Table of Contents

1	Getting Started	1-1
	Introduction	1-2
	Capabilities and features	1-2
	Organization of manual sections	1-3
	General information	1-3
	Warranty information	1-3
	Contact information	1-3
	Unpacking and inspection	1-3
	Options and accessories	1-4
	User's and Reference manuals	1-5
	Front and rear panel familiarization	1-6
	Front panel summaries	1-6
	Rear panel summaries	1-9
	Cooling vents	1-13
	Power-up	1-14
	Line power connection	1-14
	Power-up sequence	1-15
	Beeper	1-15
	Display modes	1-16
	Editing controls	1-17
	Source and compliance editing	1-17
	Menu navigation	1-18
	Menu types	1-19
	Interface configuration	1-21
	USB storage overview	1-21
	Connecting the USB flash drive	1-21
	1-21
	Using the file system	1-22
	File system navigation	1-22
	Error and status messages	1-23
2	DUT Test Connections	2-1
	Input/output connectors	2-2
	Input/output LO and chassis ground	2-4
	Sensing methods	2-6
	2-wire local sensing	2-6
	4-wire remote sensing	2-8
	Sense mode selection	2-9
	Contact check connections	2-9
	Multiple SMU connections	2-10
	Guarding and shielding	2-12
	Guarding	2-13
	Noise shield	2-14
	Safety shield	2-16
	Using shielding and guarding together	2-18
	Test fixture	2-20
	Floating an SMU	2-20
	Output-off states	2-23
	Selecting the output-off state	2-23
3	Basic Operation	3-1
	Overview	3-3

Operation overview	3-3
Source-measure capabilities	3-3
Compliance limit	3-4
Setting the compliance limit	3-5
Basic circuit configurations	3-6
Operation considerations	3-6
Warm-up	3-6
Auto zero	3-7
NPLC caching	3-8
Basic source-measure procedure	3-8
Front panel source-measure procedure	3-8
Remote source-measure procedure	3-10
Triggering in local mode	3-11
Configuring trigger attributes in local mode	3-12
Measure only	3-13
Sink operation and interface	3-14
Ohms measurements	3-14
Ohms calculations	3-14
Ohms ranging	3-14
Basic ohms measurement procedure	3-14
Ohms sensing	3-15
Sense selection	3-16
Remote ohms programming	3-17
Power measurements	3-18
Power calculations	3-18
Basic power measurement procedure	3-18
Remote power programming	3-18
Contact check measurements	3-19
Overview	3-19
Contact check commands	3-20
Contact check programming example	3-21
User setup	3-21
Saving user setups	3-21
Recalling a saved setup	3-22
To select power-on setup	3-22
Saving user setups from a command interface	3-22
4 Source-Measure Concepts	4-1
Overview	4-2
Compliance limit	4-2
Maximum compliance	4-2
Compliance principles	4-2
Overheating protection	4-3
Power equations to avoid overheating	4-3
Operating boundaries	4-6
Source or sink	4-6
Continuous power operating boundaries	4-6
I-Source operating boundaries	4-7
V-Source operating boundaries	4-11
Source I measure I, source V measure V	4-14
Basic circuit configurations	4-15
Source I	4-15
Source V	4-15
Measure only (V or I)	4-16
Contact check	4-17
Guard	4-18
Guard overview	4-18
Guard connections	4-19
Settling time considerations	4-20
Measurement settling time considerations	4-20
Reduction in gain-bandwidth	4-22

5	High-Capacitance Mode	5-1
	Overview	5-2
	Understanding high-capacitance mode	5-2
	Understanding source settling times.....	5-2
	Adjusting the voltage source.....	5-3
	Enabling high-capacitance mode	5-4
	Front panel.....	5-4
	Command interface	5-5
6	Range, Digits, Speed, Rel, and Filters	6-1
	Overview	6-2
	Range.....	6-2
	Available ranges	6-2
	Maximum source values and readings	6-3
	Ranging limitations	6-3
	Manual ranging.....	6-3
	Auto ranging	6-3
	Low range limits.....	6-3
	Range considerations.....	6-4
	Range programming.....	6-4
	Digits	6-6
	Setting display resolution.....	6-6
	Remote digits programming.....	6-6
	Speed.....	6-6
	Setting speed.....	6-7
	Remote speed programming	6-7
	Rel.....	6-8
	Front panel rel.....	6-8
	Remote rel programming	6-9
	Filters	6-9
	Filter types	6-9
	Front panel filter control.....	6-10
	Remote filter programming.....	6-12
7	Reading Buffers	7-1
	Reading buffer overview	7-2
	Working with reading buffers in the local state.....	7-2
	Reading buffer options.....	7-2
	Configuring reading buffers	7-3
	Appending or overwriting existing reading buffers	7-3
	Storage operation	7-4
	Saving reading buffers.....	7-4
	Recalling readings.....	7-5
	Working with reading buffers in the remote state	7-5
	Reading buffer commands.....	7-7
	Buffer status.....	7-9
	Dynamic reading buffers	7-10
	Buffer examples.....	7-10
8	Digital I/O	8-1
	Digital I/O port	8-2
	Port configuration.....	8-2
	Digital I/O configuration	8-3
	Controlling digital I/O lines	8-4
	Output enable (Models 2601A/2602A).....	8-5
	Overview.....	8-5
	Operation.....	8-6
	Front panel control of output enable.....	8-6
	Remote control of output enable.....	8-7
	Legacy mode.....	8-7
	Overview.....	8-7
	Features of legacy mode	8-7
	Enable or disable legacy mode.....	8-8
	Interlock (Models 2612A/2612A/2635A/2636A)	8-8

	Overview	8-8
	Operation	8-8
	TSP-Link synchronization lines	8-9
	Connecting to TSP-Link	8-9
	Using TSP-Link synchronization lines for digital I/O	8-9
	Remote TSP-Link synchronization line commands	8-10
9	Sweep Operation	9-1
	Overview	9-2
	Section overview	9-2
	Sweep overview	9-2
	Sweep characteristics	9-3
	Linear staircase sweeps	9-3
	Logarithmic staircase sweeps	9-5
	List sweeps	9-8
	Pulse mode sweeps	9-9
	Configuring and running sweeps	9-10
	Configuring other sweep attributes	9-10
	Configuring measurements during a sweep	9-11
	Source and measurement delays	9-11
	Initiating and running sweeps	9-11
	Aborting a sweep	9-11
	Sweeping using factory scripts	9-12
	Front panel	9-12
	Sweep programming examples	9-12
	List sweep example	9-13
10	Triggering	10-1
	Remote triggering overview	10-3
	Using the remote trigger model	10-4
	Configuring source and measure actions	10-6
	Enabling pulse mode sweeps (end pulse action)	10-6
	SMU event detectors	10-6
	Clearing SMU event detectors	10-7
	Using the TRIG key to trigger a sweep	10-7
	Using trigger events to start actions on trigger objects	10-8
	Action overruns	10-9
	Digital I/O Port and TSP-Link synchronization lines	10-9
	Common attributes	10-9
	Trigger configuration on hardware lines	10-10
	Action overruns on hardware lines	10-11
	Timers	10-11
	Timer attributes	10-11
	Triggering a timer	10-12
	Using timers to perform pulse mode sweeps	10-13
	Timer action overruns	10-17
	Event blenders	10-17
	Event blender modes	10-17
	Assigning input trigger events	10-18
	Action overruns	10-18
	LAN triggering overview	10-18
	Understanding hardware value and pseudo line state	10-18
	Understanding LXI trigger event designations	10-19
	Generating LXI trigger packets	10-19
	Logging LAN trigger events in the event log	10-20
	Accessing the event log from the command interface	10-22
	Command interface triggering	10-22
	Manual triggering	10-23
	Interactive triggering	10-23
	Detecting trigger events using the wait() function	10-23
	Using the assert() function to generate trigger events	10-24
	Using the release() function of the hardware lines	10-24
	Using the set() function to bypass SMU event detectors	10-24

	Event detector overruns.....	10-25
	Examples using interactive triggering	10-25
	Hardware trigger modes for synchronization lines	10-27
	Falling edge trigger mode	10-27
	Rising edge master trigger mode.....	10-29
	Rising edge acceptor trigger mode.....	10-30
	Either edge trigger mode	10-31
	Understanding synchronous triggering modes.....	10-32
	Synchronous master trigger mode (SynchronousM)	10-32
	Synchronous acceptor trigger mode (SynchronousA)	10-34
	Synchronous trigger mode.....	10-35
11	Display Operations	11-1
	Display functions and attributes	11-2
	Display features	11-2
	Display screen	11-2
	Measurement functions	11-3
	Display resolution	11-3
	Display messages.....	11-4
	Clearing the display	11-4
	Cursor position.....	11-4
	Displaying text messages.....	11-5
	Input prompting	11-7
	Menu.....	11-7
	Parameter value prompting	11-8
	Indicators.....	11-9
	LOCAL lockout.....	11-10
	Load test menu	11-10
	Loading and saving a user script.....	11-11
	Adding USER TESTS menu entries	11-11
	Deleting USER TESTS menu entries	11-12
	Running a test from the front panel	11-12
	Key-press codes	11-12
	Sending key codes	11-12
	Capturing key-press codes.....	11-13
12	TSP Fundamentals and Script Management	12-1
	Introduction	12-2
	Test Script Processor (TSP)	12-2
	Run-time environment	12-2
	Queries.....	12-3
	Scripts.....	12-3
	Naming scripts	12-3
	Renaming Scripts	12-4
	Functions	12-4
	Scripts that create functions	12-4
	Programming overview	12-5
	What is a chunk?	12-5
	What is a script?	12-5

The following safety precautions should be observed before using this product and any associated instrumentation. Although some instruments and accessories would normally be used with non-hazardous voltages, there are situations where hazardous conditions may be present.

This product is intended for use by qualified personnel who recognize shock hazards and are familiar with the safety precautions required to avoid possible injury. Read and follow all installation, operation, and maintenance information carefully before using the product. Refer to the user documentation for complete product specifications.

If the product is used in a manner not specified, the protection provided by the product warranty may be impaired.

The types of product users are:

Responsible body is the individual or group responsible for the use and maintenance of equipment, for ensuring that the equipment is operated within its specifications and operating limits, and for ensuring that operators are adequately trained.

Operators use the product for its intended function. They must be trained in electrical safety procedures and proper use of the instrument. They must be protected from electric shock and contact with hazardous live circuits.

Maintenance personnel perform routine procedures on the product to keep it operating properly, for example, setting the line voltage or replacing consumable materials. Maintenance procedures are described in the user documentation. The procedures explicitly state if the operator may perform them. Otherwise, they should be performed only by service personnel.

Service personnel are trained to work on live circuits, perform safe installations, and repair products. Only properly trained service personnel may perform installation and service procedures.

Keithley Instruments products are designed for use with electrical signals that are rated Measurement Category I and Measurement Category II, as described in the International Electrotechnical Commission (IEC) Standard IEC 60664. Most measurement, control, and data I/O signals are Measurement Category I and must not be directly connected to mains voltage or to voltage sources with high transient over-voltages. Measurement Category II connections require protection for high transient over-voltages often associated with local AC mains connections. Assume all measurement, control, and data I/O connections are for connection to Category I sources unless otherwise marked or described in the user documentation.

Exercise extreme caution when a shock hazard is present. Lethal voltage may be present on cable connector jacks or test fixtures. The American National Standards Institute (ANSI) states that a shock hazard exists when voltage levels greater than 30V RMS, 42.4V peak, or 60VDC are present. A good safety practice is to expect that hazardous voltage is present in any unknown circuit before measuring.

Operators of this product must be protected from electric shock at all times. The responsible body must ensure that operators are prevented access and/or insulated from every connection point. In some cases, connections must be exposed to potential human contact. Product operators in these circumstances must be trained to protect themselves from the risk of electric shock. If the circuit is capable of operating at or above 1000V, no conductive part of the circuit may be exposed.

Do not connect switching cards directly to unlimited power circuits. They are intended to be used with impedance-limited sources. NEVER connect switching cards directly to AC mains. When connecting sources to switching cards, install protective devices to limit fault current and voltage to the card.

Before operating an instrument, ensure that the line cord is connected to a properly-grounded power receptacle. Inspect the connecting cables, test leads, and jumpers for possible wear, cracks, or breaks before each use.

When installing equipment where access to the main power cord is restricted, such as rack mounting, a separate main input power disconnect device must be provided in close proximity to the equipment and within easy reach of the operator.

For maximum safety, do not touch the product, test cables, or any other instruments while power is applied to the circuit under test. ALWAYS remove power from the entire test system and discharge any capacitors before: connecting or disconnecting cables or jumpers, installing or removing switching cards, or making internal changes, such as installing or removing jumpers.

Do not touch any object that could provide a current path to the common side of the circuit under test or power line (earth) ground. Always make measurements with dry hands while standing on a dry, insulated surface capable of withstanding the voltage being measured.

The instrument and accessories must be used in accordance with its specifications and operating instructions, or the safety of the equipment may be impaired.

Do not exceed the maximum signal levels of the instruments and accessories, as defined in the specifications and operating information, and as shown on the instrument or test fixture panels, or switching card.

When fuses are used in a product, replace with the same type and rating for continued protection against fire hazard.

Chassis connections must only be used as shield connections for measuring circuits, NOT as safety earth ground connections.

If you are using a test fixture, keep the lid closed while power is applied to the device under test. Safe operation requires the use of a lid interlock.

If a  screw is present, connect it to safety earth ground using the wire recommended in the user documentation.

The  symbol on an instrument means caution, risk of danger. The user should refer to the operating instructions located in the user documentation in all cases where the symbol is marked on the instrument.

The  symbol on an instrument means caution, risk of danger. Use standard safety precautions to avoid personal contact with these voltages.

The  symbol on an instrument shows that the surface may be hot. Avoid personal contact to prevent burns.

The  symbol indicates a connection terminal to the equipment frame.

If this  symbol is on a product, it indicates that mercury is present in the display lamp. Please note that the lamp must be properly disposed of according to federal, state, and local laws.

The **WARNING** heading in the user documentation explains dangers that might result in personal injury or death. Always read the associated information very carefully before performing the indicated procedure.

The **CAUTION** heading in the user documentation explains hazards that could damage the instrument. Such damage may invalidate the warranty.

Instrumentation and accessories shall not be connected to humans.

Before performing any maintenance, disconnect the line cord and all test cables.

To maintain protection from electric shock and fire, replacement components in mains circuits - including the power transformer, test leads, and input jacks - must be purchased from Keithley Instruments. Standard fuses with applicable national safety approvals may be used if the rating and type are the same. Other components that are not safety-related may be purchased from other suppliers as long as they are equivalent to the original component (note that selected parts should be purchased only through Keithley Instruments to maintain accuracy and functionality of the product). If you are unsure about the applicability of a replacement component, call a Keithley Instruments office for information.

To clean an instrument, use a damp cloth or mild, water-based cleaner. Clean the exterior of the instrument only. Do not apply cleaner directly to the instrument or allow liquids to enter or spill on the instrument. Products that consist of a circuit board with no case or chassis (e.g., a data acquisition board for installation into a computer) should never require cleaning if handled according to instructions. If the board becomes contaminated and operation is affected, the board should be returned to the factory for proper cleaning/servicing.

Introduction

The Keithley Instruments Series 2600A System SourceMeter® instruments offer electronic component and semiconductor device manufacturers a scalable, high throughput, highly cost-effective solution for precision DC, pulse, and low frequency AC source-measure testing.

Capabilities and features

- Models 2601A/2602A System SourceMeter instruments:
 - Source \pm DC voltage from 1 μ V to 40.4 V
 - Source \pm DC current from 1pA to 3.03 A
 - Source \pm pulse current up to 10 A
 - Measure \pm pulse current up to 10 A
 - Measure \pm DC voltage from 1 μ V to 40.8 V
 - Measure \pm DC current from 1 pA to 3.06 A
- Models 2611A/2612A System SourceMeter instruments:
 - Source \pm DC voltage from 1 μ V to 202 V
 - Source \pm DC current from 1p A to 1.515 A
 - Source \pm pulse current up to 10 A
 - Measure \pm pulse current up to 10 A
 - Measure \pm DC voltage from 1 μ V to 204 V
 - Measure \pm DC current from 1 pA to 1.53 A
- Models 2635A/2636A System SourceMeter instruments:
 - Source +/- DC voltage from 1 μ V to 20 2V
 - Source +/- DC current from 20 fA to 1.515 A
 - Source \pm pulse current up to 10 A
 - Measure \pm pulse current up to 10 A
 - Measure +/- DC voltage from 1 μ V to 204 V
 - Measure +/- DC current from 1 fA to 1.53 A
- Resistance and power measurement functions.
- LXI Class C.
- High Capacitance mode for load impedance up to 50 μ f.
- Contact check function.
- Two independent source-measure channels (Models 2602A, 2612A, and 2636A only).
- Four-quadrant sink or source operation.
- Embedded Test Script Processor (TSP™) accessible from any host interface; responds to high-speed test scripts comprised of instrument control commands.
- Linear, logarithmic, and custom sweeping and pulsing.
- Internally stores five user setup options.
- Two dedicated reading buffers per SMU that can each store and recall over 140,000 measurements. Additional dynamic reading buffers can be created.
- Filtering to reduce reading noise.
- Supports IEEE-488 (GPIB), RS-232, and Ethernet.
- TSP-Link: Allows TSP-enabled instruments to trigger and communicate with each other.
- Digital I/O port: Allows the Series 2600A to control other devices.
- Trigger model supports robust triggering and synchronization schemes at hardware speeds.
- Advanced TSP features enable parallel script execution across the TSP-Link network.
- USB flash drive access for saving data buffers, test scripts, and user setups.

- Web-based characterization tool that provides easy access to data gathering, sweeping, and pulsing features.

Organization of manual sections

The manual sections in the PDF version of this manual can be viewed by clicking the “Bookmarks” tab on the left side of this window. This tab also provides direct links to the various sections and section topics.

The manual sections are also listed in the Table of Contents located at the beginning of this manual.

General information

Warranty information

Warranty information is located at the front of this manual. Should your Series 2600A require warranty service, contact the Keithley Instruments representative or authorized repair facility in your area for further information. When returning the instrument for repair, be sure to complete and return the service form at the back of this manual to provide the repair facility with the relevant information.

Contact information

If you have any questions, please contact your local Keithley Instruments representative or call one of our Application Engineers at 1-888-KEITHLEY (1-888-534-8453), U.S. and Canada only. You can also contact us through our website at www.keithley.com.

Unpacking and inspection

Inspection for damage

The Series 2600A was carefully inspected electrically and mechanically before shipment. After unpacking all items from the shipping carton, check for any obvious signs of physical damage that may have occurred during transit (there may be a protective film over the display lens, which can be removed). Report any damage to the shipping agent immediately. Save the original packing carton for possible future shipment. Before removing the Series 2600A from the bag, observe the following handling precautions.

Handling precautions

- Always grasp the Series 2600A by the covers or by the handle.
- After removing the Series 2600A from its anti-static bag, inspect it for any obvious signs of physical damage. Report any such damage to the shipping agent immediately.
- When the Series 2600A is not installed and connected, keep the unit in its anti-static bag and store it in the original packing carton.

Package content

The following items are included with every Series 2600A order:

- Model 2601A, 2602A, 2611A, 2612A, 2635A, or 2636A SourceMeter instrument with line cord
- Two RJ-45 crossover cables

- Certificate of calibration
- Quick Start Guide
- CD-ROMs that contain:
 - PDFs of the User's and Reference Manuals
 - Test Script Builder script development software
- Accessories as ordered

The following items are included with Models 2601A, 2602A, 2611A, and 2612A only:

- 2600-KIT Screw terminal connector kit (two with Models 2602A and 2612A and one with Models 2601A and 2611A)

The following items are included with Models 2635A and 2636A only:

- 2600-IAC interlock connector
- CS-1423-3 inverted mini plug
- 2636-002 wire cutting
- 2600-ALG-2 low noise triax cable with alligator clips, UL approved for up to 42 V, 2m (6.6 ft) (two with Model 2636A and one with Model 2635A)
- Quick Start Guide

Options and accessories

GPIB cables, interfaces, and adaptors (connects Series 2600A to the GPIB bus)

Models 7006-1 and 7006-2: Single-shielded GPIB cables. Terminated with one straight connector (non-stacking) and one feed-through connector. Model 7006-1 is 1m long; Model 7006-2 is 2m long.

KPCI-488LP: IEEE-488 interface/controller for the PCI Bus.

KPXI-488: IEEE-488 interface board for the PXI Bus.

KUSB-488A: USB-to-GPIB interface adapter.

Models 7007-05, 7007-1, 7007-2, and 7007-4: Double-shielded premium GPIB cables. Each end is terminated with a feed-through metal housing for longest life and best performance. Model 7007-05 is 0.5m long; 7007-1 is 1m long; Model 7007-2 is 2m long; Model 7007-4 is 4m long.

Model 7010: Shielded GPIB-to-GPIB bus adapter. Provides additional clearance between the rear panel and GPIB cable connector. Allows easier access to cables and other connectors.

RS-232 cable (connects Series 2600A to the RS-232)

Model 7009-5 shielded RS-232 cable: This straight-through cable connects the RS-232 of the Series 2600A to the RS-232 interface of your PC. This cable is 5 ft long and uses shielded cable and connectors to reduce electromagnetic interference (EMI).

TSP-Link cable (connects Series 2600A to the TSP-Link or LAN)

CA-180-3A CAT 5 cable: Crossover CAT5 LAN cable that connects the TSP-Link of the Series 2600A to other instruments. It can also be used to connect the instrument to LAN equipment with Auto_MDIX or to connect the LAN port of the Series 2600A to a PC.

Digital I/O port cables (connects Digital I/O to other devices)

CA-126-1 DB-25 cable: DB-25 male to female DB-25 cable, 1.5 m (5 ft) long, used to connect the digital I/O port to other instruments.

2600-TLINK trigger cable: Cable used to connect the digital I/O port of Series 2600A instruments to other Keithley instruments equipped with Trigger Link (TLINK).

User's and Reference manuals

The Series 2600A's User and Reference Manuals are provided on the product information CD-ROM in PDF format. The User's Manual provides the fundamental operating information for the instrument. The Reference Manual provides additional information on the topics covered in the User's Manual. The Reference Manual also includes advanced operation topics and maintenance information.

Front and rear panel familiarization

Front panel summaries

The front panels of the Series 2600A are shown in [Figure 1-1](#). The descriptions of the front panel controls follow [Figure 1-1](#).

Figure 1-1
Front panel (see definitions below figure)

NOTE The Models 2601A, 2611A, and 2635A have one source measure channel (Channel A), and the Models 2602A, 2612A, and 2636A have two source measure channels (Channel A and Channel B).

1. Special keys and power switch:

DISPLAY	Toggles between the various source-measure displays and the user message mode. Selects Model 2602A, 2612A, 2636A single or dual-channel display.
CONFIG	Use to configure a function or operation.
POWER	Power switch: The in position turns SourceMeter instrument on (I); the out position turns it off (O).
Number	The number keys (0-9, +/-, 0000) allow direct numeric entry in the EDIT mode. Keys

2. Source-measure setup, performance control, and special operation:

Top row

Models 2601A, 2602A, 2611A, 2612A, 2635A, and 2636A:

SRC	Channel A selects the source function (V or A) and places cursor in the source field for editing.
MEAS	Channel A cycles through measure functions (V, A, Ω , or W).
LIMIT	Channel A places the cursor in the compliance limit field for editing.
MODE	Channel A directly chooses the measurement function (V, A, Ω , or W).

Models 2602A, 2612A, and 2636A only:

SRC	Channel B selects the source function (V or A) and places cursor in the source field.
MEAS	Channel B cycles through measure functions (V, A, Ω , or W).
LIMIT	Channel B places the cursor in the compliance limit field for editing.
MODE	Channel B directly chooses the measurement function (V, A, Ω , or W).

Middle row

Models 2601A, 2602A, 2611A, 2612A, 2635A, and 2636A:

DIGITS	Channel A changes display resolution to 4-1/2, 5-1/2, or 6-1/2 digits.
SPEED	Channel A sets the measurement speed by controlling the A/D converter measurement aperture.
REL	Channel A controls relative, which allows a baseline value to be subtracted from a reading.
FILTER	Channel A controls the digital filter, which can be used to reduce reading noise.

Models 2602A, 2612A, and 2636A only:

DIGITS	Channel B changes display resolution to 4-1/2, 5-1/2, or 6-1/2 digits.
SPEED	Channel B sets the measurement speed by controlling the A/D converter measurement aperture.
REL	Channel B controls relative, which allows a baseline value to be subtracted from a reading.
FILTER	Channel B controls the digital filter, which can be used to reduce reading noise.

Bottom row

LOAD	Loads factory or user-defined scripts for execution.
RUN	Runs the last selected factory or user-defined scripts.
STORE	Stores readings, source values, and timestamp values in one of two internal buffers per channel for later recall.
RECALL	Recalls stored readings, source values, and timestamp values from either of the two buffers.
TRIG	Triggers readings.
MENU	Accesses the main menu for saving and recalling setups, selecting a remote interface, line frequency, self-tests, serial number, and beeper control.
EXIT	Cancels selection and backs out of menu structure. Also used as a LOCAL key to take the unit out of remote.
ENTER	Accepts selection and moves to the next choice or exits the menu.

3. Range keys:

\triangle and ∇	Selects the next higher or lower source or measure range.
AUTO	Enables or disables source or measure auto range.

4. Output control and LED status indicator:

OUTPUT ON/OFF	Turns source output on or off.
LED indicator	Turns on when output is on.

5. Navigation Wheel, USB port, and cursor keys:

Use the **CURSOR** keys to move the cursor left or right. Once you select the desired source or compliance value, push the **navigation wheel** to edit the value. You can use the navigation wheel to enable or disable the edit mode.

Use the **CURSOR** keys or navigation wheel to navigate through menu items. To view a menu value, use the **CURSOR** keys for cursor control and then rotate the navigation wheel to change the value. Push the **navigation wheel** to open the submenu items or to select a menu option or a value.

Use the USB port to connect with a USB flash drive. The USB flash drive stores reading buffer data, scripts, and user setup options.

6. Display indicators (not shown):

EDIT	Unit is in the source editing mode
ERR	Questionable reading or invalid cal step
REM	Unit in remote mode
TALK	Unit is addressed to talk
LSTN	Unit is addressed to listen
SRQ	Service request
REL	Relative mode enabled
FILT	Digital filter is enabled
AUTO	Auto source or measure range is selected
ARM	Unit is armed and ready to run
* (asterisk)	Readings are being stored in the buffer

Rear panel summaries

The rear panels of Models 260A, 2611A and Models 2602A, 2612A are shown in *Figure 1-2*. The descriptions of the rear panel components follow *Figure 1-2*. The rear panels of Models 2625A and 2636A are shown in *Figure 1-3*. The descriptions of the rear panel components follow *Figure 1-3*.

Figure 1-2
Models 2601A/2611A and 2602A/2612A rear panels (see definitions below figure)

1. CHANNEL A and CHANNEL B (Channel B on 2602A/2612A only)

Input/output connections for source, sense, and guard.

2. DIGITAL I/O

Female DB-25 connector. Fourteen pins for digital input or output, one pin for output enable (2601A/2602A) or safety interlock (2611A/2612A); +5V and GND pins are also provided.

Use a cable equipped with a male DB-25 connector (Keithley Instruments part number CA-126-1CA).

3. IEEE-488

Connector for IEEE-488 (GPIB) operation. Use a shielded cable, such as the Model 7007-1 or Model 7007-2.

4. Cooling exhaust vent

Exhaust vent for the internal cooling fan. Keep the vent free of obstructions to prevent overheating.

5. Chassis ground

Ground screw for connections to chassis ground.

6. Low noise chassis ground

Ground jack for connecting Output HI or LO to chassis.

7. RS-232

Female DB-9 connector. For RS-232 operation, use a straight-through (not null modem) DB-9 shielded cable (Keithley Instruments Model 7009-5) for connection to the PC.

8. TSP-Link

Expansion interface that allows a Series 2600A and other TSP-enabled instruments to trigger and communicate with each other. Use a category 5e or higher LAN crossover cable (Keithley Instruments part number CA-180-3A).

9. Power module

Contains the AC line receptacle and power line fuse. The instrument can operate on line voltages of 100V to 240V AC at line frequencies of 50Hz or 60Hz.

10. LAN

Use this RJ-45 connector to connect the instrument to the local area network. The RJ-45 connector connects a network card, a network switch, a router or a hub. When connecting directly to a PC, a crossover cable (included) must be used. When connecting to a network switch, router, or hub, a normal CAT-5 cable (not provided) should be used unless your equipment has Auto-MDIX capabilities. If it does have Auto-MDIX, the crossover cables may be used.

Figure 1-3
Models 2635A/2636A rear panels (see definitions below figure)

1. CHANNEL A and CHANNEL B (Channel B on Model 2636A only)

Triax connectors for input/output, guard, and sense connections. Use only low-noise triax cables such as the Keithley Instruments Model 7078-TRX (available in several lengths). Connector terminals and associated triax cable conductors are as follows:

Table 1-1
Connectors and triax cable conductors

Connector	Center conductor	Inner ring	Outer ring
LO	Sense LO	Input/Output LO	Chassis ground
HI	Input/Output HI	Guard	Chassis ground
SENSE HI	Sense HI	Guard	Chassis ground
Triax cable	Center conductor	Inner shield	Outer shield

WARNING *When connecting to the model 2611A, 2612A, 2635A and 2636A SMU outputs, with cables not rated for voltages above 42V, such as the 2600A-ALG-2, you must disable the high voltage output by using the INTERLOCK function as defined in section 10 of this manual. Leaving the high voltage enabled while not properly insulating the external connections to the unit poses a shock hazard which could cause serious injury to the user. It is also recommended that the LO connection terminal not be allowed to float by connecting it to signal ground or another known signal reference.*

2. DIGITAL I/O

Female DB-25 connector. Fourteen pins for digital input or output, one pin for safety interlock. Use a cable equipped with a male DB-25 connector (Keithley Instruments part number CA-126-1CA).

3. IEEE-488

Connector for IEEE-488 (GPIB) operation. Use a shielded cable, such as the Model 7007-1 or Model 7007-2.

4. Cooling exhaust vent

Exhaust vent for internal cooling fan. Keep vent free of obstructions to prevent overheating.

5. Chassis ground

Ground screw for connections to chassis ground.

6. RS-232

Female DB-9 connector. For RS-232 operation, use a straight-through (not null modem) DB-9 shielded cable for connection to the PC (Keithley Instruments Model 7009-5).

7. TSP-Link

Expansion interface that allows a Series 2600A and other TSP-enabled instruments to trigger and communicate with each other. Use a category 5e or higher LAN crossover cable (Keithley Instruments part number CA-180-3A).

8. Power module

Contains the AC line receptacle and power line fuse. The instrument can operate on line voltages of 100V to 240V AC at line frequencies of 50Hz or 60Hz. See [Section 21](#) of this manual for line fuse replacement instructions.

9. Triax connector on Ground Module

Channel A and Channel B low noise chassis ground triax connectors. Use only low-noise triax cables such as the Keithley Model 7078-TRX. Connector terminals and associated triax cable connectors are as follows:

Table 1-2

Triax connector on ground module

Connector	Center conductor	Inner ring	Outer ring
LO	Output Lo	Floating	Chassis Ground
Triax cable	Center conductor	Inner shield	Outer shield

10. Phoenix connector on Ground Module

Channel A and Channel B Low noise chassis ground Phoenix connector.

11. LAN

Use this RJ-45 connector to connect the instrument to the local area network. The RJ-45 connector connects a network card, a network switch, a router or a hub. When connecting directly to a PC, a crossover cable (included) must be used. When connecting to a network switch, router, or hub, a normal CAT-5 cable (not provided) should be used unless your equipment has Auto-MDIX capabilities. If it does have Auto-MDIX, the crossover cables may be used.

Cooling vents

The Series 2600A has side intake and rear exhaust vents. One side must be unobstructed when rack mounted to dissipate heat. Do not place a container of liquid (water or coffee for instance) on the top cover. If it spills, the liquid will enter the case through the vents and cause severe damage.

Excessive heat could damage the Series 2600A and degrade its performance. The Series 2600A must be operating in an environment where the ambient temperature does not exceed 50°C.

CAUTION To prevent damaging heat build-up and ensure specified performance, observe to the following precautions:

The rear exhaust vent and at least one side vent must be kept free of any obstructions. Even partial blockage could impair proper cooling.

DO NOT position any devices adjacent to the Series 2600A that force air (heated or unheated) into or onto its cooling vents or surfaces. This additional airflow could compromise accuracy performance.

When rack mounting the Series 2600A, make sure there is adequate airflow around at least one side to ensure proper cooling. Adequate airflow enables air temperatures within approximately one inch of the Series 2600A surfaces to remain within specified limits under all operating conditions.

Rack mounting high power dissipation equipment adjacent to the Series 2600A could cause excessive heating to occur. The specified ambient temperature must be maintained around the surfaces of the Series 2600A to specified accuracies. A good measure to ensure proper cooling in rack situations with convection cooling only is to place the hottest equipment (for instance, the power supply) at the top of the rack. Precision equipment (such as the Series 2600A) should be placed as low as possible in the rack where temperatures are coolest. Adding space panels below the Series 2600A will help ensure adequate air flow.

Power-up

Line power connection

Follow the procedure below to connect the Series 2600A to line power and turn on the instrument. The Series 2600A operates from a line voltage of 100V to 240V at a frequency of 50Hz or 60Hz. Line voltage is automatically sensed. There are no switches to set. Make sure the operating voltage in your area is compatible.

CAUTION Operating the instrument on an incorrect line voltage may cause damage to the instrument, possibly voiding the warranty.

1. Before plugging in the power cord, make sure that the front panel power switch is in the off (O) position.
2. Connect the female end of the supplied power cord to the AC receptacle on the rear panel.
3. Connect the other end of the power cord to a grounded AC outlet.

WARNING *The power cord supplied with the Series 2600A contains a separate ground wire for use with grounded outlets. When proper connections are made, the instrument chassis is connected to power line ground through the ground wire in the power cord. Failure to use a grounded outlet may result in personal injury or death due to electric shock.*

4. Turn the instrument on by pressing the front panel power switch to the on (I) position.

Line frequency

The Series 2600A will operate at line frequencies of either 50Hz or 60Hz. For best measurement noise performance, the unit should be configured to match the actual line frequency used, as follows:

1. Press the **MENU > LINE-FREQ** and then press **ENTER**.
2. Select the appropriate frequency and then press **ENTER**.
Note: Select **AUTO** to automatically detected the line frequency.
3. Press **EXIT** to back out of the menu structure.

Via remote, use the `localnode.linefreq` command to set the line frequency. For example, the following command sets the line frequency to 60Hz:

```
localnode.linefreq = 60
```

To set automatic line frequency detection from a remote interface use:

```
localnode.autolinefreq = true
```

Fuse replacement

A rear panel fuse drawer is located below the AC receptacle (refer to [Figure 1-2](#) for Models 2601A/2602A/2611A/2612A and [Figure 1-3](#) for Models 2635A/2636A). This fuse protects the power line input of the instrument. If the line voltage fuse needs to be replaced, refer to [Line fuse replacement](#) in [Section 21](#).

Power-up sequence

On power-up, the Series 2600A performs self-tests and momentarily lights all segments and indicators. If a failure is detected, the instrument rotates through any error messages detected at start-up (error messages are listed in [Appendix A](#)).

NOTE If a problem develops while the instrument is under warranty, return it to Keithley Instruments, Inc., for repair.

Assuming no errors occur, the Series 2600A will power-up as follows:

1. The OUTPUT indicators and display pixels flash briefly.
2. The following items are shown in sequence:
 - The firmware revision number.
 - The line frequency.
 - The TSP-Link node.
 - The enabled command interface(s) and address (GPIB/LAN/RS-232).

System identification

Serial number, firmware revision, and calibration dates can be displayed by selecting **SYSTEM-INFO** from the main menu.

Complete the following steps to view the system information.

1. Press **MENU > SYSTEM-INFO**.
2. Choose one of the following:
 - **FIRMWARE**
 - **SERIAL#**
 - **CAL**

For remote programming, use the `*IDN?` query to read system information.

Beeper

With the beeper enabled, a beep will be issued to acknowledge the following actions:

- A short beep, emulating a key click, is issued when a front panel key is pressed.
- A short beep is also issued when the navigation wheel is turned or pressed.
- A longer beep is issued when the source output is turned on.

Complete the following steps to turn the beeper on or off.

1. select **MENU > BEEPER**.
2. Choose one of the following:
 - **ENABLE**
 - **DISABLE**

Via remote, use the `beeper.enable` command to control the beeper. For example, the following enables the beeper:

```
beeper.enable = 1
```

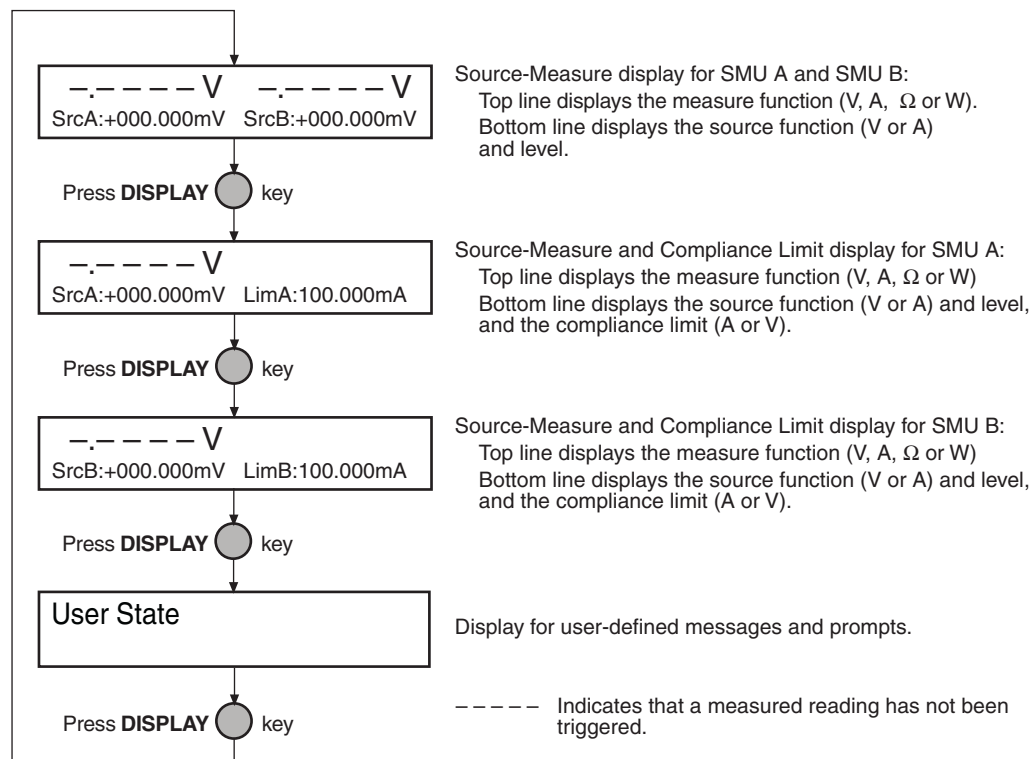

Display modes

Use the **DISPLAY** key to cycle through the various display modes shown in [Figure 1-4](#).

(Models 2602A, 2612A, and 2636A only) Press the **DISPLAY** key more than once to cycle through the dual channel and single channel display modes. This applies to CHANNEL A (SMU A) and CHANNEL B (SMU B).

The Models 2601A, 2611A, and 2635A are a single channel (SMU A). Refer to [Section 11](#) for more information on display messaging.

Figure 1-4
Display modes

Editing controls

Source and compliance editing

When the Series 2600A is in the edit mode (EDIT indicator on), the editing controls are used to set source and compliance values. Note that source auto ranging will turn off when editing the source value.

Editing source values

Complete the following steps to edit the source.

1. Press the **SRC** key. The cursor flashes in the source value field.
2. Use the **CURSOR** arrow keys or the **navigation wheel** to move the cursor to the desired digit.
3. Push the **navigation wheel** or **ENTER** to edit the source value. The EDIT indicator is illuminated.
4. Do one of the following to change the source value:
 - Rotate the **navigation wheel** to adjust the digit.
Note: The digit automatically overflows or underflows to the next digit when wrapping from 9 to 0 or from 0 to 9.
 - If the keypad feature is enabled, use the numeric keys (0-9, +/-, 0000) to enter the source value.
Note: The +/- toggles the polarity, and 0000 sets the value to 0.
5. Once the desired value displays, press **ENTER**.
Note: The EDIT indicator is *not* illuminated.
6. (Optional) Press the **EXIT** key to cancel source editing.

Editing compliance values

Complete the following steps to edit the compliance value.

1. Do one of the following:
 - (Model 2601A/2611A/2635A and 2602A/2612A/2636A in single-channel display mode only) Press the **LIMIT** key.
 - (Model 2602A/2612A/2636A dual-channel display mode only) Press **LIMIT** or **CONFIG > LIMIT** to edit the compliance limit.
2. Choose one of the following:
 - **VOLTAGE**
 - **CURRENT**
3. Use the **CURSOR** arrow keys to move the cursor to the desired value.
4. Press the **navigation wheel** or **ENTER** to enter edit mode. The EDIT indicator is illuminated.
5. Do one of the following to modify the compliance limit value:
 - Rotate the **navigation wheel** to adjust the value.
Note: The digit automatically overflows or underflows to the next digit when wrapping from 9 to 0 or from 0 to 9.
 - If the keypad feature is enabled, use the numeric keys (0-9) to enter the value.
6. Press **ENTER** to complete editing.
Note: The EDIT indicator is *not* illuminated.
7. (Optional) Press the **EXIT** key cancel changes.

Menu navigation

When the Series 2600A is not in the edit mode (the EDIT indicator is not illuminated), the editing controls are used to navigate the Main and Configuration menus to make selections and/or set values (see [Menu navigation](#) for more information). After entering a menu structure, use the editing keys as follows:

Selecting menu items

- Use the **CURSOR** arrow keys to select a menu or an option.
- Press the **ENTER** key to select an item or menu option.
- Rotate the **navigation wheel** (clockwise or counter-clockwise) to select a value.
- Use the **EXIT** key to cancel changes or to return to the main menu.

NOTE You can use the **navigation wheel** to select items from the menu or a submenu.

Setting a value

There are two ways to adjust a value: Value adjust or numeric entry. To use the keypad, the keypad feature must be enabled. Both methods use the following editing techniques:

- To set a value to zero, press the **0000** numeric entry key.
- To toggle the polarity of a value, press the **+/-** numeric entry key.

Value adjust method

1. Use the **CURSOR** arrow keys to move the cursor to the value that you want to edit.
2. Push the **navigation wheel** or **ENTER** to enter edit mode. The EDIT indicator is illuminated.
3. Rotate the **navigation wheel** to set the appropriate value.
4. Press **ENTER** to select the value. Press **EXIT** to cancel the change.

Numeric entry method

1. Use the **CURSOR** arrow keys to move the cursor to the value that you want to edit.
2. Press the number entry key (**0** to **9**). The cursor moves to the next value on the right.
3. Repeat [Step 2.](#) as required to set the desired values.
4. Press **ENTER** to select the value.
5. (Optional) Press **EXIT** the cancel change and to return to the main menu.

NOTE The numeric entry method may only be used if the numeric keypad is enabled.

Menu types

Many aspects of operation are configured through menus. There are two types of menus. Refer to [Menu navigation](#) for more details on using menus.

Main menu

The main menu is summarized in [Table 1-3](#), along with the reference for each main selection. To access the menu items shown in [Table 1-3](#), press the **MENU** key, and then make your selection.

Table 1-3
Main menu

Menu selection	Description	Reference
SCRIPT LOAD SAVE	Recalls users scripts saved. Loads scripts into nonvolatile memory. Saves scripts.	Section 12
SETUP SAVE RECALL POWERON	Saves and recalls user and factory setup options. Saves user setup options. Recalls user setup options. Sets the default configuration.	Section 1
GPIB ADDRESS ENABLE	Configure the GPIB interface options. Configure the address for the GPIB interface. Enables and disables the GPIB interface.	Section 15 Section 15 Section 8
LAN STATUS CONFIG APPLY_SETTINGS RESET ENABLE	Use to configure the local area network (LAN) Displays connection status. Use to configure the IP address and gateway. Applies the configurations selected from the CONFIG menu. Restores the default settings. Enables and disables the LAN.	Section 16
RS232 BAUD BITS PARITY FLOW-CTRL ENABLE	Controls the options for the RS-232 interface Sets the baud rate Configures the number of bits Sets the parity Configures the flow control Use to enable and disable the RS-232 interface	Section 15
TSPINK NODE RESET	An alternate way to configure the instrument for TSP-Link Selects the instrument node identifier Use to reset the TSP-Link network	Section 14
UPGRADE	Used to upgrade the firmware from a USB memory stick	Section 21

RESET-PASSWORD	Reset the system password.	

Configuration menus

The configuration menus are summarized in [Table 1-4](#), along with the reference for each main selection. There are two ways to make selections:

- Press **CONFIG**, then navigate to the desired submenu.
- Press **CONFIG**, then press the associated key. For example, pressing **CONFIG** followed by **REL** takes you directly to the Relative menu.

Table 1-4
Configuration menus

Menu selections	Shortcut	Description	Reference
CHANNEL-A SRC MEAS LIMIT SPEED REL FILT OUTPUT	SRC MEAS LIMIT SPEED REL FILTER OUTPUT	Configure Channel A: V-source sense, low range; I-source low range, and HighC-mode. Interface configuration

The following summarizes basic interface configuration for the Series 2600A. Details on the interfaces, including configuration, are provided in [Section 15](#). Use the editing controls for [Menu navigation](#) described earlier in this section to select and configure the interface.

Complete the following steps to select the GPIB interface:

1. Press **MENU > GPIB** and then press **ENTER**.
2. Choose **ADDRESS**, then press **ENTER**.
3. Set the **GPIB** address (0 to 30) and press **ENTER**.
4. Press **EXIT** to return to the main menu.

Complete the following steps to select the RS-232 interface

1. Press **MENU > RS232**, then press **ENTER**.
2. Do the following:
 - Set the **BAUD** rate: 300, 600, 1200, 2400, 4800, 9600, 19200, 38400, 57600, or 115200.
 - Set **BITS**: 7 or 8.
 - Set **PARITY**: NONE, ODD, or EVEN.
 - Set the **FLOW-CTRL**: NONE or HARDWARE.
3. Press **EXIT** to return to the main menu.

See [Section 15](#) for more information about communications interfaces and how to select the LAN interface.

USB storage overview

The Keithley Instruments Series 2600A System SourceMeter® instrument includes a USB port on the front panel. To store scripts and to transfer files from the instrument to the host PC, insert a USB flash drive into the USB port.

- For additional information on saving reading buffers to the USB flash drive, see [Reading Buffers](#) in [Section 7](#).
- For additional information on storing and loading scripts to and from the USB flash drive, see [Saving a user script](#) in [Section 12](#).
- For additional information on file I/O, see [File I/O](#) in [Section 19](#).
- For additional information on saving user setups, see [User setup](#) in [Section 3](#).

Connecting the USB flash drive

The Series 2600A supports flash drives that comply with USB 1.0 and 2.0 standards. You can save data to the USB flash drive from the front panel or you can create a script to save data to the USB flash drive.

To connect the USB flash drive, insert the USB flash drive into the USB port, located on the front panel of the instrument (see [Figure 1-5](#)).

Figure 1-5
USB port

Using the file system

File system navigation

The Lua `fs` library provides the command set necessary to navigate the file system and list the available files on a flash drive. The instrument encapsulates this command set as an `fs` logical instrument, so that the file system of any given node is available to the entire TSP-Link system. For example, the command `node[5].fs.readdir(". ")` can be used to read the contents of the current working directory on Node 5.

To allow for future enhancements, the root folder of the USB flash drive has the absolute path `"/usb1/"`.

NOTE Both slash (/) and backslash (\) are supported as directory separators.

The following Lua `fs` commands, which support basic navigation and directory listing, are included for your reference:

```
fs.chdir
fs.cwd
fs.is_dir
fs.is_file
fs.mkdir
fs.readdir
fs.rmdir
```

The following Lua `fs` commands are not supported at this time:

```
fs.chmod
fs.chown
fs.stat
```

Error and status messages

Error and status messages briefly displayed. During operation and programming, you will encounter a number of front panel messages. Typical messages are either status or error notifications, as listed in [Appendix A](#).

Messages, both status and error, are held in queues. For information on retrieving error messages from queues, refer to [Appendix A](#).

Input/output connectors

The Keithley Instruments Series 2600A System SourceMeter® Models 2601A, 2602A, 2611A, and 2612A use screw connectors for input and output connections to devices under test (DUTs). The Model 2602A/2612A uses two connectors as shown in [Figure 2-1](#) (one for each source-measure unit (SMU) channel). The Model 2601A/2611A has only one connector for a single SMU. Models 2635A and 2636A use triax connectors as shown in [Figure 2-2](#).

A connector can be removed from the rear panel by loosening the two captive retaining screws and pulling it off the rear panel. Each screw can accommodate from 24 AWG (0.2mm²) to 12 AWG (2.5mm²) conductors.

After making the wire connections from a connector to a DUT, reinstall the connector onto the rear panel and tighten the two captive screws.

WARNING *Hazardous voltages may be present on the output and guard terminals. To prevent electrical shock that could cause injury or death, NEVER make or break connections to the Series 2600A while the output is on. Power off the equipment from the front panel or disconnect the main power cord from the rear of the SourceMeter instrument before handling cables connected to the outputs. Putting the equipment into standby does not guarantee the outputs are not powered if a hardware or software fault occurs.*

Maximum floating (common mode) voltage for a SMU is 250V. Exceeding this level could damage the instrument and create a shock hazard. See [Floating an SMU](#) later in this section for details on floating the SMUs.

The input/output connectors of the SourceMeter instruments are rated for connection to circuits rated Installation Category I only, with transients rated less than 1500V peak. Do not connect the Series 2600A terminals to CAT II, CAT III, or CAT IV circuits. Connections of the input/output connectors to circuits higher than CAT I can cause damage to the equipment or expose the operator to hazardous voltages.

To prevent electric shock and/or damage to the SourceMeter instrument, when connecting to a source with a greater current capability than the Series 2600A, a fuse should be provided in-line with the Series 2600A input/output connectors rated no more than 3A.

Figure 2-1
2602A/2612A input/output connectors

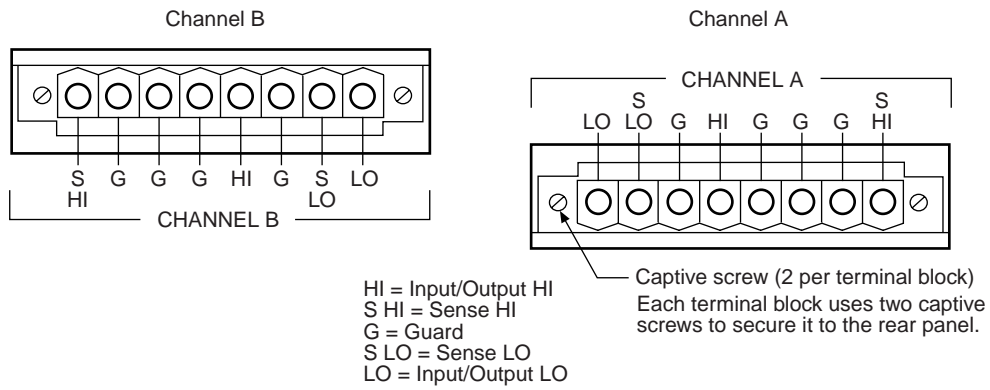

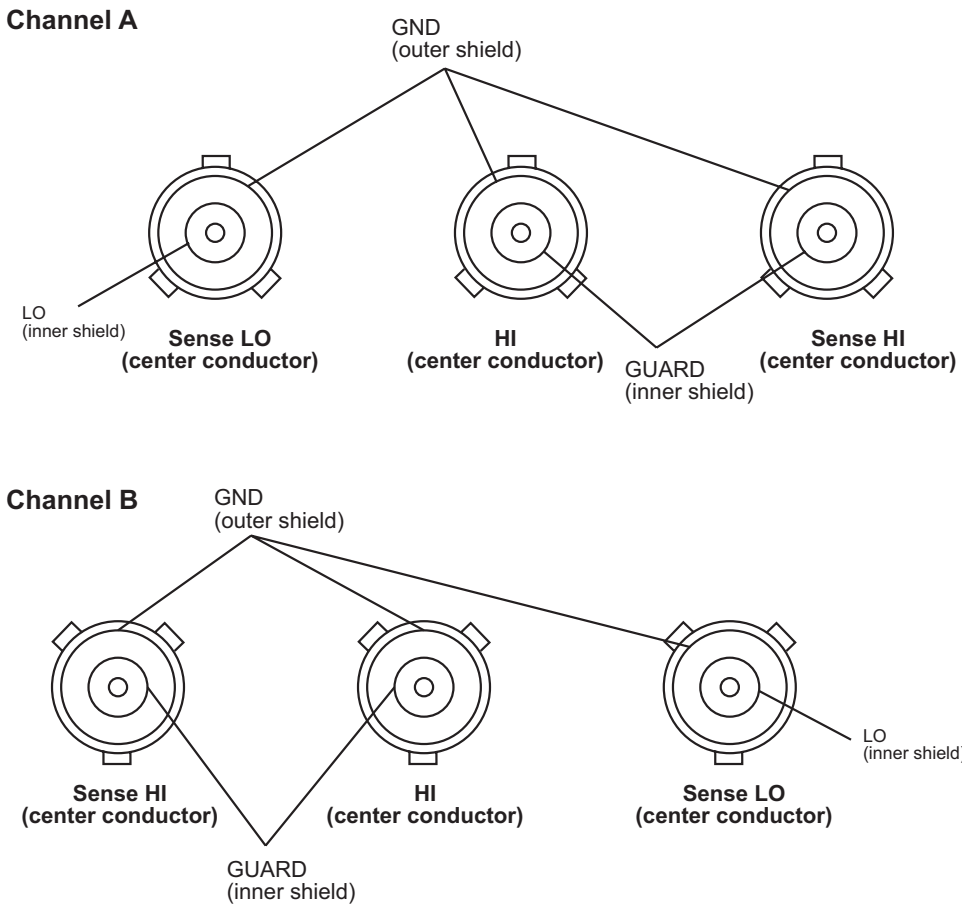

Figure 2-2
Model 2636A input/output connectors

Input/output LO and chassis ground

As shown in [Figure 2-3](#), SMU input/output LOs are available at the rear panel terminal blocks. Input/output LOs are not connected between channels and are electrically isolated from chassis ground.

