operation during detection.

A portion of the 3rd IF signal from the bandpass filter (FI3) is amplified at the noise amplifier circuit (Q9, IC5, Q11). The amplified signal is rectified at the noise detector circuit (D10) for conversion into DC voltage. The DC voltage is applied to the NB control circuit (Q12, Q13) to control the NB switch (Q14).

Some DC voltage is fed back to the noise amplifier circuit (IC5) via the DC amplifier (Q10). The DC amplifier function as an AGC circuit to reduce averaged noise. Therefore, the noise blanker function shuts off pulse-type noise only.

4-1-17 AGC CIRCUIT (MAIN UNIT)

The AGC (Auto Gain Control) circuit reduces IF amplifier gain to keep the audio output at a constant level.

A portion of the 3rd IF signal from the IF amplifier (Q18) is applied to the AGC detector circuit (D20). The detected signal is applied to the AGC control circuit (Q20, Q21, Q25, Q27) and then applied to the IF amplifiers (Q2, Q4, Q15-Q17). The AGC voltage is also applied to the RF-A and RF-B unit via the current-amplifier circuit (IC32b). The current-amplified AGC signal is applied to the IF amplifier and AGC control circuit in the RF-A unit (IF amp.: Q8, AGC control: Q3), and the buffer-amplifier circuit in the RF-B unit (IC1a).

When strong signals are received, the detected voltage increases and the output level of the AGC control circuit decreases. The AGC voltage is used as the bias voltage for the IF amplifiers, therefore, the IF amplifier gain is decreased.

AGC response time is controlled by changing the time constant at the AGC control line with resistors (R179, R180, R503) and capacitors (C134-C137). R179, R180, C134 and C135 are used for AGC slow, and R503, C136 and C137 are used for AGC fast mode's time constant. The time constant for AGC slow is connected to the AGC control line while AGC is set to slow. However, it's disconnected from the AGC control line, and the time constant for AGC fast is connected to the AGC control line while AGC is set to fast. Both time constants are disconnected from the AGC control line while scanning or when WFM or FM mode is selected for faster response than AGC fast mode.

4-1-18 S-METER CIRCUIT (MAIN UNIT)

The S-meter circuit indicates the relative received signal strength while receiving and changes depending on the received signal strength.

A portion of the AGC signal is applied to the meter amplifier circuit (IC9a). The amplified signal is then applied to the CPU (IC33) as an SMAD signal to drive the S-meter.

The SMAD signal is also used for noise and S-meter squelch operation by comparison with the [SQUELCH] control setting level and receiving signal strength at the CPU.

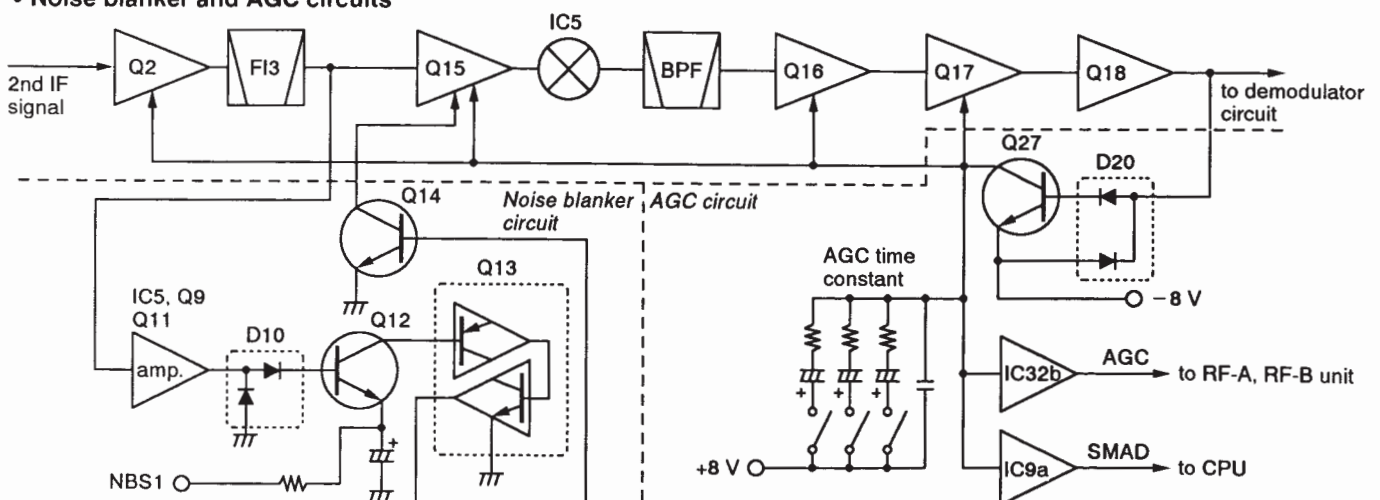

4-1-19 APF CIRCUIT (MAIN UNIT)

The APF (Audio Peak Filter) circuit boosts a specified frequency to pick up desired CW signals, etc.