As shown, there is a low-noise chassis ground banana jack that can be used as a common signal ground point for Input/Output LOs. This low-noise signal ground banana jack is connected to the chassis through a Frequency Variable Resistor (FVR).

The FVR (see [Figure 2-4](#)) is used to isolate the SMUs from high frequencies that may be present on the chassis of the Series 2600A. As frequencies on the chassis increase, the resistance of the FVR increases to dampen its effects.

NOTE Keep in mind that the chassis should never be used as a ground point for signal connections. High frequencies present on the chassis of the Series 2600A may result in higher noise. The chassis should only be used as a safety shield. Use the chassis screw for connections to the chassis of the Series 2600A. For Model 2636A, connect to ground on the ground module not to the chassis screw.

Figure 2-3
Model 2602A/2612A input/output LO and chassis ground terminals

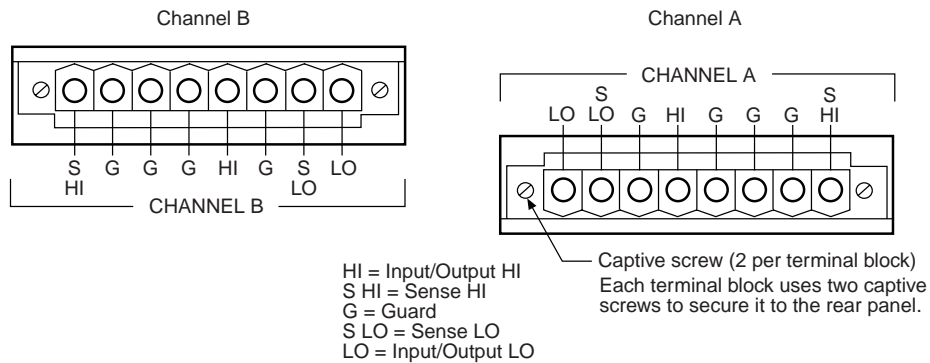

Figure 2-4
Model 2636A input/output and chassis ground

Figure 2-5
Model 2602A/2612A Low-Noise Chassis Ground Banana Jack and Chassis Screw

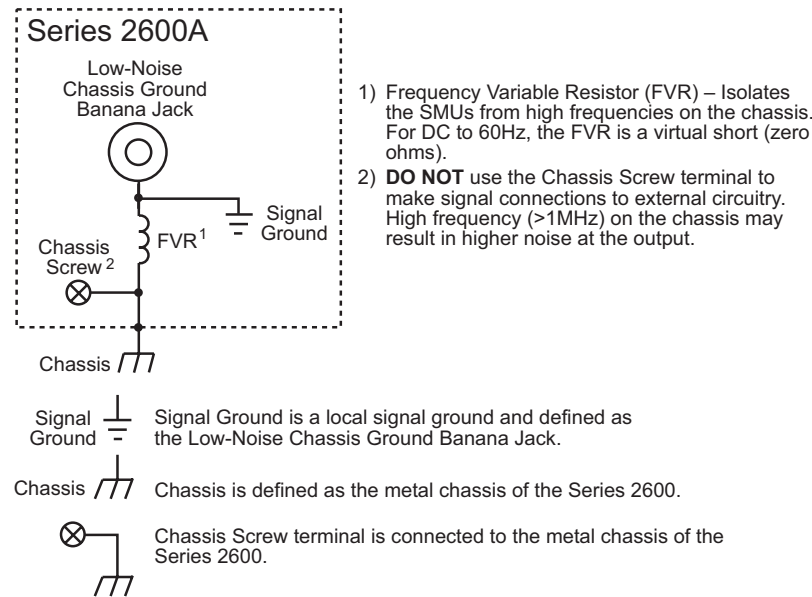

Figure 2-6
Model 2636A

WARNING When connecting to the model 2611A, 2612A, 2635A, and 2636A SMU outputs, with cables not rated for voltages above 42V, such as the 2600A-ALG-2, you must disable the high voltage output by using the INTERLOCK function as defined in [Section 8](#) of this manual. Leaving the high voltage enabled while not properly insulating the external connections to the unit poses a shock hazard which could cause serious injury to the user. It is also recommended that the LO connection terminal not be allowed to float by connecting it to signal ground or another known signal reference.

Sensing methods

Source-measure operations are performed using either 2-wire local sense connections or 4-wire remote sense connections.

NOTE The default sense setting is 2-wire local. See [Sense mode selection](#) later in this section to check and or change the sense mode.

2-wire local sensing

Two-wire local sensing (as shown in [Figure 2-7](#)) can be used for the following source-measure conditions:

- Sourcing and measuring current.
- Sourcing and/or measuring voltage in high impedance (>1kΩ) test circuits.

Figure 2-7
Model 2602A/2612A two-wire connections (local sensing)

Figure 2-8
Model 2636A two-wire connections (local sensing, non-floating)

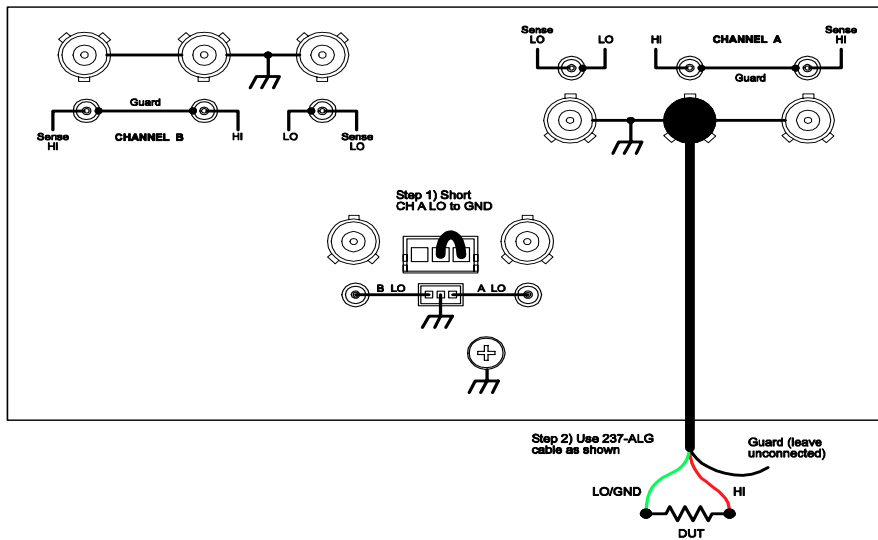

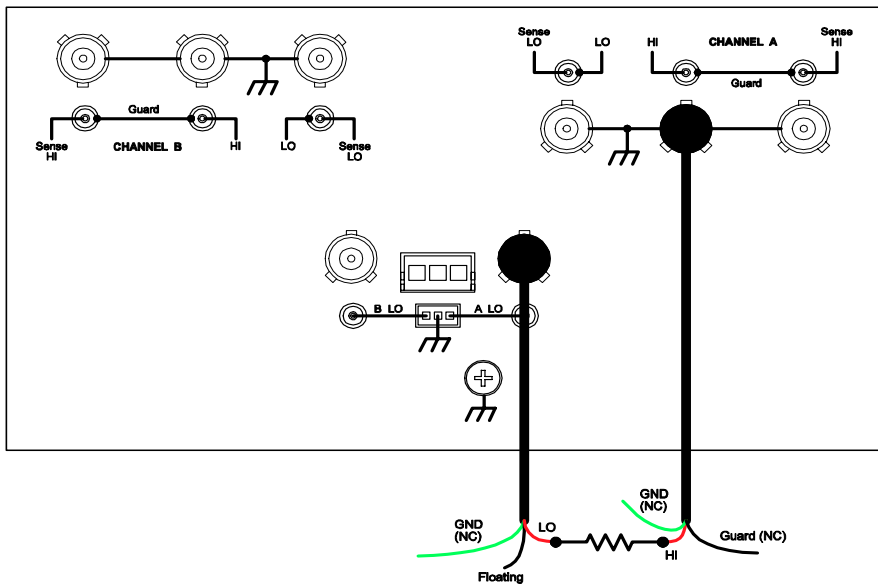

Figure 2-9
Model 2636A two-wire connections (local sensing, floating)

4-wire remote sensing

When sourcing and/or measuring voltage in a low-impedance test circuit (see [Figure 2-10](#)), there can be errors associated with IR drops in the test leads. Voltage source and measure accuracy are optimized by using 4-wire remote sense connections. When sourcing voltage, 4-wire remote sensing ensures that the programmed voltage is delivered to the DUT. When measuring voltage, only the voltage drop across the DUT is measured.

Use 4-wire remote sensing for the following source-measure conditions:

- Sourcing and/or measuring voltage in low impedance (<1kΩ) test circuits.
- Enforce voltage compliance limit directly at the DUT.

Figure 2-10

Model 2602A/2612A four-wire connections (remote sensing)

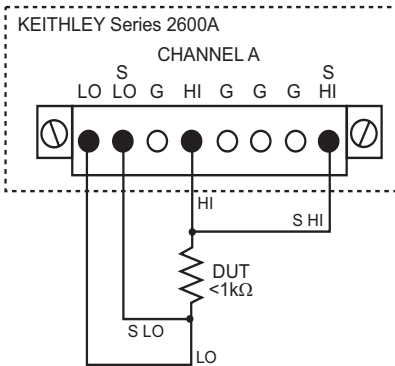

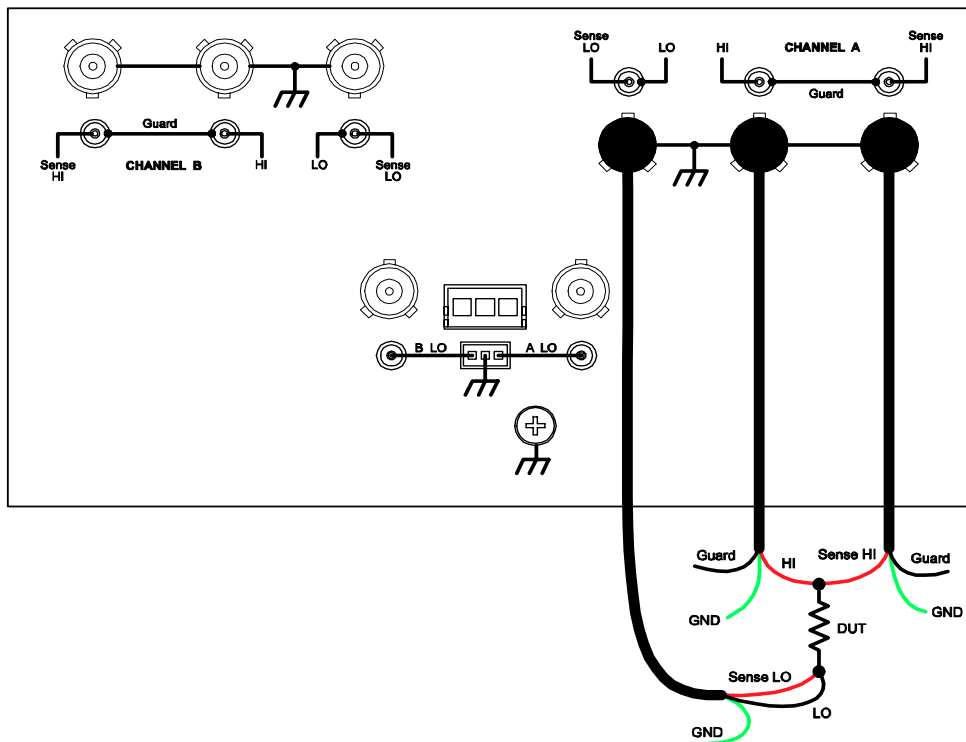

Figure 2-11

Model 2636A four-wire connections (remote sensing)

Sense mode selection

The sense mode can be set for 2-wire local or 4-wire remote connections.

Front panel sense selection

[Table 2-1](#) summarizes the steps to check and/or change the sense mode front panel. When in the menu structure, use the navigation wheel (or **CURSOR** keys) to position the blinking cursor on the desired menu item, and press **ENTER** to select it. Use the **EXIT** key to back out of the menu structure.

Table 2-1

Selecting the sense mode from the front panel

Model 2601A/2611A/2635A	Model 2602A/2612A/2636A
1) Press CONFIG key	1) Press CONFIG key
2) Select SRC or MEAS menu*	2) Select CHANNEL-A or CHANNEL-B
3) Select V-SOURCE menu	3) Select SRC or MEAS menu*
4) Select SENSE-MODE menu	4) Select V-SOURCE menu
5) Select 2-WIRE or 4-WIRE	5) Select SENSE-MODE menu
	6) Select 2-WIRE or 4-WIRE

* The sense mode can be set from either the **SRC** or **MEAS** menu.

Remote programming sense selection

[Table 2-2](#) summarizes the commands to select the sense mode. See [Section 19](#) for details on using these commands.

Table 2-2

Commands to select sense mode

Command*	Description
<code>smuX.source.output = smuX.OUTPUT_OFF</code>	Turns off the SMU output.
<code>smuX.sense = smuX.SENSE_LOCAL</code>	Selects local (2-wire) sense.
<code>smuX.sense = smuX.SENSE_REMOTE</code>	Selects remote (4-wire) sense.

* Model 2601A/2611A/2635A: smuX = smua. Model 2602A/2612A/2636A: smuX = smua (Channel A) or smub (Channel B).

Contact check connections

The contact check function prevents measurement errors due to excessive resistance in the force or sense leads. Connections for contact check measurements are shown in [Figure 2-12](#). See [Section 3](#) for operation and [Section 19](#) for details on contact check commands.

Multiple SMU connections

Figure 2-13 shows how to use two SMUs to test a 3-terminal device, such as an N-channel JFET. A typical application is for SMU B to source a range of gate voltages, while SMU A sources voltage to power the device and measures current at each gate voltage.

Figure 2-13
Model 2602A/2612A two SMUs connected to a 3-terminal device (local sensing)

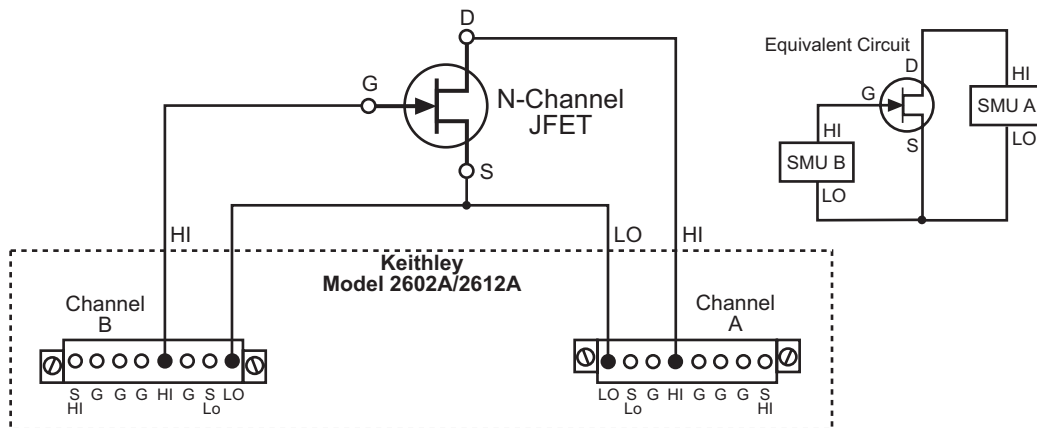

Figure 2-14
Model 2636A, two SMUs connected to a 3-terminal device (local sensing, floating)

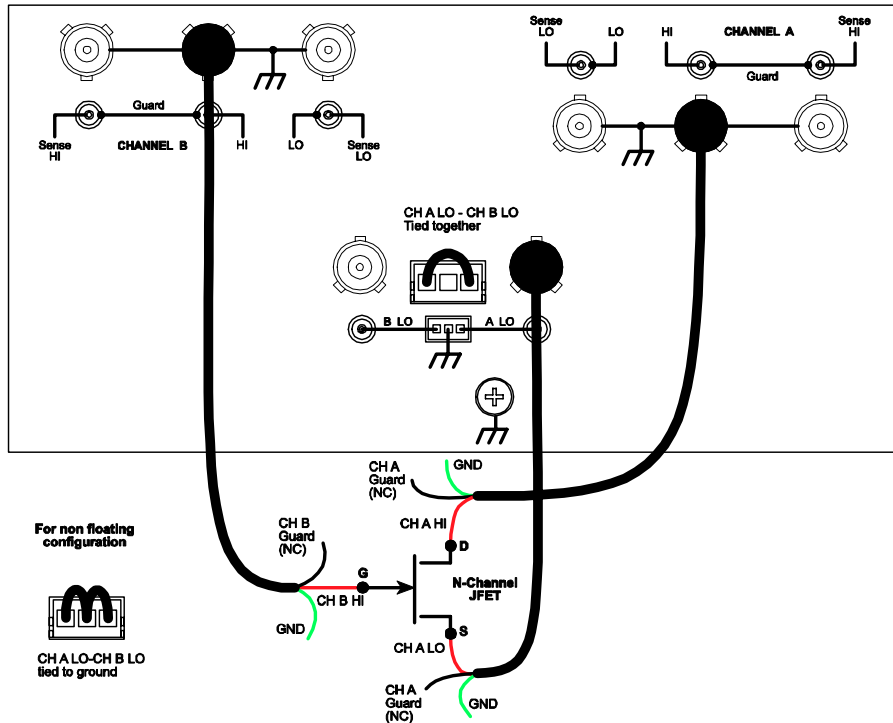

Figure 2-15 shows how to use three SMUs to test the same 3-terminal device. The third SMU is connected to the source (S) terminal of the JFET. This allows the source terminal to be biased above signal low. Setting this SMU to output 0V effectively connects the source terminal of the JFET to signal low.

Figure 2-15
Three SMUs connected to a 3-terminal device

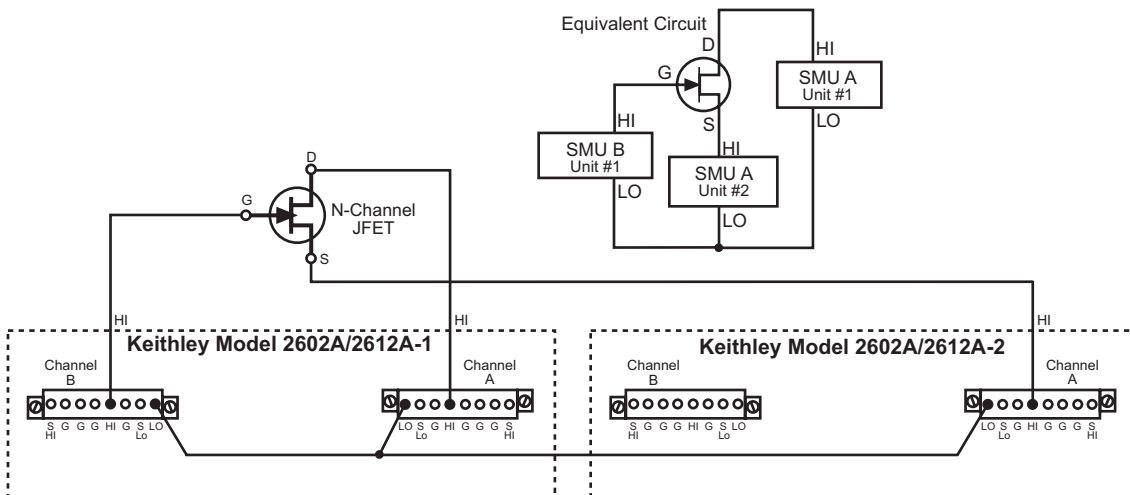

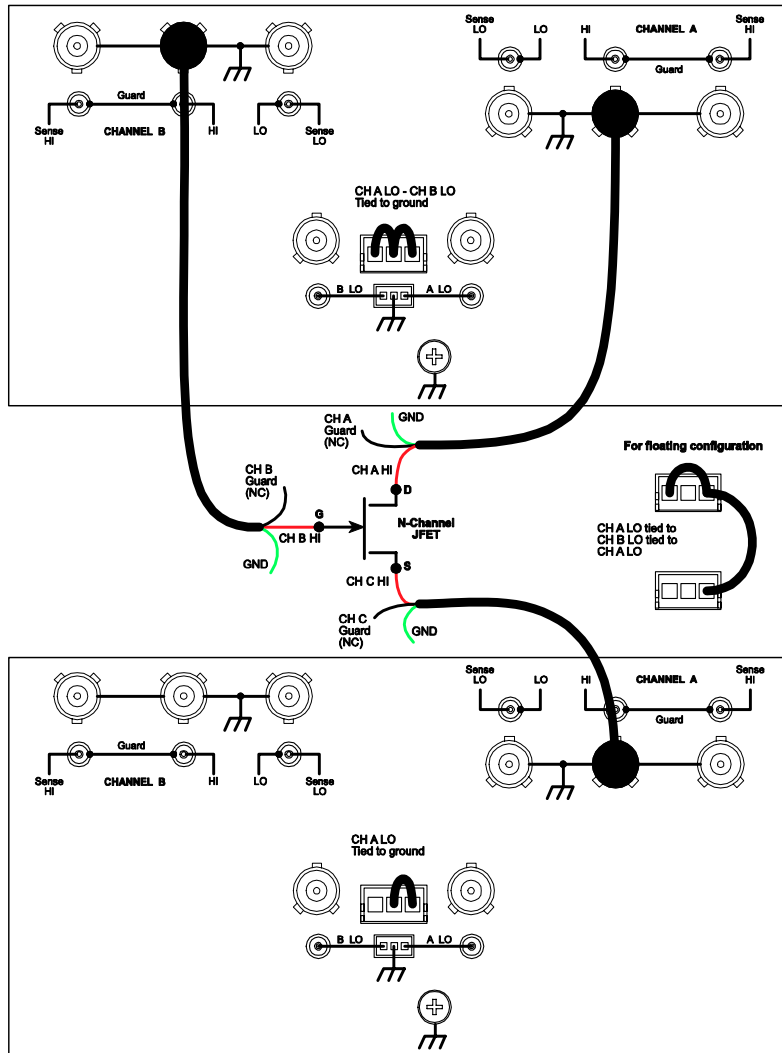

Figure 2-16
Model 2636A, three SMUs connected to a 3-terminal device (local sensing, non-floating)

Guarding and shielding

Source-measure performance and safety are optimized with the effective use of guarding and shielding (noise and safety shields).

Guarding

A driven guard is always enabled and provides a buffered voltage that is at the same level as the input/output HI voltage. The purpose of guarding is to eliminate the effects of leakage current (and capacitance) that can exist between input/output high and low. Without guarding, leakage and capacitance in the external high-impedance test circuit could be high enough to adversely affect the performance of the SourceMeter instrument.

Guarding (shown in [Figure 2-16](#)) should be used for the following source-measure condition:

- Test circuit impedance is $>1G\Omega$.

NOTE See [Guarding and shielding](#) for details on the principles of guarding.

Figure 2-17
Models 2602A and 2612A high-impedance guarding

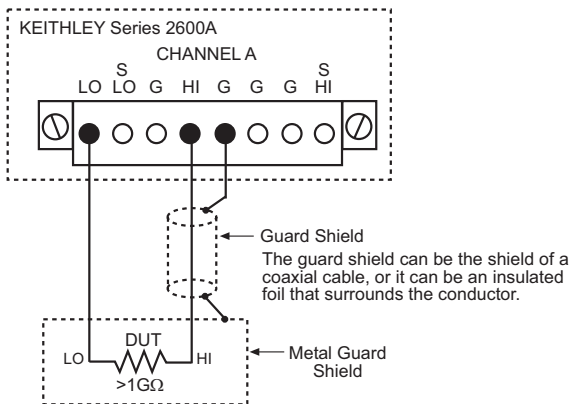

Figure 2-18
Model 2636A high-impedance guarding (floating)

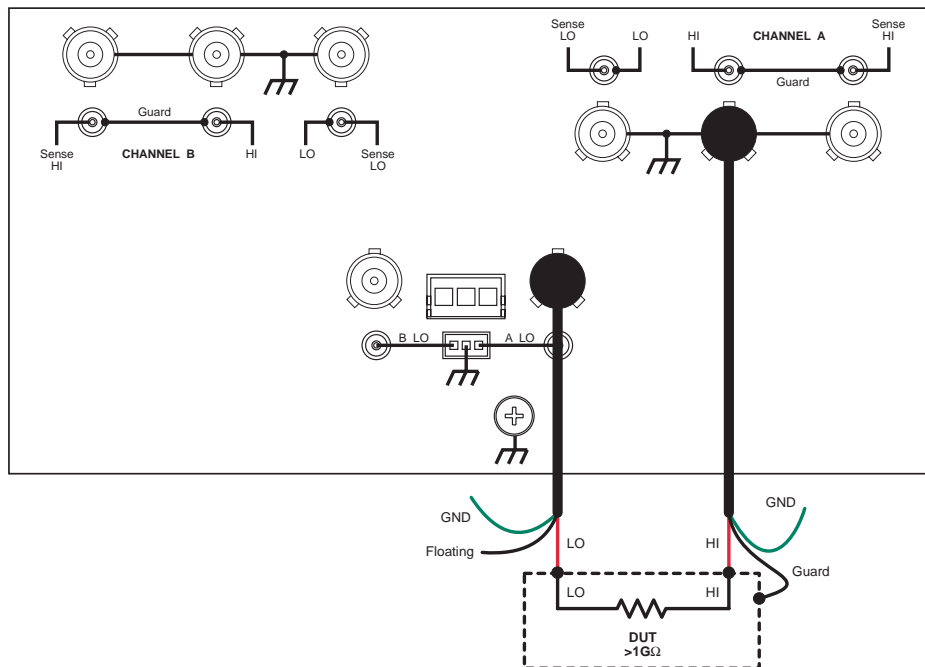

Figure 2-19
Model 2636A High-impedance guarding (non-floating)

Noise shield

A noise shield (see [Figure 2-20](#)) is used to prevent unwanted signals from being induced into the test circuit. Low-level signals may benefit from effective shielding. The metal noise shield surrounds the test circuit and should be connected to SMU LO as shown in [Figure 2-20](#).

Figure 2-20
Models 2602A and 2612A noise shield

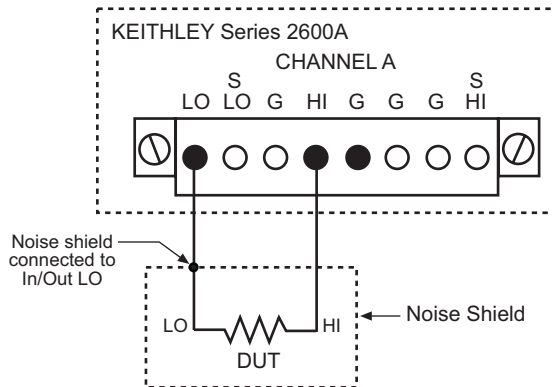

Figure 2-21
Model 2636A noise shield (non-floating)

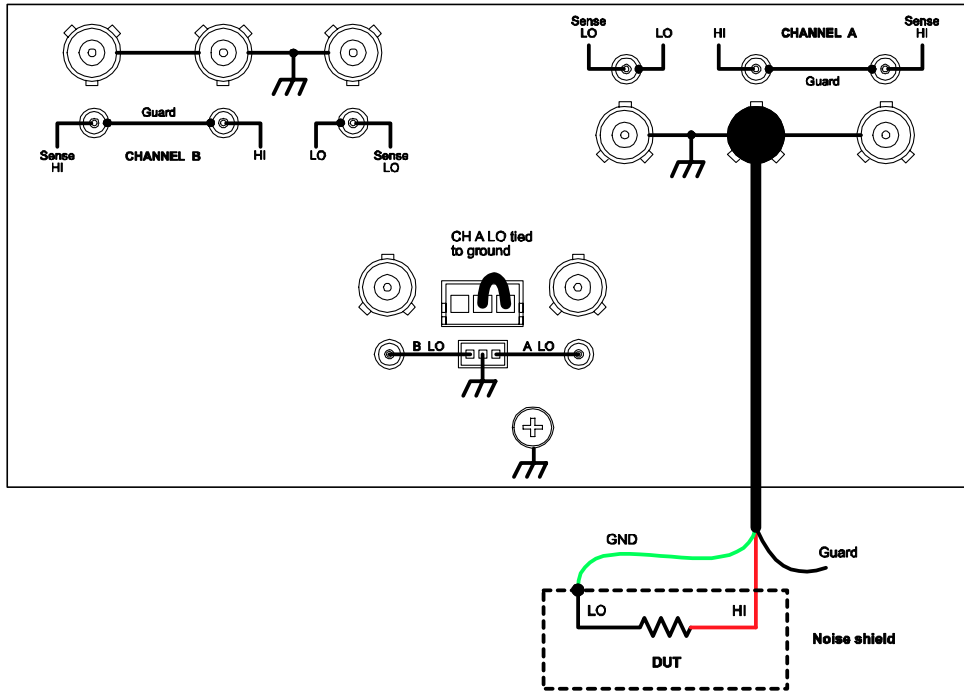

Figure 2-22
Model 2636A noise shield (non-floating)

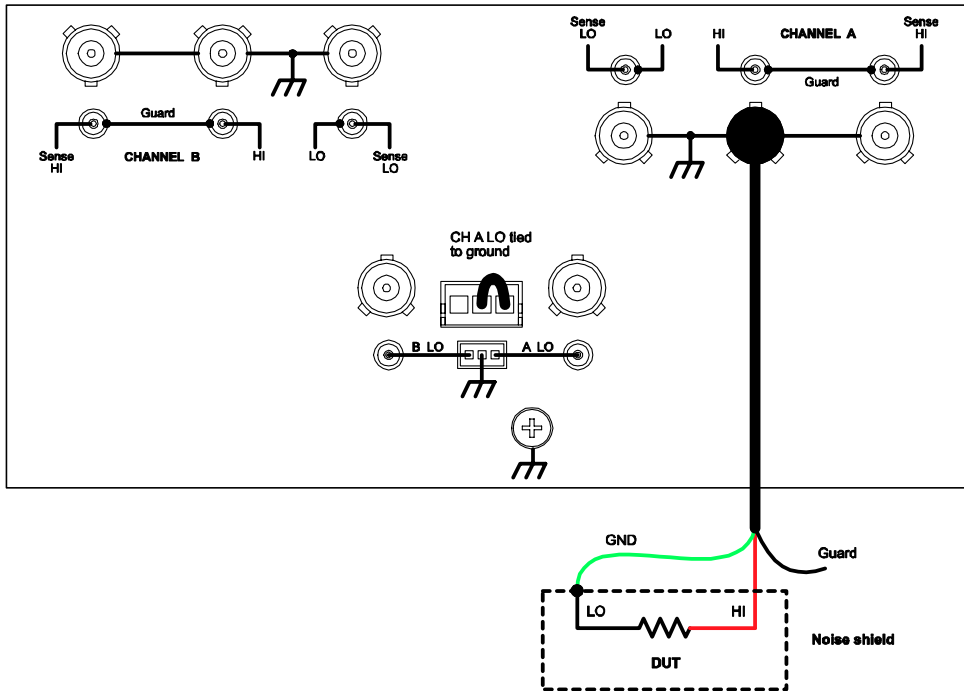

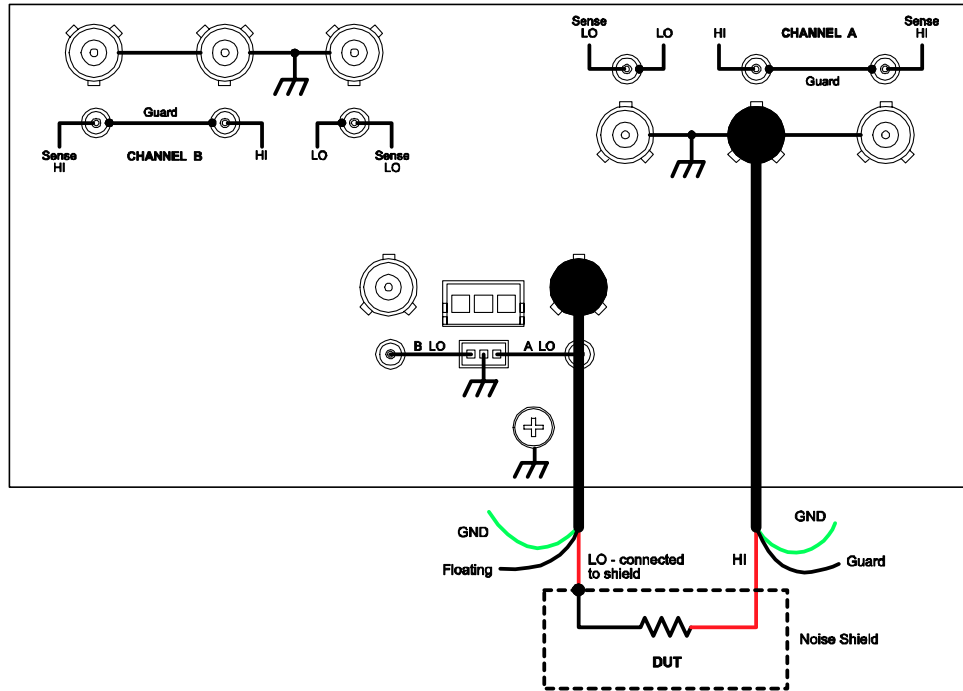

Figure 2-23
Model 2636A noise shield (floating)

Safety shield

A safety shield must be used whenever hazardous voltages ($>30 V_{\text{rms}}$, $42 V_{\text{peak}}$) will be present in the test circuit. The safety shield can be metallic or nonmetallic, and must completely surround the DUT test circuit. A metal safety shield must be connected to a known safety earth ground and chassis ground. See [Test fixture](#) later in this section for important safety information on the use of a metal or nonmetallic enclosure.

Model 2601A/2602A safety shield

The maximum output voltage for a Model 2601A/2602A channel is 40V, which is considered a non-hazardous level. However, using two or more Model 2601A/2602A voltage sources in a series configuration can cause test circuit voltage to exceed 42V. For example, the SMUs of two Model 2601A/2602A instruments can be connected in series to apply 80V to a DUT (see [Figure 2-24](#)).

The connections for the test configuration in [Figure 2-24](#) are shown in [Figure 2-25](#). Use #18 AWG wire or larger for connections to safety earth ground and chassis.

NOTE Floating an SMU may also cause test circuit voltage to exceed 42V (see [Floating an SMU](#) for more information).

Figure 2-24
Safety shield for hazardous voltage using two 2601A/2602A channels (>42V)

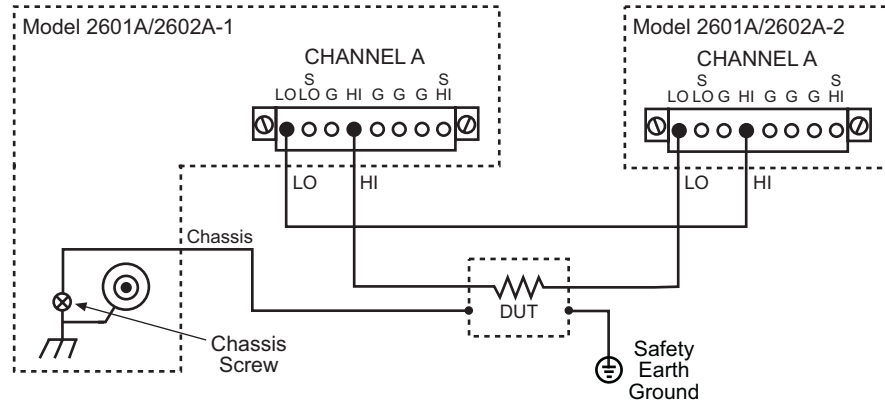

Figure 2-25
Model 2601A/2602A-1 connections for test circuit shown in Figure 2-24

Model 2611A/2612A/2635A/2636A safety shield

The maximum output voltage for a Model 2611A/2612A/2635A/2636A channel is 200V, which is considered hazardous and requires a safety shield (Figure 2-26). The connections for the test configuration in Figure 2-26 are shown in Figure 2-28. Use # 18 AWG wire or larger for connections to safety earth ground and chassis.

Figure 2-26
Safety shield for Models 2611A/2612A/2635A/2636A hazardous voltage (200V maximum)

Figure 2-27
Model 2601A/2602A-1 connections for test circuit shown in Figure 2-26

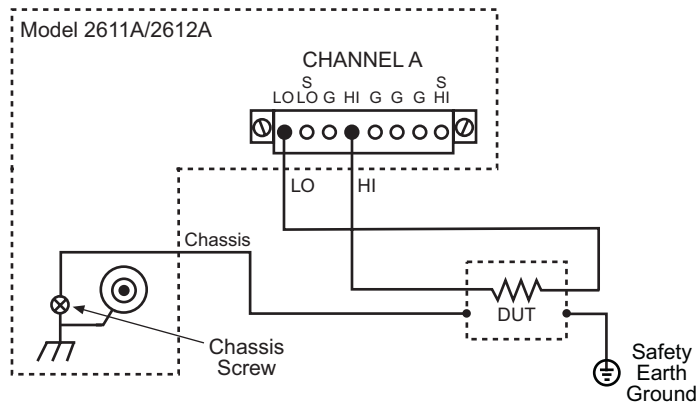

Figure 2-28
Model 2636A connections for test circuit shown in Figure 2-26

Using shielding and guarding together

Figure 2-29 shows connections for a test system that uses a noise shield, a safety shield, and guarding. The guard shields are connected to the driven guard (G) of the SMU. The noise shield is connected to SMU LO. The safety shield is connected to the chassis and to a safety earth ground.

Figure 2-29
Model 2601A/2602A-1 connections for noise shield, safety shield, and guarding

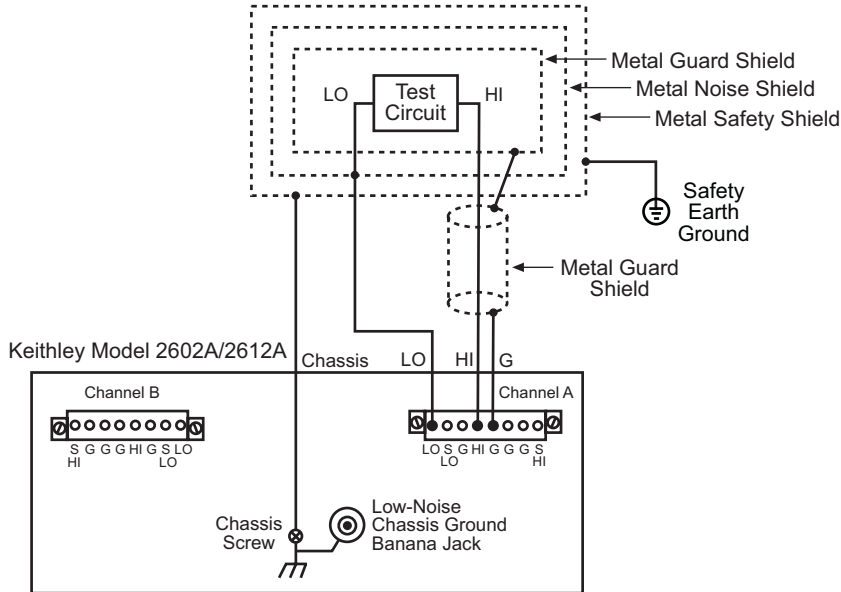

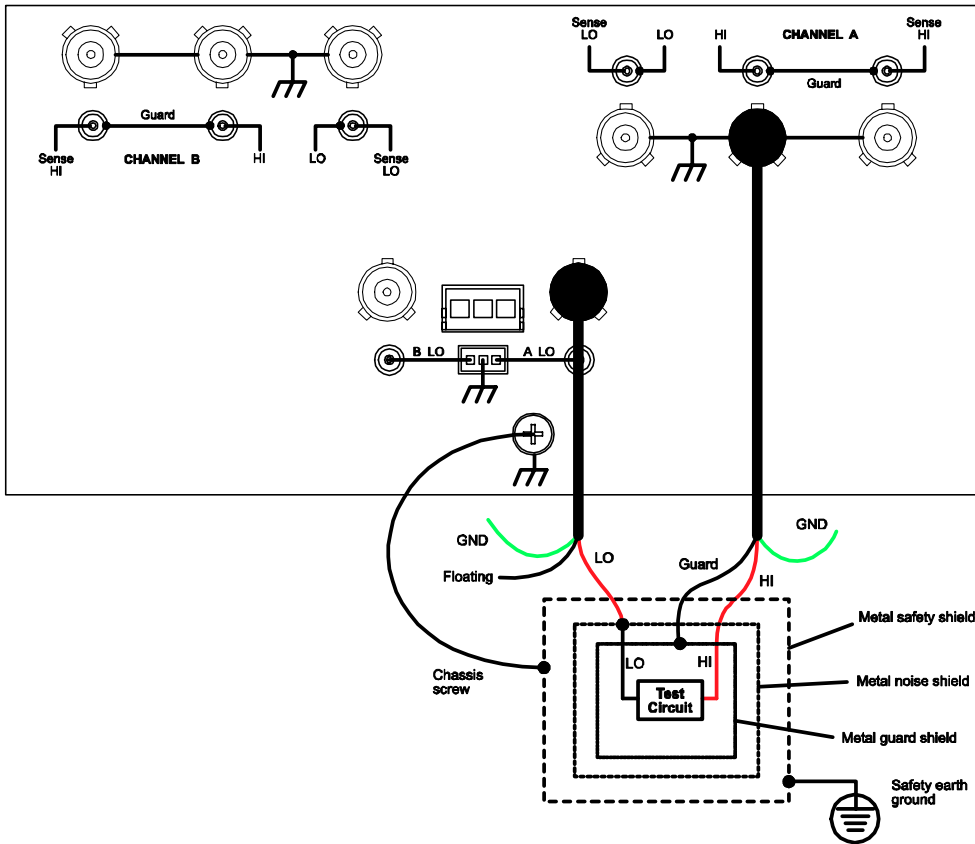

Figure 2-30
Model 2636A connections for noise shield, safety shield, and guarding

Test fixture

A test fixture can be used for an external test circuit. The test fixture can be a metal or nonmetallic enclosure, and is typically equipped with a lid. The test circuit is mounted inside the test fixture. When hazardous voltages (>30 Vrms, 42 Vpeak) will be present, the test fixture must have the following safety requirements:

WARNING To provide protection from shock hazards, an enclosure should be provided which surrounds all live parts.

Nonmetallic enclosures must be constructed of materials suitably rated for flammability and the voltage and temperature requirements of the test circuit.

For metallic enclosures, the test fixture chassis must be properly connected to safety earth ground. A grounding wire (#18 AWG or larger) must be attached securely to the test fixture at a screw terminal designed for safety grounding. The other end of the ground wire must be attached to a known safety earth ground.

Construction material: A metal test fixture must be connected to a known safety Earth Ground as described in the above **WARNING**. A nonmetallic test fixture must be constructed of materials that are suitable for flammability, voltage, and temperature conditions that may exist in the test circuit. The construction requirements for a nonmetallic enclosure are also described in the **WARNING** above.

Test circuit isolation: With the lid closed, the test fixture must completely surround the test circuit. A metal test fixture must be electrically isolated from the test circuit. Input/output connectors mounted on a metal test fixture must also be isolated from the test fixture. Internally, Teflon standoffs are typically used to insulate the internal pc-board or guard plate for the test circuit from a metal test fixture.

Interlock switch: The test fixture must have a normally-open interlock switch. The interlock switch must be installed so that when the lid of the test fixture is opened, the switch will open, and when the lid is closed, the switch will close.

WARNING *When an interlock is required for safety, a separate circuit should be provided that meets the requirements of the application to reliably protect the operator from exposed voltages.*

*The output enable pin on the **digital I/O port** on the Models 2601A and 2602A are not suitable for control of safety circuits and should not be used to control a safety interlock. The Interlock pin on the **digital I/O port** for the Models 2611A, 2612A, 2635A, and 2636A can be used to control a safety interlock.*

Floating an SMU

Using an external source in the test system may require that a Series 2600A SMU float off chassis earth ground. An example of such a test system is shown in [Figure 2-31](#), which includes an

external voltage source. Notice that output low of the voltage source is connected to chassis earth ground.

For the test circuit shown in [Figure 2-31](#), the Series 2600A must float off chassis earth ground. As shown, SMU LO of the Series 2600A is floating +10V above chassis earth ground. If SMU LO of the Series 2600A was instead connected to chassis ground, the external voltage source would be shorted through chassis ground.

The Series 2600A connections for the floating configuration ([Figure 2-31](#)) are shown in [Figure 2-32](#). In order to float the SMU, input/output LO must be isolated from chassis ground. This is accomplished by NOT connecting input/output LO to chassis ground.

The external voltage source in [Figure 2-31](#) and [Figure 2-32](#) can instead be a SMU of a second Series 2600A instrument. Keep in mind that if the combined outputs of the sources exceeds 42V, then a safety shield will be required for the DUT (see the following WARNINGS).

WARNING *The maximum floating (common mode) voltage for a SMU is $\pm 250V$. Exceeding this level may cause damage to the instrument and create a shock hazard.*

Using an external source to float a SMU could create a shock hazard in the test circuit. A shock hazard exists whenever $>42V$ peak is present in the test circuit. Appropriately rated cables or insulators must be provided for all connections to prevent access to live parts

When $>42V$ is present, the test circuit must be insulated for the voltage used or surrounded by a metal safety shield that is connected to a known safety earth ground and chassis ground (see [Safety shield](#)).

Figure 2-31
Floating the Series 2600A

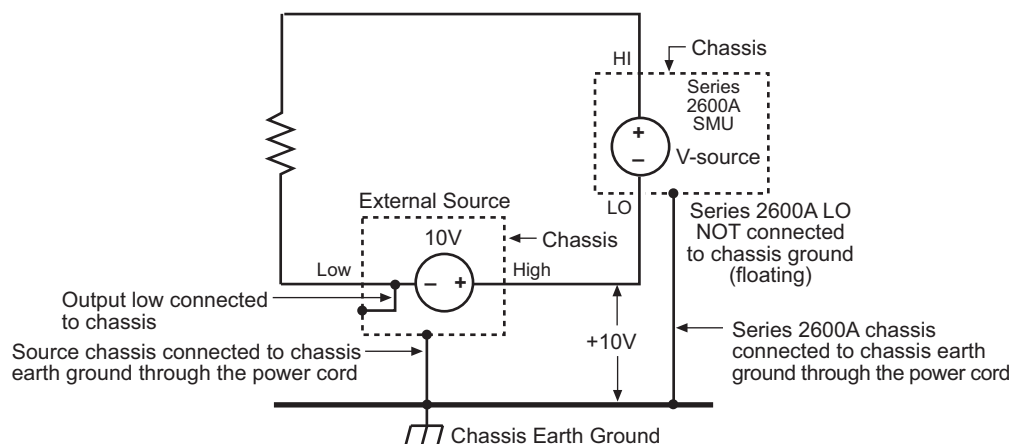

Figure 2-32
Model 2601A/2602A-1 SMU connections

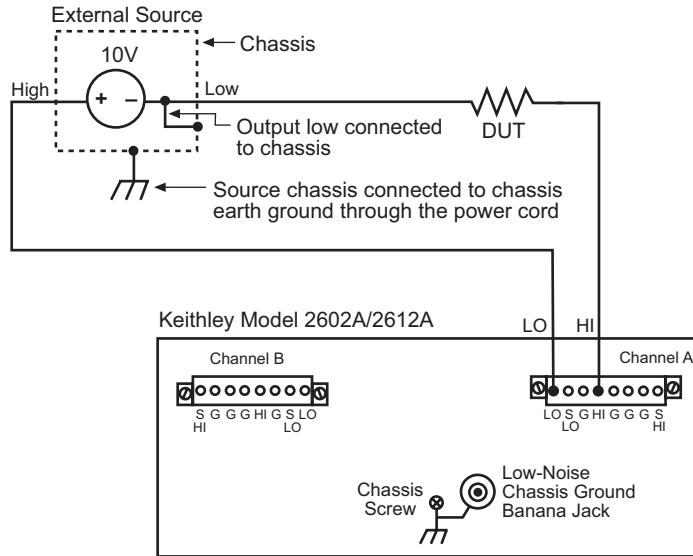

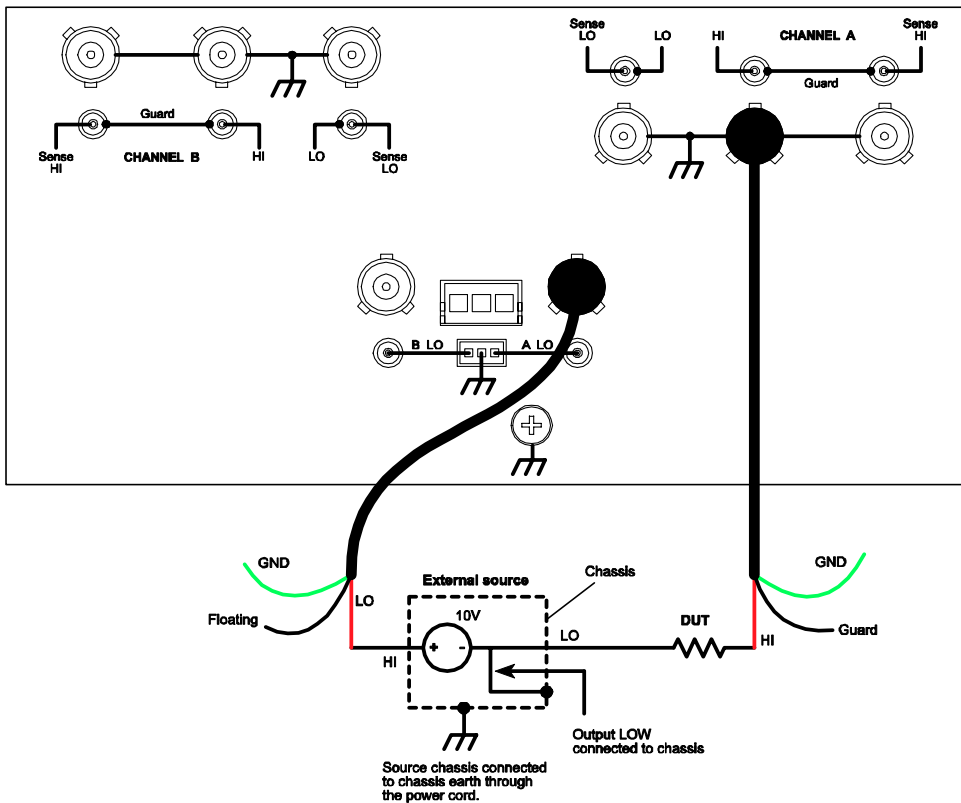

Figure 2-33
Model 2636A SMU connections for the floating configuration shown in [Figure 2-31](#)

Output-off states

When a SMU is turned off, it may not be completely isolated from the external circuit that it is connected to. There are three output-off states for a Series 2600A SMU: Normal, High Impedance or zero. For the Models 2602A, 2612A, and 2636A, each SMU channel can have its own unique output-off state.

Normal output-off state

For the normal output-off state (which is the default setting), the SMU will source 0V. The current compliance determined by the `smuX.source.offlimiti` command (default 1mA) is used. Therefore, the SMU may source or sink a very small amount of power. In most cases, this source or sink power level is not significant.

High-impedance output-off state

For the high-impedance output-off state, the output relay opens when the output is turned off. This disconnects external circuitry from the input/output of the SMU. To prevent excessive wear on the output relay, do not use this output off state for tests that turn the output off and on frequently.

Zero output-off state

When in this output-off state, the Series 2600A is configured as follows:

When the V-Source is the selected source:

- The programmed V-Source value remains on the display.
- Internally, the V-Source is set to 0V.
- The current compliance setting remains the same as the output-on value. Real compliance detection remains active.
- Measurements are performed and displayed.

When the I-Source is the selected source:

- The programmed I-Source value remains on the display.
- Internally, the V-Source is selected and set to 0V.
- Current compliance is set to the programmed Source I value or to 10% full-scale of the present current range, whichever is greater.
- Measurements are performed and displayed.

While in the zero output-off state, the Series 2600A can be used as an I-Meter since it will output 0V, but measure current.

Selecting the output-off state

Output-off state menu

To access the OUTPUT configuration menu:

1. Press the **CONFIG** key.
2. Select the appropriate **OUTPUT ON/OFF** key.
3. In the configuration menu, select **OFF STATE** to display the OUTPUT OFF STATE menu.

NOTE The OUTPUT OFF STATE menu can also be accessed by navigating the configuration menu that is displayed by pressing the **CONFIG** key.

With the OUTPUT OFF STATE menu displayed, select the desired output-off state: **HI-Z** (high-impedance), **NORMAL**, or **ZERO**.

Remote programming

[Table 2-3](#) lists the commands to select the output-off state.

Table 2-3

Commands to select the output-off state

Command*	Description
<code>smuX.source.offlimiti = ivalue</code>	Sets current limit in normal output-off state.
<code>smuX.source.offmode = smuX.OUTPUT_NORMAL</code>	Selects normal output-off state.
<code>smuX.source.offmode = smuX.OUTPUT_HIGH_Z</code>	Selects high-impedance output-off state.
<code>smuX.source.offmode = smuX.OUTPUT_ZERO</code>	Selects zero output-off state.

* Model 2601A/2611A/2635A: smuX = smua, Model 2602A/2612A/2636A: smuX = smua (Channel A) or smub (Channel B).

Overview

The documentation in this section provides basic operating instructions for the Keithley Instruments Series 2600A System SourceMeter® instrument and includes the following:

- [Operation overview](#)
- [Operation considerations](#)
- [Measure only](#)
- [Sink operation and interface](#)
- [Ohms measurements](#)
- [Power measurements](#)
- [Contact check measurements](#)

Operation overview

Source-measure capabilities

From the front panel, the instrument can be configured to perform the following operations:

- **Source voltage:** Display current and/or voltage measurement.
- **Source current:** Display voltage and/or current measurement.
- **Measure resistance:** Display resistance calculated from voltage and current components of measurement.
- **Measure power:** Display power calculated from voltage and current components of measurement.
- **Measure only (V or I):** Display voltage or current measurement.

Voltage and current

[Table 3-1](#) lists the source and measure limits for the voltage and current functions.

The full range of operation is explained in [Operating boundaries](#) in [Section 4](#).

Table 3-1
Source-measure capabilities

Model 2601A/2602A			Model 2611A/2612A			Model 2635A/2636A		
Range	Source	Measure	Range	Source	Measure	Range	Source	Measure
100mV	±101mV	±102mV	200mV	±202mV	±204mV	200mV	+/-202mV	+/-204mV
1V	±1.01V	±1.02V	2V	±2.02V	±2.04V	2V	+/-2.02V	+/-2.04V

			10A ²	±10.1A	±10.2A	100mA	±101mA	±102mA
						1A	±1.01A	±1.02A
						1.5A	±1.515A	±1.53A
Max Power = 40.4W per channel			Max Power = 30.603W per channel 1. 200V source range available only when interlock is enabled. See Section 8 . 2. 10A range available only in pulse mode.			Max Power = 30.603W per channel 3. 200V source range available only when interlock is enabled. See Section 8 .		

Compliance limit

When sourcing voltage, the Series 2600A can be set to limit current. Conversely, when sourcing current, the Series 2600A can be set to limit voltage. The Series 2600A output will not exceed the compliance limit. The maximum compliance limit is the same as the maximum values listed in [Table 3-2](#). Note that the compliance value will take the same sign as the source value, and the maximum compliance limits are based on source range. See [Compliance limit](#) for more information.

NOTE The only exception to the compliance limit not being exceeded is the VLIMIT when operating as an ISOURCE. To avoid excessive (and potentially destructive) currents from flowing, the VLIMIT will source or sink up to 102mA for ISOURCE ranges on or below 100mA. For the ranges 1A and above, the maximum current allowed is the current source setting.

Table 3-2
Maximum compliance values

Model 2601A/2602A		Model 2611A/2612A		Model 2635A/2636A	
Source range	Maximum compliance value	Source range	Maximum compliance value	Source range	Maximum compliance value
100mV	3A	200mV	1.5A	200mV	1.5A
1V	3A	2V	1.5A	2V	1.5A
6V	3A	20V	1.5A	20V	1.5A
40V	1A	200V	100mA	200V	100mA
100nA	40V	100nA	200V	1nA	200V
1µA	40V	1µA	200V	10nA	200V
10µA	40V	10µA	200V	100nA	200V
100µA	40V	100µA	200V	1µA	200V
1mA	40V	1mA	200V	10µA	200V
10mA	40V	10mA	200V	100µA	200V
100mA	40V	100mA	200V	1mA	200V
1A	40V	1A	20V	10mA	200V
3A	6V	1.5A	20V	100mA	200V
				1A	20V
				1.5A	20V

Setting the compliance limit

Front panel compliance limit

Set the compliance limit from the front panel as follows:

1. For the Model 2601A/2611A/2635A or the Model 2602A/2612A/2636A single-channel display mode, press the **LIMIT** key to directly access compliance editing.
2. For the Model 2602A/2612A/2636A dual-channel display mode, press the **LIMIT** key, then select **CURRENT** or **VOLTAGE** as desired. Press **ENTER** or the **navigation wheel**.
3. Press the **navigation wheel**, set the compliance limit to the desired value, and then press **ENTER** or the **navigation wheel** to complete editing.
4. Press **EXIT** to return to the normal display.

Remote compliance limit

[Table 3-3](#) summarizes basic commands to program the compliance limit. See [Section 19](#) for more details on these commands. To program the compliance, simply send the command using the desired parameter. For example, the following commands set the current and voltage compliance to 50mA and 4V respectively:

```
smua.source.limiti = 50e-3
smua.source.limitv = 4
```

The following command prints the compliance state:

```
print(smua.source.compliance)
```

A returned value of 1 indicates that the voltage limit has been reached if the unit is configured as a current source, or that the current limit has been reached if the unit is configured as a voltage source.

Table 3-3
Compliance commands

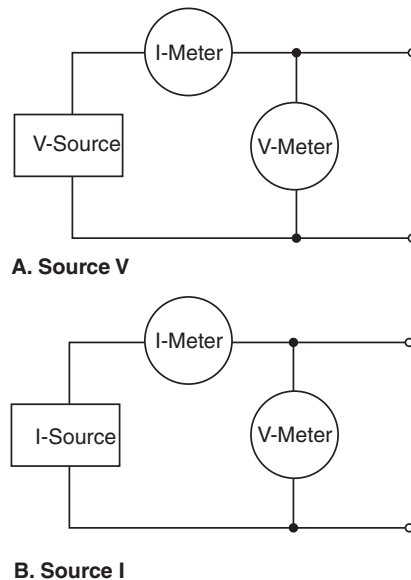

Command*	Description
<code>smuX.source.limiti = limit</code>	Set current compliance limit.
<code>smuX.source.limitv = limit</code>	Set voltage compliance limit.
<code>compliance = smuX.source.compliance</code>	Test if in compliance (1 = in compliance; 0 = not in compliance).

*smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

Basic circuit configurations

The fundamental source-measure configurations for the Series 2600A are shown in [Figure 3-1](#). When sourcing voltage, you can measure current or voltage (configuration A). When sourcing current, you can measure voltage or current (configuration B). See [Basic circuit configurations](#) in [Section 4](#) for more detailed information on these circuit configurations.

Figure 3-1
Fundamental source measure configuration

Operation considerations

The following paragraphs discuss the warm-up period and auto zero.

Warm-up

The Series 2600A must be turned on and allowed to warm up for at least two hours to achieve rated accuracies.

Auto zero

The Series 2600A uses a ratiometric A/D conversion technique. To ensure accuracy of readings, the instrument must periodically obtain fresh measurements of its internal ground and voltage reference. The time interval between needing to update these reference measurements is determined by the integration aperture being used for measurements. Separate reference and zero measurements are used for each aperture.

There are three different settings for auto zero as summarized in [Table 3-4](#). By default, the instrument automatically checks these reference measurements whenever a signal measurement is made (AUTO). If the reference measurements are out of date when a signal measurement is made, the instrument will automatically take two more A/D conversions, one for the reference and one for the zero, before returning the result. Thus, occasionally, a measurement takes longer than normal.

This extra time can cause problems in sweeps and other test sequences in which measurement timing is critical. To avoid the extra time for the reference measurements in these situations, the OFF selection can be used to disable the automatic reference measurements. Keep in mind that with automatic reference measurements disabled, the instrument may gradually drift out of specification.

To minimize the drift, a reference and zero measurement should be made just prior to the critical test sequence. The ONCE setting can be used to force a refresh of the reference and zero measurements used for the current aperture setting.

Table 3-4

Auto zero settings

Auto zero setting	Description
OFF	Turns automatic reference measurements off.
ONCE	Turns automatic reference measurements off, but immediately taking one reference and one zero measurement.
AUTO	Automatically takes new acquisitions when processor determines reference and zero values are out-of-date.

Front panel auto zero

Set the auto zero from the front panel as follows:

1. Press the **CONFIG** key, and select **MEAS** from the menu.
2. Select **AUTO-ZERO**, then press **ENTER** or the **navigation wheel**.
3. Select the desired mode (**OFF**, **ONCE**, or **AUTO**), and then press **ENTER** or the **navigation wheel**.
4. Press **EXIT** as necessary to return to the normal display.

Remote command auto zero

Use the auto zero command with the appropriate option shown in [Table 3-5](#) to set auto zero via remote (see [Section 6](#) for more details). For example, send the following command to activate Channel A automatic reference measurements:

```
smua.measure.autozero = smua.AUTOZERO_AUTO
```

Table 3-5
Auto zero command and options

Command*	Description
smuX.measure.autozero = smuX.AUTOZERO_OFF	Disable auto zero**
smuX.measure.autozero = smuX.AUTOZERO_ONCE	Force one ref and zero
smuX.measure.autozero = smuX.AUTOZERO_AUTO	Force ref and zero with each measurement

*smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

**Old NPLC cache values will be used when auto zero is disabled (see [To minimize the drift, a reference and zero measurement should be made just prior to the critical test sequence. The ONCE setting can be used to force a refresh of the reference and zero measurements used for the current aperture setting.](#)).

NPLC caching

NPLC caching speeds up operation by caching A/D reference and zero values for up to the ten most recent measurement aperture settings. Whenever the integration rate is changed via the **SPEED** key, or a user setup is recalled, the NPLC cache is checked. If the integration rate is already stored in the cache, the stored reference and zero values are recalled and used. Otherwise, a reference and zero value are acquired and stored in the cache. If there are already ten NPLC values stored, the oldest one will be overwritten by the newest one. When auto zero is off, NPLC values stored in the cache will be used regardless of how old they are. If there are no entries in the cache for the aperture being used, the unit will acquire them when the first measurement is made

Basic source-measure procedure

Front panel source-measure procedure

Use the following procedure to perform the basic source-measure operations of the Series 2600A. The following procedure assumes that the Series 2600A is already connected to the DUT as explained in Section 3.

WARNING *Hazardous voltages may be present on the output and guard terminals. To prevent electrical shock that could cause injury or death, NEVER make or break connections to the Series 2600A while the output is on. Power off the equipment from the front panel or disconnect the main power cord from the rear of the Series 2600A before handling cables connected to the outputs. Putting the equipment into standby does not guarantee the outputs are not powered if a hardware or software fault occurs.*

Step 1: Select and set source level.

Perform the following steps to select the source and edit the source value:

1. Press **SRC** as needed to select the **V-Source** or **I-Source** as indicated by the units in the source field on the display. The flashing digit (cursor) indicates which value is presently selected for editing.

2. Move the cursor to the digit to change, then press the **navigation wheel** to enter the EDIT mode, as indicated by the EDIT indicator.
3. Use the **RANGE** keys to select a range that will accommodate the value you want to set. (See [Section 6](#) for range information.) For best accuracy, use the lowest possible source range.
4. Enter the desired source value, then press **ENTER** or the **navigation wheel** to complete editing.

Step 2: Set compliance limit.

Perform the following steps to edit the compliance limit value:

1. For the Model 2601A/2611A/2635A or the Model 2602A/2612A/2636A single-channel display mode, press the **LIMIT** key.
2. For the Model 2602A/2612A/2636A dual-channel display mode, press **CONFIG** then **LIMIT**, then select **CURRENT** or **VOLTAGE**. Press **ENTER** or the **navigation wheel**.
3. Move the cursor to the digit to change, then press the **navigation wheel** to enter the EDIT mode, as indicated by the EDIT indicator.
4. Enter the desired limit value, then press **ENTER** or the **navigation wheel** to complete editing.

Step 3: Select measurement function and range.

Select measurement function and range as follows:

1. Put the Model 2602A/2612A/2636A in the single-channel display mode, then select the desired measurement function by pressing **MEAS** or **MODE**.
2. Select the desired measurement range with the **RANGE** keys, or enable **AUTO RANGE**, keeping the following points in mind:
 - When measuring the source (such as Source V Measure V), you cannot select the measurement range using the **RANGE** keys. The selected source range determines the measurement range.
 - When not measuring the source (such as Source V Measure I), measurement range selection can be done manually or automatically. When using manual ranging, use the lowest possible range for best accuracy. In auto range, the Series 2600A automatically goes to the most sensitive range to make the measurement.

Step 4: Turn output on.

Turn the output on by pressing the **ON/OFF OUTPUT** key. The OUTPUT indicator light will turn on.

Step 5: Observe readings on the display.

Observe the readings on the display. Press **TRIG** if necessary to trigger the unit to begin taking readings. For the single-channel display mode, the readings will appear on the top line, while source and limit values are on the bottom line.

Step 6: Turn output off.

When finished, turn the output off by pressing the **ON/OFF OUTPUT** key. The OUTPUT indicator light will turn off.

Remote source-measure procedure

Basic source-measurement procedures can also be performed via remote by sending appropriate commands in the right sequence. [Table 3-6](#) summarizes basic source-measure commands. See [Section 19](#) for more information on using these commands.

Table 3-6

Basic source-measure commands

Command*	Description
<pre>smuX.measure.autorangei = smuX.AUTORANGE_ON smuX.measure.autorangev = smuX.AUTORANGE_ON smuX.measure.autorangei = smuX.AUTORANGE_OFF smuX.measure.autorangev = smuX.AUTORANGE_OFF smuX.measure.rangei = rangeval smuX.measure.rangev = rangeval reading = smuX.measure.i() reading = smuX.measure.v() reading = smuX.measure.iv() reading = smuX.measure.r() reading = smuX.measure.p()</pre>	<p>Enable current measure auto range. Enable voltage measure auto range. Disable current measure auto range. Disable voltage measure auto range. Set current measure range. Set voltage measure range. Request a current reading. Request a voltage reading. Request a current and voltage reading. Request a resistance reading. Request a power reading.</p>
<pre>smuX.source.autorangei = smuX.AUTORANGE_ON smuX.source.autorangev = smuX.AUTORANGE_ON smuX.source.autorangei = smuX.AUTORANGE_OFF smuX.source.autorangev = smuX.AUTORANGE_OFF smuX.source.func = smuX.OUTPUT_DCVOLTS smuX.source.func = smuX.OUTPUT_DCAMPS smuX.source.leveli = sourceval smuX.source.levelv = sourceval smuX.source.limiti = level smuX.source.limitv = level smuX.source.output = smuX.OUTPUT_ON smuX.source.output = smuX.OUTPUT_OFF smuX.source.rangei = rangeval smuX.source.rangev = rangeval smuX.sense = smuX.SENSE_LOCAL smuX.sense = smuX.SENSE_REMOTE</pre>	<p>Enable current source auto range. Enable voltage source auto range. Disable current source auto range. Disable voltage source auto range. Select voltage source function. Select current source function. Set current source value. Set voltage source value. Set current limit. Set voltage limit. Turn on source output. Turn off source output. Set current source range. Set voltage source range. Local sense (2-wire). Remote sense (4-wire).</p>
<p>* smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.</p>	

Requesting readings

You can request readings by including the appropriate measurement command as the argument for the `print` command. For example, the following will request a Channel A current reading:

```
print(smua.measure.i())
```

Source-measure programming example

The set-up and command sequence for a basic source-measure procedure is shown below:

- Source function and range: volts, auto range
- Source output level: 5V
- Current compliance: 10mA
- Measure function and range: current, 10mA

```
smua.reset()                -- Restore Series 2600A defaults.
smua.source.func = smua.OUTPUT_DCVOLTS  -- Select voltage source function.
smua.source.autorangev = smua.AUTORANGE_ON  -- Set source range to auto.
smua.source.levelv = 5                -- Set voltage source to 5V.
smua.source.limiti = 10e-3            -- Set current limit to 10mA.
smua.measure.rangei = 10e-3          -- Set current range to 10mA.
smua.source.output =smua.OUTPUT_ON      -- Turn on output.
print(smua.measure.i())              -- Request current reading.
smua.source.output =smua.OUTPUT_OFF     -- Turn off output.
```

Triggering in local mode

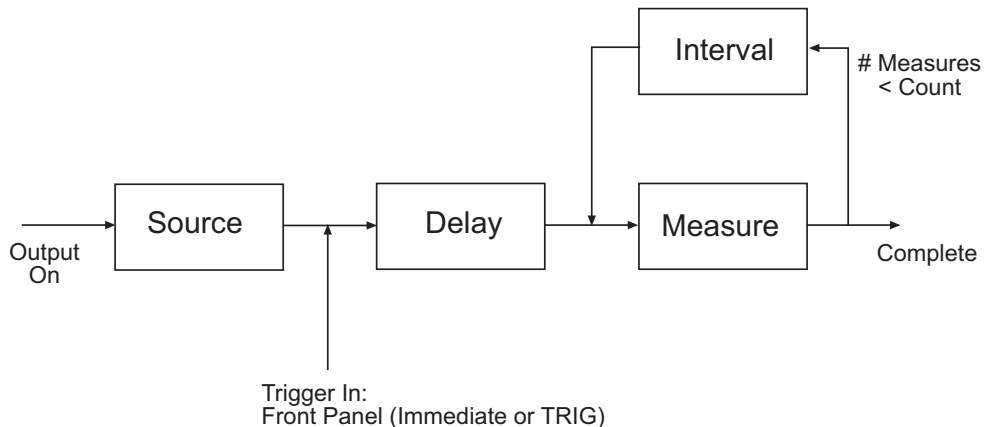

It is not necessary to change any trigger settings to use the basic source and measurement procedures covered in this section, however it is important to reset the instrument before triggering in local mode.

Use **MENU > SETUP > RECALL > INTERNAL > FACTORY** to reset the factory default conditions.

Figure 3-2 shows the general sequence for measurement triggering. The basic sequence is as follows:

- When the output is turned on, the programmed source value is immediately applied to the device under test (DUT).
- (Front panel operation only) If the immediate trigger source is selected, a measurement will be triggered immediately. However, if the manual trigger source is selected, the front panel **TRIG** key must be pressed.
- The unit waits for the programmed delay period (if any).
- The instrument takes one measurement.
- If the number of measurements is less than the programmed trigger count, it cycles back to take another measurement (the measurement cycle will be repeated indefinitely if the infinite trigger count is selected).
- For multiple measurements, the unit waits for the programmed trigger interval (if any) before taking the next measurement.

Figure 3-2
Local triggering

Configuring trigger attributes in local mode

- From the front panel, press **CONFIG > TRIG**. The following menu items are shown:

TRIGGER-IN: Use these options to select the trigger-in source:

- IMMEDIATE:** Triggering occurs immediately and the unit starts once it is ready to take measurements (for example, after the source output is turned on).
- MANUAL:** The front panel **TRIG** key must be pressed to trigger the instrument to take readings.

COUNT: Sets the trigger count (number of measurements) as follows:

- FINITE:** The unit will cycle through measurement cycles for the programmed trigger count (1 to 99999).
- INFINITE:** The unit will cycle through measurement cycles indefinitely until halted.

INTERVAL: Sets the time interval between measurements (0s to 999.999s) when the **COUNT** is greater than 1.

DELAY: Sets the delay period between the trigger and the start of measurement (0s to 999.999s).

Front panel triggering example

This example configures the trigger parameters to meet the following requirements:

- Manual triggering (**TRIG** key)
- Infinite trigger count (cycle indefinitely through measurement cycles)
- Interval (time between measurements): 1s
- Delay (time from trigger to measurement): 2s

Configure the trigger parameters as follows:

- Press **CONFIG** then **TRIG**.
- Select **TRIGGER-IN**, then press the **ENTER** key or the **navigation wheel**.
- Select **MANUAL**, then press the **ENTER** key or the **navigation wheel**.
- Choose **COUNT**, then select **INFINITE**, and press the **ENTER** key or the **navigation wheel**.
- Select **INTERVAL**, set the interval to 1s, then press the **ENTER** key or the **navigation wheel**.
- Choose **DELAY**, set the delay to 2s, then press the **ENTER** key.

7. Press **EXIT** to return to normal display.
8. Push **OUTPUT** to turn the output on and then press **TRIG**. A 2-second delay occurs before the first measurement. The unit cycles through measurements indefinitely with a 1s interval between measurements.
9. Turn off the **OUTPUT** to stop taking readings.

Measure only

In addition to being used for conventional source-measure operations, the Series 2600A can also be used to measure only voltage or current. Perform the following steps to use the Series 2600A to measure voltage or current:

1. Select source-measure functions.
Measure voltage only (voltmeter): Press **SRC** to select the I-Source, and press **MEAS** to select the voltage measurement function.
Measure current only (ammeter): Press **SRC** to select the V-Source, and press **MEAS** to select the current measurement function.
2. Set source and compliance levels.
Use the editing procedure provided in steps 1 and 2 of the [Front panel source-measure procedure](#) to edit the source and compliance levels:
 - a. Select the lowest source range and set the source level to zero (000.000nA or 000.000mV, 0.00000nA for Models 2635A/2636A).
 - b. Set compliance to a level that is higher than the expected measurement.

CAUTION When using the Series 2600A as a voltmeter, V-Compliance must be set higher than the voltage that is being measured. Failure to do this could result in excessive current flow into the Series 2600A (<150mA) and incorrect measurements.

3. Select range:
Use the **RANGE** keys to select a fixed measurement range that will accommodate the expected reading. Use the lowest possible range for best accuracy.
When measuring the function opposite from the source function, AUTO range can be used instead. The Series 2600A automatically goes to the most sensitive range.
4. Connect voltage or current to be measured. Connect the DUT to the SourceMeter instrument using 2-wire connections (see [Section 3](#)).
5. Turn output on. Press the **ON/OFF** key to turn the output on.
6. Take reading from display (press **TRIG** if necessary). When finished, turn output off.

Sink operation and interface

When operating as a sink (V and I have opposite polarity), the SourceMeter instrument is dissipating power rather than sourcing it. An external source (for example, a battery) or an energy storage device (i.e., capacitor) can force operation into the sink region.

For example, if a 12V battery is connected to the V-Source (In/Out HI to battery high) that is programmed for +10V, sink operation will occur in the second quadrant (Source +V and measure - I).

CAUTION When using the I-Source as a sink, ALWAYS set V-Compliance to a level that is higher than the external voltage level. Failure to do so could result in excessive current flow into the SourceMeter instrument (<102mA) and incorrect measurements. See [Compliance limit](#) for details.

NOTE The only exception to the compliance limit not being exceeded is the VLIMIT when operating as an ISOURCE. To avoid excessive (and potentially destructive) currents from flowing, the VLIMIT will source or sink up to 102mA for ISOURCE ranges on or below 100mA. For the ranges 1A and above, the maximum current allowed is the current source setting.

The sink operating limits are shown in [General SourceMeter instrument power equation](#) in [Section 4](#).

Ohms measurements

Ohms calculations

Resistance readings are calculated from the measured current and measured voltage as follows:

$$R = V/I$$

Where: R is the calculated resistance

V is the measured voltage

I is the sourced current

Ohms ranging

The front panel ohms function does not use ranging. The unit formats a calculated V/I reading to best fit the display. There may be leading zeros if the ohms reading is very small (<1m Ω).

Basic ohms measurement procedure

Perform the following steps to perform ohms measurements. The following procedure assumes that the SourceMeter instrument is already connected to the DUT as explained in [Section 3](#).

WARNING *Hazardous voltages may be present on the output and guard terminals. To prevent electrical shock that could cause injury or death, NEVER make or break connections to the Series 2600A while the output is on. Power off the equipment from the front panel or disconnect the main power cord from the rear of the SourceMeter instrument before handling cables connected to the outputs. Putting the equipment into standby does not guarantee the outputs are not powered if a hardware or software fault occurs.*

To take an ohms measurement:

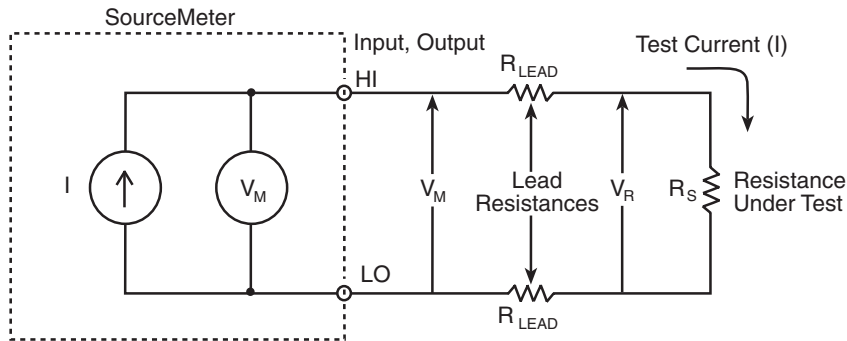

1. For the Model 2602A/2612A/2636A, press the **DISPLAY** key to select the single-channel display mode.
2. Press **SRC** to select the current source function, then set the output current to the desired value based on the expected resistance. See Step 1 of [Front panel source-measure procedure](#) earlier in this section.
3. Press the **LIMIT** key. Set the voltage limit high enough for the expected voltage across the resistance to be measured based on both the resistance value and programmed source current. See Step 2 of [Front panel source-measure procedure](#) earlier in this section.
4. Press the **MEAS** or **MODE** key to display voltage, then make sure that AUTO measurement range is on.
5. Press the **MEAS** or **MODE** key to display ohms.
6. Turn on the output, then note the reading on the display. If necessary, press the **TRIG** key to display continuous readings. Turn off the output when finished.

Ohms sensing

Ohms measurements can be made using either 2-wire or 4-wire sensing (see [Section 2](#) for information on connections and sensing methods).

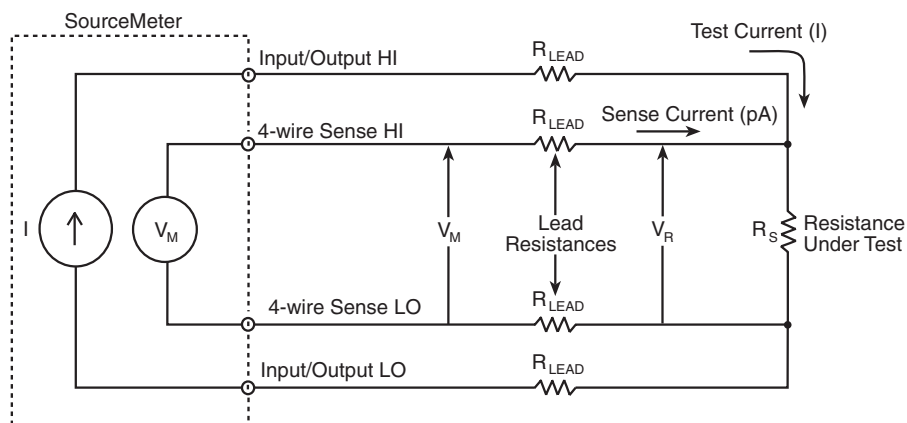

The 2-wire sensing method has the advantage of requiring only two test leads. However, as shown in [Figure 3-3](#), test lead resistance can seriously affect the accuracy of 2-wire resistance measurements, particularly with lower resistance values. The 4-wire sensing method shown in [Figure 3-4](#) minimizes or eliminates the effects of lead resistance by measuring the voltage across the resistor under test with a second set of test leads. Because of the high input impedance of the voltmeter, the current through the sense leads is negligible, and the measured voltage is essentially the same as the voltage across the resistor under test.

Figure 3-3

2-wire resistance sensing

I = Current sourced by SourceMeter
 V_M = Voltage measured by SourceMeter
 V_R = Voltage across resistor
 Measured resistance = $\frac{V_M}{I} = R_S + (2 \times R_{LEAD})$
 Actual resistance = $\frac{V_R}{I} = R_S$

Figure 3-4

4-wire resistance sensing

I = Current sourced by SourceMeter
 V_M = Voltage measured by SourceMeter
 V_R = Voltage across resistor
 Because sense current is negligible, $V_M = V_R$
 and measured resistance = $\frac{V_M}{I} = \frac{V_R}{I} = R_S$

Sense selection**Front panel sense selection**

To select sensing mode:

1. Press the **CONFIG** key then press **MEAS**. Choose **V-MEAS**, and then press **ENTER** or the **navigation wheel**.
2. Select **SENSE-MODE**, then press **ENTER**.

3. Choose **2-WIRE** or **4-WIRE**, as desired, and then press **ENTER** or the **navigation wheel**.

Remote sense selection

Use the `smuX.sense` command to control sense selection by remote. For example, send this command to enable 4-wire sensing:

```
smua.sense = smua.SENSE_REMOTE
```

See [Table 3-6](#) and [Section 19](#) for details.

Remote ohms programming

The following paragraphs summarize basic commands necessary for remote ohms programming and also give a programming example for a typical ohms measurement situation.

Remote ohms command

Use the following command to obtain a resistance reading:

```
reading = smuX.measure.r()
```

See [Table 3-6](#) for more commands necessary to set up source and measure functions, and [Section 19](#) for more details.

Ohms programming example

The set-up and command sequence for a typical ohms measurement is shown below:

- Source function: current, 10mA range, 10mA output
- Voltage measure range: auto
- Voltage compliance: 10V
- Sense mode: 4-wire

```
-- Restore Series 2600A defaults.
smua.reset()
-- Select current source function.
smua.source.func = smua.OUTPUT_DCAMPS
-- Set source range to 10mA.
smua.source.rangei = 10e-3
-- Set current source to 10mA.
smua.source.leveli = 10e-3
-- Set voltage limit to 10V.
smua.source.limitv = 10
-- Enable 4-wire ohms.
smua.sense = smua.SENSE_REMOTE
-- Set voltage range to auto.
smua.measure.autorangev = smua.AUTORANGE_ON
-- Turn on output.
smua.source.output = smua.OUTPUT_ON
-- Get resistance reading.
print(smua.measure.r())
-- Turn off output.
smua.source.output = smua.OUTPUT_OFF
```

Power measurements

Power calculations

Power readings are calculated from the sourced and measured current or voltage as follows:

$$P = V \times I$$

Where: P is the calculated power

V is the sourced or measured voltage

I is the measured or sourced current

Basic power measurement procedure

Perform the following steps to perform power measurements. The following procedure assumes that the SourceMeter instrument is already connected to the DUT as explained in [Section 19](#).

WARNING *Hazardous voltages may be present on the output and guard terminals. To prevent electrical shock that could cause injury or death, NEVER make or break connections to the Series 2600A while the output is on. Power off the equipment from the front panel or disconnect the main power cord from the rear of the SourceMeter instrument before handling cables connected to the outputs. Putting the equipment into standby does not guarantee the outputs are not powered if a hardware or software fault occurs.*

1. For the Model 2602A/2612A/2636A, press the **DISPLAY** key to select the single-channel display mode.
2. Set source function and value. Press **SRC** to select the voltage or current source function as required, then set the output voltage or current to the desired value. See Step 1 of [Front panel source-measure procedure](#) earlier in this section.
3. Press the **LIMIT** key, and set the voltage or current limit high enough for the expected voltage or current across the DUT to be measured. See Step 2 of [Front panel source-measure procedure](#) earlier in this section.
4. Press the **MEAS** or **MODE** key to display power.
5. Turn on the output, then note the reading on the display. If necessary, press the **TRIG** key to display continuous readings.
6. Turn off the output when finished.

Remote power programming

The following paragraphs summarize basic commands necessary for remote power programming and also give a programming example for a typical power measurement situation.

Remote power command

Use the following command to obtain a power reading:

```
reading = smuX.measure.p()
```

See [Table 3-6](#) for more commands necessary to set up source and measure functions and also [Section 19](#) for more details.

Power programming example

The set-up and command sequence for a typical power measurement is shown below:

- Source function: voltage, auto source range, 5V output
- Current measure function and range: current, auto
- Current compliance: 50mA

```
smua.reset()                --Restore Series 2600A defaults.
smua.source.func = smua.OUTPUT_DCVOLTS  --Select voltage source function.
smua.source.autorangev = smua.AUTORANGE_ON  --Set source range to auto.
smua.source.levelv = 5        --Set voltage source to 5V.
smua.source.limitsi = 50e-3    --Set current limit to 50mA.
smua.measure.autorangei = smua.AUTORANGE_ON  --Set current range to auto.
smua.source.output = smua.OUTPUT_ON        --Turn on output.
print(smua.measure.p())          --Get power reading.
smua.source.output = smua.OUTPUT_OFF       --Turn off output.
```

Contact check measurements

Overview

The contact check function prevents measurements that may be in error due to excessive resistance in the force or sense leads when making remotely sensed (Kelvin) measurements. Potential sources for this resistance include poor contact at the DUT, failing relay contacts on a switching card, and wires that are too long or thin. The contact check function will also detect an open circuit that may occur with a four-point probe is misplaced or misaligned. This relationship is shown schematically in [Figure 3-5](#), where R_C is the resistance of the mechanical contact at the DUT, and R_S is the series resistance of relays and cables.

WARNING *Hazardous voltages may be present on the output and guard terminals. To prevent electrical shock that could cause injury or death, NEVER make or break connections to the Series 2600A while the output is on. Power off the equipment from the front panel or disconnect the main power cord from the rear of the SourceMeter instrument before handling cables connected to the outputs. Putting the equipment into standby does not guarantee the outputs are not powered if a hardware or software fault occurs.*

Contact check commands

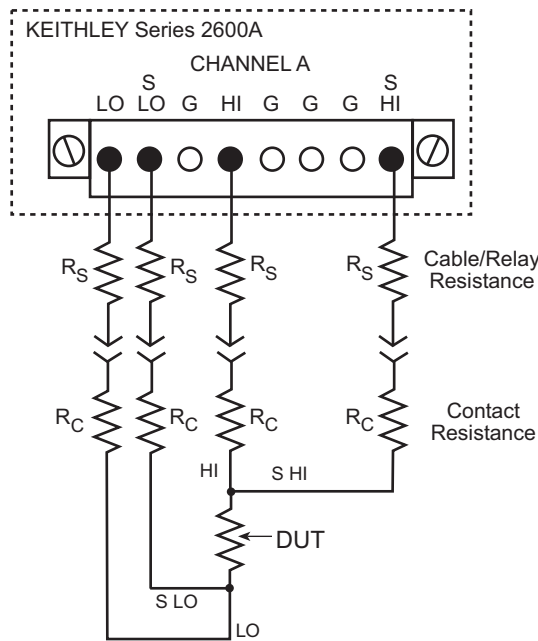

Table 3-7 summarizes basic contact check commands. See Section 19 for more information on using these commands.

Table 3-7
Basic contact check commands

Command*	Description
<pre>flag = smuX.contact.check() rhi, rlo = smuX.contact.r() smuX.contact.speed = speed_opt</pre>	Determine if contact resistance is lower than threshold. Return the contact resistance. Set speed_opt to one of the following: 0 or smuX.CONTACT_FAST 1 or smuX.CONTACT_MEDIUM 2 or smuX.CONTACT_SLOW
<pre>smuX.contact.threshold = rvalue</pre>	Resistance threshold for the contact check function.

*smuX = smua for the Model 2601A/2611A/2625A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

Figure 3-5
Contact check measurements

Contact check programming example

The command sequence for a typical contact measurement is shown below. These commands set the contact check speed to fast and the threshold to 10Ω. A contact check measurement against the threshold is then made. If it fails, a more accurate contact check measurement is made, and the test is aborted. Otherwise, the output is turned on, and the test continues.

```

smua.reset()                -- Restore defaults.
smua.contact.speed = smua.CONTACT_FAST  -- Set speed to fast.
smua.contact.threshold = 10  -- Set threshold to 10Ω.

if (not smua.contact.check()) then  -- Check contacts against threshold.
    smua.contact.speed = smua.CONTACT_SLOW  -- Set speed to slow.
    rhi, rlo = smua.contact.r()  -- Get resistance readings.
    print(rhi, rlo)  -- Return contact resistances to the host.
    exit()  -- Terminate execution.
end
smua.source.output = smua.OUTPUT_ON  -- Turn output on and continue.

```

User setup

The Series 2600A can be restored to one of six setup configurations: Five user setups and one factory default. As shipped from the factory, the Series 2600A powers-up to the original default settings, which are also saved in the five user setup locations. Original default settings are listed in the Instrument Command Library found in [Section 19](#). The instrument will power-up to whichever default setup was saved as the power-on setup.

Saving user setups

To save a user setup to nonvolatile memory:

1. Configure the Series 2600A for the desired operating modes to be saved.
2. Press **MENU > SETUP** and then press **ENTER**.
3. Select **SAVE** menu item, then press **ENTER**.
4. Select **INTERNAL**, then press **ENTER**.
5. Select the user number (1 through 5), and press **ENTER**.

To save a user setup to an external USB flash drive:

1. Configure the Series 2600A for the desired operating modes to be saved.
2. Insert the USB flash drive into the USB port on the front panel of the Series 2600A.
3. Press **MENU > SETUP**, then press **ENTER**.
4. Select **SAVE** menu item, then press **ENTER**.
5. Select **USB1**. The file `setup000.set` is displayed.
6. Use the **navigation wheel** to change the last three digits of the file name and then press **ENTER**.

Recalling a saved setup

Setups can be recalled from internal nonvolatile memory or a USB flash drive at any time. To recall a saved setup:

1. Press the **MENU** key to access the main menu.
2. Select **SETUP**, then press **ENTER**.
3. Select the **RECALL** menu item, then press **ENTER**.
4. Choose one of the following:
 - **INTERNAL**
 - **USB1**
5. (**INTERNAL** only) Do one of the following:
 - Select the user number (1 through 5), then press **ENTER**
 - Select **FACTORY** to restore factory defaults, then press **ENTER**.
6. (**USB1** only) Select the appropriate file and then push **ENTER**.

To select power-on setup

1. Press the **MENU** key to access the main menu.
2. Select **SETUP**, and then press **ENTER**.
3. Select **POWERON**, and then press **ENTER**.
4. Do one of the following:
 - Choose **FACTORY** to load the original defaults
 - Select **USER NUMBER** (1 through 5) to load a user preference.
5. Press **ENTER**.
6. Press **EXIT** to return to the main menu.

Saving user setups from a command interface

Saving and recalling user setups

The `setup.save` and `setup.recall` functions are used to save and recall user setups:

```
setup.save(n)      -- Save present setup to nonvolatile memory.
setup.recall(n)   -- Recall saved user setup from nonvolatile memory.
```

Where:

```
n = 1, 2, 3, 4 or 5
```

Restoring the factory default setups

The reset functions return the Series 2600A to the original factory defaults:

```
reset() or *rst   -- Restore all factory defaults.
smua.reset()      -- Restore Channel A defaults.
smub.reset()      -- Restore 2602A/2612A/2636A Channel B defaults.
setup.recall(0)   -- Restore all factory defaults.
```

Selecting the power-on setup

The `setup.poweron` attribute is used to select which setup to return to upon power-up. To select the power-on setup:

```
setup.poweron = n          -- Select power-on setup.
```

Where:

n = 0 (*RST defaults)

n = 1 to 5 (user setups 1-5)

Overview

The documentation in this section provides detailed information on source-measure concepts and includes the following information:

- [Compliance limit](#)
- [Overheating protection](#)
- [Operating boundaries](#)
- [Basic circuit configurations](#)
- [Guard](#)

Compliance limit

When sourcing voltage, the Keithley Instruments Series 2600A System SourceMeter® instrument can be set to limit current. Conversely, when sourcing current, the SourceMeter instrument can be set to limit voltage. The Series 2600A output does not exceed the compliance limit, except for the compliance limit conditions described in [Section 3](#).

Maximum compliance

The maximum compliance values for the source ranges are summarized in [Table 4-1](#).

Table 4-1

Maximum compliance limits

Model 2601A/2602A		Model 2611A/2612A		Model 2635A/2636A	
Source range	Maximum compliance value	Source range	Maximum compliance value	Source range	Maximum compliance value
100mV	3A	200mV	1.5A	200mV	1.5A
1V	3A	2V	1.5A	2V	1.5A
6V	3A	20V	1.5A	20V	1.5A
40V	1A	200V	100mA	200V	100mA
100nA	40V	100nA	200V	100pA	200V
1µA	40V	1µA	200V	1nA	200V
10µA	40V	10µA	200V	10nA	200V
100µA	40V	100µA	200V	100nA	200V
1mA	40V	1mA	200V	1µA	200V
10mA	40V	10mA	200V	10µA	200V
100mA	40V	100mA	200V	100µA	200V
1A	40V	1A	20V	1mA	200V
3A	6V	1.5A	20V	10mA	200V
				100mA	200V
				1A	20V
				1.5A	20V

Compliance principles

Compliance acts as a clamp. If the output reaches the compliance value, the SourceMeter instrument attempts to prevent the output from exceeding that value. This action implies that the source will switch from a V-source to an I-source (or from an I-source to a V-source) when in compliance.

As an example, assume the following:

SourceMeter instrument: $V_{SRC} = 10V$; $I_{CMPL} = 10mA$

Device under test (DUT) resistance: 10Ω

With a source voltage of 10V and a DUT resistance of 10Ω , the current through the DUT should be: $10V / 10\Omega = 1A$. However, because the compliance is set to 10mA, the current will not exceed that value, and the voltage across the resistance is limited to 100mV. In effect, the 10V voltage source is transformed into a 10mA current source with a 100mV compliance value.

Overheating protection

Proper ventilation is required to keep the SourceMeter instrument from overheating. Even with proper ventilation, the Series 2600A can overheat if the ambient temperature is too high or the SourceMeter instrument is operated in sink mode for long periods of time. The SourceMeter instrument has an over-temperature protection circuit that will turn the output off in the event that the instrument overheats. If the output trips due to overheating, a message indicating this condition will be displayed. You will not be able to turn the output back on until the instrument cools down.

Power equations to avoid overheating

To avoid overheating, each channel on the Series 2600A should not be operated in a manner that forces the instrument to exceed the maximum duty cycle (DC_{MAX}) computed using the [General SourceMeter instrument power equation](#) below. Factors such as the ambient temperature, quadrant of operation, and high power pulse levels (if applicable) affect the maximum duty cycle. Exceeding the calculated maximum duty cycle may cause the temperature protection mechanism to engage. When this happens, an error message will be displayed, and the SourceMeter instrument output will be disabled until the internal temperature of the SourceMeter instrument is reduced to an acceptable level.

You do **not** have to be concerned about overheating if **all** of the following are true:

- The SourceMeter instrument used as a power source and not a power sink.
- The ambient temperature is $\leq 30^{\circ}C$.
- High power pulse operation is not being used.

However, if any one of these is false, the SourceMeter instrument may overheat if operated in a manner that exceeds the calculated maximum duty cycle, DC_{MAX} .

The maximum duty cycle equation is derived from the power equation below by solving for DC_{MAX} . The general power equation describes how much power a SourceMeter instrument channel can source and/or sink before the total power cannot be fully dissipated by the Series 2600A cooling system. This equation takes into account all of the factors that can influence the power being dissipated by the SourceMeter instrument.

General SourceMeter instrument power equation

$$|(V_{OA} - V_P)(I_P)|\sqrt{DC_{MAX}} + |(V_{OA} - V_B)(I_B)| \leq (P_{CS} - P_{DER})$$

P_{CS} = The maximum power generated in a SourceMeter instrument channel that can be properly dissipated by the SourceMeter instrument cooling system.

T_{AMB} = The ambient temperature of the SourceMeter instrument operating environment.

$$P_{DER} = T_{AMB} - 30$$

- This factor represents the number of watts the SourceMeter instrument is de-rated when operating in environments above 30°C. This is represented as a temperature because the maximum output power of each SourceMeter instrument channel is reduced by 1W per degree C above 30°C.
- P_{DER} is 0 when the ambient temperature is below 30°C.

V_{OA} = The SourceMeter instrument output amplifier voltage. This constant can be found in the tables below.

V_P = The voltage level the SourceMeter instrument is attempting to force while at the pulse level.

- When operating in quadrants 1 or 3 (sourcing power), the sign of this voltage must be **positive** when used in the power equations.
- When operating in quadrants 2 or 4 (sinking power), the sign of this voltage must be **negative** when used in the power equations.

V_B = The voltage level the SourceMeter instrument is attempting to force while at the bias level.

- When operating in quadrants 1 or 3 (sourcing power), the sign of this voltage must be **positive** when used in the power equations.
- When operating in quadrants 2 or 4 (sinking power), the sign of this voltage must be **negative** when used in the power equations.

I_P = The current flowing through the SourceMeter instrument channel while at the pulse level.

I_B = The current flowing through the SourceMeter instrument channel while at the bias level.

Maximum duty cycle equation ¹

$$DC_{MAX} \leq \left[\frac{(P_{CS} - P_{DER}) - |(V_{OA} - V_B)(V_B)|}{|(V_{OA} - V_P)(I_P)|} \right]^2 \times 100$$

NOTE When attempting to determine the maximum duty cycle where the off state will be 0V or 0A:

- I_B is 0
- I_P and V_P are the voltage and current levels when the SourceMeter instrument is on.

1. Equations apply to both channels, sinking or sourcing power simultaneously. If a duty cycle less than 100% is required to avoid overheating, the maximum on time must be less than 10 seconds

CAUTION This maximum duty cycle equation is an approximation. In general, if the duty cycle calculation yields a number > 90%, then DC under those conditions should not cause the SourceMeter instrument to overheat. However, if the calculation yields a number < 10%, the calculated duty cycle should not be exceeded by more than 0.5% to avoid potential overheating.

Table 4-2

Model 2601A/2602A Maximum Duty Cycle equation constants

Constant	100mV range	1V range	6V range	40V range
P _{CS}	56	56	56	56
V _{OA}	18	18	18	55

Table 4-3

Model 2611A/2612A/2635A/2636A Maximum Duty Cycle equation constants

Constant	200mV range	2V range	20V range	200V range
P _{CS}	56	56	56	56
V _{OA}	40	40	40	220

Examples

Example 1:

Using a Model 2611A to charge a 5V battery with 1.5A, while operating at 50°C ambient temperature; what is the maximum duty cycle?

Assuming the 20V range will be used to measure the voltage:

$$DC_{MAX} \leq \left[\frac{(56 - 20) - |(40 - (5))(0)|}{|(40 - (5))(1.5)|} \right]^2 \times 100$$

$$DC_{MAX} \leq 47.0\%$$

Example 2:

Using a Model 2602A to pulse 10A of current from a bias level of 500mA, into a very low impedance (100 mΩ), while operating at 40°C ambient temperature; what is the maximum duty cycle?

Assuming the 1V range will be used to measure the voltage:

$$DC_{MAX} \leq \left[\frac{(56 - 10) - |(18 - (0.1)(0.5))(0.5)|}{|(18 - (10)(0.1))(10)|} \right]^2 \times 100$$

$$DC_{MAX} \leq 4.7\%$$

Example 3:

Using a Model 2612A to charge a 12V battery by sourcing 100mA and then discharging the battery by sinking 5A, while operating at 35°C ambient temperature; what is the maximum duty cycle?

Assuming the 20V range will be used to measure the voltage:

$$DC_{MAX} \leq \left[\frac{(56 - 5) - |(40 - (12))(0.1)|}{|(40 - (-12))(-5)|} \right]^2 \times 100$$

$$DC_{MAX} \leq 3.4\%$$

Operating boundaries

Source or sink

Depending on how it is programmed and what is connected to the output (load or source), the SourceMeter instrument can operate in any of the four quadrants. The four quadrants of operation are shown in [Figure 4-1](#) and [Figure 4-2](#). When operating in the first (I) or third (III) quadrant, the SourceMeter instrument is operating as a source (V and I have the same polarity). As a source, the SourceMeter instrument is delivering power to a load.

When operating in the second (II) or fourth (IV) quadrant, the SourceMeter instrument is operating as a sink (V and I have opposite polarity). As a sink, it is dissipating power rather than sourcing it. An external source or an energy storage device, such as a capacitor or battery, can force operation in the sink region.

Continuous power operating boundaries

Model 2601A/2602A continuous power operating boundaries

The general operating boundaries for Model 2601A/2602A continuous power output are shown in [Figure 4-1](#) (for derating factors, see [General SourceMeter instrument power equation](#), described earlier in this section). In this drawing, the 3A, 6V and 1A, 40V magnitudes are nominal values. Also note that the boundaries are not drawn to scale.

Figure 4-1
Model 2601A/2602A continuous power operating boundaries

Model 2611A/2635A/2612A/2636A continuous power operating boundaries

The general operating boundaries for Model 2611A/2612A continuous power output are shown in [Figure 4-2](#) (see [General SourceMeter instrument power equation](#) in this section for derating factors). In this drawing, the 1.5A, 20V and 100mA, 200V magnitudes are nominal values. Also note that the boundaries are not drawn to scale.

Figure 4-2
Model 2611A/2612A/2635A/2636A continuous power operating boundaries

I-Source operating boundaries

Model 2601A/2602A I-Source operating boundaries

[Figure 4-3](#) shows the operating boundaries for the I-Source. Only the first quadrant of operation is covered. Operation in the other three quadrants is similar.

Figure 4-3A shows the output characteristics for the I-Source. As shown, the Series 2601A and 2602A can output up to 1.01A at 40V, or 3.03A at 6V. Note that when sourcing more than 1.01A, voltage is limited to 6V.

Figure 4-3B shows the limit lines for the I-Source. The current source limit line represents the maximum source value possible for the presently selected current source range. The voltage compliance limit line represents the actual compliance that is in effect (see [Compliance limit](#)). These limit lines are boundaries that represent the operating limits of the SourceMeter instrument for this quadrant of operation. The operating point can be anywhere inside (or on) these limit lines. The limit line boundaries for the other quadrants are similar.

Figure 4-3
Model 2601A/2602A I-Source boundaries

A) Output Characteristics

B) Limit Lines

Model 2611A/2612A/2635A/2636A I-Source operating boundaries

Figure 4-4 shows the operating boundaries for the I-Source. Only the first quadrant of operation is covered. Operation in the other three quadrants is similar.

Figure 4-4A shows the output characteristics for the I-Source. As shown, the Model 2611A/2612A/2635A/2636A SourceMeter instrument can output up to 101mA at 200V, or 1.515A at 20V. Note that when sourcing more than 101mA, voltage is limited to 20V.

Figure 4-4B shows the limit lines for the I-Source. The current source limit line represents the maximum source value possible for the presently selected current source range. The voltage compliance limit line represents the actual compliance that is in effect (see [Compliance limit](#)). These limit lines are boundaries that represent the operating limits of the SourceMeter instrument for this quadrant of operation. The operating point can be anywhere inside (or on) these limit lines. The limit line boundaries for the other quadrants are similar.

Figure 4-4

Model 2611A/2612A/2635A/2636A I-Source boundaries

A) Output Characteristics

B) Limit Lines

Load considerations

The boundaries the SourceMeter instrument operates in depends on the load (DUT) that is connected to its output. [Figure 4-5](#) shows operation examples for resistive loads that are 50Ω and 200Ω , respectively. For these examples, the SourceMeter instrument is programmed to source 100mA and limit 10V .

In [Figure 4-5A](#), the SourceMeter instrument is sourcing 100mA to the 50Ω load and subsequently measures 5V . As shown, the load line for 50Ω intersects the 100mA current source line at 5V .

[Figure 4-5B](#) shows what happens if the resistance of the load is increased to 200Ω . The DUT load line for 200Ω intersects the voltage compliance limit line placing the SourceMeter instrument in compliance. In compliance, the SourceMeter instrument will not be able to source its programmed current (100mA). For the 200Ω DUT, the SourceMeter instrument will only output 50mA (at the 10V limit).

Notice that as resistance increases, the slope of the DUT load line increases. As resistance approaches infinity (open output), the SourceMeter instrument will source virtually 0mA at 10V . Conversely, as resistance decreases, the slope of the DUT load line decreases. At zero resistance (shorted output), the SourceMeter instrument will source 100mA at virtually 0V .

Regardless of the load, voltage will never exceed the programmed compliance of 10V .

V-Source operating boundaries

Model 2601A/2602A V-Source operating boundaries

Figure 4-6 shows the operating boundaries for the V-Source. Only the first quadrant of operation is covered. Operation in the other three quadrants is similar.

Figure 4-6A shows the output characteristics for the V-Source. As shown, the Series 2601A and 2602A can output up to 6.06V at 3A, or 40.4V at 1A. Note that when sourcing more than 6.06V, current is limited to 1A.