When [APF] is turned ON, the AF signals from the squelch control gate (IC19) are applied to the APF circuit (IC29-IC31, IC39). The [APF] control adjusts the peak frequency within 200-1000 Hz. IC29 is a triple 2-channel analog switch IC and the AF signals are either passed through or bypass the APF circuit.

The APF circuit functions as a tone control while WFM, FM, AM or SSB mode is selected.

4-1-20 CENTER DETECTOR AND CENTER INDICATOR CIRCUITS (MAIN UNIT)

(1) WFM and FM modes

A portion of the detected audio signals from the demodulator circuit (IC2 for WFM, IC8 for FM) are applied to the center detector circuit (IC4b). The applied audio signals are converted into DC voltage, and also amplified at the center detector. The output DC voltage is then applied to the CPU (IC33) as a CMAD signal for center indication and AFC (Auto Frequency Control) operation, and is also applied to the window-comparator (IC13) for center scan stop.

The output signal from the window-comparator is applied to the CPU as a STOP signal.

(2) AM mode

A portion of the 3rd IF signal from the IF amplifier (Q18) is amplified at the buffer-amplifier circuit (Q65), and then converted into an IF phase signal at the AM center circuit (IC40c). The BFO signal is applied to the AM center circuit (IC40d) to be converted into a BFO phase signal after being amplified at the buffer-amplifier (Q66).

Both IF and BFO phase signals are applied to the phase detector circuit (IC41) to detect phase differences. The phase detector circuit outputs pulse-type signals according to the phase difference from pin 8, and the output signals are rectified at the rectifier section (D60). The rectified signal is then applied to the CPU (IC33) as a STOP signal via Q67 and Q68.

4-1-21 VSC CIRCUIT (MAIN UNIT)

The VSC (Voice Scanning Control) detects the AF signals during scanning and skips undesired signals such as unmodulated, beat and noise component signals.

A portion of the AF signals from the squelch gate (IC19) are applied to the VSC control circuit (IC10-IC12, Q30) after being amplified at Q62. The amplified AF signals are amplified and limited at the two-step amplifier section (IC10) then the output signal is applied to the one-shot multi circuit (IC11) as a trigger signal. The one-shot multi circuit functions as an F-V convertor, and the output voltage is proportional to the number of pulses within the singular time.

The output signals from the one-shot multi circuit are passed through the low-pass filter (IC12a) to detect AF signals. The filtered signals are then applied to the window comparator (IC12b). The window comparator outputs a high level signal when the applied signals from the low-pass filter exceeds the reference voltage.

The output signal is applied to the CPU (IC33) as a VSC signal via IC11c.

4-2 PLL CIRCUITS

4-2-1 1ST LO PLL CIRCUIT (PLL UNIT)

The 1st LO circuit generates the 1st LO frequency, and the signals are applied to the 1st mixer circuit in the RF-A and RF-B units. The 1st LO circuit consists of a DDS, VCO-A circuits and PLL IC, etc.

(1) DDS loop circuit

The signal generated at the VCO circuit (Q2, D1, D2) is

amplified at the buffer-amplifier (Q3) then applied to the DDS circuit (IC3). The DDS circuit generates digital signal using the applied signal as a clock frequency. The phase detector section in IC3 compares its phase with the reference frequency which is generated at the reference oscillator (X1; 30.2 MHz). IC3 outputs off-phase components as pulse signals via pins 52, 53.

The output pulses are converted into DC voltage at the loop filter circuit (Q44, Q45) and then applied to the VCO circuit to generate an approx. 6.5 MHz reference signal for the main loop circuit.

The D/A convertor (R10-R33), bandpass filter (F11) and buffer-amplifier (IC4) circuits are connected to the DDS output to convert the digital oscillated signals into smooth analog signals.

(2) Main loop circuit

The generated signal from the VCO-A circuit (VCO-A board, Q1, Q3) is buffer-amplified at the buffer-amplifier (IC6). The buffer-amplified signal is applied to the prescaler section in the PLL IC (IC5, pin 11) via the low-pass filter circuit (L74, L75, C263-C267). The applied signal from the VCO-A circuit is prescaled in the PLL IC based on the divided ratio (N-data) to produce approx. 50 kHz phase signals. The phase signals are applied to the phase detector section.

The signal from the VCO in the sub loop circuit is applied to the programmable divider section in the PLL IC (IC5, pin 20) to produce approx. 50 kHz reference phase signals. The reference phase signals are applied to the phase detector section.

The phase detector section compares 2 of the applied phase signals. The phase detected signals are passed through the charge pump section and then output from pin 6 of the PLL IC. The output signals are applied to the loop filter circuit (Q38, Q39, Q42, Q43) to be converted into DC voltage as a PLL lock voltage. The PLL lock voltage is applied to the VCO-A circuit via the VCO switch (IC20).

The reference signal from the divider circuit (IC11; 15.1 MHz) is divided at the programmable divider section in the PLL IC. The output signals from these section are phase detected at the phase detector section, and then output from pin 6 of the PLL IC via the charge pump section.