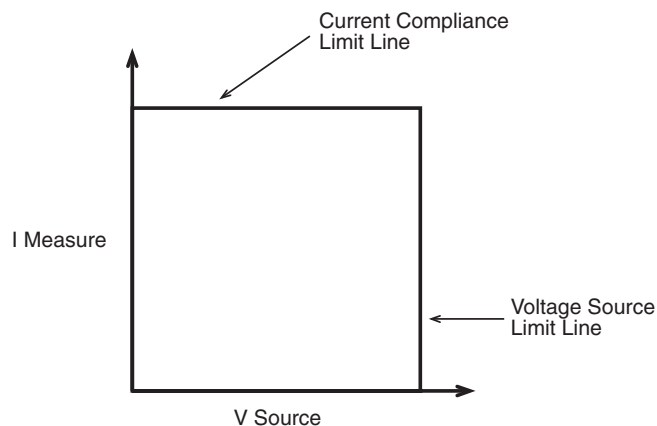

Figure 4-6B shows the limit lines for the V-Source. The voltage source limit line represents the maximum source value possible for the presently selected voltage source range. For example, if you are using the 6V source range, the voltage source limit line is at 6.3V. The current compliance limit line represents the actual compliance in effect (see *Compliance limit*). These limit lines are boundaries that represent the operating limits of the SourceMeter instrument for this quadrant of operation. The operating point can be anywhere inside (or on) these limit lines. The limit line boundaries for the other quadrants are similar.

Figure 4-6

B) Limit lines

Model 2611A/2612A/2635A/2636A V-Source operating boundaries

[Figure 4-7](#) shows the operating boundaries for the V-Source. Only the first quadrant of operation is covered. Operation in the other three quadrants is similar.

[Figure 4-7A](#) shows the output characteristics for the V-Source. As shown, the Series 2611A/2612A/2635A/2636A can output up to 20.2V at 1.5A, or 202V at 100mA. Note that when sourcing more than 20.2V, current is limited to 100mA.

[Figure 4-7B](#) shows the limit lines for the V-Source. The voltage source limit line represents the maximum source value possible for the presently selected voltage source range. For example, if you are using the 20V source range, the voltage source limit line is at 20.2V. The current compliance limit line represents the actual compliance in effect (see [Compliance limit](#)). These limit lines are boundaries that represent the operating limits of the SourceMeter instrument for this quadrant of operation. The operating point can be anywhere inside (or on) these limit lines. The limit line boundaries for the other quadrants are similar.

Load considerations

The boundaries the SourceMeter instrument operates in depends on the load (DUT) that is connected to the output. [Figure 4-8](#) shows operation examples for resistive loads that are $2\text{k}\Omega$ and 800Ω , respectively. For these examples, the SourceMeter instrument is programmed to source 10V and limit 10mA.

In [Figure 4-8A](#), the SourceMeter instrument is sourcing 10V to the $2\text{k}\Omega$ load and subsequently measures 5mA. As shown, the load line for $2\text{k}\Omega$ intersects the 10V voltage source line at 5mA.

[Figure 4-8B](#) shows what happens if the resistance of the load is decreased to 800Ω . The DUT load line for 800Ω intersects the current compliance limit line placing the SourceMeter instrument in compliance. In compliance, the SourceMeter instrument will not be able to source its programmed voltage (10V). For the 800Ω DUT, the SourceMeter instrument will only output 8V (at the 10mA limit).

Notice that as resistance decreases, the slope of the DUT load line increases. As resistance approaches infinity (open output), the SourceMeter instrument will source virtually 10V at 0mA. Conversely, as resistance increases, the slope of the DUT load line decreases. At zero resistance (shorted output), the SourceMeter instrument will source virtually 0V at 10mA.

Regardless of the load, current will never exceed the programmed compliance of 10mA.

Figure 4-8
V-Source operating examples

A) Normal V-source operation

B) V-Source in compliance

Source I measure I, source V measure V

The SourceMeter instrument can measure the function it is sourcing. When sourcing a voltage, you can measure voltage. Conversely, if you are sourcing current, you can measure the output current. For these measure source operations, the measure range is the same as the source range.

This feature is valuable when operating with the source in compliance. When in compliance, the programmed source value is not reached. Thus, measuring the source lets you measure the actual output voltage.

Basic circuit configurations

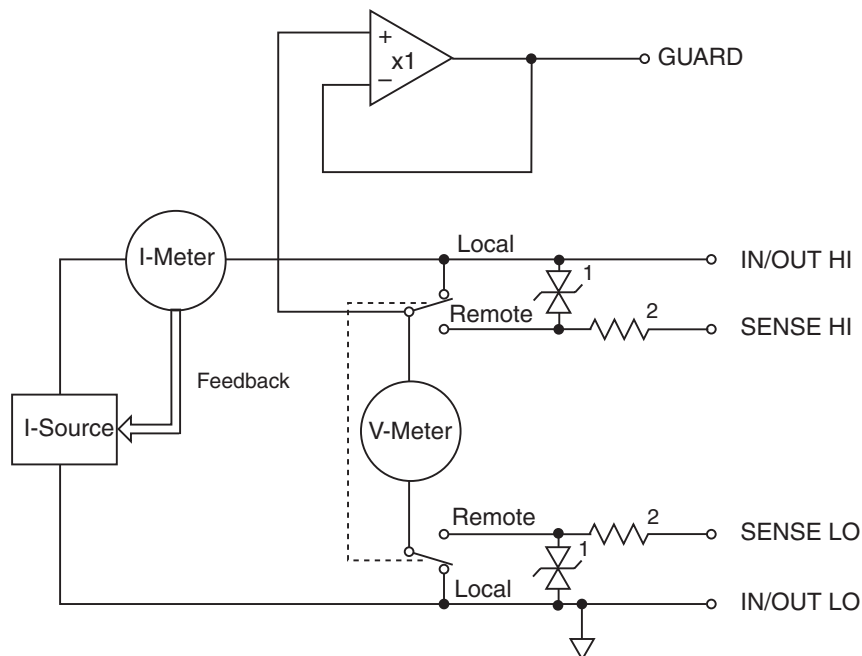

Source I

When configured to source current (I-Source) as shown in [Figure 4-9](#), the SourceMeter instrument functions as a high-impedance current source with voltage limit capability and can measure current (I-Meter) or voltage (V-Meter).

For 2-wire local sensing, voltage is measured at the Input/Output terminals of the SourceMeter instrument. For 4-wire remote sensing, voltage is measured directly at the DUT using the sense terminals. This eliminates any voltage drops that may be in the test leads or connections between the SourceMeter instrument and the DUT.

The current source does not require or use the sense leads to enhance current source accuracy. With 4-wire remote sensing selected, the sense leads must be connected or incorrect operation will result.

Figure 4-9
Source I configuration

NOTES: 1. This represents a protection circuit that is very high impedance until the voltage across it exceeds approximately 3V. Above 3V, the protection turns on and allows current to flow through it.
2. Approximately 13k Ω .

Source V

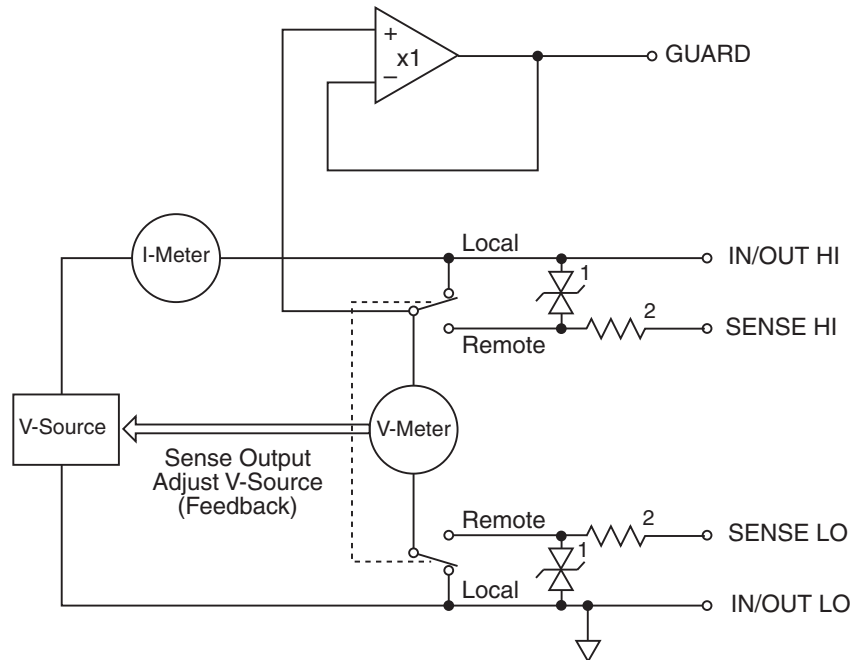

When configured to source voltage (V-Source) as shown in [Figure 4-10](#), the SourceMeter instrument functions as a low-impedance voltage source with current limit capability and can measure current (I-Meter) or voltage (V-Meter).

Sense circuitry is used to continuously monitor the output voltage and make adjustments to the V-Source as needed. The V-Meter senses the voltage at the input/output terminals (2-wire local sense) or at the DUT (4-wire remote sense using the sense terminals) and compares it to the programmed voltage level. If the sensed level and the programmed value are not the same, the

V-Source is adjusted accordingly. Remote sense eliminates the effect of voltage drops in the test leads ensuring that the exact programmed voltage appears at the DUT.

The voltage error feedback to the V-Source is an analog function. The source error amplifier is used to compensate for IR drop in the test leads.

Figure 4-10
Source V configuration

- NOTES: 1. This represents a protection circuit that is very high impedance until the voltage across it exceeds approximately 3V. Above 3V, the protection turns on and allows current to flow through it.
2. Approximately 13kΩ.

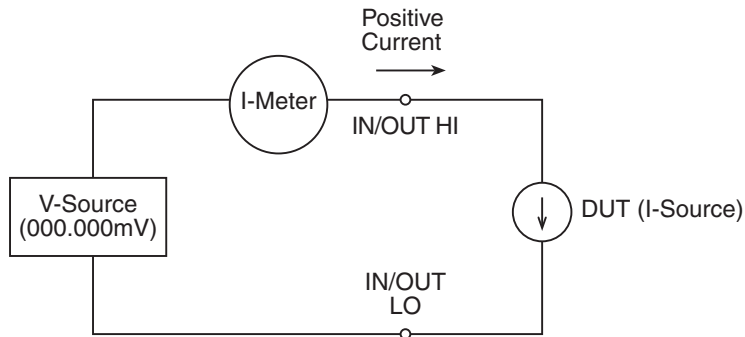

Measure only (V or I)

Figure 4-11 shows the configurations for using the SourceMeter instrument exclusively as a voltmeter or ammeter. As shown in Figure 4-11A, the SourceMeter instrument is configured to measure voltage-only by setting it to source 0A and measure voltage.

CAUTION V-Compliance must be set to a level that is higher than the measured voltage. Otherwise, excessive current will flow into the SourceMeter instrument. This current could damage the SourceMeter instrument. Also, when connecting an external voltage to the I-Source, set the output off state to the high-impedance mode. See ["Compliance limit"](#) earlier in this section for details.

In Figure 4-11B, the SourceMeter instrument is configured to measure current-only by setting it to source 0V and measure current. Note that in order to obtain positive (+) readings, conventional current must flow from IN/OUT HI to LO.

Figure 4-11

Measure only configurations**A. Measure Voltage Only**

Note: Positive current flowing out of IN/OUT HI results in positive (+) measurements.

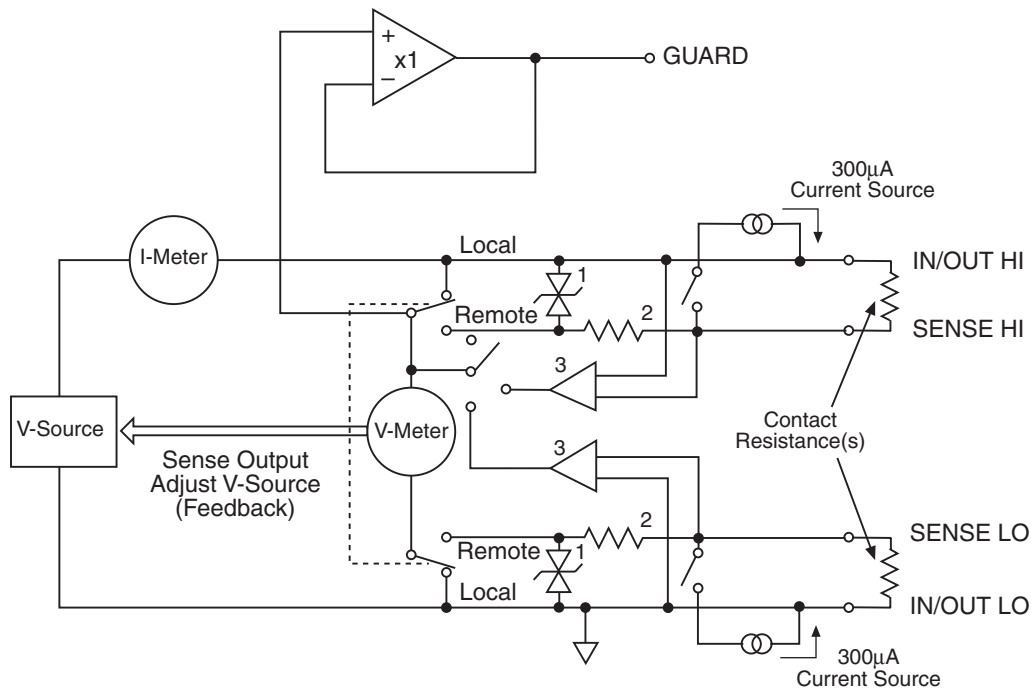

B. Measure Current Only

Note: Use 2-wire local sensing.

Contact check

When a contact check measurement is being performed, two small current sources are switched in between the HI and SENSE HI terminals and the LO and SENSE LO terminals. By controlling the switches illustrated in [Figure 4-12](#), the current from these sources flows through the test leads and through the contact resistance as shown. To accurately measure the resulting contact resistance, the differential amplifier outputs are measured once with the current sources connected, and again with the current sources disconnected. This allows for compensation of various offset voltages that can occur.

Figure 4-12
Contact check circuit configuration

- NOTES: 1. This represents a protection circuit that is very high impedance until the voltage across it exceeds approximately 3V. Above 3V, the protection turns on and allows current to flow through it.
 2. Approximately 13kΩ.
 3. High impedance differential amplifier.

Guard

WARNING *GUARD is at the same potential as output HI. Thus, if hazardous voltages are present at output HI, they are also present at the GUARD terminal.*

Guard overview

The driven guard (available at the rear panel GUARD terminals) is always enabled and provides a buffered voltage that is at the same level as the Input/Output HI (or Sense HI for remote sense) voltage. The purpose of guarding is to eliminate the effects of leakage current (and capacitance) that can exist between input/output high and low. In the absence of a driven guard, leakage in the external test circuit could be high enough to adversely affect the performance of the SourceMeter instrument.

Leakage current can occur through parasitic or non-parasitic leakage paths. An example of parasitic resistance is the leakage path across the insulator in a coax or triax cable. An example of non-parasitic resistance is the leakage path through a resistor that is connected in parallel to the DUT.

Guard connections

Guard is typically used to drive the guard shields of cables and test fixtures. Guard is extended to a test fixture from the cable guard shield. Inside the test fixture, the guard can be connected to a guard plate or shield that surrounds the DUT.

WARNING *To prevent injury or death, a safety shield must be used to prevent physical contact with a guard plate or guard shield that is at a hazardous potential (>30Vrms or 42.4V peak). This safety shield must completely enclose the guard plate or shield and must be connected to safety earth ground. [Figure 4-13B](#) shows the metal case of a test fixture being used as a safety shield.*

NOTE See [Section 2](#) for details on guarded test connections.

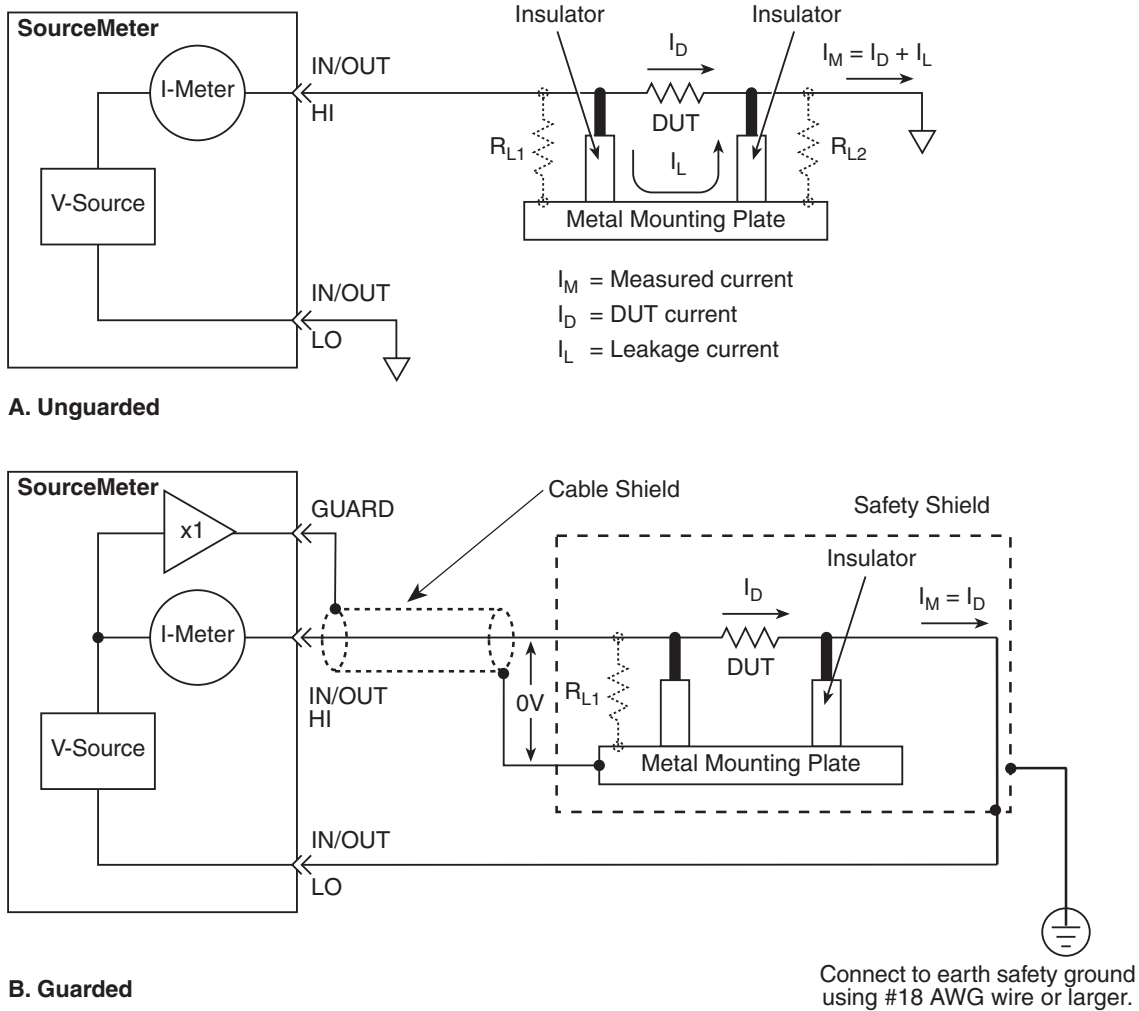

Inside the test fixture, a triaxial cable can be used to extend guard to the DUT. The center conductor of the cable is used for In/Out HI, the inner shield is used for guard, and the outer shield is used for In/Out LO and is connected to the safety shield (which is connected to safety earth ground).

A coaxial cable can be used if the guard potential does not exceed 30Vrms (42.4V peak). The center conductor is used for In/Out HI, and the outer shield is used for guard. For higher guard potentials, use a triaxial cable as previously explained.

[Figure 4-13](#) shows how cable guard can eliminate leakage current through the insulators in a test fixture. In [Figure 4-13A](#), leakage current (I_L) flows through the insulators (R_{L1} and R_{L2}) to In/Out LO, adversely affecting the low-current (or high-resistance) measurement of the DUT.

In [Figure 4-13B](#), the driven guard is connected to the cable shield and extended to the metal guard plate for the insulators. Since the voltage on either end of R_{L1} is the same (0V drop), no current can flow through the leakage resistance path. Thus, the SourceMeter instrument only measures the current through the DUT.

Figure 4-13
Comparison of unguarded and guarded measurements

Settling time considerations

Measurement settling time considerations

Several outside factors can influence measurement settling times. Effects such as dielectric absorption, cable leakages, and noise can all extend the times required to make stable measurements. Care should be taken to use appropriate shielding, guarding, and aperture selections when making low current measurements.

Each current measurement range has a combination of a range resistor and a compensating capacitor that must settle out to allow a stable measurement. By default (on power up or after `smuX.reset()`), delays are enforced to account for approximately 6τ or 6 time constants of a given range (to reach 0.1% of the final value, assuming 2.3τ per decade). The table below lists the

current ranges and associated default delays. In addition, a 1Hz analog filter is used by default on the 1nA and 100pA ranges.

Table 4-4
Current Measure Settling Time^{1, 2}

Time required to reach 0.1% of final value after source level command is processed on a fixed range. Values below for $V_{out} = 2V$ unless otherwise noted	
Current range	Settling time
1.5A to 1A	<120 μ s (typical)(Rload>6 Ω)
100mA to 10mA	<80 μ s (typical)
1mA	<100 μ s (typical)
100 μ A	<150 μ s (typical)
10 μ A	<500 μ s (typical)
1 μ A	<2.5ms (typical)
100nA	<15ms (typical)
10nA	<90ms (typical)
1nA ¹	<360ms (typical)
100pA ³	<360ms (typical)

1. Delay factor set to 1. Compliance equal to 100 mA.
2. Time for measurement to settle after a Vstep.
3. With default analog filter setting < 450ms.

NOTE Delays are on by default for Models 2635A/2636A. Delays are off by default for Models 2601A/2602A/2611A/2612A but can be enabled.

Both the analog filter and the default delays can be manipulated for faster response times. The analog filter may be turned off to yield faster settling times. The default delays may also be controlled by using the delay factor multiplier. The default value for delay factor multiplier is 1.0, but adjusting to other values will result in either a faster or slower response. For example, increasing the delay factor to 1.3 will account for settling to 0.01% of the final value. The commands to manipulate the delay factor and analog filter are shown below:

For controlling settling time delay

```
-- To turn off measure delay (default setting is smuX.DELAY_AUTO).
smuX.measure.delay = 0
```

```
-- set measure delay for all ranges to Y (in seconds).
smuX.measure.delay = Y
```

```
-- To adjust the delay factor.
smuX.measure.delayfactor = 1.0
```

This factor is used to multiply the default delays. Setting this value above 1.0 increases the delays, while a value below 1.0 decreases the delay. Setting this value to 0.0 essentially turns off measurement delays. This attribute is only used when:

```
smuX.measure.delay is set to smuX.DELAY_AUTO.
```

For analog filter (2635A/2636A only)

```
-- Default.
smuX.measure.analogfilter = 1
```

This filter is only active when the amps measure range is 1nA/100pA. Setting the attribute to zero disables the filter.

Reduction in gain-bandwidth

The settling time of the SMU can be influenced by the impedance of the DUT in several ways. One influence is caused by an interaction between the impedances of the SMU current source feedback element and the DUT. This interaction can cause a reduction in gain-bandwidth. When the SMU gain-bandwidth is reduced, the settling time of the current source increases.

Table 4-5 below can be used to determine the affect of various DUT impedances on the gain-bandwidth when the SMU is operating on each current source range. If the ratio of DUT impedance to current source feedback impedance drops below the indicated 60kHz ratio, then the settling time will increase beyond the specified times. Therefore, there is a minimum DUT impedance for each current source range. The settling time on a current range can increase significantly when measuring DUTs that have an impedance that is lower than that listed in Table 4-5.

Table 4-5
Current source gain-bandwidth

Range	SMU feedback impedance	60kHz ratio (DUT / SMU impedance)	Minimum DUT impedance
1nA	1G Ω	0.5	2G Ω
10nA	120M Ω	0.5	60M Ω
100nA	40M Ω	0.5	20M Ω
1 μ A	1.2M Ω	0.5	600k Ω
10 μ A	400k Ω	0.5	200k Ω
100 μ A	12k Ω	0.5	6k Ω
1mA	4k Ω	0.5	2k Ω
10mA	120 Ω	0.5	60 Ω
100mA	40 Ω	0.5	20 Ω
1A	1 Ω	6	6 Ω
1.5A	1 Ω	6	6 Ω
3A	0.3 Ω	5	1.5 Ω

High-Capacitance Mode

Understanding source settling times	5-2
Adjusting the voltage source	5-3
Enabling high-capacitance mode	5-4
Front panel	5-4
Command interface	5-5

Overview

The Keithley Instruments Series 2600A System SourceMeter® instrument features a high-capacitance mode.

Because the source measure unit (SMU) has the ability to measure low current, issues can arise when driving a capacitive load. The pole formed by the load capacitance and the current range resistor can cause a phase shift in the SMU voltage control loop. This shift can lead to overshoot, ringing, and instability. Due to the large dynamic range of current measurement and wide range of internal resistors, the operating conditions for a given capacitive load can vary.

Based on the type, some test applications may require capacitors larger than 10nF. While running test scripts, it may not be possible to disconnect the capacitor from the IC (integrated circuit) and extract accurate data. For this purpose, you can use the high-capacitance mode to minimize overshoot, ringing and instability.

This section provides the details that you need to estimate performance based on load capacitance and measurement conditions.

Understanding high-capacitance mode

Each SMU in the Series 2600A drives 10nF of capacitance in normal operation. Typically, an internal capacitor across the current measuring element provides phase lead to compensate for the phase lag caused by the load capacitance on the output. This internal capacitance across the range resistance limits the speed for a specific measurement range.

It is important to note that each SMU in the Series 2600A implements frequency compensation to achieve the highest throughput possible for a 10nF or less load. In addition you must consider the settling time, voltage range, measure delay, the quality of the capacitor, the current measure range resistor, and the load resistor.

In normal operation, each SMU in the Series 2600A can drive capacitive loads as large as 10nF. In high-capacitance mode, each SMU can drive a maximum of 50 μ F of capacitance.

NOTE NOTE: When high-capacitance mode is enabled, a minimum load capacitance of 100nF is recommended. In absence of this minimum load capacitance, overshoot and/or ringing may occur.

Highest throughput is achieved by using normal operation. In high capacitance mode, the speed of the Series 2600A SMU is reduced in order to compensate for the larger load capacitance. Stability is achieved by inserting an internal capacitance across the current measuring element of the SMU. This internal capacitor limits the speed for the source and measurement ranges. Therefore, when optimizing the speed of your test configuration in high-capacitance mode, you must consider the settling time, voltage, and current ranges, measure delay, quality of the load capacitor, and load resistance.

Understanding source settling times

Each Series 2600A SMU can drive up to 50 μ F of a capacitance in high-capacitance mode. In order to accomplish this, the speed of the Series 2600A SMU is reduced. Source settling times increase when high-capacitance mode is enabled. [Table 5-1](#) and [Table 5-2](#) compare the source settling times for the Series 2602A, 2612A, and 2636A in normal and high-capacitance modes.

Table 5-1
Models 2601A and 2602A source settling times

Range	Normal mode	High capacitance mode
100 mV	50 μ s	200 μ s
1 V	50 μ s	200 μ s
6 V	100 μ s	200 μ s
40 V	150 μ s	7 ms

Table 5-2
Models 2611A/2612A and 2635A/2636A source settling times

Range	Normal mode	High capacitance mode
200 mV	50 μ s	600 μ s
2 V	50 μ s	600 μ s
20 V	110 μ s	1.5 ms
200 V	700 μ s	20 ms

In high-capacitance mode, the frequency compensation capacitance across the measure range resistors increases. This increase leads to longer settling times on some current measure ranges. The same range elements that are used to measure current are used to source current. Therefore, the current limit response times will respond in a similar manner.

[Table 5-3](#) displays the current measure and current limits in normal mode and high-capacitance mode.

Table 5-3
Current measure and source settling times

Current measure range	Normal mode (typical)	High capacitance mode (typical)
1A - 1.5 A (2612A/2636A)	120 μ s	120 μ s ($R_{load} > 6\Omega$)
1A - 3 A (2602A)	80 μ s	120 μ s ($R_{load} > 2\Omega$)
100 mA	100 μ s	100 μ s
10 mA	80 μ s	100 μ s
1 mA	100 μ s	3 ms
100 μ A	150 μ s	3 ms
10 μ A	500 μ s	230 ms
1 μ A	2 ms	230 ms

When high-capacitance mode is enabled, the amount of time to change the current measure range increases for each SMU. The current measure range and the current limit range are locked together. Setting the current limit automatically updates the measure range.

Adjusting the voltage source

When driving large capacitive loads with high-capacitance mode enabled, the response time may be lengthened by the current limit. For example, see [Table 5-3](#). If a 1 μ F capacitor charges to 10V in 10 μ s with a 1A limit $i = C \frac{\Delta v}{\Delta t}$ and the limit is set to 100nA, the charging time will be 100 seconds.

The total response times while in high-capacitance mode are a combination of the time spent charging the capacitor (current limit) or the response time, whichever is greater. There is a direct relationship between the current limit and the charging time. As the current limit decreases, the amount of time required to charge the capacitor increases.

Understanding the capacitor

Based on the capacitor dielectric absorption the settling time may change and the values in [Table 5-3](#) may differ.

Note the following:

- Tantalum or electrolytic capacitors are well known for long dielectric absorption settling times.
- Film capacitors and ceramics perform better, with NPO/COG dielectric ceramics yielding the best settling response.

Charging the capacitor and taking readings

Complete the following to charge the capacitor in high-capacitance mode.

1. Set the current limit to a higher value.
2. After the capacitor charges, lower the current limit and measure range to obtain the current measurement.

Enabling high-capacitance mode

Note the following before enabling high-capacitance mode:

- It is important to read the previous section to understand the impact of high-capacitance mode.
- Test the DUT and the capacitor to determine the best current source and range of output voltages.
- The settling times can vary based on the DUT. It is important to test the limits of the DUT before you use high-capacitance mode.
- Failure to test the DUT for the appropriate current source and output voltages can result in damage to or destruction of the DUT.
- For optimal performance, do not continuously switch between normal mode and high-capacitance mode.
- Before you charge the capacitor, start with 0 (zero) voltage across the capacitor.
- When high-capacitance mode is enabled, a minimum load capacitance of 100nF is recommended. In absence of this minimum load capacitance, overshoot and/or ringing may occur.

Front panel

Complete the following steps to enable high-capacitance mode from the front panel:

1. Press **CONFIG > SRC > HIGHC-MODE**.
2. Select **SRC-ENABLE > ENABLE**. High-capacitance mode is enabled.
3. Push the **ENTER** key.
4. Press **EXIT** to back out of the menu structure.

Command interface

Turning on High-C mode has the following effects on the SMU settings:

- `smuX.measure.autorangei` is set to `smuX.AUTORANGE_FOLLOW_LIMIT` and cannot be changed.
- Current ranges below 1uA are not accessible.
- If `smuX.source.limiti` is less than 1uA, it is raised to 1uA.
- If `smuX.source.rangei` is less than 1uA, it is raised to 1uA.
- If `smuX.source.lowrangei` is less than 1uA, it is raised to 1uA.
- If `smuX.measure.lowrangei` is less than 1uA, it is raised to 1uA.

Measuring current

The following inputs are required to test leakage using the factory leakage script as shown in the script example below.

- **SMU:** Indicates the Series 2600A source measure unit to use.
- **levelv:** Setting the voltage level to source.
- **limiti:** Sets the current limit for discharging or charging the capacitor.
- **Sourcedelay:** Solve $i = C \frac{\Delta v}{\Delta t}$ to determine the amount of time before taking a current reading.
Where: i is the `limiti` setting and current limit.
- **measurei:** Sets the current measure range.
- **measuredelay:** Defines the delay after the limit is lowered to measure before the measurement is taken.

Script example

Use the `smuX.source.highc` attribute to set and control the options for high capacitance mode.

NOTE The Series 2600A must be configured as a voltage source to use the `smuX.source.func` attribute to enable high-capacitance mode.

The following code contains examples that you can use to enable high-capacitance mode on SMU A:

1. To enable high-capacitance mode, send the following:

```
-- Enables high-capacitance mode.
smua.source.highc = smua.ENABLE
```
2. Run the `i_leakage_measure()` function in the KIHighC factory script (see [Figure 5-1](#)):

```
-- Charges the capacitor.
smua.source.levelv = 5
smua.source.output = smua.OUTPUT_ON
delay(1)

imeas = i_leakage_measure(smua, 0, 1, 300e-3, 10e-6, 100e-3)
-- The parameters in the i_leakage_measure() function represent
-- the following:
-- smu = smua
-- levelv = 0V
```

```
-- limiti = 1A
-- sourcedelay = 300ms
-- measurei = 10uA range
-- measuredelay = 100ms
```

NOTE Adjust the voltage level and source delays based on the value and type of capacitor along with the magnitude of the voltage step and the current measure range.

- [Rel](#)
- [Filters](#)

Range

The selected measurement range affects the accuracy of the measurements as well as the maximum signal that can be measured. Note that dashed lines are displayed (for example, --.---- μ A), to indicate that the previous measurement is not recent. This usually happens when a change occurs such as selecting a different range.

Available ranges

[Table 6-1](#) lists the available source and measurement ranges for the Keithley Instruments Series 2600A System SourceMeter® instruments.

Table 6-1
Source and measurement ranges

Model 2601A/2602A		Model 2611A/2612A		Model 2635A/2636A	
Voltage Ranges	Current Ranges	Voltage Ranges	Current Ranges	Voltage Ranges	Current Ranges
100mV	100nA	200mV	100nA	200mV	100pA ²

2. 100pA range only in measure.

Maximum source values and readings

The full-scale output for each voltage and current source range is 101% of the selected range, while the full-scale measurement is 102% of the range. For example, $\pm 1.01A$ is the full-scale source value for the 1A range, and $\pm 102mA$ is the full-scale reading for the 100mA measurement range. Input levels that exceed the maximum levels cause the overflow message to be displayed. Note, however, that the instrument will auto range at 100% of the range.

Ranging limitations

- Model 2601A/2602A: With the 40V V-Source range selected, the highest current measurement range is 1A. With the 3A I-Source range selected, the highest voltage measurement range is 6V.
- Model 2611A/2612A/2636A: With the 200V V-Source range selected, the highest current measurement range is 100mA. With I-Source ranges above 100mA selected, the highest voltage measurement range is 20V.
- For Source V Measure I or Source I Measure V, you can set source and measure ranges separately. If both source and measure functions are the same, the measure range is locked to the source range.

Manual ranging

The **RANGE** \triangle and ∇ keys are used to select a fixed range:

- To set the source range, press **SRC**, then use the **RANGE** keys to set the range.
- To set the measure range, select the single-channel display mode (Models 2602A/2612A/2636A only), press **MEAS**, then set the range with the **RANGE** keys.

If the instrument displays the overflow message on a particular range, select a higher range until an on-range reading is displayed. Use the lowest range possible without causing an overflow to ensure best accuracy and resolution.

Auto ranging

To use auto source ranging, press **SRC** then **AUTO RANGE**. To use auto measure ranging, select the Model 2602A/2612A/2636A single-channel display mode, then press **MEAS** followed by **AUTO RANGE**. The AUTO indicator turns on when source or measure auto ranging is selected. With auto ranging selected, the instrument automatically chooses the best range to source or measure the applied signal. The instrument will auto range at 100% of range.

Note that source auto ranging will turn off when editing the source value.

Low range limits

The low range limits set the lowest range the Series 2600A will use when auto ranging is enabled. This feature is useful for minimizing auto range settling times when numerous range changes are involved.

Low range limits can be individually set for Source V, Source I, Measure V, and Measure I as follows:

1. Press the **CONFIG** key, then press either **SRC** for source or **MEAS** for measure.
2. Choose voltage or current source, or measure as appropriate, and then press **ENTER** or the **navigation wheel**.
3. Choose **LOWRANGE**, then press **ENTER** or the **navigation wheel**.
4. Set the low range to the desired setting, and then press **ENTER** or the **navigation wheel**.

5. Use **EXIT** to back out of the menu structure.

Range considerations

The source range and measure range settings can interact depending on the source function. Additionally, the output state (on/off) can affect how the range is set.

If the source function is the same as the measurement function (for example, sourcing voltage and measuring voltage), the measurement range is locked to be the same as the source range. However, the setting for the voltage measure range is retained and used when the source function is changed to current, and the present voltage measurement range will be used.

2601A/2602A Example:

```
smua.source.func = smua.OUTPUT_DCVOLTS
smua.source.rangev = 1
smua.measure.rangev = 6
-- will print 1, to match source range
print(smua.measure.rangev)
smua.source.func = smua.OUTPUT_DCAMPS
-- will print 6, the user's range
print(smua.measure.rangev)
```

Explicitly setting either a source or measurement range for a function will disable auto ranging for that function. Auto ranging is controlled separately for each source and measurement function: source voltage, source current, measure voltage, and measure current. Auto ranging is enabled for all four by default.

Changing the range while the output is off will not update the hardware settings, but querying will return the range setting that will be used once the output is turned on. Setting a range while the output is on will take effect immediately.

With source auto ranging enabled, the output level controls the range. Querying the range after the level is set will return the range the unit chose as appropriate for that source level.

The Series 2600A allows you to send ICL command values that may be out of range when auto range is off. An example is sending 1A on the 100mA range. The unit does not error check until the output is turned on. In this situation, the display will show a series of question marks:

```
???.???
```

With measure auto ranging enabled, the range will be changed only when a measurement is taken. Querying the range after a measurement will return the range selected for that measurement.

Range programming

Range commands

[Table 6-2](#) summarizes the commands necessary to control measure and source ranges. See [Section 19](#) for more details on these commands.

Table 6-2
Range commands

Commands ¹	Description
<p>Measure range commands: ²</p> <pre>smuX.measure.autorangei = smuX.AUTORANGE_ON smuX.measure.autorangei = smuX.AUTORANGE_OFF smuX.measure.autorangev = smuX.AUTORANGE_ON smuX.measure.autorangev = smuX.AUTORANGE_OFF smuX.measure.lowrangei = lowrange smuX.measure.lowrangev = lowrange smuX.measure.rangei = rangeval smuX.measure.rangev = rangeval</pre> <p>Source range commands: ³</p> <pre>smuX.source.autorangei = smuX.AUTORANGE_ON smuX.source.autorangei = smuX.AUTORANGE_OFF smuX.source.autorangev = smuX.AUTORANGE_ON smuX.source.autorangev = smuX.AUTORANGE_OFF smuX.source.limiti = level smuX.source.limitv = level smuX.source.lowrangei = lowrange smuX.source.lowrangev = lowrange smuX.source.rangei = rangeval smuX.source.rangev = rangeval</pre>	<p>Enable current measure auto range. Disable current measure auto range. Enable voltage measure auto range. Disable voltage measure auto range. Set lowest I measure range for auto range. Set lowest V measure range for auto range. Select manual current measure range. Select manual voltage measure range.</p> <p>Enable current source auto range. Disable current source auto range. Enable voltage source auto range. Disable voltage source auto range. Set voltage source current limit. Set current source voltage limit. Set lowest I source range for auto range. Set lowest V source range for auto range. Select manual current source range. Select manual voltage source range.</p>

¹ smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

² See [Table 6-1](#) for measure ranges.

³ See [Table 6-1](#) for source ranges.

Range programming example

The listing below shows a programming example for controlling both source and measure ranges. The Series 2600A is set up as follows:

- Voltage source range: auto
- Current measure range: 10mA
- Voltage source current limit: 10mA

```
-- Restore Series 2600A defaults.
smua.reset()

-- Set V source range to auto.
smua.source.autorangev = smua.AUTORANGE_ON

-- Select 10mA measure range.
smua.measure.rangei = 1e-2

-- Set limit level to 10mA.
smua.source.limiti = 1e-2
```

Digits

The display resolution of the measured reading depends on the DIGITS setting. This setting is global, which means the digits setting selects display resolution for all measurement functions.

The DIGITS setting has no effect on the remote reading format. The number of displayed digits does not affect accuracy or speed. Those parameters are controlled by the SPEED setting (see [Speed](#) later in this section).

Setting display resolution

To set display resolution, press the **DIGITS** key until the desired number of digits is displayed. The display resolution will cycle through 4.5, 5.5, and 6.5 digits.

NOTE For the Model 2602A/2612A/2636A dual-channel display mode, the maximum display resolution is 4.5 digits. For the Model 2602A/2612A/2636A single-channel display mode, pressing the DIGITS key for the channel not being displayed will have no effect, but the unit will display a message advising you to change to the indicated channel.

Remote digits programming

Digits commands

[Table 6-3](#) summarizes digits commands. See [Section 19](#) for more information.

Table 6-3

Digits commands

Command ¹	Description
<code>display.smuX.digits = display.DIGITS_4_5</code>	Set display to 4.5 digits.
<code>display.smuX.digits = display.DIGITS_5_5</code>	Set display to 5.5 digits.
<code>display.smuX.digits = display.DIGITS_6_5</code>	Set display to 6.5 digits.

¹ smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

Digits programming example

```
--Select 5.5 digits.
display.smua.digits = display.DIGITS_5_5
```

Speed

The **SPEED** key is used to set the integration time, or measurement aperture, of the A/D converter (period of time the input signal is measured). The integration time affects the usable digits, the amount of reading noise, and the ultimate reading rate of the instrument. The integration time is specified in parameters based on the Number of Power Line Cycles (NPLC), where 1 PLC for 60Hz is 16.67ms (1/60) and 1 PLC for 50Hz is 20ms (1/50).

In general, the fastest integration time (0.001 PLC) results in the fastest reading rate, but at the expense of increased reading noise and fewer usable digits. The slowest integration time (25 PLC)

provides the best common-mode and normal-mode noise rejection, but has the slowest reading rate. In-between settings are a compromise between speed and noise. The default power-on speed setting is **NORMAL** (1 PLC).

Setting speed

Speed is set from the SPEED configuration menu and is structured as follows.

SPEED configuration menu

Press **SPEED** (or use the **CONFIG** menu) to display the menu:

- **FAST:** Sets speed to 0.01 PLC.
- **MED:** Sets speed to 0.10 PLC.
- **NORMAL:** Sets speed to 1.00 PLC.
- **HI-ACCURACY:** Sets speed to 10.00 PLC.
- **OTHER:** Used to set speed to any PLC value from 0.001 to 25.

NOTE The **SPEED** setting affects all measurement functions. After setting speed, display resolution can be changed using the **DIGITS** key. For the Model 2602A/2612A/2636A single-channel display mode, pressing the **SPEED** key for the channel not being displayed will result in a display message to change to the other channel before setting speed.

Remote speed programming

Speed command

[Table 6-4](#) summarizes commands to control speed. See [Section 19](#) for more information.

Table 6-4

Speed command

Command ¹	Description
<code>smuX.measure.nplc = nplc</code>	Set speed (nplc = 0.001 to 25) ²

¹ smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

² The speed setting is global and affects all measurement functions.

Speed programming example

Use the NPLC command to set the speed. For example, send the following command to set the speed to 10 PLC:

```
--Set NPLC to 10.
smua.measure.nplc = 10
```

Rel

The rel (relative) feature can be used to null offsets or subtract a baseline reading from present and future readings. With rel enabled, subsequent readings will be the difference between the actual input value and the rel value as follows:

$$\text{Displayed Reading} = \text{Actual Input} - \text{Rel Value}$$

Once a rel value is established for a measurement function, the value is the same for all ranges. For example, if 0.5A is set as a rel value on the 1A range, the rel value is also 0.5A on the lower current ranges.

Selecting a range that cannot accommodate the rel value does not cause an overflow condition, but it also does not increase the maximum allowable input for that range. For example, on 1A range, the Series 2600A still overflows for a >1.02A input.

NOTE When rel is enabled, the REL indicator turns on. Changing measurement functions disables rel.

Front panel rel

Enabling and disabling rel

Rel can be used to null out zero offsets or to establish a zero baseline by pressing the **REL** key. The reading (which becomes the rel value) is subtracted from itself. As a result, a zero reading is displayed. Pressing **REL** a second time disables rel.

Defining a rel value

A unique rel value can be established for the selected measurement function from the front panel as follows:

1. Press **CONFIG** then **REL**.
2. Choose the measurement function (**CURRENT**, **VOLTAGE**, **OHMS**, or **WATTS**), then press **ENTER** or the **navigation wheel**.
3. The present rel value will be displayed.
4. Set the desired rel value.
5. With the desired rel value displayed, press **ENTER** or the **navigation wheel**, and then use **EXIT** to back out of the menu structure.

Remote rel programming

Rel commands

Rel commands are summarized in [Table 6-5](#).

Table 6-5

Rel commands

Command*	Description
To set rel values: smuX.measure.rel.leveli = relval smuX.measure.rel.levelp = relval smuX.measure.rel.levelr = relval smuX.measure.rel.levelv = relval	Set current rel value. Set power rel value. Set resistance rel value. Set voltage rel value.
To enable/disable rel: smuX.measure.rel.enablei = smuX.REL_OFF smuX.measure.rel.enablep = smuX.REL_OFF smuX.measure.rel.enabler = smuX.REL_OFF smuX.measure.rel.enablev = smuX.REL_OFF smuX.measure.rel.enablei = smuX.REL_ON smuX.measure.rel.enablep = smuX.REL_ON smuX.measure.rel.enabler = smuX.REL_ON smuX.measure.rel.enablev = smuX.REL_ON	Disable current rel. Disable power rel. Disable resistance rel. Disable voltage rel. Enable current rel. Enable power rel. Enable resistance rel. Enable voltage rel.

* smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

Rel programming example

```
-- Set current rel to 100mA.
smua.measure.rel.leveli = 0.1
-- Enable current rel.
smua.measure.rel.enablei = smua.REL_ON
```

Filters

Filter lets you set the filter response to stabilize noisy measurements. The Series 2600A uses a digital filter, which is based on reading conversions. The displayed, stored, or transmitted reading is calculated using many reading conversions (from 1 to 100).

Filter types

There are three filter types from which to choose. These three filters are broken down into two **averaging filters** and one **median filter**.

The two averaging filters are repeating and moving (see [Figure 6-1](#)). For the repeat filter (which is the power-on default), the stack (filter count) is filled, and the conversions are averaged to yield a reading. The stack is then cleared, and the process starts over.

The moving average filter uses a first-in, first-out stack. When the stack (filter count) becomes full, the measurement conversions are averaged, yielding a reading. For each subsequent conversion placed into the stack, the oldest conversion is discarded. The stack is re-averaged, yielding a new reading.

The median filter is used to pass the “middle-most” reading from a group of readings that are arranged according to size. The median filter uses a first-in, first-out stack similar to the moving average filter. For each subsequent conversion placed into the stack, the oldest conversion is discarded. The median is then re-determined.

When a moving filter is first enabled, the stack is empty. The first reading conversion is placed in the stack and is then copied to the other stack locations in order to fill it. Thus, the first filtered reading is the same as the first reading conversion. The normal moving filter process continues. Note that a true average or median reading is not yielded until the stack is filled with new reading conversions (no copies in stack). For example, in [Figure 6-1A](#), it takes ten filtered readings to fill the stack with new reading conversions. The first nine filtered readings are calculated using copied reading conversions.

Front panel filter control

Configuring filter

Filter type and count is configured from the filter configuration menu. The configured filter is the same for all measurement functions.

Filter configuration menu

Press **CONFIG** and then **FILTER** to display the filter configuration menu:

- **TYPE:** Use this menu item to select filter type:
 - **AVERAGE:** Use this menu item to select an averaging filter, then select the averaging filter type:
 - Moving
 - Repeat
 - **MEDIAN:** Use this menu item to select a median filter. The MOVING WINDOW filter type is the only option.
- **COUNT:** Use this menu item to specify filter count (1 to 100 readings).

Enabling filter

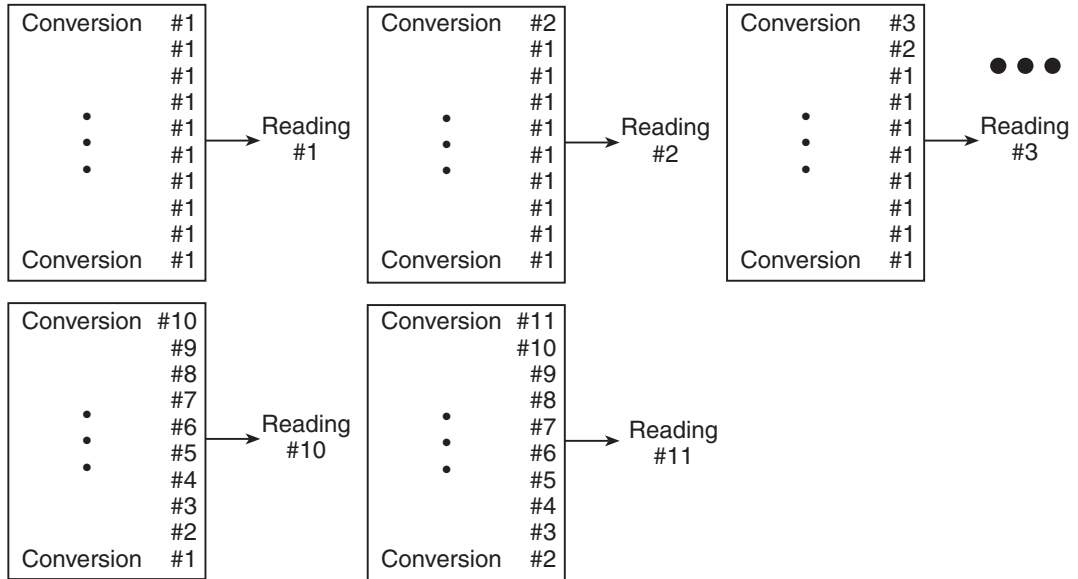

The filter is enabled by pressing the **FILTER** key. The **FILT** indicator is on while the filter is enabled. Pressing **FILTER** a second time disables filter.

Response time

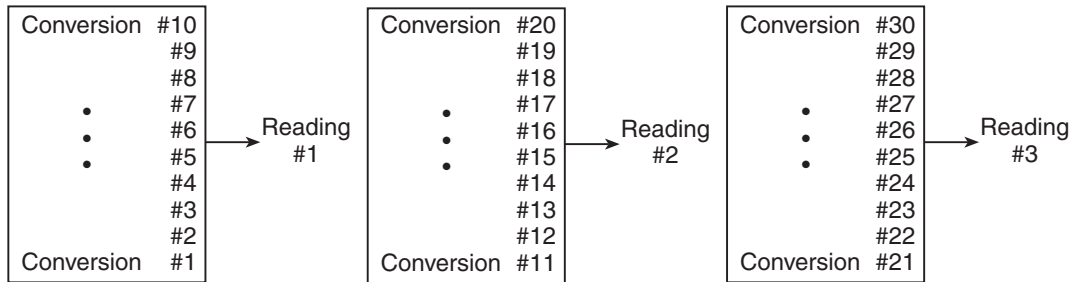

The filter parameters have speed and accuracy trade-offs for the time needed to display, store, or output a filtered reading. These affect the number of reading conversions for speed versus accuracy and response to input signal changes.

The filter averaging mode and count affect the overall reading speed. The moving averaging filter is much faster than the repeat averaging filter because the unit does not have to refill the filter stack for each reading. Also, the number of readings averaged will affect reading speed; as the number of readings averaged increases, the reading speed decreases.

Figure 6-1
Moving average and repeating filters

A. Type - Moving Average, Readings = 10

B. Type - Repeating, Readings = 10

Figure 6-2
Median Filter

C. Type - Median, Readings = 3

Remote filter programming

Filter commands

Table 6-6 summarizes filter commands. See [Section 19](#) for more details on commands.

Table 6-6

Filter commands

Commands*	Description
<code>smuX.measure.filter.count = count</code>	Set filter count (1 to 100).
<code>smuX.measure.filter.enable = smuX.FILTER_ON</code>	Enable filter.
<code>smuX.measure.filter.enable = smuX.FILTER_OFF</code>	Disable filter.
<code>smuX.measure.filter.type = smuX.FILTER_MEDIAN</code>	Select median filter type.
<code>smuX.measure.filter.type = smuX.FILTER_MOVING_AVG</code>	Select moving average filter type.
<code>smuX.measure.filter.type = smuX.FILTER_REPEAT_AVG</code>	Select repeat average filter type.

* smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

Filter programming example

The example below programs filter aspects:

- Filter type: moving average
- Filter count: 10
- Filter state: enabled

```

--Program count to 10
smua.measure.filter.count = 10
--Moving average filter type.
smua.measure.filter.type = smua.FILTER_MOVING_AVG
--Enable filter.
smua.measure.filter.enable = smua.FILTER_ON
  
```

Reading buffer overview

Reading buffers capture measurements, ranges, the instrument status, and the output state of the Keithley Instruments Series 2600A SourceMeter® instrument. The Series 2600A has two dedicated reading buffers per channel. You can use the dedicated reading buffers to acquire readings or you can use the ICL command to create dynamic reading buffers.

Each dedicated reading buffer in the Series 2600A can store over 60,000 readings with the time stamps and source values options enabled. Disable the time stamps and source values options to store over 140,000 readings internally.

You can save the dedicated reading buffers to internal nonvolatile memory in the instrument or to the USB flash drive.

Once you save the reading buffers to the USB flash drive, insert the USB flash drive into the USB port on your PC to view the data in any compatible data analysis application or transfer the data from the USB flash drive to your PC.

NOTE Reading buffers other than the dedicated reading buffers have fixed capacity and are not specifically limited to 60,000 or 140,000.

Working with reading buffers in the local state

Use this section to store and recall reading buffers while in local mode operation.

Reading buffer options

This section provides a description for the reading buffer options.

CHANA-BUFF: Configures Channel A buffer (Model 2602A/2612A/2636A only).

- **DEST:** Sets data storage destination (Buffer 1, Buffer 2, or NONE).
- **BUFFER1:** Configure Buffer 1.
 - **CLEAR:** Clear buffer (YES or NO).
 - **ELEMENTS:** Enable (ON) or disable (OFF) data storage elements; SRC-VAL (source value) or TSTAMP (time stamp).
 - **SRC-VAL:** Enable source values.
 - **TSTAMP:** Enable time stamps.
- **BUFFER2:** Configure Buffer 2.
 - **CLEAR:** Clear buffer (YES or NO).
 - **ELEMENTS:** Enable (ON) or disable (OFF) data storage elements; SRC-VAL (source value) or TSTAMP (time stamp).
 - **SRC-VAL:** Enable source values.
 - **TSTAMP:** Enable time stamps.

CHANB-BUFF: Configures Channel B buffer (Model 2602A/2612A/2636A only).

- **DEST:** Sets data storage destination (Buffer 1, Buffer 2, or NONE).
- **BUFFER1:** Configure Buffer 1.
 - **CLEAR:** Clear buffer (YES or NO).
 - **ELEMENTS:** Enable (ON) or disable (OFF) data storage elements; SRC-VAL (source value) or TSTAMP (time stamp).
 - **SRC-VAL:** Enable source values.
 - **TSTAMP:** Enable time stamps.

- **BUFFER2:** Configure Buffer 2.
 - **CLEAR:** Clear buffer (YES or NO).
 - **ELEMENTS:** Enable (ON) or disable (OFF) data storage elements; SRC-VAL (source value) or TSTAMP (time stamp).
 - **SRC-VAL:** Enable source values.
 - **TSTAMP:** Enable time stamps.

Configuring reading buffers

Complete the following steps to configure reading buffers from the front panel:

1. Press **CONFIG > STORE** and then choose one of the following:
 - **CHANA-BUFF**
 - **CHANB-BUFF**
2. Select the **DEST** option and then choose one of the following:
 - **CHANX-BUFF1**
 - **CHANX-BUFF2**
 - **NONE**
3. Select **BUFFER1** or **BUFFER2**.
4. (Optional) To clear the buffer, turn the **navigation wheel** to select **CLEAR > YES**.
5. Turn the **navigation wheel** to select **ELEMENTS**.

NOTE You must clear the reading buffer before you enable or disable the source value or the time stamp options.

6. (Optional) Push the **navigation wheel** to select **TSTAMP**, then select **OFF** or **ON**.
7. (Optional) Turn the **navigation wheel** to select **SRC-VAL**, then select **OFF** or **ON**.
8. Press the **EXIT** key to return to the main menu.

NOTE Model 2601A/2611A/2635A buffer configuration menu items are the same as covered above except for channel selection.

Appending or overwriting existing reading buffers

You can append or overwrite measurements to reading buffers with data.

Complete the following steps to configure the instrument to append or overwrite measurements the next time data is acquired:

1. Complete the steps from [Saving reading buffers](#).
2. Press **CONFIG > STORE** and then select **STORAGE-MODE**. The Storage Mode menu is shown.
3. Choose one of the following:
 - **APPEND**
 - **OVERWRITE**
4. Press **EXIT** to return to the main menu.

Storage operation

Use this option to initiate a storage operation and to configure the number of readings acquired during a store operation. The count can range from 1 to 60,000 with time stamps and source values enabled, to over 140,000 with time stamps and source values disabled.

NOTE To store the maximum number of readings in a reading buffer (over 140,000), disable the source values and time stamps for that reading buffer.

To configure the count, complete the following:

1. From the front panel, press **STORE** and then choose **TAKE_READINGS**.
2. Use the **navigation wheel** to select the number of readings.
3. Push the **navigation wheel** to switch to edit mode.
4. Use the **navigation wheel** to change the numeric value and then push the **navigation wheel** to save the numeric value.
5. Press **ENTER** to save the count.
6. Press the **Output On/Off** button to start taking readings. Note that if output-off mode is output zero it will start acquiring data immediately.

Saving reading buffers

You can save the dedicated reading buffers to nonvolatile memory or you can save them to a USB flash drive. Note that the unit will restore the dedicated reading buffers from internal nonvolatile memory when the unit is turned off and back on.

Saving the reading buffers to nonvolatile memory

After the measurements are complete, you can save the reading buffer data to the nonvolatile memory in the instrument.

To save the reading buffer data:

1. From the front panel, press **STORE** and then choose **SAVE**.
2. Select **INTERNAL** to save to internal nonvolatile memory.
3. Select one of the following:
 - **SMUA_BUFFER1**
 - **SMUA_BUFFER2**
 - **SMUB_BUFFER1**
 - **SMUB_BUFFER2**
4. The front panel displays Saving... This may take awhile.
5. Press the **EXIT** key to return to the main menu.

Saving the reading buffer to the USB flash drive

Complete the following steps to save the reading buffer data to a USB flash drive:

1. Insert the USB flash drive into the USB port.
2. Press **STORE** and use the **navigation wheel** to select **SAVE > USB1**.
3. Select one of the following file formats:
 - **CSV**
 - **XML**

4. Use the **navigation wheel** to select the desired reading buffer.
5. Use the **navigation wheel** to change the file name.
6. Push the **navigation wheel** or the **ENTER** key to save the file.
7. Push **EXIT** to return to the main menu.

Recalling readings

To recall the data stored in a reading buffer, press the **RECALL** key.

NOTE (Models 2601A/2611A/2635A) Pressing the **RECALL** key toggles between the two dedicated reading buffers for Channel A. (Models 2602A/2612A/2636A) Pressing the **RECALL** key cycles through the reading buffers for each channel. Channel A, Buffer 1 is always the first buffer displayed.

The reading display is on the top left, while the buffer location number is on the right. The source values are positioned at the lower left side of the display (if enabled), while the time stamp (if used) is positioned at the lower right side. When toggling between buffers with **RECALL**, the source display field will identify the buffer: SrcA1 (Buffer 1, Channel A), then SrcA2 (Buffer 2, Channel A); followed by (Model 2602A/2612A/2636A only) SrcB1 (Buffer 1, Channel B) then SrcB2 (Buffer 2, Channel B).

Buffer location number

The buffer location number indicates the memory location of the source-measure reading. For example, location #000001 indicates that the displayed source-measure reading is stored at the first memory location.

Time stamp

If the time stamp is enabled, the first source-measure reading stored in the buffer (#0000001) is time stamped at .000 seconds. Subsequent readings are time stamped relative to when the first measurement was made. The interval between readings will depend on the reading rate.

Displaying other buffer readings

Turn the **navigation wheel** to increment and decrement the selected digit of the location number by one. Press the **navigation wheel** or **CURSOR** keys to move to the next digit that the **navigation wheel** will change.

To exit from the reading buffer recall mode, press **EXIT**.

Working with reading buffers in the remote state

Readings can be obtained in multiple ways including synchronous or overlapped measurements. Routines that make single point measurements can be configured to make multiple measurements where one would ordinarily be made. The measured value is not the only component of a reading. The measurement status (for example, "In Compliance" or "Overranged") is also an element of data associated with a particular reading.

All routines that return measurements can return the measurements in the reading buffers. Overlapped measurements always return readings in a reading buffer. Synchronous measurement functions can return single-point measurement values or store multiple values in a reading buffer.

A reading buffer is based on a Lua table. The measurements are accessed by ordinary array accesses. If `rb` is a reading buffer, the first measurement is accessed as `rb[1]` and the 9th measurement as `rb[9]`, and so on. The additional information in the table is accessed as additional members of the table.

The load, save, and write operations for reading buffers function differently in the remote state. From a remote command interface, you can extract data from reading buffers as the instrument acquires the data.

Reading buffer designations

Each SMU contains two dedicated reading buffers:

- `smuX.nvbuffer1` (Buffer 1)
- `smuX.nvbuffer2` (Buffer 2)

[Table 7-1](#) provides an example the buffers available in the Series 2601A and the 2602A.

Table 7-1

SMU buffer example

Model	Reading buffers	Channel
2601A	<code>smua.nvbuffer1</code> <code>smua.nvbuffer2</code>	A
2602A	<code>smua.nvbuffer1</code> <code>smua.nvbuffer2</code>	A
	<code>smub.nvbuffer1</code> <code>smub.nvbuffer2</code>	B

To access the reading buffer, include the name of the SMU in the attribute. For example, the following command would store readings from Channel A into Buffer 1:

```
smua.measure.overlappedi(smua.nvbuffer1)
```

Buffer storage control attributes

[Table 7-3](#) displays the attributes for buffers. Read-only attributes used to access buffer parameters are listed in [Table 7-4](#). Control examples for Channel A, Buffer 1 are shown in [Table 7-5](#), while read-only attribute programming examples are listed in [Table 7-6](#).

NOTE You must clear the buffer using the `smuX.nvbufferY.clear()` command before changing buffer control attributes.

Reading buffer commands

Table 7-2 summarizes commands associated with the reading buffers. See [Section 19](#) for more detailed information on the commands for the reading buffers.

Table 7-2
Reading buffer commands

Command ¹	Description
<pre>smuX.savebuffer(smuX.nvbufferY) smuX.nvbuffer1.clear() smuX.nvbuffer2.clear() mybuffer = smuX.makebuffer(n) mybuffer = nil savebuffer(smuX.nvbuffer1, "csv", "/usb1/mybuffer.csv")</pre> <p>Commands to store readings:</p> <pre>smuX.measure.count = count smuX.measure.overlappedi(rbuffer) smuX.measure.overlappediv(ibuffer, vbuffer)</pre> <pre>smuX.measure.overlappedp(rbuffer) smuX.measure.overlappedr(rbuffer) smuX.measure.overlappedv(rbuffer)</pre> <pre>smuX.measure.v(rbuffer) smuX.measure.i(rbuffer) smuX.measure.r(rbuffer)</pre> <pre>smuX.measure.p(rbuffer)</pre> <pre>smuX.trigger.measure.v(rbuffer) smuX.trigger.measure.i(rbuffer) smuX.trigger.measure.r(rbuffer)</pre> <pre>smuX.trigger.measure.p(rbuffer) smuX.trigger.measure.iv(ibuffer, vbuffer)</pre> <p>Commands to access readings:</p> <pre>printbuffer(start_index, end_index, st_1 [, st_n])</pre>	<p>Saves the reading buffer to the Series 2600A. Clears Buffer 1. Clears Buffer 2. Creates a dynamically allocated buffer for n readings. Deletes dynamically allocated buffer. Saves the reading buffer to the USB flash drive.</p> <p>The number of measurements to acquire. Stores the current readings in buffer. Stores the current and voltage readings in respective buffers (current and voltage are stored in separate buffers). Stores the power readings in buffer. Stores the resistance readings in buffer. Stores the voltage readings in buffer.</p> <p>Reading buffer where voltage readings will be stored. Reading buffer where current readings will be stored. Reading buffer where resistance readings will be stored. Reading buffer where power readings will be stored.</p> <p>Reading buffer where voltage readings will be stored. Reading buffer where current readings will be stored. Reading buffer where resistance readings will be stored. Reading buffer where power readings will be stored. Stores the current and voltage readings in respective buffers (current and voltage are stored in separate buffers).</p> <p>Prints data from buffer subtables: start_index (Starting index of values to print). end_index (Ending index of values to print). st_1 ... st_n (Sub-tables from which to print).</p>

1. smuX = smua for the Model 2601A/2611A/2635A; smuX = smua (Channel A) or smub (Channel B) for the Model 2602A/2612A/2636A.

Table 7-3
Buffer storage control attributes

Storage attribute	Description
appendmode	The append modes are either off or on. When the append mode is off, a new measurement to this buffer will overwrite the previous contents. When the append mode is on, the first new measurement will be stored at what was formerly rb[n+1]. This attribute is initialized to off when the buffer is created.
collectsourcevalues	When this attribute is on, source values will be stored with readings in the buffer. This value, off or on, can only be changed when the buffer is empty. When the buffer is created, this attribute is initialized to off.
collecttimestamps	When this attribute is on, timestamps will be stored with readings in the buffer. This value, off or on, can only be changed when the buffer is empty. When the buffer is created, this attribute is initialized to off.
timestampresolution	The timestamp resolution, in seconds. When the buffer is created, its initial resolution is 0.000001 seconds. At this resolution, the reading buffer can store unique timestamps for up to 71 minutes. This value can be increased for very long tests. Note: The minimum resolution setting is 1µs (0.000001 seconds).

Table 7-4
Buffer read-only attributes

Storage attribute	Description
basetimestamp	The timestamp of when the reading at rb[1] was stored, in seconds from mid-night January 1, 1970 GMT, see page 19-14 for additional details.
capacity	The total number of readings that can be stored in the reading buffer.
n	The number of readings in the reading buffer.

Table 7-5
Buffer control programming examples

Command	Description
smua.nvbuffer1.collectsourcevalues = 1	Enable source value storage.
smua.nvbuffer1.appendmode = 1	Enable buffer append mode.
smua.nvbuffer1.collecttimestamps = 0	Disable timestamp storage.
smua.nvbuffer1.timestampresolution = 0.001	Set timestamp resolution to 0.001024s.

Table 7-6
Buffer read-only attribute programming examples

Command	Description
number = smua.nvbuffer1.n	Request number of readings in buffer.
buffer_size = smua.nvbuffer1.capacity	Request buffer size.

Reading buffer attributes

Use the reading buffer attributes to access the reading buffer data. [Table 7-7](#) displays the attributes that you can use to access the reading buffer data.

For example, the following would return 100 Channel A readings from Buffer 1:

```
printbuffer(1, 100, smua.nvbuffer1.readings)
```

Similarly, the following would return 100 Channel A source values from Buffer 1:

```
printbuffer(1, 100, smua.nvbuffer1.sourcevalues)
```

Note that `readings` is the default reading attribute and can be omitted. Thus, the following would also return 100 Channel A readings from Buffer 1:

```
printbuffer(1, 100, smua.nvbuffer1)
```

Table 7-7
Recall attributes

Recall attribute ¹	Description
<code>measurefunctions</code>	An array (a Lua table) of strings indicating the function measured for the reading (Current, Voltage, Ohms or Watts).
<code>measureranges</code>	An array (a Lua table) of full-scale range values for the measure range used when the measurement was made.
<code>readings</code>	An array (a Lua table) of the readings stored in the reading buffer. This array holds the same data that is returned when the reading buffer is accessed directly, i.e., <code>rb[2]</code> and <code>rb.readings[2]</code> are the same value.
<code>sourcefunctions</code>	An array (a Lua table) of strings indicating the source function at the time of the measurement (Current or Voltage).
<code>sourceoutputstates</code>	An array (a Lua table) of strings indicating the state of the source (Off or On).
<code>sourceranges</code>	An array (a Lua table) of full-scale range values for the source range used when the measurement was made.
<code>sourcevalues</code>	If enabled, an array (a Lua table) of the sourced values in effect at the time of the reading.
<code>statuses</code>	An array (a Lua table) of status values for all of the readings in the buffer. The status values are floating-point numbers that encode the status value into a floating-point value (see Table 7-8).
<code>timestamps</code>	An array (a Lua table) of time stamps, in seconds, of when each reading occurred. These are relative to the <code>basetime</code> stamp for the buffer (Table 7-4).

1. The default attribute is `readings` and can be omitted. For example, `smua.nvbuffer1` and `smua.nvbuffer1.readings` will both return readings from Channel A, Buffer 1.

Buffer status

The buffer reading status attribute can include the status information as a numeric value shown in [Table 7-8](#). For example to access status information for second element use the following command:

```
stat_info = smua.nvbuffer1.statuses[2]
```

Table 7-8
Buffer status bits

Bit	Name	Hex value	Description
B0	TBD	0x01	Reserved for future use.
B1	Overtemp	0x02	Over temperature condition.
B2	AutoRangeMeas	0x04	Measure range was auto ranged.
B3	AutoRangeSrc	0x08	Source range was auto ranged.
B4	4Wire	0x10	4W (remote) sense mode enabled.
B5	Rel	0x20	Rel applied to reading.
B6	Compliance	0x40	Source function in compliance.
B7	Filtered	0x80	Reading was filtered.

Dynamic reading buffers

Reading buffers can also be allocated dynamically. Dynamic reading buffers are created and allocated with the `smuX.makebuffer(n)` command, where `n` is the number of readings the buffer can store. For example, the following command allocates a Channel A reading buffer named `mybuffer` that can store 100 readings:

```
mybuffer = smua.makebuffer(100)
```

Allocated reading buffers can be deleted as follows:

```
mybuffer = nil
```

Dynamically allocated reading buffers can be used interchangeably with the `smuX.nvbufferY` buffers that are described in [Reading buffer designations](#).

Buffer examples

Defined buffer example

The listing below shows a programming example for storing data using the pre-defined Buffer 1 for Channel A. The Series 2600A loops for voltages from 0.01V to 1V with 0.01V steps (essentially performing a staircase sweep), stores 100 current readings and source values in Buffer 1, and then recalls all 100 readings and source values.

```
-- Restore Series 2600A defaults.
smua.reset()
-- Select Channel A display.
display.screen = 0
-- Display current.
display.smua.measure.func = display.MEASURE_DCAMPS
-- Select measure I auto range.
smua.measure.autorangei = smua.AUTORANGE_ON
-- Select ASCII data format.
format.data = format.ASCII
-- Clear Buffer 1.
smua.nvbuffer1.clear()
-- Enable append buffer mode.
smua.nvbuffer1.appendmode = 1
-- Enable source value storage.
smua.nvbuffer1.collectsourcevalues = 1
-- Set count to 1.
smua.measure.count = 1
-- Select source voltage function.
smua.source.func = smua.OUTPUT_DCVOLTS
-- Set bias voltage to 0V.
smua.source.levelv = 0.0
-- Turn on output.
smua.source.output = smua.OUTPUT_ON
-- Loop for voltages from 0.01 V to 1 V.
for v = 0.01, 1.0, 0.01 do
  -- Set source voltage
  smua.source.levelv = v
  -- Measure current, store in buffer.
  smua.measure.i(smua.nvbuffer1)
  --Wait for reading to complete.
  waitcomplete()
end
-- Turn off output.
smua.source.output = smua.OUTPUT_OFF
-- Return readings 1-100.
printbuffer(1, 100, smua.nvbuffer1.readings)
```

```
-- Return source values 1-100.  
printbuffer(1, 100, smua.nvbuffer1.sourcevalues)
```

Dual buffer example

The listing below shows a programming example for storing both current and voltage readings using Buffer 1 for current and Buffer 2 to store voltage readings. The Series 2600A stores 100 current and voltage readings and then recalls all 100 sets of readings.

```
-- Restore Series 2600A defaults.  
smua.reset()  
-- Select measure I auto range.  
smua.measure.autorangei = smua.AUTORANGE_ON  
-- Select measure V auto range.  
smua.measure.autorangev = smua.AUTORANGE_ON  
--Select ASCII data format.  
format.data = format.ASCII  
-- Clear buffer 1.  
smua.nvbuffer1.clear()  
-- Clear buffer 2.  
smua.nvbuffer2.clear()  
-- Set buffer count to 100.  
smua.measure.count = 100  
--Set measure interval to 0.1s.  
smua.measure.interval = 0.1  
-- Select source voltage function.  
smua.source.func = smua.OUTPUT_DCVOLTS  
-- Output 1 V.  
smua.source.levelv = 1  
-- Turn on output.  
smua.source.output = smua.OUTPUT_ON  
-- Store current readings in buffer 1, current readings in  
-- buffer 2.  
smua.measure.overlappediv(smua.nvbuffer1, smua.nvbuffer2)  
-- Wait for buffer to fill.  
waitcomplete()  
-- Turn off output.  
smua.source.output =smua.OUTPUT_OFF  
-- Return buffer 1 readings 1-100.  
printbuffer(1, 100, smua.nvbuffer1)  
-- Return buffer 2 readings 1-100.  
printbuffer(1, 100, smua.nvbuffer2)
```

Dynamically allocated buffer example

The listing below shows a programming example for storing data using an allocated buffer called mybuffer for Channel A. The Series 2600A stores 100 current readings in mybuffer and then recalls all the readings.

```
-- Restore Series 2600A defaults.
smua.reset()
-- Select measure I auto range.
smua.measure.autorangei = smua.AUTORANGE_ON
-- Select measure V auto range.
smua.measure.autorangev = smua.AUTORANGE_ON
-- Select ASCII data format.
format.data = format.ASCII
-- Set buffer count to 100.
smua.measure.count = 100
--Set measure interval to 0.1 s.
smua.measure.interval = 0.1
-- Select source voltage function.
smua.source.func = smua.OUTPUT_DCVOLTS
-- Output 1 V.
smua.source.levelv = 1
-- Turn on output.
smua.source.output = smua.OUTPUT_ON
-- Store current readings in mybuffer.
smua.measure.overlappedi(mybuffer)
-- Wait for buffer to fill.
waitcomplete()
-- Turn off output.
smua.source.output = smua.OUTPUT_OFF
-- Return 1 readings 1-100 from mybuffer.
printbuffer(1, 100, mybuffer)
-- Delete mybuffer.
mybuffer = nil
```

Digital I/O port

The Keithley Instruments Series 2600A System SourceMeter® instrument has a digital input/output port that can be used to control external digital circuitry. For example, a handler that is used to perform binning operations can be used with a digital I/O port.

Port configuration

The digital I/O port is located on the rear panel and is shown in [Figure 8-1](#). Note that a standard female DB-25 connector is used with the digital I/O port.

Figure 8-1
Digital I/O port

Connecting cables

Use a cable equipped with a male DB-25 connector (Keithley Instruments part number CA-126-1), or a Model 2600-TLINK cable to connect the digital I/O port to other Keithley Instruments models equipped with a Trigger Link (TLINK).

Digital I/O lines

The port provides 14 digital I/O lines. Each output is set high (+5V) or low (0V) and can read high or low logic levels. Each digital I/O line is an open-drain signal.

+5V output

The digital I/O port provides a +5V output that is used to drive external logic circuitry. Maximum current output for this line is 600mA. This line is protected by a self-resetting fuse (one hour recovery time).

Output enable and interlock line

The Model 2601A/2602A output enable (OE) line and the Model 2611A/2612A/2635A/2636A interlock (INT) line of the digital I/O can be used with a switch in the test fixture or component handler. With proper use, power is removed from the DUT when the lid of the fixture is opened. See [Output enable \(Models 2601A/2602A\)](#) or [Interlock \(Models 2612A/2612A/2635A/2636A\)](#) for more details.

WARNING *The digital I/O port of the Model 2601A/2602A is not suitable for control of safety circuits and should not be used to control a safety interlock. When an interlock is required for safety, a separate circuit should be provided that meets the requirements of the application to reliably protect the operator from exposed voltages.*

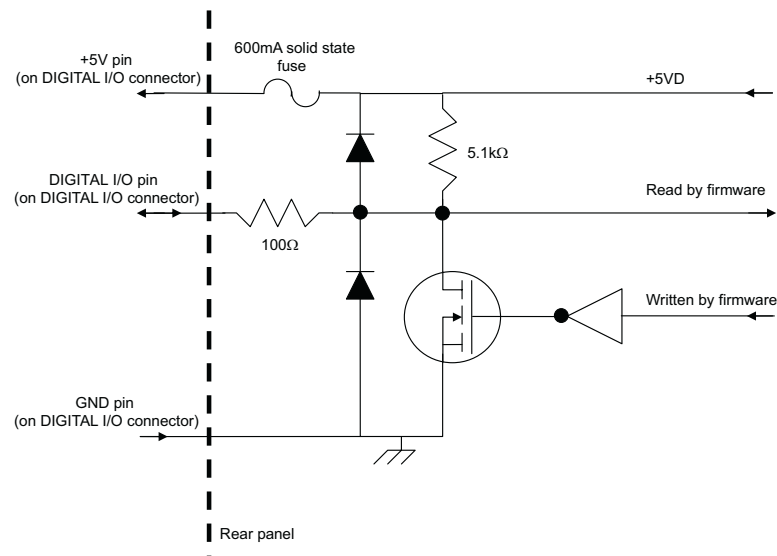

Model 2611A/2612A/2635A/2636A digital I/O ports include an interlock line that may be used as safety interlock.

Digital I/O configuration

Figure 8-2 shows the basic configuration of the digital I/O port. Writing a 1 to a line sets that line high (~ +5V). Writing a 0 to a line sets that line low (~0V). Note that an external device pulls an I/O line low by shorting it to ground, so that a device must be able to sink at least 480 μ A per I/O line.

Figure 8-2
Digital I/O port configuration

DIGITAL I/O INTERFACE (All Series 2600A Models):
 Connector: 25-pin female D
 Input/Output pins: 14 open-drain I/O bits
 Absolute maximum input voltage: 5.25V
 Absolute minimum input voltage: -0.25V
 Maximum logic low input voltage: 0.7V @ +850 μ A
 Minimum logic high input voltage: 2.1V @ +570 μ A
 Maximum source current (flowing out of digital I/O bit): +960 μ A
 Absolute Maximum sink current (flowing into digital I/O bit): -11.0A
 Maximum Sink Current @ Maximum Logic Low Voltage (0.7V): -5.0mA.

Controlling digital I/O lines

Although the digital I/O lines are primarily intended for use with a device handler for limit testing, they can also be used for other purposes such as controlling external logic circuits. You can control lines either from the front panel or via remote interface.

NOTE The trigger mode for the line must be set to `digio.TRIG_BYPASS` in order to use the line for digital I/O. See [Section 10](#) for more information.

Digital I/O bit weighting

Bit weighting for the digital I/O lines is shown in [Table 8-1](#).

Table 8-1

Digital bit weight

Line #	Bit	Decimal weighting	Hexadecimal weighting
1	B1	1	0x0001
2	B2	2	0x0002
3	B3	4	0x0004
4	B4	8	0x0008
5	B5	16	0x0010
6	B6	32	0x0020
7	B7	64	0x0040
8	B8	128	0x0080
9	B9	256	0x0100
10	B10	512	0x0200
11	B11	1024	0x0400
12	B12	2048	0x0800
13	B13	4096	0x1000
14	B14	8192	0x2000

Setting digital I/O values

To set digital I/O values:

1. Press the **MENU** key, select **DIGOUT**, and then press the **ENTER** key or push the **navigation wheel**.
2. Select **DIG-IO-OUTPUT**, and then press the **ENTER** key or the **navigation wheel**.
3. Set the decimal value as required to set digital I/O line(s) within the range of 0 to 16,383 (see [Table 8-1](#)), then press the **ENTER** key or the **navigation wheel**.
4. Press **EXIT** as needed to return to the normal.

Write protecting digital I/O lines

You can also write protect specific digital I/O lines to prevent their values from being changed:

1. Press **MENU > DIGOUT** and then press the **ENTER** key or the **navigation wheel**.
2. Select **WRITE-PROTECT**, then press the **ENTER** key or the **navigation wheel**.
3. Set the decimal value as required to write protect digital I/O line(s) within the range of 0 to 16,383 (see [Table 8-1](#)), then press the **ENTER** key or the **navigation wheel**.
4. Press **EXIT** as needed to return to the normal display.
5. To remove write protection, repeat Step 1 through Step 4 and then enter the original value.

Remote digital I/O commands

Commands that control and access the digital I/O port are summarized in [Table 8-2](#). See [Section 19](#) for complete details on these commands. See [Table 8-1](#) for decimal and hexadecimal values used to control and access the digital I/O port and individual lines. Use these commands to trigger the Series 2600A using external trigger pulses applied to the digital I/O port, or to provide trigger pulses to external devices.

Use these commands to perform basic steady-state digital I/O operations such as reading and writing to individual I/O lines or reading and writing to the entire port.

NOTE The digital I/O lines can be used for both input and output. You must write a 1 to all digital I/O lines that are to be used as inputs.

Table 8-2

Remote digital I/O commands

Command	Description
<code>digio.readbit(bit)</code>	Read one digital I/O input line
<code>digio.readport()</code>	Read digital I/O port
<code>digio.writebit(bit, data)</code>	Write data to one digital I/O output line
<code>digio.writeport(data)</code>	Write data to digital I/O port
<code>digio.writeprotect = mask</code>	Write protect mask to digital I/O port

Digital I/O programming example

The commands below set bit 1 of the digital I/O port high, and then read the entire port value.

```
digio.trigger[1].mode = digio.TRIG_BYPASS
```

```
-- Set bit 1 high.
digio.writebit(1,1)
```

```
-- Read digital I/O port.
data = digio.readport()
```

Output enable (Models 2601A/2602A)

Overview

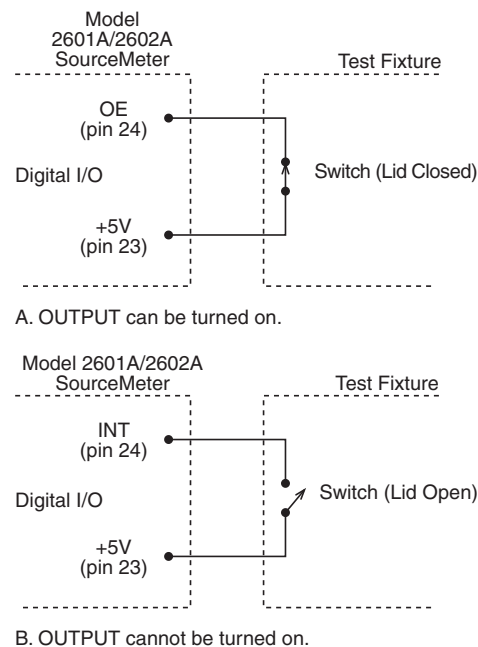

The Model 2601A/2602A digital I/O port provides an output enable line for use with a test fixture switch. When properly used, the output of the SourceMeter instrument will turn OFF when the lid of the test fixture is opened. See [Section 2](#) for important safety information when using a test fixture.

WARNING When an interlock is required for safety, a separate circuit should be provided that meets the requirements of the application to reliably protect the operator from exposed voltages. The digital I/O port of the Model 2601A or 2602A is not suitable for control of safety circuits and should not be used to control a safety interlock.

Operation

When enabled, the output of the Model 2601A or 2602A can only be turned on when the output enable line is pulled high through a switch to +5V, as shown in Figure 8-3. If the lid of the test fixture opens (see Figure 8-4), the switch opens, and the output enable line goes low, turning the output of the SourceMeter instrument off. The output will not be automatically turned on when output enable is set high. The output cannot be turned back on until +5V is applied to the output enable line.

Figure 8-3
Using Model 2601A/2602A output enable

Front panel control of output enable

To activate the output enable line:

1. Press the **CONFIG** key followed by the **OUTPUT** key.
2. Choose **DIO-CONTROL**, then press the **ENTER** key or the **navigation wheel**.
3. Select **OE_OUTPUT_OFF** to activate the output enable signal causing the SMU output to be blocked if the output enable is not asserted (connect to +5V). Select **NONE** to deactivate the output enable signal so that its state has no effect on the SMU output.
4. Press **EXIT** as needed to return to the normal display.

Remote control of output enable

Use one of these commands to control output enable action:

```
smuX.source.outputenableaction = smuX.OE_NONE
smuX.source.outputenableaction = smuX.OE_OUTPUT_OFF
```

When set to `smuX.OE_NONE`, the Model 2601A/2602A does not take action when the output enable line is low. When set to `smuX.OE_OUTPUT_OFF`, the SourceMeter instrument will turn its output off as if the `smuX.source.output = smuX.OUTPUT_OFF` command had been received. The SourceMeter instrument will not automatically turn its output on when the output enable line returns to the high state. For example, the following command activates the output enable for Channel A:

```
smua.source.outputenableaction = smua.OE_OUTPUT_OFF
```

Legacy mode

Overview

WARNING *Do not use legacy mode unless advised by Keithley Instruments as some of the advanced digital I/O features of your Series 2600A will become unavailable.*

Legacy mode is for customers that require digital I/O compatibility with original Series 2600 instruments. This feature was added in revision 2.1.4 of the firmware, please refer to the firmware release notes. This mode is disabled by default; entering legacy mode changes the way digital I/O works and should not be done without understanding the full ramifications of this configuration change.

When legacy mode is enabled, the Series 2600A instruments will display the following message at power-on:

```
LEGACY DIGITAL I/O
Advanced DIGIO features DISABLED
```

Features of legacy mode

The differences between the Series 2600A default digital I/O functionality and legacy mode are:

- When legacy mode is enabled, the default trigger mode for all lines is `TRIG_FALLING`. When legacy mode is disabled, the default trigger mode for all lines is `TRIG_BYPASS`.
- When legacy mode is enabled, all digital I/O pulsing operations are blocking, meaning that script execution is held up at the digital I/O pulsing commands. When legacy mode is disabled, all digital I/O pulsing operations are non-blocking.
- When legacy mode is enabled, the `digio.writebit` and `digio.writeport` operations are functional in all trigger modes. When legacy mode is disabled, the `digio.writebit` and `digio.writeport` operations are only functional in `TRIG_BYPASS` trigger mode.
- When legacy mode is enabled, attempting to set the stimulus of a digital I/O line fails, resulting in error 1803, "Feature not supported in legacy digital I/O mode". When legacy mode is disabled, attempting to set the stimulus succeeds.

Enable or disable legacy mode

To change the legacy mode setting:

1. Press **MENU** button
2. Under **MAIN MENU**, select **DIGOUT**
3. Under **DIGITAL I/O**, select **LEGACY-MODE**
4. Under **LEGACY DIGITAL I/O**, select **ON** to enable legacy mode or **OFF** to disable it
5. Under **REQUIRES REBOOT**, select **REBOOT**

Interlock (Models 2612A/2612A/2635A/2636A)

Overview

The Model 2611A/261A2/2635A/2636A digital I/O port provides an interlock line for use with a test fixture switch. When properly used, the output of the SourceMeter instrument will turn OFF when the lid of the test fixture is opened. See [Section 2](#) for important safety information when using a test fixture.

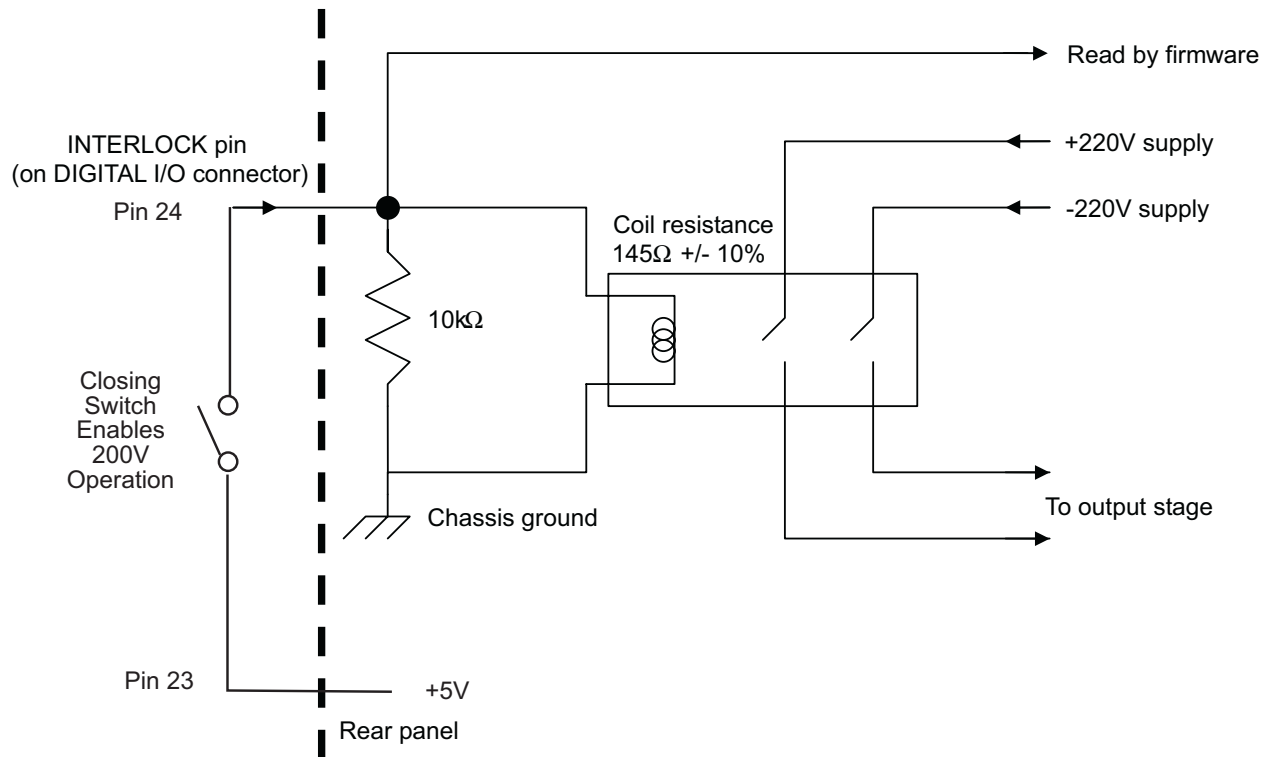

CAUTION If the interlock line is switched excessively (more than 10,000 times), its reliability may be reduced. Where the interlock is used for safety, it should be serviced regularly to ensure proper operation.

Operation

When on the 200V source range, the output of the Model 2611A/2612A/2635A/2636A can only be turned on when the interlock line is pulled high through a switch to +5V, as shown in [Figure 8-4](#). If the lid of the test fixture opens, the switch opens, and the interlock line goes low, turning the output of the Model 2611A/2612A/2635A/2636A off. The output will not be automatically turned on when the interlock line is set high. The output cannot be turned back on until the interlock line is set high.

A signal of > 3.4V at 24mA (at an absolute maximum of 6V) must be externally applied to this pin to ensure 200V operation. This signal is pulled down to chassis ground with a 10kΩ resistor. 200V operation will be blocked when the INTERLOCK signal is < 0.4V (an absolute minimum of -0.4V).

Figure 8-4
Using Model 2611A/2612A/2635A/2636A interlock

TSP-Link synchronization lines

The Series 2600A has three synchronization lines that you can use for triggering, digital I/O, and to synchronize multiple instruments on a TSP-Link network.

Connecting to TSP-Link

The TSP-Link synchronization lines are built into TSP-Link. Use the TSP-Link connectors located on the back of the Series 2600A. If you use the TSP-Link network, you do not have to modify your connections. See [System Expansion \(TSP-Link\)](#) for detailed information about connecting to TSP-Link.

Using TSP-Link synchronization lines for digital I/O

Each synchronization line is an open-drain signal. When using the TSP-Link synchronization lines for digital I/O, any node that sets the programmed line state to 0 (zero) causes all nodes to read 0 from the line state. This occurs regardless of the programmed line state of any other node.

Digital I/O bit weighting

Table 8-3 displays the bit weighting for the digital I/O lines.

Table 8-3

Digital I/O bit weight.

Line #	Bit	Decimal weighting	Hexadecimal weighting
1	B1	1	0x0001
2	B2	2	0x0002
3	B3	4	0x0004

Remote TSP-Link synchronization line commands

Commands that control and access the TSP-Link synchronization port are summarized in Table 8-4. See Section 19 for complete details on these commands. See Table 8-3 for the decimal and hexadecimal values used to control and access the digital I/O port and individual lines.

Use the commands in Table 8-4 to perform basic steady-state digital I/O operations, for example, you can program the Series 2600A to read and write to a specific TSP-Link synchronization line or to the entire port.

NOTE The TSP-Link synchronization lines can be used for both input and output. You must write a 1 to all TSP-Link synchronization lines that are used as inputs.

Table 8-4

Remote synchronization line commands

Command	Description
<code>tsplink.readbit(bit)</code>	Reads one digital I/O input line
<code>tsplink.readport()</code>	Read the digital I/O port
<code>tsplink.writebit(bit, data)</code>	Writes data to one digital I/O line
<code>tsplink.writeport(data)</code>	Writes data to the digital I/O port
<code>tsplink.writeprotect = mask</code>	Write protect mask to the digital I/O port

Programming example

The commands below set bit 1 of the I/O port high, and then read the entire port value.

```
tsplink.trigger[1].mode = tsplink.TRIG_BYPASS

-- Set bit 1 high.
tsplink.writebit(1,1)

-- Read I/O port.
data = tsplink.readport()
```

Overview

Section overview

Following a brief overview of the types of sweeps (linear staircase, logarithmic staircase, and list), the documentation in this section provides detailed information on characteristics, commands, and programming for each type of sweep.

Sweep overview

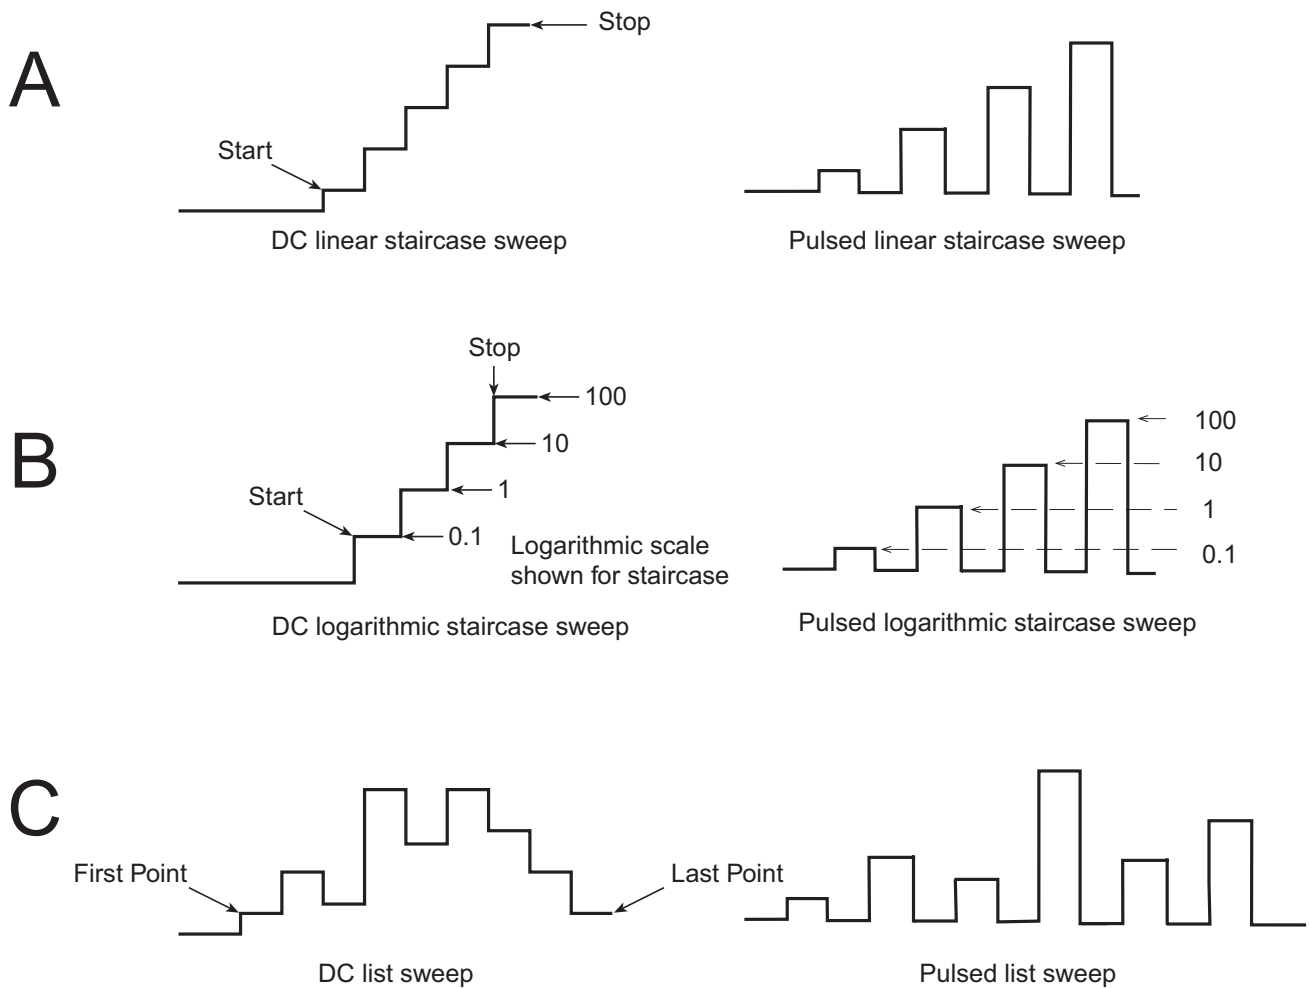

As shown in [Figure 9-1](#), the Keithley Instruments Series 2600A System SourceMeter® instrument can generate DC and pulsed sweeps to perform source-only sweeps, source-and-measure sweeps, or measure-only sweeps. The following sweeps can be programmed:

DC and pulsed linear staircase sweeps: With these sweeps, the voltage or current increases or decreases in specific steps, beginning with a start voltage or current and ending with a stop voltage or current. [Figure 9-1A](#) shows an increasing linear staircase sweep and a pulsed staircase sweep. Pulsed linear staircase sweeps function the same way as DC linear staircase sweeps except they return to the idle level between pulses.

DC and pulsed logarithmic staircase sweeps: In this case, the current or voltage increases or decreases geometrically, beginning with a start voltage or current and ending with a stop voltage or current. [Figure 9-1B](#) shows an increasing logarithmic staircase sweep and a pulsed logarithmic staircase sweep. Pulsed logarithmic staircase sweeps function the same way as DC logarithmic staircase sweeps except they return to the idle level between pulses.

DC and pulsed list sweeps: The list sweep allows you to program arbitrary sweep steps anywhere within the output voltage or current range of the Series 2600A. [Figure 9-1C](#) shows a list sweep with arbitrary steps and a pulsed list sweep. Pulsed list sweeps function the same way as DC list sweeps except they return to the idle level between pulses.

Figure 9-1
Sweep types

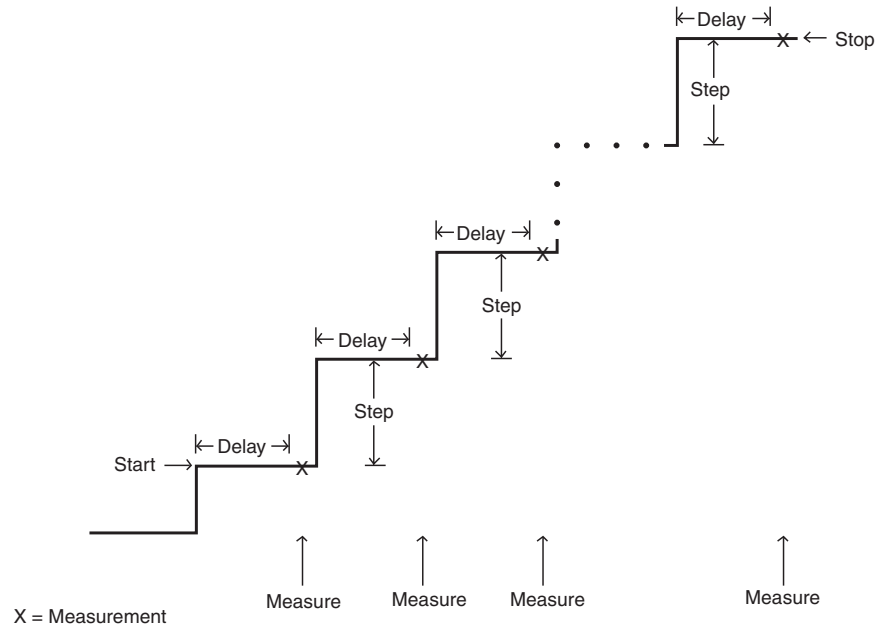

Sweep characteristics

NOTE For any of the sweep types, program a pulse mode sweep by configuring the end pulse action. Refer to [Pulse mode sweeps](#) for more information.

Linear staircase sweeps

As shown in [Figure 9-2](#), this sweep type steps from a start voltage or current value to an ending (stop) value. A measurement is made at each point after source and measurement settling time.

Figure 9-2
Linear staircase sweep

A linear staircase sweep is configured using a start level, a stop level, and the total number of points, including the start and stop points. The step size is determined by the start and stop levels, and the number of sweep points:

$$\text{step} = (\text{stop} - \text{start}) / (\text{points} - 1)$$

NOTE The number of sweep steps actually performed is determined by the trigger count. Refer to [Section 10](#) for more information.

The sweep can be either positive-going or negative-going, depending on the relative values of the start and stop parameters. When the sweep starts, the output will go to the start source level. The output will then change in equal steps until the stop level is reached. If the trigger count is greater than the number of points specified, the SMU will start over at the beginning value.

To configure a linear staircase sweep, use the following function:

```
smuX.trigger.source.linearY
```

This function configures the source values the SMU will output when performing a linear sweep. After configuring the sweep you must also enable the source action by setting the following attribute:

```
smuX.trigger.source.action
```

Example:

```
-- Sweep from 0 to 10V in 1V steps.
smua.trigger.source.linearv(0, 10, 11)
-- Enable the source action.
smua.trigger.source.action = smua.ENABLE
```

For more information, see [smuX.trigger.source.linearY](#).

Logarithmic staircase sweeps

This sweep is similar to the linear staircase sweep. The steps, however, are done on a logarithmic scale. [Figure 9-3](#) and [Figure 9-4](#) show sample sweeps.

Like a linear staircase sweep, logarithmic sweeps are configured using a start level, a stop level and the number of points in between. The step size is determined by the start and stop levels, and the number of sweep points. However, in a logarithmic sweep, the step size increases or decreases exponentially. To create an increasing logarithmic sweep, set the stop value to be greater than the start value. To create a decreasing logarithmic sweep, set the stop value to be less than the start value. A measurement is made at each step after source and measurement settling time.

NOTE The number of sweep steps actually performed is determined by the trigger count. See [Section 10](#) for more information.

The formula for a log sweep is:

$$v_i = A + kb^i$$

Where: v is the source value at source point i .

i ranges from 0 to $N-1$.

N is the number of points in the sweep.

k is the initial source value as an offset from the asymptote.

b is the step size ratio.

A is the asymptote value.

The asymptote is used to change the inflection of the sweep curve and allow it to sweep through zero. [Figure 9-3](#) and [Figure 9-4](#) depict the effect of the asymptote on the inflection of the sweep curve.

Figure 9-3
Increasing logarithmic sweep

Figure 9-4
Decreasing logarithmic sweep

Solving for k and b provides the following formulas:

$$k = V_{start} - A$$

$$b = 10^{\left(\frac{\log_{10}(V_{end} - A) - \log_{10}(V_{start} - A)}{N - 1} \right)}$$

Where: V_{end} is the source value at the end point.
 V_{start} is the source value at the start point.
 N is the number of points in the sweep.
 A is the asymptote value.

NOTE The number of points in a sweep is one greater than the number of steps in the sweep.

Figure 9-5 is an example of a 5-point log sweep from 1V to 10V.

Figure 9-5
Logarithmic staircase sweep (1V to 10V, five steps)

In this example:

$$A = 0, V_{start} = 1, V_{end} = 10, N = 5$$

Using the formula above $k = 1$

Step size (b) for the sweep in [Figure 9-5](#) is calculated as follows:

$$\left(\begin{aligned} \text{Log Step Size} &= \frac{\log_{10}(\text{stop}-0) - \log_{10}(\text{start}-0)}{\text{Points} - 1} \\ &= \frac{\log_{10}(10) - \log_{10}(1)}{5 - 1} \\ &= \frac{(1 - 0)}{4} \\ &= 0.25 \end{aligned} \right)$$

Therefore, $b = 10^{(\log \text{ step size})} = 1.7783$

The five log steps for this sweep are listed in [Table 9-1](#).

Table 9-1
Logarithmic sweep points

Measure point (<i>N</i>)	Source level (<i>V</i>)	Step number (<i>i</i>)
Point 1	1	0
Point 2	1.7783	1
Point 3	3.1623	2
Point 4	5.6234	3
Point 5	10	4

When this sweep starts, the output will go to the start level (1V) and sweep through the symmetrical log points.

To configure a logarithmic staircase sweep, use the following function:

```
smuX.trigger.source.logY
```

This function configures the source values the SMU will output when performing a logarithmic sweep. After configuring the sweep you must also enable the source action by setting the following attribute:

```
smuX.trigger.source.action
```

Example:

```
-- Sweep from 1 to 10V in 10 steps with an asymptote of 0V.
smua.trigger.source.logv(1, 10, 11, 0)
-- Enable the source action.
smua.trigger.source.action = smua.ENABLE
```

For more information, see [smuX.trigger.source.logY](#).

List sweeps

Use a list sweep to configure a sweep with arbitrary steps. A measurement is made at each point after source and measurement settling time.

To configure a list sweep, use the following function:

```
smuX.trigger.source.listY
```

This function configures the source values the SMU will output when performing a list sweep. After configuring the sweep you must also enable the source action by setting the following attribute:

```
smuX.trigger.source.action
```

Example:

```
-- Sweep through 3V, 1V, 4V, 5V, and 2V.
smua.trigger.source.listv({3, 1, 4, 5, 2})
-- Enable the source action.
smua.trigger.source.action = smua.ENABLE
```

When the sweep is started, the output level goes to the first point in the sweep. The sweep will continue through the steps in the order they were programmed.

[Figure 9-6](#) shows a different example of a list sweep with six measurement points. When the sweep starts, the current or voltage goes to the first point in the sweep. The unit cycles through the sweep points in the programmed order.

Figure 9-6
List sweep example

Pulse mode sweeps

A pulse mode sweep can be created for any of the sweep types by configuring the end pulse action. To configure a pulse mode sweep, use:

```
smuX.trigger.endpulse.action = smuX.SOURCE_IDLE
```

To configure a DC sweep, use:

```
smuX.trigger.endpulse.action = smuX.SOURCE_HOLD
```

Timers must be used to configure pulse width and period. Refer to [Section 10](#) for details on how to use timers in pulse mode sweeps.

As shown in [Figure 9-7](#), the pulse rise time is the interval it takes the pulse to go from 10% of maximum value to 90% of maximum value. For the Series 2600A, pulse rise and fall times depend on the transient response and source output settling times, which are in turn affected by the selected source range. See the Series 2600A specifications for details on transient response and source settling times.

Figure 9-7
Pulse rise and fall times

Pulsing in the extended operating area (EOA)

Pulse sweeps can be performed outside of the standard operating area by setting the appropriate compliance level. Please review the specifications for the Series 2600A to determine the maximum current and voltage values available in pulse mode. When pulsing in the extended operating area (EOA), the SMU will force the pulse to end early if the pulse width exceeds the maximum value. It will also hold off the next source action as necessary to stay within the duty cycle capabilities of the SMU.

Pulse duty cycle

Duty cycle is the percentage of time during the pulse period that the output is on. It is calculated as follows:

$$\text{Duty cycle} = \text{Pulse width} / (\text{Pulse width} + \text{Off time})$$

For example, if the pulse width is 10ms and the off time is 90ms, the duty cycle is calculated as follows:

$$\begin{aligned} \text{Duty cycle} &= 10\text{ms} / (10\text{ms} + 90\text{ms}) \\ &= 10\text{ms} / 100\text{ms} \\ &= 0.10 \\ &= 10\% \end{aligned}$$

Configuring and running sweeps

Configuring other sweep attributes

Compliance

Voltage and current limits can be configured using the `smuX.trigger.source.limitY` attributes which set the sweep source limits. For example, to set the sweep limit to 10V:

```
smua.trigger.source.limitv = 10
```

End sweep action

Use the end sweep action to configure the source action at the end of the sweep. The SMU can be programmed to return to the idle source level or hold the last value of the sweep. Configure the end sweep action by setting the `smuX.trigger.endsweep.action` attribute. For example, send the following command to program SMU A to return the source back to the idle source level at the end of a sweep:

```
smua.trigger.endsweep.action = smua.SOURCE_IDLE
```

Configuring measurements during a sweep

Measurements can be performed during a sweep using the `smuX.trigger.measure.Y` function. When sweeps are run, measurements are stored in the specified reading buffer for later recall. The reading buffer in which to store the readings can be specified. For example, to store voltage readings during the sweep:

```
smua.trigger.measure.v(vbuffername)
smua.trigger.measure.action = smua.ENABLE
```

Sweep data can be recalled as follows:

- **Front panel:** Press the **RECALL** key, select the channel and buffer, and then choose reading numbers to display using the **navigation wheel** or **cursor keys**. Recalling readings from the reading buffer using the front panel can only be done if one of the dedicated reading buffers is used to store the sweep data.
- **Remote:** Use the `printbuffer` command to request buffer readings.

See [Section 7](#) for details on recalling data from the buffer.

NOTE *When measurements are disabled during a sweep, the source values will not be displayed on the front panel.*

Source and measurement delays

Whenever the SMU outputs a source value in a sweep, it also applies the programmed source delay. The default source delay is zero seconds. Set an additional source delay using `smuX.source.delay`.

Whenever the SMU performs a measurement in a sweep, it also applies any configured measurement delays. Use `smuX.measure.delay` to program a specific measurement delay. The default measurement delay varies by model.

Initiating and running sweeps

In order to run a sweep, the number of sweep points to output and the number of sweeps to perform must be configured. Use the trigger count to set the number of sweep points to output. Use the arm count to set the number of times to perform the sweep. See [Section 10](#) for more information.

Example:

To sweep 15 source points:

```
smua.trigger.count = 15
```

To perform 8 sweeps:

```
smua.arm.count = 8
```

To start a sweep, use the `smuX.trigger.initiate` function. Sweeps are overlapped operations, so you can use the `waitcomplete` function as a way to suspend further operation until the sweep is complete.

Aborting a sweep

The `smuX.abort` command can be used to terminate all overlapped operations on a SMU, including sweeps. It returns the SMU to the idle state of the remote trigger model. See [Section 10](#) for more information.

Sweeping using factory scripts

Factory script functions that perform linear staircase, logarithmic staircase, and list sweeps are defined in [Section 19](#). You can use the factory script functions to perform and execute simple sweeps or use them as examples on which to program your own custom sweeps.

Front panel

To run a sweep, press the **LOAD** key, then select **FACTORY**, and then the name of the test to run. Press the **RUN** key, then follow the display prompts to complete the test. See [Section 19](#) for more information on using factory scripts.

Press the **RECALL** key to access sweep data stored in dedicated reading Buffer 1. See [Section 7](#) for more details on the buffer.

Sweep programming examples

Procedures for programming and running a sweep for three sweep types are given on the following pages. Each of these procedures includes commands for a typical sweep example. [Table 9-2](#) summarizes parameters for each of these examples.

Table 9-2
Sweep example parameters

Sweep type	Parameters for sweep examples
Linear staircase sweep	Start current: 1mA Stop current: 10mA # points: 10 Settling time: 0.1s
Pulse current sweep	Bias current: 1mA On current: 10mA Pulse on time: 10ms Pulse off time: 50ms # points: 10
List sweep	Five points: 3V, 1V, 4V, 5V, 2V Settling time 0.1s

Linear staircase sweep example

1. Configure source functions.

Examples: The following commands restore defaults and set the compliance to 1V:

```
-- Restore Series 2600A defaults.
smua.reset()
-- Set compliance to 1V.
smua.source.limitv = 1
```

2. Configure and execute the sweep.

Example: The following parameters configure a linear staircase current sweep from 1mA to 10mA with 10 points and a 0.1 second settling time:

```
-- Linear staircase sweep, Channel A, 1mA to 10mA, 0.1 second delay,
-- 10 points.
SweepILinMeasureV(smua, 1e-3, 10e-3, 0.1, 10)
```

3. Request readings.

Request readings from Buffer 1 as follows:

```
printbuffer(1, 10, smua.nvbuffer1.readings)
```

Pulse sweep example**1. Configure source functions**

Examples: The following commands restore defaults and set the compliance to 10V:

```
-- Restore Series 2600A defaults.
smua.reset()
--Set compliance to 10V.
smua.source.limitv = 10
```

2. Configure and execute the sweep.

Example: The following parameters configure a 10mA current pulse sweep with a 10ms pulse on time, a 50ms pulse off time, and 10 pulse-measure cycles:

```
-- Pulse current sweep, Channel A, 1mA bias, 10mA level, 10ms pulse on,
-- 50ms pulse off, 10 cycles.
PulseIMeasureV(smua, 1e-3, 10e-3, 20e-3, 50e-3, 10)
```

3. Request readings.

Request readings from Buffer 1 as follows:

```
printbuffer(1, 10, smua.nvbuffer1.readings)
```

List sweep example**1. Configure source functions**

Examples: The following commands restore defaults and set the compliance to 10mA:

```
-- Restore Series 2600A defaults.
smua.reset()
-- Set compliance to 10mA.
smua.source.limiti = 10e-3
```

2. Configure and execute the sweep.

Example: The following parameters configure a list sweep with 3V, 1V, 4V, 5V, 2V points using a 0.1s settling time:

```
-- Define voltage list.
vlist = {3, 1, 4, 5, 2}
-- List sweep, channel A, 3V, 1V, 4V, 5V, 2V steps, 0.1s delay, 5
-- points.
SweepVListMeasureI(smua, vlist, 0.1, 5)
```

3. Request readings.

Request readings from Buffer 1 as follows:

```
printbuffer(1, 5, smua.nvbuffer1.readings)
```

This page left blank intentionally.

Remote triggering overview

There are two programming methods for triggering:

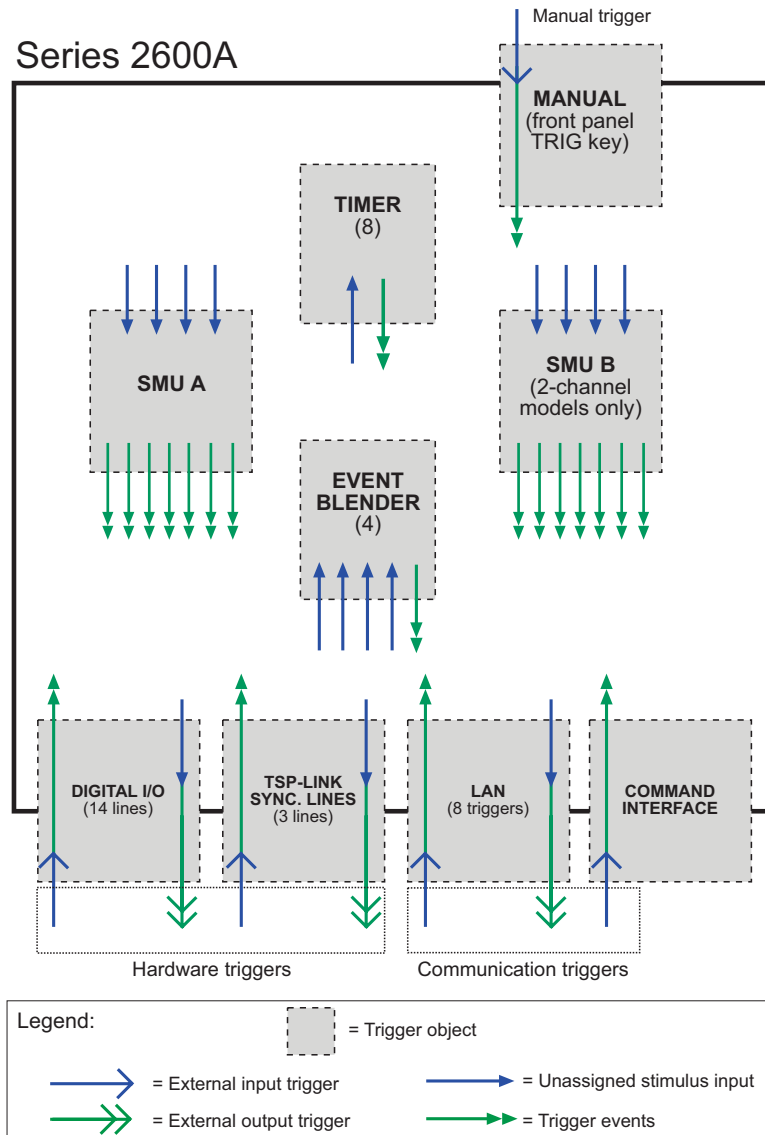

- Using the trigger model.
- Interactive triggering.

Using the trigger model to control the actions of the SMU allows the user to obtain very precise timing and synchronization between SMUs of a single instrument or between channels of multiple instruments. To achieve such precise timing, a static trigger configuration must be used. When a static trigger configuration is not possible, the interactive triggering method can be used to control the timing and actions of the SMU.

Both programming methods use trigger objects. Trigger objects generate and monitor for trigger events. External triggers are possible using digital I/O, TSP-Link synchronization lines, LAN, command interface, and the manual trigger (the **TRIG** key).

Figure 10-1 graphically represents all the trigger objects of the Series 2600A instrument.

Figure 10-1
Triggering overview

Trigger events are identified by means of an event ID. [Table 10-1](#) describes the trigger event IDs.

Table 10-1
Event IDs

Event ID	Event description
<code>smuX.trigger.SWEEPING_EVENT_ID</code>	Occurs when the SMU transitions from idle state to arm layer of trigger mode.
<code>smuX.trigger.ARMED_EVENT_ID</code>	Occurs when the SMU moves from the arm layer in to the trigger layer of the trigger model.
<code>smuX.trigger.SOURCE_COMPLETE_EVENT_ID</code>	Occurs when the SMU completes a source action.
<code>smuX.trigger.MEASURE_COMPLETE_EVENT_ID</code>	Occurs after the SMU completes a measure action.
<code>smuX.trigger.PULSE_COMPLETE_EVENT_ID</code>	Occurs after the SMU completes a pulse.
<code>smuX.trigger.SWEEP_COMPLETE_EVENT_ID</code>	Occurs when the SMU completes a sweep.
<code>smuX.trigger.IDLE_EVENT_ID</code>	Occurs when the SMU returns to the idle state.
<code>digio.trigger[N].EVENT_ID</code>	Occurs when an edge is detected on a digital I/O line.
<code>tsplink.trigger[N].EVENT_ID</code>	Occurs when an edge is detected on a TSP-Link line.
<code>lan.trigger[N].EVENT_ID</code>	Occurs when the appropriate LXI trigger packet is received on LAN trigger object N.
<code>display.trigger.EVENT_ID</code>	Occurs when the TRIG key on the front panel is pressed.
<code>trigger.EVENT_ID</code>	Occurs when a *TRG command is received on the remote interface. (GPIB only) Occurs when a GET bus command is received. (VXI-11 only) Occurs with the VXI-11 command <code>device_trigger</code> . Note: Reference the VXI-11 standard for additional details on the device trigger operation.
<code>trigger.blender[N].EVENT_ID</code>	Occurs after a collection of events is detected.
<code>trigger.timer[N].EVENT_ID</code>	Occurs when a delay expires.

Using the remote trigger model

Each source measure unit (SMU) in Series 2600A has a remote trigger model that supports a wide range of triggering features for source sweeps, triggered measurements, and pulse actions.

[Figure 10-2](#) graphically illustrates the remote trigger model. The trigger model consists of an idle state and two layers, arm and trigger.

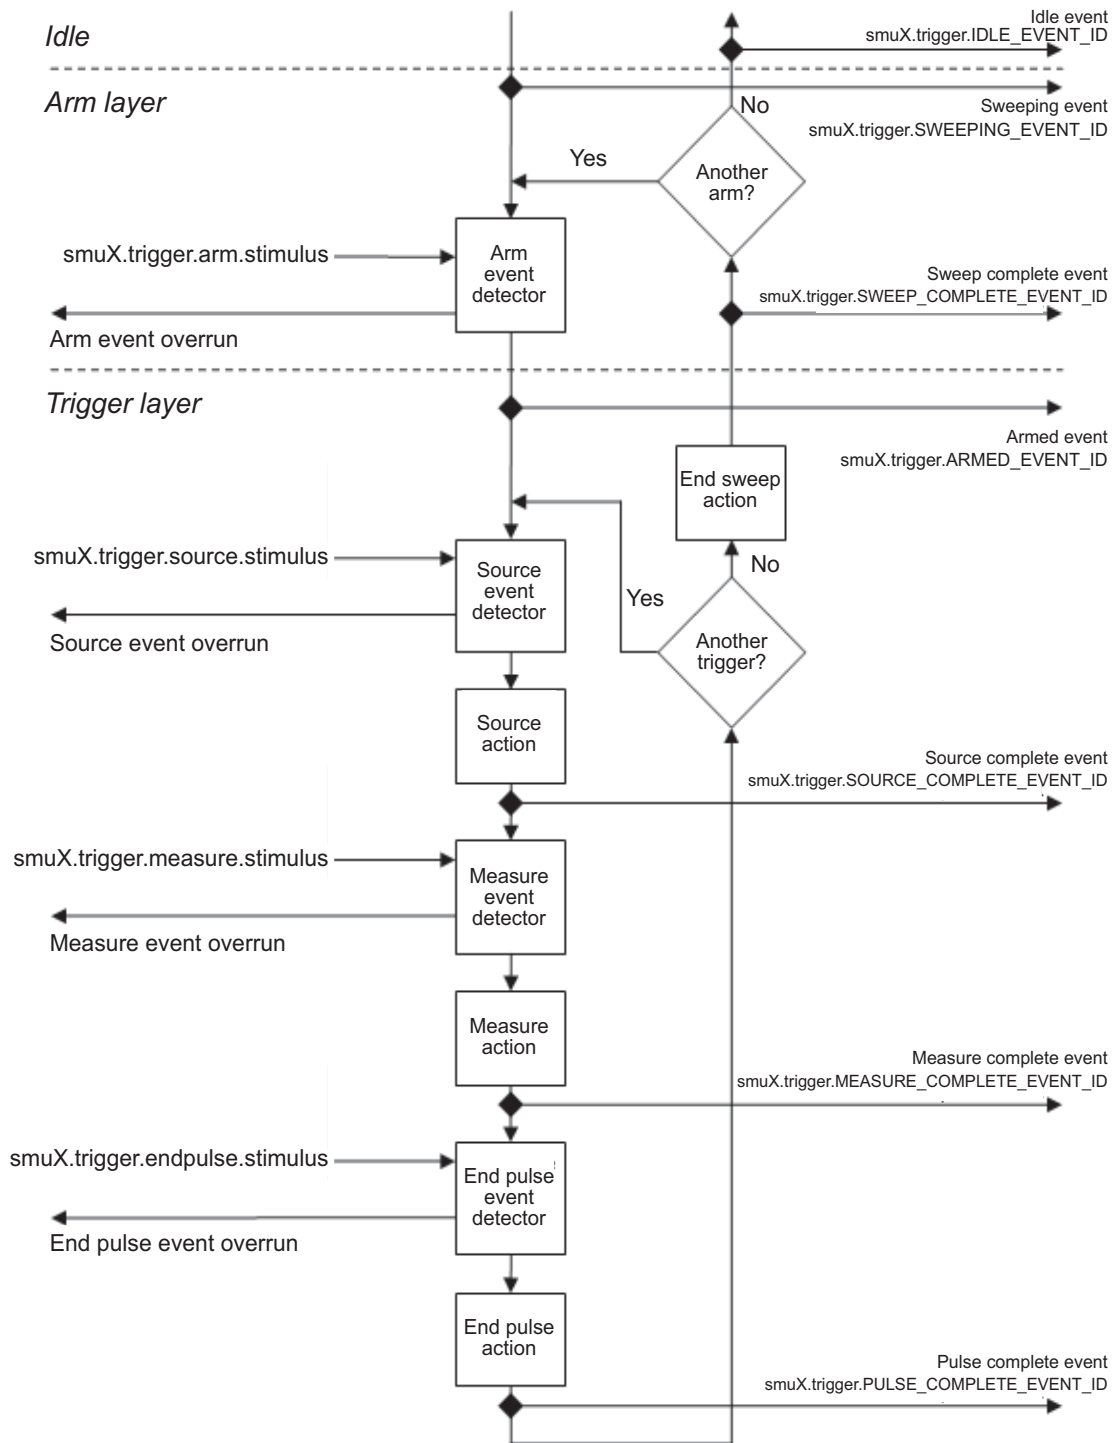

Idle state: If a sweep is not in process, the SMU is in the idle state. Use the ICL command `smuX.trigger.initiate` to move the SMU from the idle state in to the arm layer.

Each layer in the trigger model performs a function:

- **Arm:** Begins a sweep. Each sweep starts and ends in the arm layer.
- **Trigger:** All source, measure, and pulse actions occur in the trigger layer.
 - **Source:** Outputs the programmed voltage or current source value.
 - **Measure:** Where the current, voltage, resistance, and power measurements occur.
 - **End pulse:** The end pulse action turns the SMU off if the pulse mode is enabled.

The remote trigger model dictates the sequence of operation for the SMU when it is configured to perform a sweep. When the SMU comes to an event detector, it suspends operation and waits for the event you have assigned to the stimulus input. If no event is assigned, the SMU continues uninterrupted through the trigger model. When the SMU comes to an action block, it performs the appropriate action. The SMU loops through the arm and trigger layers until the programmed arm and trigger counts are satisfied.

Figure 10-2
Remote trigger model

Configuring source and measure actions

The source action can be configured using any of the following functions:

```
smuX.trigger.source.linearY
smuX.trigger.source.logY
smuX.trigger.source.listY
```

Where: "X" is the SMU channel and "Y" designates the source function. Source functions cannot be changed within a sweep. See [Section 9](#) for more details on the sweep functions.

To enable the source action, set `smuX.source.action` to `smuX.ENABLE`.

The SMU can be configured to perform any or all available measurements during a sweep using the `smuX.trigger.measure.Y` function. To enable the measure action, set `smuX.measure.action` to `smuX.ENABLE`.

Configured source and measure delays are imposed when the SMU executes the source and measure action blocks. Additionally, if the measure count setting is greater than one, then the measure count is satisfied each time the measure action is performed. Refer to [Section 9](#) for information on configuring source and measure sweeps.

The arm and trigger counts must be set to control how many times the SMU executes the source and measure actions. The arm count indicates the number of times to execute the complete sweep. The trigger count sets the number of loops in the trigger layer. Typically, you set the trigger count to be equal to the number of points in the configured sweep. If the trigger count is not equal to the number of points configured in the sweep, then one of the following occurs:

- If the trigger count is greater than the number of points in a sweep as configured by `smuX.trigger.source.linearY`, or `smuX.trigger.source.logY`, or `smuX.trigger.source.listY`, then the SMU will satisfy the trigger count by restarting the sweep values from the beginning.
- If the trigger count is less than the number of source values configured, then the SMU will satisfy the trigger count and ignore the remaining source values.

For example, configure a three-point linear voltage sweep from 1 to 3 volts, with the trigger count set to 2. The SMU will output 1 V, 2 V. If the trigger count is set to 6, then the SMU will output the values 1 V, 2 V, 3 V, 1 V, 2 V, 3 V, repeating the source values twice in a single sweep.

Enabling pulse mode sweeps (end pulse action)

Enable pulse mode sweeps using the end pulse action. Configure pulse mode sweeps by setting the end pulse action as shown in the following example:

```
smua.trigger.endpulse.action = smua.SOURCE_IDLE
```

Timers can be used to configure the pulse width and period (see [Timers](#) for more information). To disable pulse mode sweeps, set the `smuX.trigger.endpulse.action` attribute to `smuX.SOURCE_HOLD`.

SMU event detectors

As shown in [Figure 10-2](#), the SMU has multiple event detectors (see [Table 10-2](#)) in order to control the timing of various actions. Each event detector monitors for the trigger event assigned to the stimulus input. Operation through the trigger model is held up at the event detector until the programmed trigger event occurs.

If the stimulus input is set to zero, then the SMU continues uninterrupted through the remote trigger model.

Table 10-2
Event detectors

Event detector	Function
Arm	Controls entry into the trigger layer of the trigger model.
Source	Controls execution of the source action.
Measure	Controls execution of the measurement action.
End pulse	Controls execution of the end pulse action.

Clearing SMU event detectors

When an event detector is cleared, the event detector discards previously detected trigger events. This prevents the SMU from using trigger events that were detected during the last sweep or while in the arm layer and allows it to start monitoring for new trigger events.

SMU event detectors are automatically cleared when:

- A sweep is initiated using the `smuX.trigger.initiate` command.
- The SMU moves from the arm layer into the trigger layer and the `smuX.trigger.autoclear` attribute is enabled.

Using the TRIG key to trigger a sweep

The SMU can be configured to perform a sweep where each source step is triggered by the front panel **TRIG** key. The source action is preceded by the source event detector (see [Figure 10-1](#)). The SMU pauses operation at an event detector until a programmed event occurs. The SMU can be programmed to wait at the source event detector (that is, not start the source action) until the front panel **TRIG** key is pressed.

To configure the front panel **TRIG** key to trigger the source action, assign the trigger event created by the **TRIG** key (`digio.trigger[N].EVENT_ID`) to the source stimulus input (`smuX.trigger.source.stimulus`).

The example below shows a command sequence to configure a ten-point linear voltage sweep on SMU A where each step is triggered by the front panel **TRIG** key:

```
-- Configure a 10-point source voltage sweep.
smua.trigger.source.linearv(1, 10, 10)
smua.trigger.source.action = smua.ENABLE

-- Configure TRIG key press as input trigger for source action.
smua.trigger.source.stimulus = display.trigger.EVENT_ID

-- Command SMU to execute a single 10-point sweep.
smua.trigger.count = 10
smua.trigger.arm.count = 1

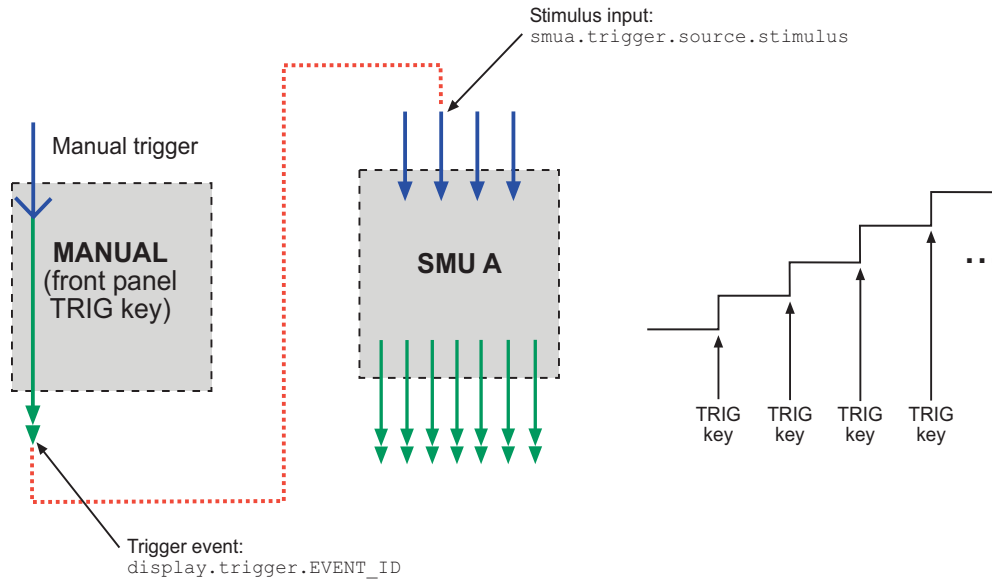

-- Turn on the output in preparation for the sweep
smua.source.output = suma.OUTPUT_ON

-- Start the sweep and clear the event detectors.
smua.trigger.initiate()

-- The SMU will wait for the front panel TRIG key press before executing
-- each source action.
```

[Figure 10-3](#) graphically illustrates this example. See [Section 9](#) for more information on sweep operation.

Figure 10-3
Front panel TRIG key triggering

Using trigger events to start actions on trigger objects

Trigger objects can be configured to respond to events generated by other trigger objects, such as using a digital I/O trigger to initiate a sweep. To configure a trigger object to monitor for an event, assign the event ID of the trigger event to the stimulus input. When the specified trigger event occurs, the trigger object will perform an action.

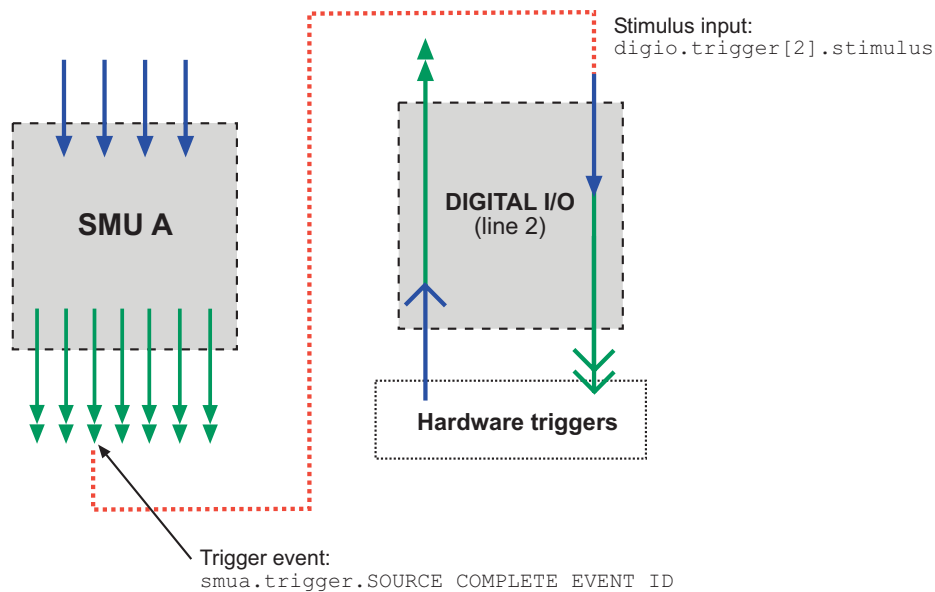

Example:

```
-- Configure digio line 2 to generate an output trigger pulse each
-- time SMU A generates a source complete event.
digio.trigger[2].stimulus = smua.trigger.SOURCE_COMPLETE_EVENT_ID
```

[Figure 10-4](#) illustrates this example.

The stimulus input can be configured to monitor for only one trigger event ID at a time. To monitor more than one event, use an event blender. For example, you can configure the Series 2600A to generate an external output trigger when sweeps on both SMU A and SMU B are complete. See [Event blenders](#) for more information.

Figure 10-4
Using trigger events to start actions

Action overruns

An action overrun occurs when a trigger object receives a trigger event and is not ready to act on it. The action overruns of all trigger objects are reported in the operation event registers of the status model. Please refer to [Appendix C](#) and the appropriate sections on each trigger object for further details on conditions under which an object generates an action overrun.

Digital I/O Port and TSP-Link synchronization lines

The Series 2600A has two sets of hardware lines that can be used for triggering: 14 digital I/O lines and 3 TSP-Link synchronization lines. These trigger objects can be configured and controlled in the same way.

See [Section 8](#) for more information on connections and direct control of the digital I/O and TSP-Link synchronization lines.

Common attributes

Mode

Indicates the type of edge the hardware lines detects as an external input trigger. Mode also indicates the type of signal generated as an external output trigger. [Table 10-3](#) describes the hardware trigger modes for the hardware trigger lines. The hardware trigger modes are described in greater detail in [Hardware trigger modes for synchronization lines](#).

NOTE Setting the mode to bypass will not allow the hardware line to be used for triggering.

Pulsewidth

Specifies the pulse width of the output trigger signal when the hardware line is asserted.

Table 10-3
Hardware trigger mode summary

Trigger mode	Output		Input
	Unasserted	Asserted	Detects
Bypass	N/A	N/A	N/A
Either Edge	High	Low	Either
Falling Edge	High	Low	Falling
Rising Edge	The programmed state of the line determines if the behavior is similar to RisingA or RisingM: <ul style="list-style-type: none"> • High similar to RisingA • Low similar to RisingM 		
RisingA	High	Low	Rising
RisingM	Low	High	None
Synchronous	High latching	Low	Falling
SynchronousA	High latching	High	Falling
SynchronousM	High	Low	Rising

Trigger configuration on hardware lines

The Series 2600A can be configured to send digital signals to trigger external instruments. Linking these output triggers to the completion of certain source-measure actions enables hardware handshaking.

Example:

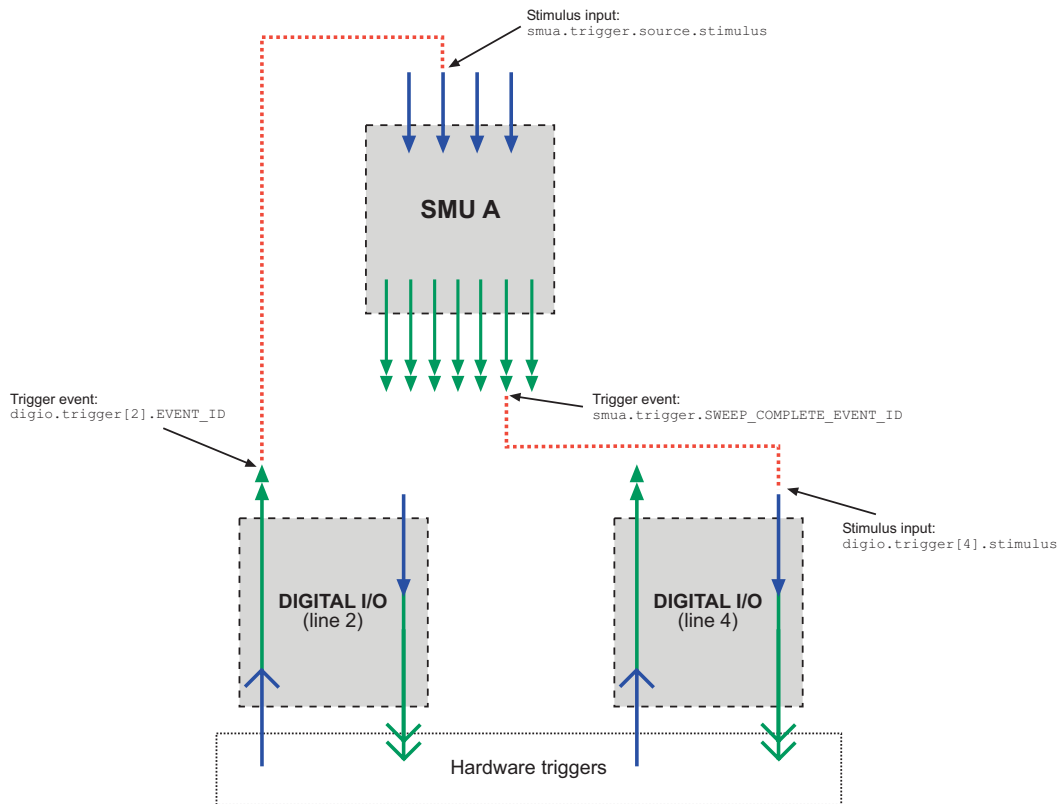

```
-- Configure Series 2600A to detect rising edge on digital I/O line 2.
digio.trigger[2].mode = digio.TRIG_RISINGA
digio.trigger[2].clear()
```

```
-- Configure SMU A to start its source action when a trigger event
-- occurs on digital I/O line 2.
smua.trigger.source.stimulus = digio.trigger[2].EVENT_ID
```

```
-- Configure digital I/O line 4 to output a 1ms rising-edge trigger
-- pulse at the completion of SMU sweep.
digio.trigger[4].mode = digio.TRIG_RISINGM
digio.trigger[4].pulsewidth = 0.001
digio.trigger[4].stimulus = smua.trigger.SWEEP_COMPLETE_EVENT_ID
```

This example's triggering setup is shown in [Figure 10-5](#).

Figure 10-5
External instrument triggering

Action overruns on hardware lines

An action overrun occurs when a trigger event is received before the digital I/O or TSP-Link line is ready to process it. The generation of an action overrun is dependent upon the trigger mode selected for that line. For more details on the causes of action overruns, see [Hardware trigger modes for synchronization lines](#).

Timers

A timer is a trigger object that performs a delay when triggered. Timers can be used to create delays and to start measurements and step the source value at timed intervals. When a delay expires the timer generates a trigger event. The Series 2600A has 8 independent timers.

Timer attributes

Each timer has four attributes that can be configured.

Count

Configures the number of events to generate each time the timer is triggered. Each event is separated by a delay.

To configure the count, use the following attribute:

```
trigger.timer[N].count
```

Set the count number to 0 (zero) to cause the timer to generate trigger events indefinitely.

Timer delays

Timers can be configured to perform the same delay each time or configured with a delay list that allows the timer to sequence through an array of delay values. All delay values are specified in seconds.

- **Delay**
 - A delay is the period of time after the timer is triggered and before the timer generates a trigger event. Use the following as an example to configure the delay attribute:

```
trigger.timer[N].delay = 10
```

- **Delay list**
 - A custom list can be configured to allow the timer to use a different interval each time it performs a delay. Each time the timer is triggered, it uses the next delay in the list. The timer repeats the delay list after all of the elements in the delay list have been used.

Use the following example to configure the delay list attribute:

```
-- Configure timer 4 to complete delays of 2 seconds, 10 seconds,
-- 15 seconds, and 7 seconds.
trigger.timer[3].delaylist = {2, 10, 15, 7}
```

NOTE Assigning a value to the delay attribute creates a one element delay list.

Pass-through

When enabled, the timer generates a trigger event immediately when it is triggered. The timer generates additional trigger events each time a delay expires. If the pass-through attribute is disabled, the timer does not generate a trigger event until after the first delay elapses.

To enable passthrough mode, use the following command:

```
trigger.timer[N].passthrough = true
```

Triggering a timer

A timer can be configured to start a delay when a trigger object generates a trigger event. Timers cannot be started with a command. A trigger event from a trigger object must be used to initiate a delay.

Assigning the stimulus attribute

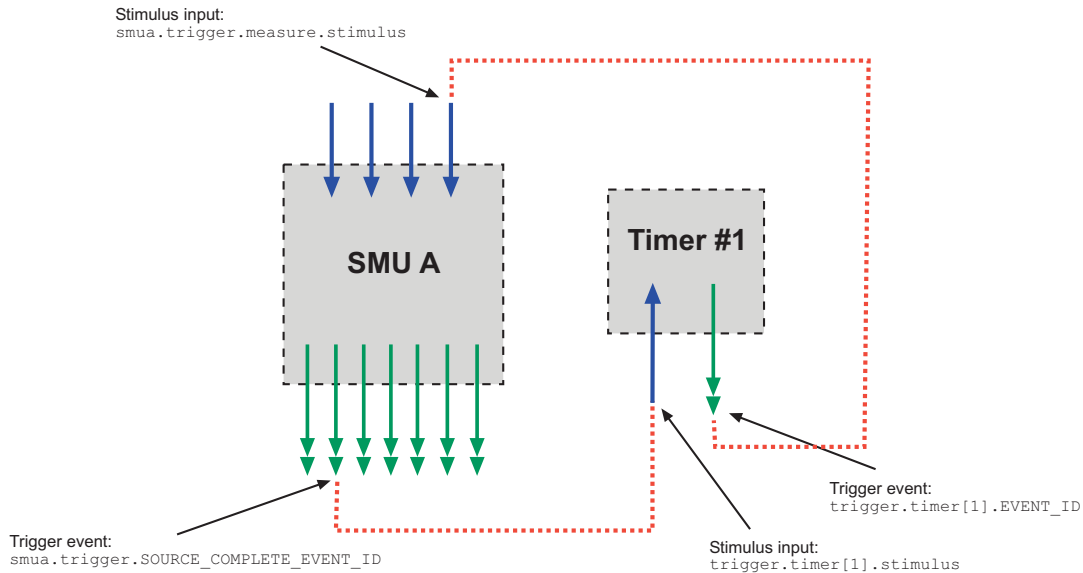

Assign the event ID to the `trigger.timer[N].stimulus` attribute to configure the timer to start a delay when a specific trigger event occurs.

Use the following example to configure a source - delay - measure (SDM) cycle.

```
-- Configure the timer to begin when source action completes.
trigger.timer[1].stimulus = smua.trigger.SOURCE_COMPLETE_EVENT_ID
```

```
-- SMUA delay before a measurement begins.
smua.trigger.measure.stimulus = trigger.timer[1].EVENT_ID
```

Figure 10-6
Using a timer for an SDM cycle

Using timers to perform pulse mode sweeps

Timers can also be used to control the pulse width during a pulsed sweep. To create a pulse train, a second timer must be used to configure the pulse period. The examples below show a single pulse output and a pulse train output.

NOTE The SMU endpulse action `smux.trigger.endpulse.action` must be set to `smuX.SOURCE_IDLE` in order to create a pulse.

Single pulse example:

- Set the delay attribute of a timer equal to the desired pulse width.
 - Trigger the timer to start when the SMU moves out of the arm layer of the trigger model.
 - Assign the trigger event generated by the timer to the stimulus input of the SMU end pulse event detector.
 - Configure the source action to start immediately by setting the stimulus input of the source event detector to 0.
 - Set the endpulse action to `SOURCE_IDLE`.
- ```
-- Generate a single 500us, 5V pulse.

-- Configure a single-point voltage list sweep.
smua.trigger.source.listv({5})
smua.trigger.source.action = smua.ENABLE
smua.trigger.measure.action = smua.DISABLE

-- Configure other source parameters for best timing possible.
smua.trigger.source.limiti = 0.1
smua.source.rangev = 5

-- Configure timer parameters to output a single 500us pulse.
```

```

trigger.timer[1] = 0.0005
trigger.timer[1].count = 1
trigger.timer[1].passthrough = false

-- Trigger timer when the SMU passes through the ARM layer.
trigger.timer[1].stimulus = smua.trigger.ARMED_EVENT_ID

-- Configure source action to start immediately.
smua.trigger.source.stimulus = 0

-- Configure endpulse action to achieve a pulse.
smua.trigger.endpulse.action = smua.SOURCE_IDLE
smua.trigger.endpulse.stimulus = trigger.timer[1].EVENT_ID

-- Set appropriate counts of trigger model.
smua.trigger.count = 1
smua.trigger.arm.count = 1

-- Turn on output and trigger SMU to output a single pulse.
smua.source.output = smua.OUTPUT_ON
smua.trigger.initiate()

```

Figure 10-7 shows the trigger setup for this example.

Figure 10-7  
Single pulse triggering

### Pulse train example:

In this example, two timers are required: one to control the pulse period and a second to control the pulse width.

Configure the timers and SMUs as follows:

#### Timer 1: Pulse period timer

- Set delay attribute to the desired pulse period (see [Figure 10-8](#)).

- Trigger the timer to start when the sweep is initiated.
- Enable the passthrough attribute so that the timer generates a trigger event at start of the first delay.
- Set the count equal to one less than the total number of pulses to output.

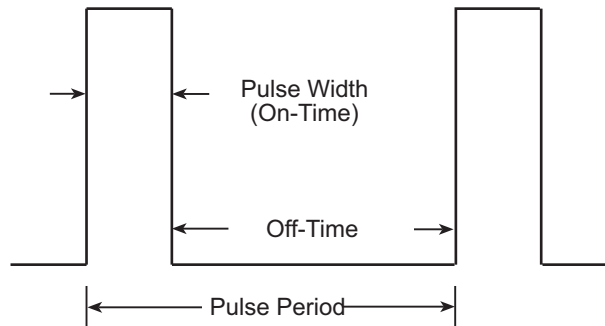

#### Timer 2: Pulse width timer

- Set the delay attribute to the desired pulse width (see [Figure 10-8](#)).
- Set the stimulus input to Timer 1 event ID (the start of each pulse is the start of the pulse period).
- Set the count equal to 1 so that only one pulse is issued per period.

#### SMU A

- Set the source stimulus input to Timer 1 event ID so that the source action starts when the period starts.
- Set the endpulse action to `SOURCE_IDLE` so that the output is returned to idle value after the source action completes.
- Set the endpulse stimulus input to Timer 2 event ID so that the endpulse action executes when the pulse width timer expires.
- Set the trigger count equal to 1.
- Set the arm count equal to the total number of pulses to output.

Figure 10-8  
Pulse train

```
-- Generate a 10-point pulse train where each pulse has a width of 600
-- microseconds and a pulse period of 5 milliseconds.
```

```
-- Alias the trigger timers to use for pulse width and period.
period_timer = trigger.timer[1]
pulse_timer = trigger.timer[2]
```

```
-- Create a fixed level voltage sweep.
smua.trigger.source.listv({5})
smua.trigger.source.action = smua.ENABLE
smua.source.rangev = 5
smua.trigger.measure.action = smua.DISABLE
```

```
-- Set pulse width.
pulse_timer.delay = 0.0006
```

```
-- Trigger pulse width timer with period timer.
pulse_timer.stimulus = period_timer.EVENT_ID
```

```
-- Output one pulse per period.
pulse_timer.count = 1

-- Set the pulse period.
period_timer.delay = 0.005

-- Set pulse period count to generate 10 pulses.
period_timer.count = 9

-- Trigger pulse period timer when a sweep is initiated.
period_timer.stimulus = smua.trigger.SWEEPING_EVENT_ID

-- Configure the timer to output a trigger event when it starts the first
-- delay.
period_timer.passthrough = true

-- Trigger SMU source action using pulse period timer
smua.trigger.source.stimulus = period_timer.EVENT_ID

-- Trigger SMU endpulse action using pulse width timer.
smua.trigger.endpulse.stimulus = pulse_timer.EVENT_ID

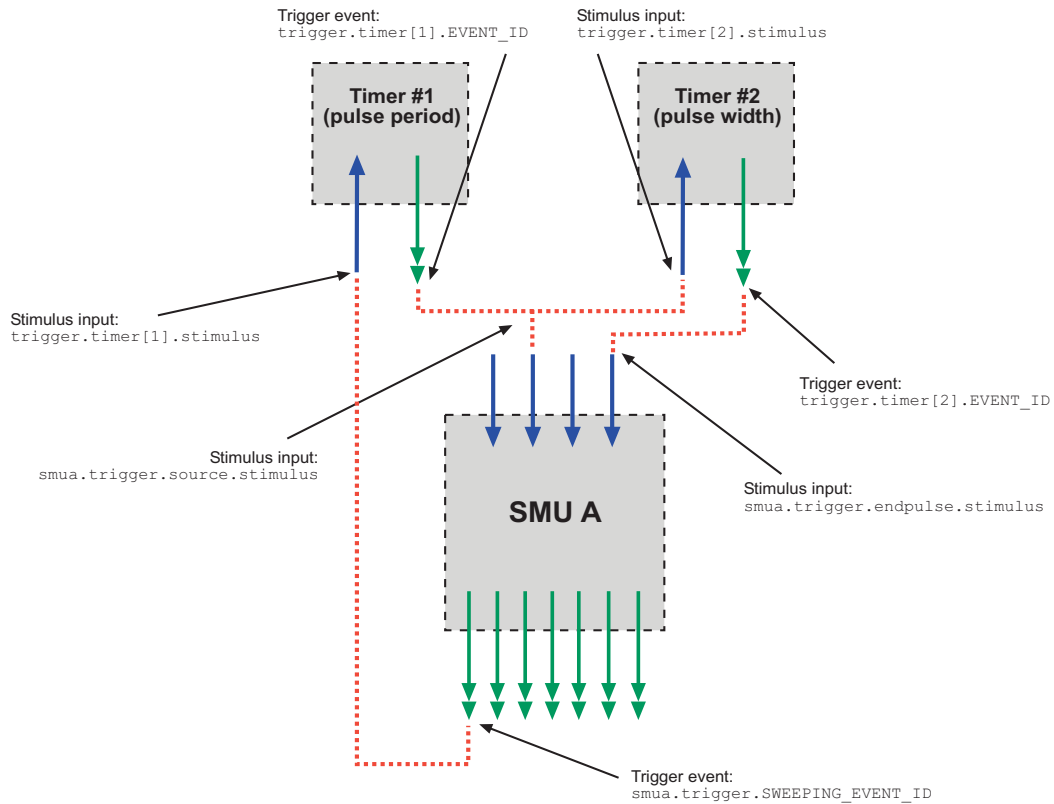

-- Set Trigger Model counts.
smua.trigger.count = 1

-- Configure the SMU to execute a 10-point pulse train.
smua.trigger.arm.count = 10

-- Prepare SMU to output pulse train.
smua.source.output = smua.OUTPUT_ON
smua.trigger.initiate()
```

[Figure 10-9](#) shows the trigger setup for this example.

Figure 10-9  
Pulse train triggering

## Timer action overruns

The timer generates an action overrun when it is triggered while a timer delay is still in progress.

## Event blenders

The ability to combine trigger events that occur at different times is known as event blending. An event blender can be used to wait for a specific input trigger or to wait for up to four input triggers to occur before responding with an output event.

There are four event blenders that can be used to monitor and respond to multiple stimulus events. Each event blender can be configured to monitor a maximum of four different trigger events.

## Event blender modes

Event blenders can be used to perform logical AND and logical OR functions on trigger events. For example, trigger events can be triggered when either a manual trigger or external input trigger is detected.

- **Or:** Generates an event when an event is detected on *any* one of the four stimulus inputs.
- **And:** Generates an event when an event is detected on *all* of the assigned stimulus inputs.

Set the `trigger.blender[N].orenable` attribute to configure the event blender mode. Setting the attribute to `true` enables OR mode; setting the attribute to `false` enables AND mode.

## Assigning input trigger events

Each event blender has four stimulus inputs. A different trigger event ID can be assigned to each stimulus input. The following example assigns the source complete event IDs of SMUA and SMU B to stimulus inputs 1 and 2 of event blender 1:

```
trigger.blender[1].stimulus[1] = smua.SOURCE_COMPLETE_EVENT_ID
trigger.blender[1].stimulus[2] = smub.SOURCE_COMPLETE_EVENT_ID
```

## Action overruns

Action overruns are generated by event blenders depending on the mode, as shown in [Table 10-4](#).

Table 10-4  
Action overruns

| Mode | Action overrun                                                                                               |
|------|--------------------------------------------------------------------------------------------------------------|
| And  | Generates an overrun when a second event on any of its inputs is detected before generating an output event. |
| Or   | Generates an overrun when two events are detected simultaneously.                                            |

## LAN triggering overview

Triggers can be sent and received over the LAN interface. The Series 2600A supports LAN extensions for Instrumentation (LXI) and has eight LAN triggers that generate and respond to LXI trigger packets.

## Understanding hardware value and pseudo line state

LAN triggering is very similar to hardware synchronization except LXI trigger packets are used instead of hardware signals. The **hardware value** is a bit in the LXI trigger packet that simulates the state of a hardware trigger line. The Series 2600A stores the hardware value of the last LXI trigger packet sent or received as the **pseudo line state**.

The **stateless event flag** is a bit in the LXI trigger packet that indicates if the hardware value should be ignored. If set, the Series 2600A ignores the hardware value of the packet and generates a trigger event. The Series 2600A always sets the stateless flag for outgoing LXI trigger packets. If the stateless event flag is not set, then the hardware value indicates the state of the signal. Changes in the hardware value of consecutive LXI trigger packets are interpreted as edge transitions. Edge transitions generate trigger events. If the hardware value does not change between successive LXI trigger packets, the Series 2600A assumes an edge transition was missed and generates a trigger event. [Table 10-5](#) illustrates edge detection in LAN triggering.

---

NOTE Instruments that are compliant to LXI versions prior to 1.2 always process the hardware value. Instruments compliant to LXI version 1.2 and later are required to ignore the hardware value when the stateless event flag is set.

---

Table 10-5  
LXI trigger edge detection

| Stateless event flag | Hardware value | Pseudo line state | Falling edge | Rising edge |
|----------------------|----------------|-------------------|--------------|-------------|
| 0                    | 0              | 0                 | Detected     | Detected    |
| 0                    | 1              | 0                 | -            | Detected    |
| 0                    | 0              | 1                 | Detected     | -           |
| 0                    | 1              | 1                 | Detected     | Detected    |
| 1                    | -              | -                 | Detected     | Detected    |

Set the LAN trigger mode to configure edge detection method in incoming LXI trigger packets. The mode selected also determines the hardware value in outgoing LXI trigger packets. [Table 10-6](#) lists the LAN trigger modes.

Table 10-6  
LAN trigger modes

| Trigger mode | Input   | Output    | Notes                |
|--------------|---------|-----------|----------------------|
|              | Detects | Generates |                      |
| Either Edge  | Either  | Negative  |                      |
| Falling Edge | Falling | Negative  |                      |
| Rising Edge  | Rising  | Positive  |                      |
| Rising A     | Rising  | Positive  | Same as Rising       |
| RisingM      | Rising  | Positive  | Same as Rising       |
| Synchronous  | Falling | Positive  | Same as SynchronousA |
| SynchronousA | Falling | Positive  |                      |
| SynchronousM | Rising  | Negative  |                      |

The following is an example of how to configure the LAN trigger mode:

```
-- Set LAN trigger 2 to have falling-edge mode.
lan.trigger[2].mode = lan.TRIG_FALLING
```

## Understanding LXI trigger event designations

LAN trigger objects generate LXI trigger events. The LXI standard designates trigger events as LAN0 to LAN7 (zero based). In the command table, the LXI trigger events can be accessed using `lan.trigger[1]` through `lan.trigger[8]`. `lan.trigger[1]` corresponds to LXI trigger event LAN0 and `lan.trigger[8]` corresponds to LXI trigger event LAN7.

## Generating LXI trigger packets

The Series 2600A can be configured to output a LXI trigger packet to other LXI instruments. In order to generate LXI trigger packets, you must first call the `lan.trigger[N].connect` function. Select the event that triggers the outgoing LXI trigger packet by assigning the specific event ID to the LAN stimulus input.

## Logging LAN trigger events in the event log

The event log can be used to record all LXI triggers generated and received by the Series 2600A and can be viewed over any command interface. The event log can also be viewed using the embedded web interface. [Figure 10-10](#) shows the view of the LXI event log from the embedded web interface.

Figure 10-10  
Event log

The time stamp, event identifier, the IP address and the domain name identify the incoming and outgoing LXI trigger packets. [Table 10-7](#) provides detailed descriptions for the columns in the event log.

Table 10-7  
Event log descriptions

| Column title  | Description                                                                                                                                                                                                                                      | Example                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Received Time | <ul style="list-style-type: none"> <li>Displays the date and time of the LAN trigger occurred.</li> <li>Displays the value in UTC, 24-hour time.</li> </ul>                                                                                      | 06:56:28.000 8 May 2008                                                                                                                                                                                                                                                                                      |
| EventID       | Identifies the <code>lan.trigger[N]</code> that generates an event.                                                                                                                                                                              | LAN0 = <code>lan.trigger[1]</code><br>LAN1 = <code>lan.trigger[2]</code><br>LAN2 = <code>lan.trigger[3]</code><br>LAN3 = <code>lan.trigger[4]</code><br>LAN4 = <code>lan.trigger[5]</code><br>LAN5 = <code>lan.trigger[6]</code><br>LAN6 = <code>lan.trigger[7]</code><br>LAN7 = <code>lan.trigger[8]</code> |
| From          | Displays the IP address for the device that generates the LAN trigger.                                                                                                                                                                           | <ul style="list-style-type: none"> <li><code>localhost</code></li> <li><code>192.168.5.20</code></li> </ul>                                                                                                                                                                                                  |
| Timestamp     | A timestamp that identifies the time the event occurred. The timestamp uses the following: <ul style="list-style-type: none"> <li>PTP timestamp</li> <li>Seconds</li> <li>Fractional Seconds</li> </ul>                                          | The Series 2600A does not support the IEEE 1588 standard. The values in this field are always 0 (zero).                                                                                                                                                                                                      |
| HWDetect      | Identifies a valid LXI trigger packet                                                                                                                                                                                                            | LXI                                                                                                                                                                                                                                                                                                          |

## Accessing the event log from the command interface

The Instrument Control Library (ICL) can be used to view the event log from any command interface. The event log must be enabled before LXI trigger events can be viewed.

To enable the event log:

```
eventlog.enable = 1
```

To view the event log from a remote interface:

```
print(eventlog.all())
```

This command returns one or more strings similar to the following:

```
14:14:02.000 17 Jun 2008, LAN0, 10.80.64.191, LXI, 0, 1213712000, not available, 0, 0x10,0x00
```

The string displays the same information as the web interface. Commas separate the different fields. The fields are returned in the following order:

- UTC time
- Event Id
- Sender
- HwDetect/ version
- Domain
- sequence number
- ptp time
- epoch (from 1588)
- flags
- Data

See [Table 10-7](#) for detailed descriptions.

## Command interface triggering

A command interface trigger occurs when:

- A GPIB GET command is detected (GPIB only).
- A VXI-11 `device_trigger` method is invoked (VXI-11 only).
- A \*TRG message is received.

Use `trigger.EVENT_ID` to monitor for command interface triggers. To ensure that commands and triggers issued over the command interface are processed in the correct order, a trigger event is not generated until:

- The trigger command is executed.
- `trigger.wait()` retrieves the trigger command from the input queue before it would normally be executed.

Command interface triggering does not generate action overruns. The triggers are processed in the order that they are received in the Series 2600A input queue. The Series 2600A does not process incoming commands while a script is running. Input triggers that are not processed can cause an overflow in the input queue. It is important to make sure a script processes triggers while it is running.

---

**NOTE** The input queue can fill up with trigger entries if too many \*TRG messages are received while a test script is running. This can be averted by using the `localnode.prompts4882` attribute (see [Section 19](#) for more information) and by using `trigger.wait()` calls that remove the \*TRG messages from the input queue. If the input queue fills with too many trigger entries, messages like **abort** will not be processed.

---

## Manual triggering

The **TRIG** key is the stimulus input for manual triggering. Each time the **TRIG** key is pressed, a trigger event is generated. You can monitor for a manual trigger event using the event ID `display.trigger_EVENT_ID`. See [Using the TRIG key to trigger a sweep](#) for an example of how to use a manual trigger.

There are no action overruns for manual triggering.

## Interactive triggering

The complexity of certain test system configurations may not permit a static trigger setup, but instead requires more dynamic control of triggering. In such cases, the interactive triggering programming method allows the generation and detection of trigger events that can be controlled on demand under remote control. For example, interactive triggering can be used when you need to make multiple source function changes or implement conditional branching to other test setups based on recent measurements.

## Detecting trigger events using the `wait()` function

All of the Series 2600A trigger objects (except the SMUs) have built-in event detectors that monitor for trigger events. The event detector only monitors events generated by that object and cannot be configured to monitor events generated by any other trigger object. Using the `wait()` function of the trigger object causes the Series 2600A instrument to suspend the script until a trigger event occurs or until the specified timeout period elapses.

For example, use `trigger.blender[N].wait(Y)` to suspend script operation until an event blender generates an event, where `N` is the specific event blender and `Y` is the timeout period. After executing the `wait` function, the event detector of the trigger object is cleared.

Example:

```
-- Wait up to 10 seconds for a front panel TRIG key press.
display.trigger.wait(10)

-- Wait up to 60 seconds for timer 1 to complete its delay.
trigger.timer[1].wait(60)

-- Wait up to 30 seconds for input trigger to digital I/O line 10.
digio.trigger[10].wait(30)
```

## Using the `assert()` function to generate trigger events

Certain trigger objects can be used to generate output triggers on demand. These trigger objects are the digital I/O lines, TSPLink synchronization lines and the LAN.

To generate an output trigger, use the `assert` function of the trigger object as shown in the following example:

```
-- Generate a falling-edge trigger on digital I/O line 3.
digio.trigger[3].mode = digio.TRIG_FALLING
digio.trigger[3].assert()

-- Generate a rising edge trigger on TSP-Link sync line 1.
tsplink.trigger[1].mode = tsplink.TRIG_RISINGM
tsplink.trigger[1].assert()

-- Generate a LAN trigger on LAN pseudo line 6.
lan.trigger[6].mode = lan.TRIG_EITHER
lan.trigger[6].assert()
```

## Using the `release()` function of the hardware lines

Use the `release()` function to allow the hardware line to output another external trigger when the pulse width is set to 0.

Setting the pulse width to 0 results in an indefinite length pulse when the `assert()` function is used to output an external trigger. The `release()` function must be used to release the line in order to output another external trigger.

The `release()` function can also be used to release latched input triggers when the hardware line mode is set to Synchronous. In Synchronous mode, the receipt of a falling edge trigger latches the line low. The `release()` function releases this line high in preparation for another input trigger.

Example:

```
-- Set digio line 1 to output a indefinite external trigger.
digio.trigger[1].mode = digio.TRIG_FALLING
digio.trigger[1].pulsewidth = 0
digio.trigger[1].assert()

-- Release digio line 1.
digio.trigger[1].release()

-- Output another external trigger.
digio.trigger[1].assert()
```

## Using the `set()` function to bypass SMU event detectors

The `set()` function is useful whenever you want the SMU to continue operation without waiting for a programmed trigger event.

There is a `set()` function for each SMU event detector. When called, the function immediately satisfies the event detector, allowing the SMU to continue through the trigger model.

A common example of when the `set()` function can be used is when you want the SMU to immediately perform an action the first time through the trigger model even if a programmed trigger event does not occur. The `set()` function can be used to start actions on the SMU in case of a missed trigger event.

Example:

```
-- Immediately satisfies the Arm Event Detector of SMU A.
smua.trigger.arm.set()

-- Sets the Measure Event Detector of SMU A.
smua.trigger.measure.set()
```

## Event detector overruns

If another trigger event is generated before the event detector clears then the trigger object will generate a detector overrun. Detector overruns can be checked by reading the `overrun` attribute of the trigger object. The attribute is set to `true` when an overrun occurs. The `clear()` function can be used to immediately clear the event detector, discarding any history of previous trigger events. The `clear()` function also clears any detector overruns.

---

**NOTE** Detector overruns are not the same as action overruns that are reported in the status model.

---

The following is an example of how to check and respond to detector overruns:

```
testOver = digio.trigger[4].overrun
if testOver == true then
 print ("Digital I/O overrun occurred.")
end
```

## Examples using interactive triggering

### Command interface interactive trigger example

The example below clears triggers, turns on the SMU output, and then enables a 30 second timeout to wait for a command interface trigger. Upon receipt of the trigger, the Series 2600A performs a voltage reading.

**\*TRG example:**

```
-- Clear any previously detected command interface triggers.
trigger.clear()

-- Turn on output.
smua.source.output = smua.OUTPUT_ON

-- Wait 30 seconds for a command interface trigger.
triggered = trigger.wait(30)

-- Get voltage reading.
reading = smua.measure.v()

-- Send command interface trigger to trigger the measurement.
*TRG
```

## Manual triggering example

The following code pauses a script and prompts the operator to press the **TRIG** key when they are ready to continue. If the **TRIG** key is not pressed, the test will continue after waiting 10 minutes (600 seconds).

```
display.clear()
display.trigger.clear()
display.setcursor(1, 1, 0)
display.settext("Take a Break")
display.setcursor(2, 1, 0)
display.settext("Press TRIG to continue")
display.trigger.wait(600)
display.clear()
```

## Digital I/O triggering interactive example

The following example configures digital I/O line 2 as an input trigger and digital I/O line 14 as an output trigger. It commands the Series 2600A to wait for an external input trigger on digital I/O line 2. If a trigger event occurs, the Series 2600A outputs an external trigger on digital I/O line 14. If no trigger event is received on digital I/O line 2, the test is aborted.

```
-- Configure digital I/O lines 2 and 14 for input trigger detection and
-- output trigger generation, respectively.
digio.trigger[2].mode = digio.TRIG_RISINGA
digio.trigger[2].clear()
digio.trigger[14].mode = digio.TRIG_FALLING
digio.trigger[14].pulsewidth = 0.0001

--Wait 15 seconds for a trigger event to occur on digital I/O line 2
trigInput = digio.trigger[2].wait(15)

-- If a trigger event occurs on digital I/O line 2, assert an output
-- trigger on digital I/O line 14. If a trigger event does not occur,
-- then turn off the output of smua and issue a message on the front
-- panel display.
if trigInput == true then
 digio.trigger[14].assert()
else
 smua.source.output = smua.OUTPUT_OFF
 display.screen = display.USER
 display.clear()
 display.setcursor(1, 1)
 display.settext("No trigger received. Test aborted.")
 exit()
end
```

## Hardware trigger modes for synchronization lines

Use hardware triggers to integrate Keithley Instruments and non-Keithley instruments in a test system. The Series 2600A supports 14 digital I/O lines and three TSP-Link synchronization lines that can be used for input or output triggering. For additional information on the hardware trigger modes, see [Section 19](#).

---

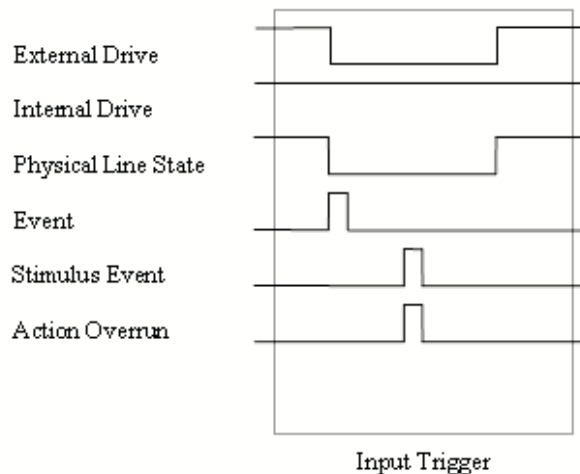

NOTE For direct control of the line state, use the bypass trigger mode.

---

### Falling edge trigger mode

The falling edge trigger mode generates low pulses and detects all falling edges. [Figure 10-11](#) shows the characteristics of the falling edge input trigger. [Figure 10-12](#) shows the falling edge output trigger.

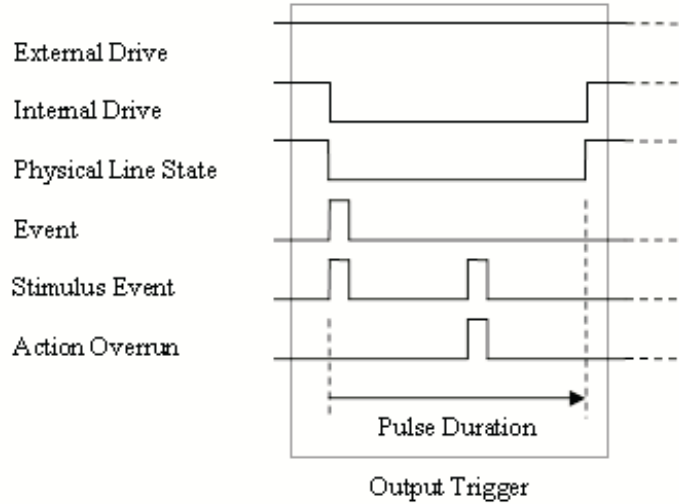

Figure 10-11  
Falling edge input trigger

#### Input characteristics:

- Detects all falling edges as input triggers.
- Output triggers generate a low pulse on the line.

Figure 10-12  
**Falling edge output trigger**

### Output characteristics

- In addition to trigger events from other trigger objects, the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands generate a low pulse for the programmed pulse duration.
- An action overrun occurs if the physical line state is low and a source event occurs.

## Rising edge master trigger mode

Use the rising edge master (RisingM) trigger mode (see [Figure 10-13](#)) to synchronize with non-Keithley instruments that require a high pulse. Input trigger detection is not available in this trigger mode. You can use the RisingM trigger mode to generate rising edge pulses.

---

**NOTE** The RisingM trigger mode does not function properly if the line is driven low by an external drive.

---

Figure 10-13

### RisingM output trigger

#### Output characteristics:

- Configured trigger events as well as the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands cause the physical line state to float high during the trigger pulse duration.
- An action overrun occurs if the physical line state is high while a source event occurs.

## Rising edge acceptor trigger mode

The rising edge acceptor trigger mode (RisingA) generates a low pulse and detects rising edge pulses. [Figure 10-14](#) displays the RisingA input trigger. [Figure 10-15](#) shows the RisingA output trigger.

Figure 10-14  
RisingA input trigger

### Input characteristics:

- All rising edges generate an input event.

Figure 10-15  
RisingA output trigger

### Output characteristics:

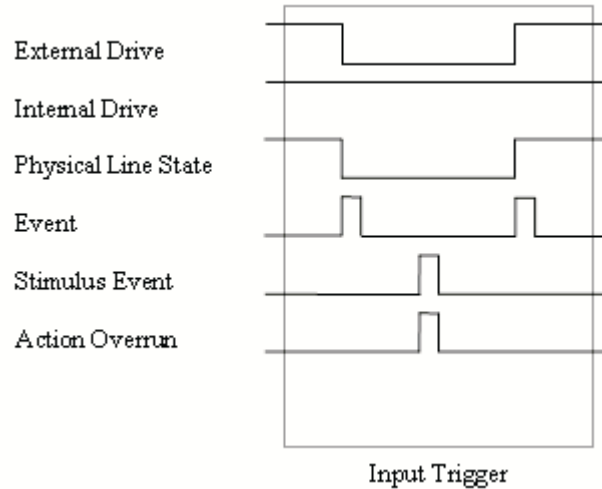

- In addition to trigger events from other trigger objects, the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands generate a low pulse that is similar to the falling edge trigger mode.

## Either edge trigger mode

The either edge trigger mode generates a low pulse and detects both rising and falling edges.

Figure 10-16

### Either Edge input trigger

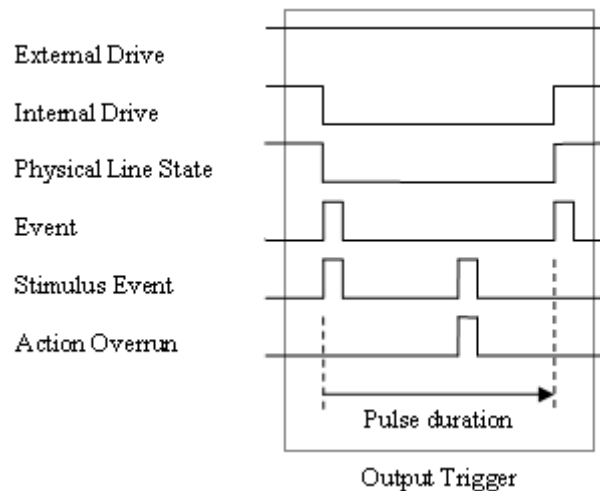

#### Input characteristics:

- All rising or falling edges generate an input trigger event

Figure 10-17

### Either edge output trigger

#### Output characteristics:

- In addition to trigger events from other trigger objects, the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands generate a low pulse that is similar to the falling edge trigger mode.
- An action overrun occur if the physical line state is low while a source event occurs.

## Understanding synchronous triggering modes

Use the synchronous triggering modes to implement bidirectional triggering, to wait for one node, or to wait for a collection of nodes to complete all triggered actions.

All non-Keithley instrumentation must have a trigger mode that functions similar to the SynchronousA or SynchronousM trigger modes.

To use synchronous triggering, configure the triggering master to SynchronousM trigger mode or the non-Keithley equivalent. Configure all other nodes in the test system to SynchronousA trigger mode or a non-Keithley equivalent.

### Synchronous master trigger mode (SynchronousM)

Use the synchronous master trigger mode (SynchronousM) to generate falling edge output triggers, to detect the rising edge input triggers, and to initiate an action on one or more external nodes with the same trigger line.

In this mode, the output trigger consists of a low pulse. All non-Keithley instruments attached to the synchronization line in a trigger mode equivalent to SynchronousA must latch the line low during the pulse duration.

To use the SynchronousM trigger mode, configure the triggering master as SynchronousM and then configure all other nodes in the test system as Synchronous, SynchronousA, or to the non-Keithley Instruments equivalent.

---

**NOTE** Use the SynchronousM trigger mode to receive notification when the triggered action on all nodes is complete.

---

Figure 10-18  
**SynchronousM input trigger**

#### Input characteristics:

- All rising edges are input triggers
- When all external drives release the physical line, the rising edge is detected as an input trigger
- A rising edge is not detected until all external drives release the line and the line floats high

Figure 10-19  
**SynchronousM output trigger**

**Output characteristics:**

- In addition to trigger events from other trigger objects, the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands generate a low pulse that is similar to the falling edge trigger mode
- An action overrun occurs if the physical line state is low while a source event occurs

## Synchronous acceptor trigger mode (SynchronousA)

Use the synchronous acceptor trigger mode (SynchronousA) in conjunction with the SynchronousM trigger mode. The role of the internal and external drives are reversed in the SynchronousA trigger mode.

Figure 10-20

### SynchronousA input trigger

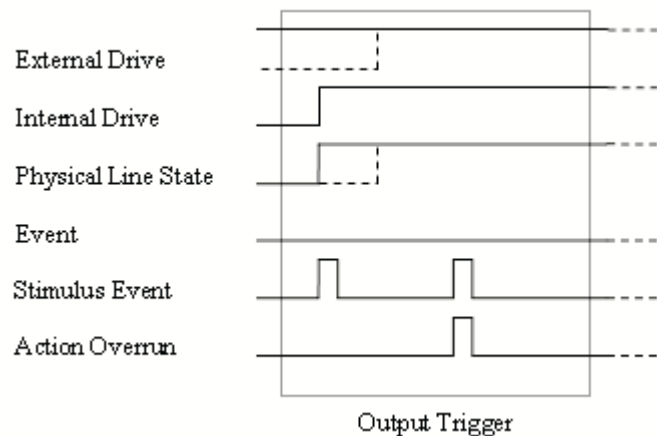

### Input characteristics:

- The falling edge is detected as the external drive pulses the line low, and the internal drive latches the line low.

Figure 10-21

### SynchronousA output trigger

### Output characteristics:

- In addition to trigger events from other trigger objects, the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands release the line if the line is latched low. The pulse width is not used.
- The physical line state does not change until all drives (internal and external) release the line.
- Action overruns occur if the internal drive is not latched low and a source event is received.

## Synchronous trigger mode

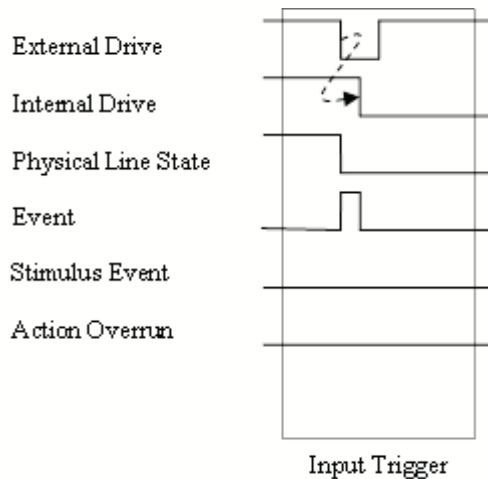

The synchronous trigger mode is a combination of SynchronousA and SynchronousM trigger modes. Use the Synchronous trigger mode for compatibility with older Keithley Instruments products.

---

NOTE Keithley Instruments recommends using SynchronousA and SynchronousM modes only.

---

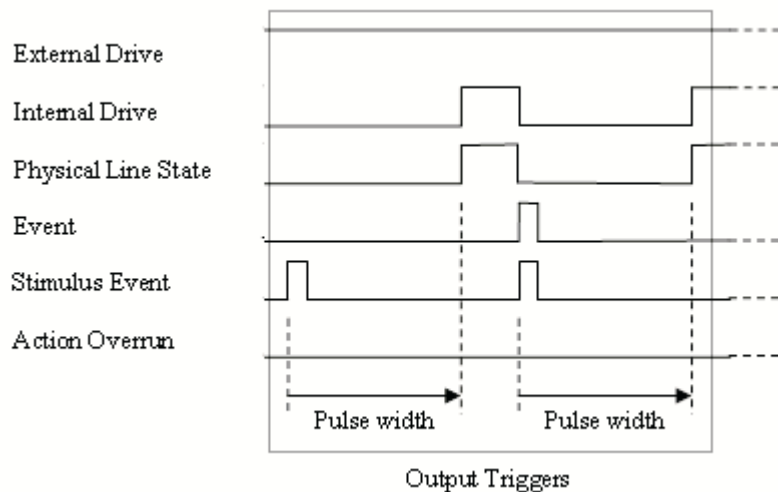

Figure 10-22  
**Synchronous input trigger**

**Input characteristics:**

- The falling edge generates an input event and latches the internal drive low

Figure 10-23  
**Synchronous output trigger**

**Output characteristics:**

- In addition to trigger events from other trigger objects, the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands generate a low pulse for the programmed pulse duration if the line is latched low, a falling edge does not occur.
- A normal falling edge pulse generates when the internal drive is not latched low and the `digio.trigger[N].assert` and `tsplink.trigger[N].assert` commands are issued.
- To mirror the SynchronousA trigger mode, set the pulse width to 1  $\mu$ s or any small nonzero value.
- Action overruns are disabled.

---

## Display Operations

## Display features

### Display screen

The Keithley Instruments Series 2600A System SourceMeter® instrument can display source-measure values and readings or user defined messages. The display screen options include the following:

- Source-measure, compliance screens:
  - Display source and compliance values, and measure readings for SMU A.
  - Display source and compliance values, and measure readings for SMU B (Models 2602A/2612A/2636A only).
- Source-measure screen – Display source values and measure readings for SMU A and SMU B (Models 2602A/2612A/2636A only).
- User screen – Display user-defined messages and prompts.

The `display.screen` attribute is used to select the display screen:

```
display.screen = displayId
```

where: `displayId` is set to one of the following values or names:

```
0 Or display.SMUA
```

```
1 Or display.SMUB
2 Or display.SMUA_SMUB
3 Or display.USER
```

**Display screen example:**

The following command displays source-measure and compliance for SMU A:

```
display.screen = display.SMUA
```

## Measurement functions

With a source-measure screen selected, the measured reading can be displayed as volts, amps, ohms or watts.

The `display.smuX.measure.func` attribute is used to select the displayed measure function:

```
display.smuX.measure.func = function
```

where: `smuX = smua Or smub`

`function` is set to one of the following values:

```
0 Or display.MEASURE_DCAMPS
1 Or display.MEASURE_DCVOLTS
2 Or display.MEASURE_OHMS
3 Or display.MEASURE_WATTS
```

**Measurement function example:**

The following command sets SMU A to display ohms measurements:

```
display.smua.measure.func = display.MEASURE_OHMS
```

## Display resolution

Display resolution for measured readings can be set to 4-1/2, 5-1/2 or 6-1/2 digit resolution.

The `display.smuX.digits` attribute is used to set display resolution for measured readings:

```
display.smuX.digits = digits
```

Where: `smuX = smua Or smub`

`digits` is set to one of the following values:

```
4 Or display.DIGITS_4_5
5 Or display.DIGITS_5_5
6 Or display.DIGITS_6_5
```

**Display resolution example:**

The following command sets SMU A for 5-1/2 digit resolution for measured readings:

```
display.smua.digits = display.DIGITS_5_5
```

## Display messages

---

**NOTE** Most of the display functions and attributes that are associated with display messaging will automatically select the user screen. The attribute for the display screen is explained in [Display screen](#).

The reset functions (`reset` or `smuX.reset`) have no effect on the defined display message or its configuration, but will set the display mode back to the previous source-measure display mode.

---

The display of the Series 2600A can be used to display user-defined messages. For example, while a test is running, the following message can be displayed on the Series 2600A.

```
Test in Process
Do Not Disturb
```

The top line of the display can accommodate up to 20 characters (including spaces). The bottom line can display up to 32 characters (including spaces) at a time.

---

**NOTE** The `display.clear`, `display.setcursor`, and `display.settext` functions (which are explained in the following paragraphs) are overlapped, non-blocking commands. The script will NOT wait for one of these commands to complete.

These non-blocking functions do not immediately update the display. For performance considerations, they write to a shadow and will update the display as soon as processing time becomes available.

---

## Clearing the display

When sending a command to display a message, a previously defined user message is not cleared. The new message starts at the end of the old message on that line. It is good practice to routinely clear the display before defining a new message.

After displaying an input prompt, the message will remain displayed even after the operator performs the prescribed action. The `clear` function must be sent to clear the display.

The following command clears both lines of the display, but does not affect any of the indicators:

```
display.clear()
```

## Cursor position

When displaying a message, the cursor position determines where the message will start. On power-up, the cursor is positioned at Row 1, Column 1 (see [Figure 11-1](#)). At this cursor position, a user-defined message will be displayed on the top row (Row 1).

Top line text will not wrap to the bottom line of the display automatically. Any text that does not fit on the current line will be truncated. If the text is truncated, the cursor will be left at the end of the line.

Figure 11-1  
**Row/column format for display messaging**

The function to set cursor position can be used two ways:

```
display.setcursor(row, column)
```

```
display.setcursor(row, column, style)
```

where: row = 1 or 2

column = 1 to 20 (Row 1)

= 1 to 32 (Row 2)

style = 0 (invisible)

= 1 (blink)

When set to 0, the cursor will not be seen. When set to 1, a display character will blink to indicate its position.

The `display.getcursor` function returns the present cursor position, and can be used three ways:

```
row, column, style = display.getcursor()
```

```
row, column = display.getcursor()
```

```
row = display.getcursor()
```

**Example:** The following code positions the cursor on Row 2, Column 1, and then reads the cursor position:

```
display.setcursor(2, 1)
```

```
row, column = display.getcursor()
```

```
print (row, column)
```

Output: 2.000000e+00 1.000000e+00

## Displaying text messages

The `display.settext` function is used to define and display a message. The message will start at the present cursor position.

```
display.settext(text)
```

where: text is the text string to be displayed.

**Example:** The following code will display “Test in Process” on the top line, and “Do Not Disturb” on the bottom line:

```
display.clear()
display.setcursor(1, 1, 0)
display.settext("Test in Process")
display.setcursor(2, 6, 0)
display.settext("Do Not Disturb")
```

## Character codes

The following special codes can be embedded in the `text` string to configure and customize the message:

|      |                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| \$N  | Newline – Starts text on the next line. If the cursor is already on line 2, text will be ignored after the '\$N' is received. |
| \$R  | Sets text to Normal.                                                                                                          |
| \$B  | Sets text to Blink.                                                                                                           |
| \$D  | Sets text to Dim intensity.                                                                                                   |
| \$F  | Set text to background blink.                                                                                                 |
| \$\$ | Escape sequence to display a single "\$".                                                                                     |

In addition to displaying alpha-numeric characters, other special characters can be displayed. Refer to [Appendix D](#) for a complete listing of special characters and their corresponding codes. For example, to display the Greek symbol omega,  $\Omega$ , use the following:

```
display.clear()
c = string.char(18)
display.settext(c)
```

## Examples

The following code uses the \$N and #B character codes to display the message “Test in Process” on the top line and the blinking message “Do Not Disturb” on the bottom line:

```
display.clear()
display.settext("Test in Process NBDo Not Disturb")
```

The following code uses the \$\$ character code to display the message “You owe me \$8” on the top line:

```
display.clear()
display.setcursor(1, 1)
display.settext("You owe me $$8")
```

If the extra \$ character is not included, the \$8 would be interpreted as an undefined character code and will be ignored. The message “You owe me” will instead be displayed.

---

**NOTE** Care must be taken when imbedding character codes in the text string. It is easy to forget that the character following the `$` is part of the code. For example, assume you want to display “Hello” on the top line and “Nate” on the bottom line, and so you send the following command:

```
display.settext("Hello$Nate")
```

The above command displays “Hello” on the top line and “ate” on the bottom line. The correct syntax for the command is as follows:

```
display.settext("Hello$NNate")
```

---

## Returning a text message

The `display.gettext` function returns the displayed message and can be used in five ways:

```
text = display.gettext()
```

```
text = display.gettext(embellished)
```

```
text = display.gettext(embellished, row)
```

```
text = display.gettext(embellished, row, column start)
```

```
text = display.gettext(embellished, row, column start, column end)
```

`embellished` Set to `false` to return text as a simple character string. Set to `true` to include character codes.

`row` Set to 1 or 2 to select which row to read text from. If not included, text from both rows is read.

`column start` Set to starting column for reading text.

`column end` Set to ending column for reading text.

Sending the command without the `row` parameter returns both lines of the display. The `$N` character code will be included to show where the top line ends and the bottom line begins. The `$N` character code will be returned even if `embellished` is set to `false`.

With `embellished` set to `true`, all other character codes that were used in the creation of each message line will be returned along with the message. With `embellished` set to `false`, only the message will be returned.

Sending the command without the `column start` parameter defaults to Column 1. Sending the command without the `column end` argument defaults to the last column (Column 20 for Row 1, Column 32 for Row 2).

## Input prompting

Display messaging can also be used along with front panel controls to make a user script interactive. For an interactive script, input prompts are displayed so that the operator can perform a prescribed action using the front panel controls. While displaying an input prompt, the test will pause and wait for the operator to perform the prescribed action from the front panel.

## Menu

A user-defined menu can be presented on the display. The menu consists of the menu name on the top line, and a selectable list of menu items on the bottom line. The following function is used to define a menu:

```
display.menu(menu, items)
```

where: `menu` is the name of the menu (string up to 20 characters, including spaces). The `items` string is made up of one or more menu items, where each item must be separated by whitespace.

When the `display.menu` function is executed, script execution will wait for the operator to select one of the menu items. Rotate the Wheel to place the blinking cursor on the desired menu item. Items that don't fit in the display area will be displayed by rotating the wheel to the right. With the cursor on the desired menu item, press the Rotary Wheel (or the Enter key) to select it.

Pressing the EXIT key will not abort the script while the menu is displayed, but it will return `nil`. The script can be aborted by calling the `exit` function when `nil` is returned.

Example: The menu for the following code will present the operator with the choice of two menu items: Test1 or Test2. If Test1 is selected, the message "Running Test1" will be displayed. If Test2 is selected, the message "Running Test2" will be displayed.

```
display.clear()
menu = display.menu("Sample Menu", "Test1 Test2")
if (menu == "Test1") then
 display.settext("Running Test1")
else display.settext("Running Test2")
end
```

## Parameter value prompting

There are two functions to create an editable input field on the user screen at the present cursor position: `display.inputvalue` and `display.prompt`.

The `display.inputvalue` function uses the user screen at the present cursor position. Once the command is finished, it returns the user screen back to its previous state. The `display.prompt` function creates a new edit screen and does not use the user screen.

Each of these two functions can be used in four ways:

```
display.inputvalue(format)
display.inputvalue(format, default)
display.inputvalue(format, default, min)
display.inputvalue(format, default, min, max)
display.prompt(format, units, help)
display.prompt(format, units, help, default)
display.prompt(format, units, help, default, min)
display.prompt(format, units, help, default, min, max)
```

`format` – The `format` string creates an editable input field on the user screen at the present cursor position. Examples of the `format` for an input field:

```
+0.00 00 +00.0000E +00 0.00000E+0
```

Value field:

- + Include a "+" sign for positive/negative value entry. Not including the "+" sign prevents negative value entry.
- 0 Defines the digit positions for the value. Up to six zeros (0) can be used for the value (as shown above in the third and fourth examples).

- . If used, include the decimal point (.) where needed for the value.

Exponent field (optional):

- E Include the “E” for exponent entry.
- + Include a “+” sign for positive/negative exponent entry. Not including the “+” sign prevents negative exponent entry.
- 0 Defines the digit positions for the exponent.

`default` – Use this option to set a default value for the parameter. The `default` value will be displayed when the command is sent.

`min and max` There are options to specify minimum and maximum limits for the input field. When NOT using the “+” sign for the value field, the minimum limit cannot be set to less than zero. When using the “+” sign, the minimum limit can be set to less than zero (for example, -2).

`units and help` `units` is a text string to identify the units for the value (8 characters maximum). Example units text is “V” for volts and “A” or amps. `help` is an information text string to display on the bottom line (32 characters maximum).

The two functions are similar in that they both display the editable input field, but the `display.inputvalue` function does not include the text strings for `units` and `help`.

After one of the above functions is executed, script execution will pause and wait for the operator in input the source level. The program will continue after the operator enters the value by pressing the Rotary Wheel or the Enter key.

### Examples:

The following code will prompt the operator to enter a source value:

```
display.clear()
value = display.prompt("0.00", "V", "Enter source voltage")
display.screen = display.SMUA
smua.source.levelv = value
```

The script will pause after displaying the prompt message and wait for the operator to enter the voltage level. The display will then toggle to the source-measure display for SMU A and set the source level to `value`.

---

**NOTE** If the operator presses EXIT instead of entering a source value, `value` will be set to `nil`.

---

The second line of the above code can be replaced using the other input field function:

```
value = display.inputvalue("0.00")
```

The only difference is that the display prompt will not include the “V” units designator and the “Enter source value” message.

## Indicators

Send the following code to determine which display indicators are turned on:

```
annun = display.getannunciators()
print(annun)
```

The 16-bit binary equivalent of the returned value is a bitmap. Each bit corresponds to an indicator. If the bit is set to “1”, the indicator is turned on. If the bit is set to “0”, the indicator is turned off.

[Table 11-2](#) identifies the bit position for each indicator. The table also includes the weighted value of each bit. The returned value is the sum of all the weighted values for the bits that are set.

For example, assume the returned bitmap value is 34061. The binary equivalent of this value is as follows:

```
1000010100001101
```

For the above binary number, the following bits are set to “1”: 16, 11, 9, 4, 3 and 1. Using [Table 11-2](#), the following indicators are on: REL, REM, EDIT, AUTO, 4W and EDIT.

Table 11-2

**Bit identification for indicators**

|                 |       |       |      |      |      |      |      |      |
|-----------------|-------|-------|------|------|------|------|------|------|
| Bit             | 16    | 15    | 14   | 13   | 12   | 11   | 10   | 9    |
| Annunciator     | REL   | REAR  | SRQ  | LSTN | TALK | REM  | ERR  | EDIT |
| Weighted Value* | 32768 | 16384 | 8192 | 4096 | 2048 | 1024 | 512  | 256  |
| Binary Value    | 0/1   | 0/1   | 0/1  | 0/1  | 0/1  | 0/1  | 0/1  | 0/1  |
| Bit             | 8     | 7     | 6    | 5    | 4    | 3    | 2    | 1    |
| Annunciator     | SMPL  | STAR  | TRIG | ARM  | AUTO | 4W   | MATH | FILT |
| Weighted Value* | 128   | 64    | 32   | 16   | 8    | 4    | 2    | 1    |
| Binary Value    | 0/1   | 0/1   | 0/1  | 0/1  | 0/1  | 0/1  | 0/1  | 0/1  |

\* The weighted values are for bits that are set to “1.” Bits set to “0” have no value.

Note that not all of the above indicators shown in [Table 11-2](#) are used by the Series 2600A.

## LOCAL lockout

The front panel LOCAL key is used to cancel remote operation and return control to the front panel. However, the LOCAL key can be locked out to prevent a test from being interrupted. When locked, the LOCAL key becomes a NO-OP (no operation). Use the following attribute to lock or unlock the LOCAL key:

```
display.locallockout = lockout
```

where lockout is set to one of the following values:

```
0 or display.UNLOCK
```

```
1 or display.LOCK
```

**LOCAL lockout example:**

The following command locks out the LOCAL key:

```
display.locallockout = display.LOCK
```

## Load test menu

The LOAD TEST menu lists script tests (USER and FACTORY) that can be run from the front panel. Factory script tests (functions) are pre-loaded and saved in nonvolatile memory at the factory. They are available in the FACTORY TESTS submenu.

After a user script is loaded into the Series 2600A, it is not automatically added to the front panel USER TESTS submenu. A menu name and a chunk is added by the user (see [Adding USER TESTS menu entries](#)).

## Loading and saving a user script

After a user script is loaded into the Series 2600A it can be saved in nonvolatile memory. If it is not stored in nonvolatile memory, the script will be lost when the Series 2600A is turned off.

When loading a script from the Test Script Builder, the launch can be configured to save the script in nonvolatile memory (see [Using Test Script Builder](#) in [Section 13](#)).

When loading a user script from another program, `myscript.save()` is used to save the script in nonvolatile memory (see [Saving a user script](#) in [Section 12](#)).

## Adding USER TESTS menu entries

The following function can be used in two ways to add an entry into the USER TESTS submenu:

```
display.loadmenu.add(displayname, chunk)
```

```
display.loadmenu.add(displayname, chunk, memory)
```

`displayname`    Name string to add to the menu.

`chunk`            Chunk is the code to be executed.

`memory`          Save or don't save `chunk` and `displayname` in nonvolatile memory.

Set `memory` to one of the following values:

0 Or `display.DONT_SAVE`

1 Or `display.SAVE`

The default `memory` setting is `display.SAVE`.

The `chunk` can be made up of scripts, functions, variables and commands. With `memory` set to `display.SAVE`, commands are saved with the `chunk` in nonvolatile memory. Scripts, functions and variables used in the `chunk` are not saved by `display.SAVE`. Functions and variables need to be saved along with the script (see [Loading and saving a user script](#)). If the script is not saved in nonvolatile memory, it will be lost when the Series 2600A is turned off. See **Example 1** below.

### Example 1:

Assume a script with a function named “DUT1” has already been loaded into the Series 2600A, and the script has NOT been saved in nonvolatile memory.

Now assume you want to add a test named “Test” to the USER TESTS menu. You want the test to run the function named “DUT1” and sound the beeper. The following command will add “Test” to the menu, define the chunk, and then save `displayname` and `chunk` in nonvolatile memory:

```
display.loadmenu.add("Test", "DUT1() beeper.beeper(2, 500)", display.SAVE)
```

When “Test” is run from the front panel USER TESTS menu, the function named “DUT1” will execute and the beeper will beep for two seconds.

Now assume you cycle power on the Series 2600A. Since the script was not saved in nonvolatile memory, the function named “DUT1” is lost. When “Test” is again run from the front panel, the beeper will beep, but “DUT1” will not execute because it no longer exists in the chunk.

### Example 2:

The following command adds an entry called “Part1” to the front panel “USER TESTS” submenu for the chunk “testpart([[Part1]], 5.0)”, and saves it in nonvolatile memory:

```
display.loadmenu.add("Part1", "testpart([[Part1]], 5.0)", display.SAVE)
```

## Deleting USER TESTS menu entries

The following function can be used to delete an entry from the front panel USER TESTS submenu:

```
display.loadmenu.delete(displayname)
displayname Name to delete from the menu.
```

### Example:

The following command removes the entry named "Part1" from the front panel USER TESTS submenu:

```
display.loadmenu.delete("Part1")
```

## Running a test from the front panel

Front panel user tests and factory tests can be run as follows:

1. Press the LOAD key to display the LOAD TEST menu.
2. Select the USER or FACTORY menu item.
3. Position the blinking cursor on the test to be run and press ENTER or the wheel.
4. Press the RUN key to run the test.

## Key-press codes

### Sending key codes

Key codes are provided to remotely "press" a front key or the navigation wheel. There are also key codes to "rotate" the **navigation wheel** to the left or right (one click at a time). Use the `display.sendkey` function to perform these actions:

```
display.sendkey(keycode)
```

Where: `keycode` is the value of the front panel control. The key code for each control is listed alphabetically in [Table 11-3](#).

### Key press example:

Either of the following commands will press the **MENU** key:

```
display.sendkey(display.KEY_MENU)
```

```
display.sendkey(68)
```

Table 11-3  
**Key codes to send for `display.sendkey`**

|                                        |                                          |
|----------------------------------------|------------------------------------------|
| <code>display.KEY_AUTO</code> or 73    | <code>display.KEY_OUTPUTA</code> or 88   |
| <code>display.KEY_CONFIG</code> or 80  | <code>display.KEY_OUTPUTB</code> or 96   |
| <code>display.KEY_DIGITSA</code> or 87 | <code>display.KEY_RANGEDOWN</code> or 81 |
| <code>display.KEY_DIGITSB</code> or 84 | <code>display.KEY_RANGEUP</code> or 65   |
| <code>display.KEY_DISPLAY</code> or 72 | <code>display.KEY_RECALL</code> or 85    |
| <code>display.KEY_ENTER</code> or 82   | <code>display.KEY_RELA</code> or 70      |
| <code>display.KEY_EXIT</code> or 75    | <code>display.KEY_RELB</code> or 67      |
| <code>display.KEY_FILTERA</code> or 77 | <code>display.KEY_RIGHT</code> or 103    |
| <code>display.KEY_FILTERB</code> or 74 | <code>display.KEY_RUN</code> or 71       |
| <code>display.KEY_LEFT</code> or 104   | <code>display.KEY_SPEEDA</code> or 94    |
| <code>display.KEY_LIMITA</code> or 93  | <code>display.KEY_SPEEDB</code> or 91    |
| <code>display.KEY_LIMITB</code> or 90  | <code>display.KEY_SRCA</code> or 79      |
| <code>display.KEY_LOAD</code> or 95    | <code>display.KEY_SRCB</code> or 76      |
| <code>display.KEY_MEASA</code> or 86   | <code>display.KEY_STORE</code> or 78     |
| <code>display.KEY_MEASB</code> or 83   | <code>display.KEY_TRIG</code> or 92      |
| <code>display.KEY_MENU</code> or 68    | <code>display.WHEEL_ENTER</code> or 97   |
| <code>display.KEY_MODEA</code> or 69   | <code>display.WHEEL_LEFT</code> or 107   |
| <code>display.KEY_MODEB</code> or 66   | <code>display.WHEEL_RIGHT</code> or 114  |

## Capturing key-press codes

A history of the key code for the last pressed front panel key is maintained by the Series 2600A. When the instrument is powered-on (or when transitioning from local to remote), the key code is set to 0 (`display.KEY_NONE`).

When a front panel key is pressed, the key code value for that key can be captured and returned. There are two functions associated with the capture of key-press codes: `display.getlastkey` and `display.waitkey`.

### `display.getlastkey`

The `display.getlastkey` function is used to immediately return the key code for the last pressed key:

```
key = display.getlastkey()
print(key)
```

The above code will return the key code value (see [Table 11-4](#)). Keep in mind that a value of 0 (`display.KEY_NONE`) indicates that the key code history had been cleared.

Table 11-4  
**Key code values returned for display.getlastkey**

|                            |                           |
|----------------------------|---------------------------|
| 0 (display.KEY_NONE)       | 82 (display.KEY_ENTER)    |
| 65 (display.KEY_RANGEUP)   | 83 (display.KEY_MEASB)    |
| 67 (display.KEY_RELB)      | 84 (display.KEY_DIGITSB)  |
| 68 (display.KEY_MENU)      | 85 (display.KEY_RECALL)   |
| 69 (display.KEY_MODEA)     | 86 (display.KEY_MEASA)    |
| 70 (display.KEY_RELA)      | 87 (display.KEY_DIGITSA)  |
| 71 (display.KEY_RUN)       | 90 (display.KEY_LIMITB)   |
| 72 (display.KEY_DISPLAY)   | 91 (display.KEY_SPEEDB)   |
| 73 (display.KEY_AUTO)      | 92 (display.KEY_TRIG)     |
| 74 (display.KEY_FILTERB)   | 93 (display.KEY_LIMITA)   |
| 75 (display.KEY_EXIT)      | 94 (display.KEY_SPEEDA)   |
| 76 (display.KEY_SRCB)      | 95 (display.KEY_LOAD)     |
| 77 (display.KEY_FILTERA)   | 97 (display.WHEEL_ENTER)  |
| 78 (display.KEY_STORE)     | 103 (display.KEY_RIGHT)   |
| 79 (display.KEY_SRCA)      | 104 (display.KEY_LEFT)    |
| 80 (display.KEY_CONFIG)    | 114 (display.WHEEL_RIGHT) |
| 81 (display.KEY_RANGEDOWN) |                           |

---

**NOTE** The OUTPUT ON/OFF keys for SMU A and SMU B cannot be tracked by this function.

---

### **display.waitkey**

The `display.waitkey` function captures the key code value for the next key press:

```
key = display.waitkey()
```

After sending the `display.waitkey` function, the script will pause and wait for the operator to press a front panel key. For example, if the **MEAS** key is pressed, the function will return the value 86, which is the key code for that key. The key code values are listed in [Table 11-3](#).

**Example:** The following code will prompt the user to press the **EXIT** key to abort the script, or any other key to continue it:

```
display.clear()
display.setcursor(1, 1)
display.settext("Press EXIT to Abort")
display.setcursor(2, 1)
display.settext("or any key to continue")
key = display.waitkey()
display.clear()
display.setcursor(1, 1)
if (key == 75) then
 display.settext("Test Aborted")
 exit()
else display.settext("Test Continuing")
end
```

The above code captures the key that is pressed by the operator. The key code value for the **EXIT** key is 75. If **EXIT** is pressed, the script aborts. If any other key is pressed, the script will continue.

---

## Introduction

Conventional instrumentation responds to command messages sent to the instrument. Each command message contains one or more commands. The instrument executes these commands in order.

To conduct a test, a computer (controller) is programmed to send sequences of commands to an instrument. The controller orchestrates the actions of the instrumentation. The controller is typically programmed to request measurement results from the instrumentation and make test sequence decisions based on those measurements.

Keithley Instruments' Test Script Processor-based instruments can operate as conventional instruments by responding to a sequence of command messages sent by a controller. They are also capable of much more.

## Test Script Processor (TSP)

**Scripting** To orchestrate a sequence of actions.

**Scripting Language** A programming language used for scripting.

The Test Script Processor (TSP) is a scripting engine that runs inside the instrument. It is capable of running code written in a scripting language called Lua ([www.lua.org](http://www.lua.org)). We will refer to Lua as the Test Script Language (TSL). The TSP runs portions of TSL code formally known as chunks. Most messages sent to the instrument are directly executed by the TSP as TSL chunks. The simplest messages sent to the instrument would be individual instrument control commands. Even though these messages are executed as TSL chunks, using them is no different than using a conventional instrument. The user sends a command message and the instrument executes that command. When sending individual command messages, it is irrelevant that the TSP is executing the message as a chunk.

Instrument control commands are implemented as a library within the TSL. The command set for a TSP-enabled instrument is referred to as the Instrument Control Library (ICL) for that instrument. Each TSP-enabled instrument will have its own ICL. Although each TSP-enabled instrument runs the same TSL, different instruments respond to different commands and the ICL for each instrument may be different.

ICL commands are very similar to the commands sent to a conventional instrument but ICL commands look like function calls or assignment statements. For example the command to set the output voltage level to one volt on Channel A is `smua.source.levelv = 1`. Similarly, the command to turn the Channel A output on is `smua.source.output = smua.OUTPUT_ON`. These commands, when sent individually as separate messages, are each a TSL chunk.

Commands do not need to be sent as separate messages. The two commands from above can be combined into one message, and thereby one chunk, by concatenating the two commands together with a space separating them. The resulting chunk would be as follows:

```
smua.source.levelv = 1 smua.source.output = smua.OUTPUT_ON
```

## Run-time environment

A feature of all scripting environments is the run-time environment. In the TSP, the run-time environment is simply a collection of global variables. A global variable can be used to remember a value as long as the unit is powered on and the variable is not assigned a new value. The command `x = smua.measure.v()` instructs the instrument to measure voltage and store the result in a global variable named "x."

A global variable can be removed from the environment by assigning it the `nil` value. For example, the command `x = nil` will remove the global variable `x` from the run-time environment. When the unit is turned off, the entire run-time environment will be lost.

## Queries

TSP-enabled instruments do not have inherent query commands. Like any other scripting environment the `print` command and other related `print` commands are used to generate output. The `print` command will create one response message.

An example of generating an output message is the following chunk (two commands) that takes a measurement and returns its value:

```
x = smua.measure.v() print(x)
```

Note that the measurement value is stored in the global variable `x` between the two commands.

## Scripts

When taking advantage of the TSP to perform more complicated sequences of commands, especially sequences utilizing advanced scripting features such as looping and branching, sending the entire sequence in one message is very cumbersome. Two special messages can be used to collect a sequence of command messages together into one chunk.

The `loadscript` message will instruct the TSP-enabled instrument to begin collecting all subsequent messages rather than executing them immediately. After sending the sequence of command messages, the `endscript` message is used to instruct the TSP-enabled instrument to compile the test sequence and make it available to run in a subsequent message. This chunk is called the “anonymous script.”

The anonymous script can be run at any time by sending the command `script.run()`. The anonymous script can be run many times without needing to re-send it. Each time the `script.run()` command is given, the anonymous script will be executed.

Sending a new script using the `loadscript` and `endscript` messages will instruct the TSP-enabled instrument to replace the anonymous script with the new script. While creating and using scripts this way is a very powerful feature of TSP-enabled instruments, only being able to access one script at a time in this way would be very limited. [Naming scripts](#) (below) describes how to use named scripts to store many scripts in the instrument at one time.

## Naming scripts

The `loadscript` message can also be used to create named scripts. When the `loadscript` message is used to create a named script, the anonymous script is not replaced with the named script. Instead, it creates an entry in the `script.user.scripts` table under the name given. In addition, a global variable with the same name in the run-time environment is created to reference the script. Because the script is referenced by a global variable, the name of the script must be a legal TSL variable name.

The name of the script can be specified by including it in the `loadscript` message. The message `loadscript MyScript` instructs the TSP-enabled instrument to begin gathering command messages that are used to create a script named `MyScript`. Upon receipt of the `endscript` message, the instrument compiles the script. If there are no errors, the script can be accessed using the global variable `MyScript`. For example, the script may be executed at any time by sending the `MyScript()` message.

If a new script is sent with the same name, the previous script becomes an unnamed script. If there are no other variables referencing the previous script, it is effectively removed. Sending new scripts with different names will not remove any previously sent scripts. By using named scripts,

any number of scripts can be made available simultaneously within the limits of the memory available to the run-time environment.

Named scripts are stored in the run-time environment which means that when the unit is powered off, they are lost. There is nonvolatile storage on the instrument that can be used to store downloaded scripts across power cycles. See [Saving a user script](#) for more information.

## Renaming Scripts

It may be useful to rename user scripts after they have already been stored. Renaming may be necessary because scripts are saved to internal nonvolatile memory by name and there can be only one script in nonvolatile storage with each given name. It may also be useful because scripts loaded from a USB memory stick will not overwrite scripts already loaded with a given name.

The name of a script can be accessed by using the `MyScript.name` command. To change the name of a script, use the following example:

```
MyScript.name = "TestScript"
```

Where: `MyScript` is the global variable and `"TestScript"` is the new name of the user script.

This command renames the script that `MyScript` was previously referencing. Changing the name of a script does not change the name of any variables that reference that script. After changing the name, the script will be found in the `script.user.scripts` table under its new name.

For example, `"TestScript"` can be run using the `script.user.scripts.TestScript()` command. It can also be run by using the command `MyScript.run()` until `MyScript` is set to `nil`.

## Functions

As previously explained, named scripts behave like TSP functions. Executing a script is just like executing a function with the same name as the script. Scripts, like functions, may return values. Unlike functions, scripts may not take any parameters. In order to pass parameters to a chunk, you must include a TSP function (referred to in this example as *function body*).

Functions are created with a message in one of the following forms:

```
MyFunction = function (parameter1, parameter2) function_body end
```

or

```
function MyFunction(parameter1, parameter2) function_body end
```

Where *function body* is a TSP chunk that will be executed when the function is called. The above function can be executed by substituting appropriate values for `parameter1` and `parameter2` and inserting them into the following message:

```
MyFunction(value_for_parameter1, value_for_parameter2)
```

Where `value_for_parameterN` represents the values to be passed to the function call for the given parameters. Note that when a function is defined, it is just another global variable in the run-time environment. Just like all global variables, functions will persist until they are removed from the run-time environment, overwritten, or the unit is turned off.

## Scripts that create functions

It is inconvenient in most cases to define a function in one message. The solution is to create a script that defines a function. The scripts will be like any other script. It will not cause any action to be performed on the instrument until it is executed. Remember that creating a function is just creating a global variable that is a function. That global variable will not exist until the chunk that

creates it is executed. In this case the chunk that creates it is a script. Therefore, the function will not exist until the script that creates it is executed. This is often confusing to first time users.

**Example:** Create the function `MyFunction` with a script named `MakeMyFunction`. The sequence of messages to do this is shown as follows:

```
loadscript MakeMyFunction
 MyFunction = function (who)
 print("Hello " .. who) -- The .. operator concatenates two strings.
 end
endscript
```

After this sequence of messages is sent, the `MakeMyFunction` script exists on the instrument in a global variable named `MakeMyFunction`. The `MyFunction` function however does not yet exist because we have not executed the `MakeMyFunction` script. Let us now send the message `MakeMyFunction()`. That message instructs the instrument to run the `MakeMyFunction` script which then creates the `MyFunction` global variable that happens to be a function.

If we now send the message `MyFunction("world")`, the instrument will execute the `MyFunction` function, which causes the instrument to generate a response message with the text "Hello world" in it.

## Programming overview

### What is a chunk?

A chunk is a single programming statement or a sequence of statements that are executed sequentially. There are non-scripted chunks and scripted chunks.

**Single statement chunk:** The following programming statement is a chunk:

```
print("This is a chunk")
```

When the above chunk is executed, it returns the following string:

```
This is a chunk
```

**Multiple statement chunk:** A chunk can also contain multiple statements. Each statement in the line of code is to be separated by white space. The following chunk contains two statements:

```
print("This is a chunk") print("that has two statements")
```

When the above chunk is executed, the two statements are executed sequentially and the following strings are returned:

```
This is a chunk
that has two statements
```

**Multiple chunks:** When sent separately, the following two lines of code are two separate chunks. The first chunk sets the source level of SMU A to 1V and the second chunk turns the output on.

```
smua.source.levelv = 1
smua.source.output = smua.OUTPUT_ON
```

**Scripted chunk:** In a script environment, the chunk is the entire listing of test programming code. If the two statements in the above example were created as a script, then those two lines of code would be considered one chunk. See the topic below, [What is a script?](#)

### What is a script?

The Series 2600A utilizes a Test Script Processor (TSP) to process and run individual chunks or programs called "scripts". A script is a collection of instrument control commands and

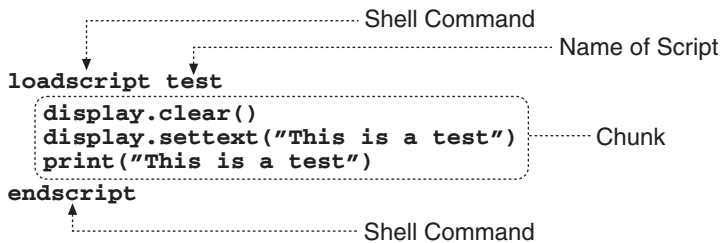

programming statements. [Figure 12-1](#) shows an example of how to create (and load) a script named “test.” When this script is run, the message “This is a test” will be displayed on the Series 2600A and sent to the PC.

As shown, a script is made up of a chunk of programming code that is framed by shell commands. The first shell command in [Figure 12-1](#) tells the instrument to start loading the script named “test.” The last shell command marks the end of the script.

The chunk in [Figure 12-1](#) consists of three lines of code. When the chunk is executed, the test messages will be sent and displayed. The following command executes the chunk: `test()`

Figure 12-1

### Script example

A script is loaded into the Series 2600A where it can be run. Running a script at the SourceMeter is faster than running a test program from the PC. The piecemeal transmission process from PC to SourceMeter instrument is eliminated by the use of a script.

Program statements control script execution and provide facilities such as variables, functions, branching, and loop control. Because scripts are programs, they are written using a programming language. This language is called the Test Script Language or TSL. TSL is an implementation of the Lua scripting language.

There are two types of scripts: Factory scripts and user scripts. A factory script was created by Keithley Instruments at the factory and stored in nonvolatile memory of the Series System 2600A SourceMeter. Factory scripts cannot be removed from nonvolatile memory. A user script can be created using your own program or the Test Script Builder integrated development environment (IDE), which is a supplied software tool (see [Using Test Script Builder](#) in [Section 13](#)). User scripts are loaded into the Series 2600A run-time environment where they can be run and/or saved to nonvolatile memory.

## Run-time environment

The run-time environment is a collection of global variables (including scripts) the user has created. After scripts are placed into the run-time environment, they are then ready to be run and/or managed. Scripts are placed in the run-time environment as follows:

- Scripts saved in [Nonvolatile memory](#) of the Series 2600A are automatically recalled into the run-time environment when the instrument is turned on
- Scripts loaded by the user since the unit was last turned on are stored in the runtime environment

## Nonvolatile memory

After a new or modified user script is loaded into the Series 2600A, it resides in the run-time environment and will be lost when the unit is turned off. To save a script after power-down, the script must be saved in the nonvolatile memory. When the Series 2600A is turned back on, all saved scripts will be loaded into the [Run-time environment](#).

Do not confuse the run-time environment with the nonvolatile memory of the Series 2600A. Making changes to a script in the run-time environment does not affect the stored version of that

script. After making changes, saving the script will overwrite the old version of the script in nonvolatile memory.

## TSP script types

Instrument Control Library (ICL) commands and TSL programming statements are used to program and control the Series 2600A System SourceMeter instruments in the test system. There are three types of scripts:

- **Factory scripts:** Scripts that are pre-loaded into the instrument by the manufacturer.
- **User scripts:** Program scripts are created and loaded into the Series 2600A, where they are executed.
- **Interactive scripts:** This type of script interacts with the operator. It provides user-defined messages on the SourceMeter instrument display to prompt the operator to enter parameters using the front panel.

## Programming model for scripts

The fundamental programming model for scripts is shown in [Figure 12-1](#). Factory scripts (created by Keithley Instruments at the factory) are permanently stored in nonvolatile memory of the Series 2600A. A user script can be created using Test Script Builder or a similar program. User-created scripts can also be stored in nonvolatile memory.

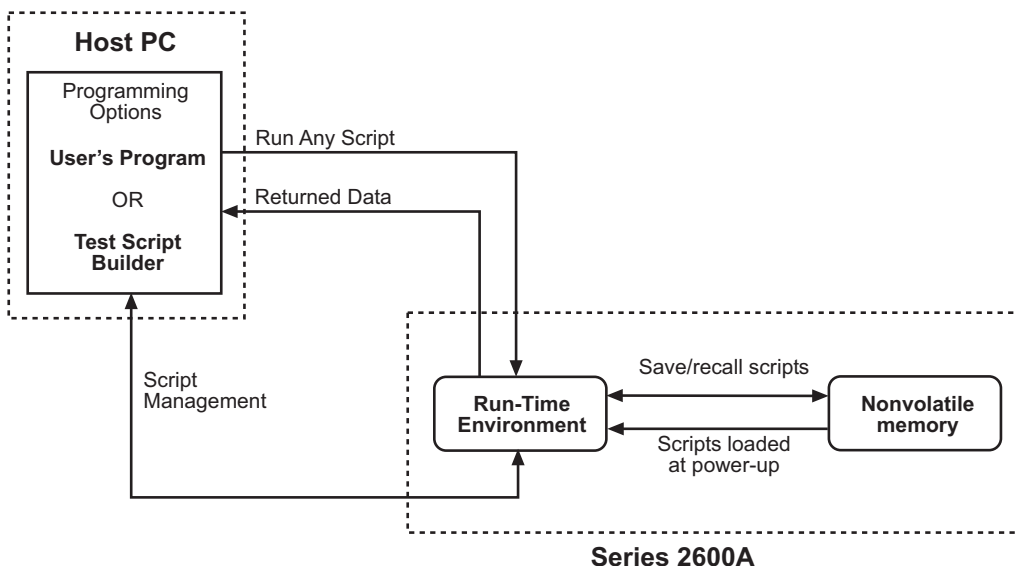

When the Series 2600A is turned on, all user scripts and factory script functions are recalled into the run-time environment from nonvolatile memory. If any user scripts have been programmed to run automatically, they will run when loaded (the `autoexec` script is the only script that will run after all scripts are loaded). Any script in the run-time environment can be run from the Test Script Builder or the user's own program.

---

**NOTE** It is common practice to say that a script is run. In actuality, it is the chunk in the script that is being run (executed).

---

Figure 12-2  
Programming model for scripts

## User scripts

User scripts can be written using your own program or the Test Script Builder. User scripts are loaded into the Series 2600A and can be saved in nonvolatile memory. Scripts not saved in nonvolatile memory will be lost when the Series 2600A is turned off.

### Creating a user script

To create a script and load it, the test program (chunk) must be framed by the following shell commands: `loadscript` or `loadandrunscript`, and `endscript`.

**Load only:** The following scripts will load only into the run-time environment of the Series 2600A. The script on the left is anonymous, while the one on the right is named (where `name` is the user-defined name):

```
loadscript loadscript name
 (chunk) (chunk)
endscript endscript
```

**Load and run:** The following scripts will load into the run-time environment and then run. Keep in mind that when a script is run, only the chunk is executed. The script on the left is anonymous, while the script on the right is named (where `name` is the user-defined name):

```
loadandrunscript loadandrunscript name
 (chunk) (chunk)
endscript endscript
```

Details on `loadscript` and `loadandrunscript` are provided as follows:

```
loadscript
loadscript name
```

where: `name` is the user-assigned name for the script.

The `loadscript` shell command loads the script into the run-time environment. The script can be assigned a name or it can be left nameless. If assigning a name that already exists for another loaded script, the old script will be overwritten with the new script.

If a script is not named when it is loaded into the run-time environment, it will be lost when another unnamed script is loaded or when the Series 2600A is turned off. After loading the anonymous script, use the `run()` or `script.run()` commands to run it.

A special name for a script is `autoexec`. After an `autoexec` script is saved in nonvolatile memory, the script will automatically run after the Series 2600A is powered on and after all other autorun scripts have been executed. For details, see [Autoexec script](#) and [Autorun scripts](#).

```
loadandrunscript
loadandrunscript name
```

where: `name` is the user-assigned name for the script.

These commands are similar to the `loadscript` commands except that the script will execute (run) after it is loaded into the run-time environment. Also, the `autorun` attribute for the script will be set to "yes" (see `myscript.autorun = "yes"`).

## Script examples

### Script using commands and statements only

The script in [Table 12-1](#) sweeps voltage (1V to 5V) and measures current at each step. The five current readings are returned to the host computer:

Table 12-1

#### Example script to sweep V and measure I

| Test Script Builder                                                                                                                                                                               | User's Program Script                                                                                                                                                                                                  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>current = {} smua.source.output = smua.OUTPUT_ON for j = 1, 5 do   smua.source.levelv = j   current[j] = smua.measure.i()   print(current[j]) end smua.source.output = smua.OUTPUT_OFF</pre> | <pre>loadscript current = {} smua.source.output = smua.OUTPUT_ON for j = 1, 5 do   smua.source.levelv = j   current[j] = smua.measure.i()   print(current[j]) end smua.source.output = smua.OUTPUT_OFF endscript</pre> |

**NOTE** When creating a script using the Test Script Builder, only the chunk is typed in as shown above. See [Using Test Script Builder](#) in [Section 13](#) for details on creating, loading and running the script.

When creating a script using a programming language, shell commands must be included to manage interactions between the host computer and TSP. The `loadscript` command loads the script into the Series 2600A and `endscript` signifies the end of the script.

### Script using a function

TSL facilitates grouping commands and statements using the `function` keyword. Therefore, a script can also consist of one or more functions. Once a script has been RUN, the host computer can then call a function in the script directly.

The script in [Table 12-2](#) contains an ICL command to set measurement speed (NPLC) and a function (named `sourcev`). When this script is run, the measurement speed will set to 0.5 PLC and make the `sourcev` function available for calling.

Table 12-2

#### Example script using a function

| Test Script Builder                                                                                                               | User's Program Script                                                                                                                                  |
|-----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>smua.measure.nplc = 0.5 function sourcev(v)   smua.source.levelv = v   i = smua.measure.i()   print(i)   return(i) end</pre> | <pre>loadscript smua.measure.nplc = 0.5 function sourcev(v)   smua.source.levelv = v   i = smua.measure.i()   print(i)   return(i) end endscript</pre> |

When calling the function, you must specify the source voltage in the argument for the function. For example, to set the source to 2V, call the function as follows:

```
sourcev(2)
```

Assuming SMU A output is on, it will output 2V and measure the current. The current reading is sent to the host PC and displayed.

### Interactive scripts

An interactive script prompts the operator (via the SourceMeter instrument's display) to input test parameters (via the SourceMeter instrument's front panel). The chunk fragment below uses display messages to prompt the operator to select an SMU Channel (A or B), a source function (I or V), and to input the source level. When an input prompt is displayed, the script will wait until the operator inputs the parameter and/or presses the **ENTER** key.

The `display.prompt` command in the following script prompts the user to input a source level. If a value is not entered, the default level (1mA or 1V) will be set when **ENTER** is pressed. The operator will not be able to input values that are not within the minimum (0.5mA or 0.1V) and maximum (3mA or 10V) limits.

#### Script Chunk Fragment (Test Script Builder or User's Program)

```
--Prompt operator to select channel:
chan = display.menu("Select Channel", "smua smub")
if (chan == "smua") then
 chan = smua
end
if (chan == "smub") then
 chan = smub
end

--Prompt operator to select (input) the source function:
func = display.menu("Select Function", "amps volts")
if (func == "amps") then
 chan.source.func = chan.OUTPUT_DCAMPS
else
 chan.source.func = chan.OUTPUT_DCVOLTS
end

--Prompt operator to set (input) source level:
if (func == "amps") then
 level = display.prompt("0.0E+00", " mA", "Enter I level",
 1E-3, 0.5E-3, 5E-3)
else
 level = display.prompt("00.0", " V", "Enter V level",
 1, 0.1, 10)
end

--Wait for operator to set source level:
if (func == "amps") then
 chan.source.leveli = level
else
 chan.source.levelv = level
end
```

## Saving a user script

A created and loaded script does not have to be saved in nonvolatile memory of the Series 2600A before it can be run. However, an unsaved script will be lost when the Series 2600A is turned off. The save command will save the script in nonvolatile memory.

The `myscript.save()` command saves the script under the current name of the script. If you save the script to a name that already exists in nonvolatile memory, it will be overwritten.

The `myscript.save("filename")` command is used to save the script to the USB memory stick as a file with the given file name.

---

NOTE .tsp is the default file extension for all scripts.

---

## Saving a named script

Only a named script can be saved in nonvolatile memory of the Series 2600A. After creating and loading a named script, use the following command to save it:

```
myscript.save()
```

Use the following to save a script to an external USB device:

```
myscript.save("/usb1/filename.tsp")
```

Where: `myscript` is the variable referencing the script and `filename.tsp` is a name of the file assigned by the user.

## Saving scripts to internal nonvolatile memory

Complete the following steps to save a script to nonvolatile memory:

1. Press **MENU > SCRIPT > SAVE**.
2. Turn the **navigation wheel** to select the script from the list.

---

NOTE You cannot save unnamed scripts to nonvolatile memory.

---

3. Select **INTERNAL** to save the script to internal nonvolatile memory.

Examples:

1. Assume a script named "test1" has been created and loaded. The following command saves the script in nonvolatile memory:

```
test1.save()
```

2. To save the script named "test1" under a new name ("test2") in nonvolatile memory, send the following commands:

```
test1.name = "test2"
test1.save()
```

## Saving scripts to the USB flash drive

You can transfer, load, and run scripts stored on the USB flash drive. Use the following steps to save a script to the USB flash drive from the front panel.

1. Insert the USB flash drive into the USB port.
2. Press **MENU > SCRIPT** and then select **SAVE** (see [Figure 12-3](#)).

Figure 12-3  
Saving a script

3. Turn the **navigation wheel** left or right to highlight the script to be saved. Press the **navigation wheel** or **ENTER** to select.
4. Use the **navigation wheel** to select **USB1** and press **ENTER** or the **navigation wheel**.
5. (Optional) Use the **navigation wheel** to change the last three characters of the file name.
6. Press **ENTER** to save the script to the USB flash drive.

---

NOTE The message “(overwrite)” is displayed if a file with the same name is stored on the USB flash drive (see [Figure 12-4](#)).

---

Figure 12-4  
Overwriting an existing file on the USB drive

### File numbering

The default file name for files saved from the front panel is `MyScript000.tsp`, where `MyScript` is the name of the script being saved. To change the file name, modify one or all of the last three digits. Each time you save an existing script from the front panel, the number represented by the last three digits in the file name increases by one. You can modify the last three digits to change the file name or to overwrite an existing file (see [Figure 12-4](#)).

## Loading scripts from the USB flash drive

You can use the **LOAD** feature to load a script from the USB flash drive to the run time environment. The Series 2600A validates the script before the load is completed. You can view the errors on the front panel of the Series 2600A.

Once a script is loaded from the USB flash drive, you can associate the script with the front panel's **RUN** button or save the script to internal nonvolatile memory.

**ACTIVE-FOR-RUN:** If this option is selected, the script can be executed by pressing the front panel's **RUN** button.

**SAVE-INTERNAL:** If this option is selected, the script is saved to internal nonvolatile memory.

To load a script from the USB flash drive:

1. Press **MENU > SCRIPT** and then choose **LOAD**.
2. Choose **USB1**.
3. Turn the **navigation wheel** left or right to view the files on the USB flash drive.
4. Select the desired file by highlighting it and pressing **ENTER** or the **navigation wheel**.
5. Choose one of the following:
  - (Save only) **SAVE-INTERNAL**
    - Select **YES**.
  - (Run only) **ACTIVE-FOR-RUN**.
    - Select **YES**.
6. If you chose **ACTIVE-FOR-RUN**, execute the script by pressing **EXIT** and then **RUN**.

## Working with subdirectories from the front panel

To access subdirectories while in local mode:

1. From the front panel, press **MENU > SCRIPT > LOAD > USB1**.
2. Turn the **navigation wheel** left or right to select the desired directory. The files in the subdirectory are displayed.

Figure 12-5  
Subdirectories

## Running a user script

### Running the anonymous script

There can only be one anonymous script in the run-time environment. If another anonymous script is created and loaded, the previous anonymous script will be removed from the run-time environment. Use one of the following commands to execute the chunk of the last loaded anonymous script. Both commands perform the same operation.

```
run()
script.run()
```

### Running a named script

Any variable that references a script in the run-time environment can be used to run the script using one of the following commands. Both commands perform the same operation.

```
myscript()
myscript.run()
```

Where: `myscript` is the variable that references the script. NOTE: The global variable will normally be the same as the name of the script unless the script has been renamed.

### Running scripts automatically

Scripts can be set to run automatically when the Series 2600A is turned on. One or more scripts can be set to autorun.

#### Autorun scripts

When a saved script is set to autorun, it will automatically load and run when the Series 2600A is turned on. Any number of scripts can be set for autorun. The run order for these scripts is arbitrary, so make sure the run order is not important.

To set a script for autorun, set the `autorun` attribute to "yes". Setting it to "no" disables autorun.

```
myscript.autorun = "yes"
```

where: `myscript` is the user-defined name of the script.

Make sure to save the script in nonvolatile memory after setting the `autorun` attribute.

Example:

Assume a script named "test5" is in the run-time environment. The script can be set to autorun as follows:

```
test5.autorun = "yes"
test5.save()
```

The next time the Series 2600A is turned on, the "test5" script will automatically load and run.

---

NOTE The `loadandrunscript` name command sets the `autorun` attribute for that script to "yes". To cancel autorun, set the `autorun` attribute to "no" and save the script.

---

#### Autoexec script

One script can be designated as the autoexec script. When the Series 2600A is turned on, the autoexec script will start after all the autorun scripts have run.

```
loadscript autoexec
loadandruncscript autoexec
```

An autoexec script can be formed by creating a new script and naming it `autoexec` (as shown above using `loadscript` or `loadandruncscript`). After loading the new script, send the `autoexec.save()` command to save it in nonvolatile memory. See [Creating a user script](#) (described earlier in this section) for details on creating a script.

An autoexec script can also be created by changing the name of an existing script that is saved in nonvolatile memory by using the following commands:

```
myscript.name = "autoexec"
myscript.save()
```

Where: `myscript` is the user-defined name of the script.

Example:

Assume a script named “test6” is loaded on the instrument. That script can be made into an autoexec script as follows:

```
test6.name = "autoexec"
test6.save()
```

The next time the Series 2600A is turned on, the “test6” script (which is now the `autoexec` script) will automatically load and start after all of the autorun scripts have run.

---

NOTE When the script is loaded at power-up, it will be called “autoexec” instead of “test 6.”

---

## Running a user script from the Series 2600A front panel controls

In order to run a user script from the front panel, an entry for the script needs to be added to the User menu for the LOAD key. The following commands are used to enter or delete a name into the User menu:

```
display.loadmenu.add(displayname, script)
display.loadmenu.delete(displayname)
```

Where: `displayname` is the name to be added to (or deleted from) the User menu and `script` is a string with the code that will be associated with the `displayname`.

It does not matter what order the items are added to the User menu. Menu items will be displayed in alphabetical order when the menu is selected.

Example:

Assume a user script named “Test9” has been loaded into the run-time environment. Add the name (“Test9”) to the User menu for the script as follows:

```
display.loadmenu.add("Test9", "Test9()")
```

After adding a name to the User menu, the script can then be run from the front panel as follows:

1. Press the **LOAD** key.
2. Select **USER**.
3. Select the user script to run and press the **RUN** key.

## Modifying a user script

A user script stored in nonvolatile memory can be modified by retrieving the script listing for the script. The retrieved script can then be modified, loaded, and saved in nonvolatile memory.

---

**NOTE** If using the Test Script Builder to modify a user script stored in nonvolatile memory, the script listing should be retrieved from in the Project Navigator (see [Retrieving scripts from the Series 2600A in Section 13](#)).

---

## Script management

Script management includes commands for the following operations:

- Downloading and saving scripts to nonvolatile memory.
- Retrieving scripts from the run-time environment so they can be modified.
- Deleting user scripts from nonvolatile memory.
- Restoring scripts in the run-time environment from nonvolatile memory.

### Retrieving the source code of a user script.

There are two ways to retrieve the source code for the user script:

- You can retrieve the listing of the script, that is, the source code line by line over the command interface.
- You can retrieve the entire user script source code as a single string.

The listing for a user script is the source code sent line by line over the command interface. The listed script can then be modified and saved as a user script under the same name or a new name.

The `myscript.list` command retrieves a script listing. The script chunk is returned, along with the shell keywords (`loadscript` or `loadandrunscript`, and `endscript`):

```
myscript.list()
```

Where: `myscript` is the user-defined name of the script.

Example:

Retrieve the listing for a saved script named "test7":

```
test7.list()
```

To retrieve the entire user script source code as a single string use the `myscript.source` attribute where `myscript` is the user-defined name of the script. The `loadscript` or `loadandrunscript` and `endscript` keywords are not included.

Example:

Retrieve source for a script named "test1":

```
print(test1.source)
```

### Deleting a script

**From the run-time environment:** Replacing, changing or deleting a script from the run-time environment does not remove the script from nonvolatile memory. To delete a script from the run-time environment, set its name to an empty string (" ") and remove all references to the script. To remove all references to the script, reassign the variable(s) that reference the script or set the variable(s) to the nil value.

Example:

```
-- Delete a user script name "test7" from the run-time environment
test7.name = ""
```

```
test7 = nil
```

**From nonvolatile memory:** Replacing, changing, or deleting a script from the run-time environment does not remove the script from nonvolatile memory. A script can be permanently removed from nonvolatile memory using either of the following commands:

```
script.delete("name")
script.user.delete("name")
```

Where: name is the user-defined name of the script.

Example:

```
-- Delete a user script named "test8" from nonvolatile memory:
script.delete("test8")
```

---

**NOTE** Removing a script from nonvolatile memory does not remove any scripts from the run-time environment.

---

## Restoring a script in the run-time environment

Once a script has been saved, you may want to remove it from the run-time environment to free up memory. The script may be restored to the run-time environment when needed. To restore the script to the run-time environment, use the one of the following commands:

```
script.restore("name")
script.user.restore("name")
```

Where: name is the user-defined name of the script to be restored.

Example:

Restore a user script named "test9" from nonvolatile memory:

```
script.restore("test9")
```

## Memory considerations for the run-time environment

The Series 2600A reserves 32MB of memory for dynamic run-time use. Of this memory, the firmware requires up to approximately 5MB for general operation. It is recommended that 1MB always be left free for the instrument's internal needs, and that 2MB be reserved for future firmware updates. That leaves approximately 24MB of memory available to the user. The run-time environment, user-created reading buffers, and active sweep configuration must fit within this 24MB of memory.

The amount of memory used by a reading buffer is approximately 15 bytes for each entry requested. There is a slight amount of overhead for a reading buffer, but this can be ignored for memory utilization calculations. For example, assume two reading buffers were created. One of them was created to store up to 1,000 readings and the other 2,500. The memory reserved for the reading buffers is calculated as follows:

$(1000 \times 15) + (2500 \times 15) = 52,500$  bytes or 52.5 kilobytes.

Note that the dedicated reading buffers do not consume memory needed by the run-time environment. Do not include them in your memory consumption calculations. Also, reading buffers for remote nodes consume memory on the remote node, not the local node. You should be sure the total reading buffer memory for any particular remote node does not exceed 24MB, but do not include that amount in your local memory consumption calculations.

The amount of memory used by a sweep configuration is based on the number of source points. The actual memory consumption can vary greatly depending on the SMU settings, but as a general rule each source point can be expected to consume at least 24 bytes.

It is possible for the memory used for these purposes to exceed 24MB. When this occurs, there is a risk that memory allocation errors will be generated and commands will not be executed as expected. If memory allocation errors are encountered, the state of the instrument cannot be guaranteed. After attempting to save off any important data, it is recommended that power to the instrument be cycled to return it to a known state. Cycling power will reset the run-time environment.

Unsaved scripts and reading buffers will be lost. The amount of memory in use can be checked using the `meminfo` function. The first value returned by `meminfo` is the number of kilobytes of memory in use.

## Checking the memory

Use the `meminfo` function to view the available free memory in the instrument (see [meminfo](#) in [Section 19](#) for more information).

---

## Test Script Builder (TSB)

### In this section:

## Installing the Test Script Builder software

To install the TSB software, close all programs, place the CD (Keithley Instruments part number: KTS-850) into your CD-ROM drive and follow the on-screen instructions. If your web browser does not start automatically and display a screen with software installation links, open the index.html file found on the CD using your web browser.

## System connections

To connect the Series 2600A to the LAN, GPIB, or RS232 connection, see [Section 15, Communications Interfaces](#).

## Using Test Script Builder

Test Script Builder is a supplied software tool that can be used to perform the following operations:

- Send ICL commands and TSL statements
- Receive responses (data) to commands and scripts
- Run factory scripts
- Create and run user scripts

[Figure 13-1](#) shows an example of the Test Script Builder. As shown, the Workspace is divided into three window panes:

### Project Navigator

The window pane on the left side of the Workspace is where the Project Navigator resides. The navigator consists of created project folders and the script files (.tsp) created for each project. Each project folder can have one or more script files.

The navigator shown in [Figure 13-1](#) has two projects; one named “BeeperTest” and one named “SourceMeasure.” As shown, the “BeeperTest” project has one script file, and the “SourceMeasure” project has three script files.

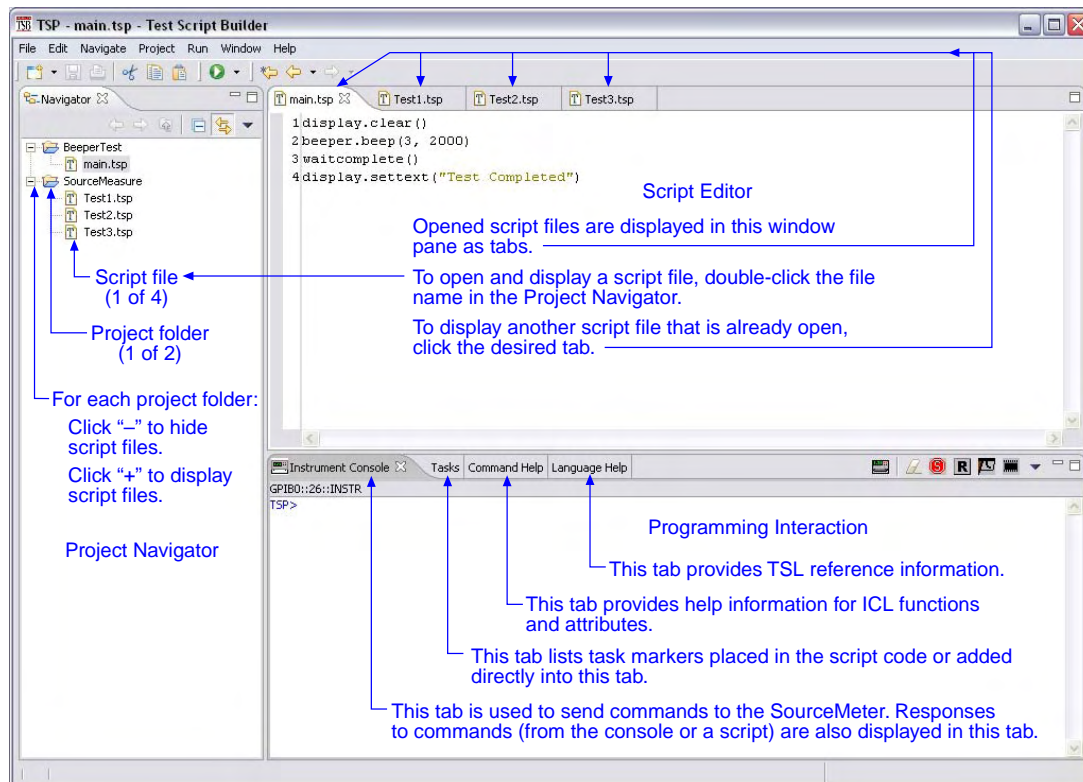

### Script Editor

The script chunk is written and/or modified in the Script Editor. Notice that there is a tab available for each opened script file. A script project is then downloaded to the SourceMeter where it can be run.

### Programming Interaction

Up to seven tabs can be displayed in the lower window pane of the Workspace to provide programming interaction between the Test Script Builder and the SourceMeter. The Instrument Console (shown open in [Figure 13-1](#)) is used to send commands to the connected SourceMeter. Retrieved data (for example, readings) from commands and scripts appear in the Instrument Console. See [Programming interaction tabs](#) later in Section 2 for details on using the other tabs.

Figure 13-1  
**Test Script Builder (example)**

## Starting Test Script Builder

Make sure the SourceMeter instrument is properly connected to the PC (see [System connections](#)) and it is turned on. On the PC desktop, double-click the Test Script Builder icon to begin:

**NOTE** The Test Script Builder can also be started from the Windows Start button on the task bar. For a default installation, follow this menu path to start the Test Script Builder:

**Start > Programs > Keithley Instruments > Test Script Builder**

**Workspace Launcher:** During the initial start-up of TSB, the Workspace Launcher window will be displayed as shown below. This window will indicate the directory path for the workspace. This is

where projects and script files will be stored. If you do not wish to see this window on subsequent power-ups, select “Use this as the default and do not ask again.” Click OK to continue start-up.

---

**NOTE** See [Creating a new workspace](#) later in Section 2 to create additional workspaces.

---

**Communications** – When Test Script Builder opens, communications to the SourceMeter instrument will be closed. With communications closed, commands cannot be sent to the SourceMeter. A script can be written using the Test Script Builder, but it cannot be run. Communications with the SourceMeter instrument are established by [Opening communications](#).

## Opening communications

In order to activate communications between Test Script Builder and the SourceMeter instrument, an instrument must be opened. The toolbar on the Instrument Console tab is used to open or close communications.

[Figure 13-2](#) illustrates how to open and close communications. The following details supplement the information in the drawing:

The Select Instrument window has a drop-down menu to select the LAN, GPIB, or RS-232 interface being used by the Series 2600A.

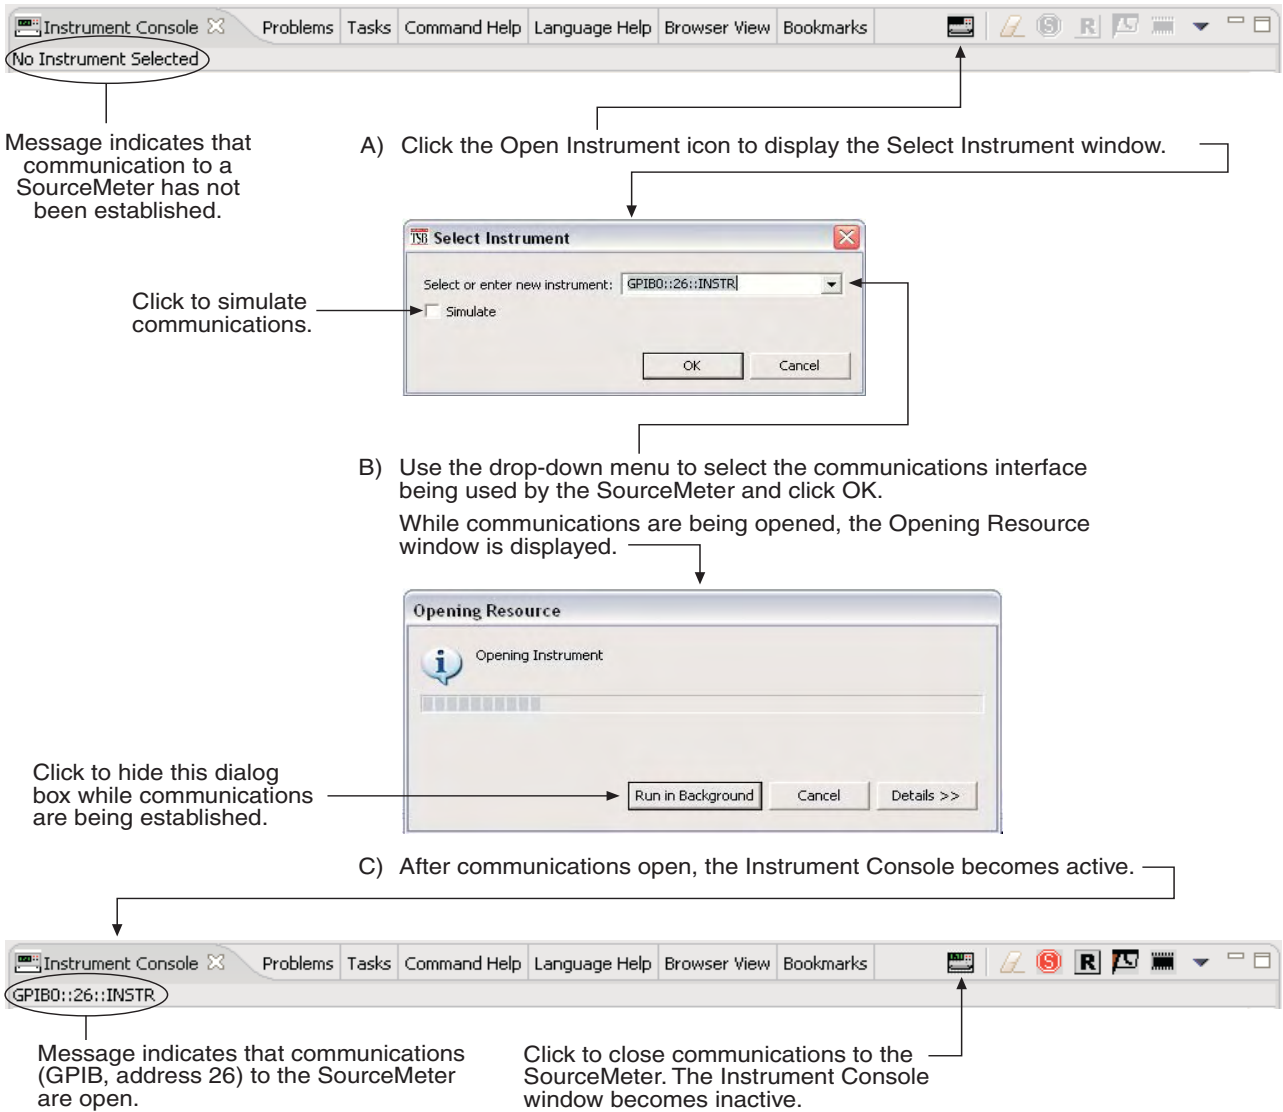

**Simulate communications:** If you select the Simulate option in the Select Instrument window, the Instrument Console will become active even though there will be no actual communication with the SourceMeter instrument. You can simulate running a script or sending a command, but the SourceMeter instrument will not respond.

---

**NOTE** The drop-down menu for the Menu icon can also be used to open or close communications between TSB and the SourceMeter instrument. See [Instrument Console icons](#) for details on using the Menu icon.

---

Figure 13-2  
**Opening and closing communications**

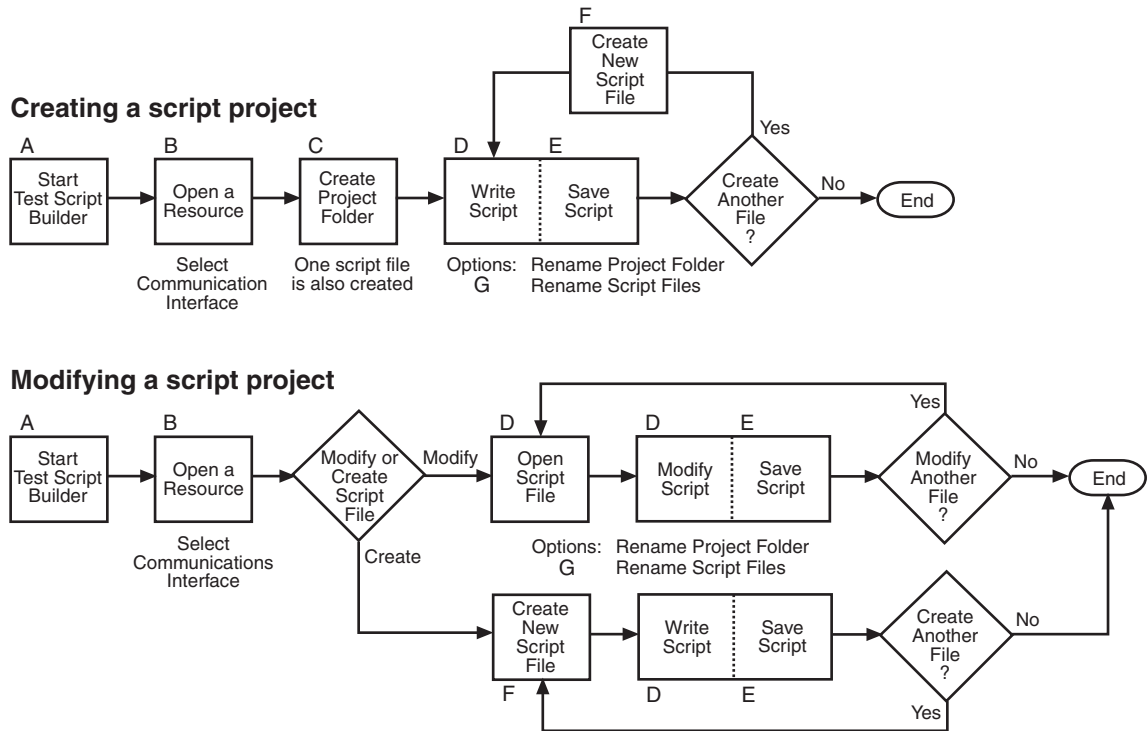

## Creating and modifying a script

The flowcharts in [Figure 13-3](#) show the basic processes to create and modify a script using the Test Script Builder. The labels (A through G) are used to identify reference links provided after the illustration.

Figure 13-3

### Creating and modifying a script using the Test Script Builder

Reference links for labels A through G shown in [Figure 13-3](#):

- A [Starting Test Script Builder](#)
- B [Opening communications](#)
- C [Creating a project folder](#)
- D [Writing or modifying a script](#)
- E [Saving a script](#)
- F [Creating new script files](#)
- G [Renaming a project folder and/or script file](#)

### Creating a project folder

When a project folder is created, the following actions occur:

- The project folder is added to the Project Navigator.
- A script file (named “main”) is created and placed in the project folder.
- The script file (which has no code) is opened and displayed in the Script Development area of the Test Script Builder.

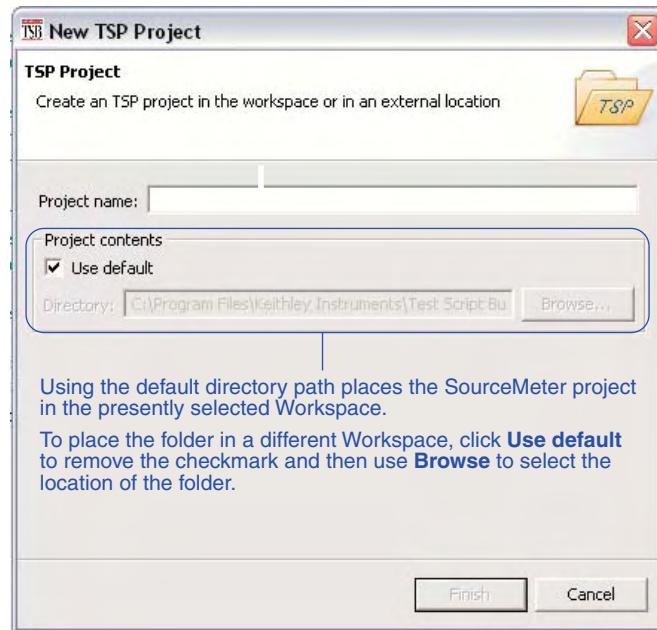

The toolbar at the top of the Test Script Builder is used to create a project folder. [Figure 13-4](#) explains how to create a project folder.

Figure 13-4  
**Creating a project folder**

- A) Open the New TSP Project dialog box as follows:  
 Click the folder icon to display the New project wizard.  
 In the wizard, select TSP Project and click Next.  
 OR  
 Click FILE to display the drop-down file menu. From the menu, click New and then click TSP Project.

- B) In the New TSP Project window, type in a Project name (e.g., SourceMeasure) and click Finish:

## Writing or modifying a script

A script is a list of ICL commands and TSL statements. [Figure 13-1](#) shows a simple example of a script. When this script is run, it performs a beeper test. After sounding the beeper for three seconds at 1kHz, the message “Test Completed” is displayed on the Series 2600A. See details on later in this section.

When a project or script file is created, the script file opens and is displayed in the Script “Editor” area of the Test Script Builder. This is where a script can be written.

To modify an existing script file, it must be open. Open script files are presented as tabs in the Script Editor. To open and display a script file, click the file name in the Project Navigator. To display a different script file that is already open, click the appropriate tab at the top of the Script Editor.

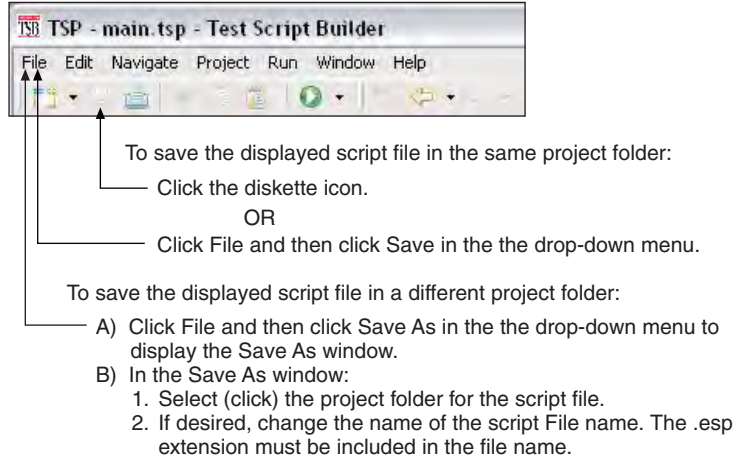

## Saving a script

It is good practice to routinely save a script file as lines of code are written or modified. The save operation performs error checking for the script. If an error occurs, an “X” will appear near the corrupt line of code, and the **Problems** tab will open to provide an explanation of the error. “X”s will also appear in the Project Navigator to indicate which project folder and which script file has the error.

The toolbar at the top of the Test Script Builder is used to save the displayed script file. As explained in [Figure 13-5](#), the script file can be saved in the same folder and/or saved in a different folder.

Figure 13-5

### Saving a script in Test Script Builder

### Creating new script files

A script project can be made up of one or more script files. [Figure 13-6](#) shows how to add a script file to a project folder.

Figure 13-6

**Creating a new script file**

A) Open the New TSP File window as follows:

Click FILE to display the drop-down file menu. From the menu, click New and then click TSP File.

OR

In the Project Navigator, right-click the project folder for the script file. From the drop-down menu, click New and then click TSP File.

- B) In the New TSP File window, make sure the desired project folder is selected. A folder is selected by clicking it.  
 C) Type in a file name (e.g., Test4) and click Finish:

**Renaming a project folder and/or script file**

When a new project is created, a script file (named “main”) is also created and placed in the Folder. [Figure 13-7](#) shows a project folder and script file that has been created and added to the Project Navigator. As shown, the project folder name and a script file name can be changed.

Figure 13-7  
**Renaming a project folder and/or script file**

**To change the name of a script file:**

- A) Right-click the script file, and click Rename in the drop-down menu.
- B) Type in the new name, making sure to include the .tsp extension, and then press the Enter key.

**To change the name of a project folder:**

- A) Right-click the project folder, and click Rename in the drop-down menu.
- B) Type in the new name, and then press the Enter key.

## Script launch configuration

A script is to be loaded into the Series 2600A where it will be executed (run). The launch configuration options include the following:

- Select which script files will be included in the launch.
- Set the launch order for the selected script files.
- Set the script launch to load-only, or to load-and-execute (run).
- Set script storage for the Series 2600A: volatile or nonvolatile. A script stored in volatile memory will be lost when the SourceMeter instrument's power is turned off. A script stored in nonvolatile memory will not be lost after power is turned off.

When a script project is created, the launch is configured initially as follows:

- Only the first script file ("main") is selected to be included in the launch.
- The launch type is set to load-and-execute (run).
- The script project is set to be stored in the volatile memory of the Series 2600A. The script will be lost when the Series 2600A power is turned off.

---

**NOTE** If the initial launch configuration meets your requirements, the script is ready to be launched and is explained in [Launching a script](#) later in this section.

---

The flowchart in [Figure 13-8](#) shows the basic process to change the launch configuration for a script. The labels (A through G) are used to identify reference links which follow the illustration.

Figure 13-8  
**Changing a launch configuration**

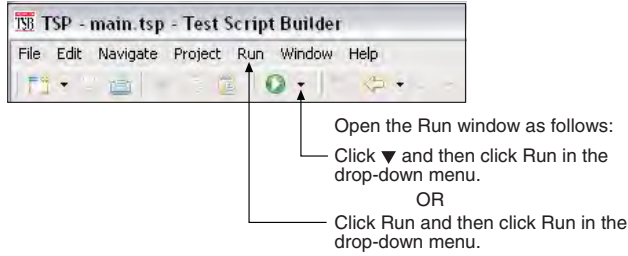

Reference links for labels A through G shown in [Figure 13-8](#):

- A [Starting Test Script Builder](#)
- B [Opening communications](#)
- C [Displaying the launch configuration window](#)
- D [Selecting a configuration](#)
- E [Selecting script files and launch order](#)
- F [Selecting the type of launch](#)
- G [Storing the script](#)

### Displaying the launch configuration window

A launch is configured from the **Run** dialog box. As shown in [Figure 13-9](#), use the toolbar at the top of the Test Script Builder to open the launch configuration window.

Figure 13-9  
**Opening the Run dialog box (launch configuration)**

Launch configuration - Main tab shown:

## Selecting a configuration

When a project is created using the Test Script Builder, a Configuration name for the launch is also created. The project name is altered to append “\_Script” to it. For example, for a project named “SourceMeasure,” the configuration will be named “SourceMeasure\_Script.”

In the Run window, the Configurations area lists the TSP Scripts. To view the launch configuration for a script, click the Configurations name. [Figure 13-9](#) shows the Main tab for “SourceMeasure\_Script.”

## Selecting script files and launch order

As shown in [Figure 13-9](#), script files for the project are shown in the Main tab of the configuration window. Script files listed on the Available Project Files side of the tab are not selected to launch. Script files on the Load Order side are selected to launch in the order that they are listed.

Make configuration changes in the Main tab as follows:

- To move a script file to the Load Order side, click the file name and then click the Add > button.
- To move a file to the Available Project Files side, click the file name then click the < Remove button.
- For script files on the Load Order side, use the Up and Down buttons in a similar manner to change the launch sequence.
- After making changes in the Main tab, click the Apply button.

## Selecting the type of launch

There are two options for the launch process:

- **Load** – The script will load into the run-time environment of the Series 2600A, but will not run. The script can be run later.
- **Load and Execute** – The script will load into the run-time environment. After the load process is completed, the script will run.
- **Auto Run** – With Load and Execute selected, Auto Run can be enabled. When enabled, the script will automatically run whenever the Series 2600A is powered on.

## Storing the script

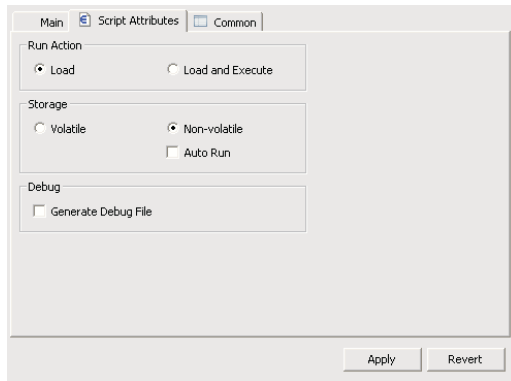

When a script is launched it can be stored in the volatile or nonvolatile memory of the Series 2600A. If stored in volatile memory, it will be lost when the SourceMeter instrument’s power is turned off. If stored in nonvolatile memory, it will not be lost when the power is turned off.

Script storage is set from the Script Attributes tab of the Run window and is shown in [Figure 13-10](#). In the Script Attributes tab, click Volatile or Non-volatile. After selecting nonvolatile memory, Auto Run can be enabled (✓) to automatically run the script whenever the SourceMeter instrument is turned on.

**Debug:** Click **Generate Debug File** to generate a read-only copy of the script. A folder named “Debug” and the debug file (.DBG) is added to the project.

After changing the storage configuration, click **Apply**.

Figure 13-10  
**Run dialog box (Script Attributes tab)**

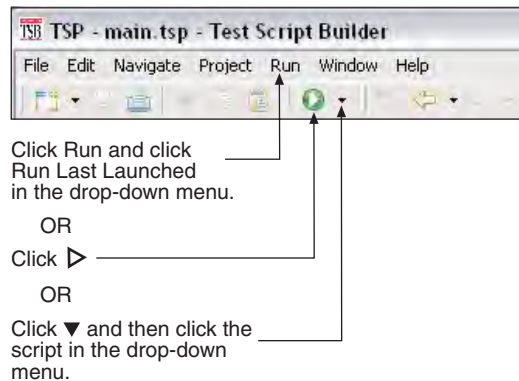

## Launching a script

After checking and/or changing a launch configuration, the script is launched from the Run dialog box by clicking the Run button shown in [Figure 13-9](#).

A script can be relaunched directly from the toolbar located at the top of the Test Script Builder. [Figure 13-11](#) explains how to relaunch a script from the toolbar.

Figure 13-11  
**Relaunching a script from the Test Script Builder toolbar**

## Running a TSP file

A TSP (.tsp) file does not have to be launched (loaded) into the Series 2600A in order to be run. The code for a TSP file can simply be sent to the Series 2600A and executed. The TSP file will not reside in the Series 2600A (it is not saved in volatile or nonvolatile memory). A TSP file can be run from the Project Navigator or from the toolbar at the top of Test Script Builder.

To run a TSP file from the Project Navigator, right-click the .tsp file name (for example, `main.tsp`), select Run in the mouse menu, and then click Run As TSP File in the submenu.

A TSP file can also be run from the TSB toolbar as explained in [Figure 13-12](#).

Figure 13-12

### Re-launching a script from the Test Script Builder toolbar

Click Run or ▼, select Run As in the drop-down menu, then click 1 TSP File in the submenu.

A TSP file can also be run from the Menu icon on the Instrument Console toolbar. For details, see [Instrument Console icons](#) later in this section.

## Retrieving scripts from the Series 2600A

A user script or factory script can be retrieved from memory of the Series 2600A. The retrieved script folder will be placed in the Project Navigator with its script files opened.

[Figure 13-13](#) explains how to import a script from the Series 2600A. It assumes that communications with the SourceMeter instrument are already open. If communications are closed, a window will appear to open communications during the import process.

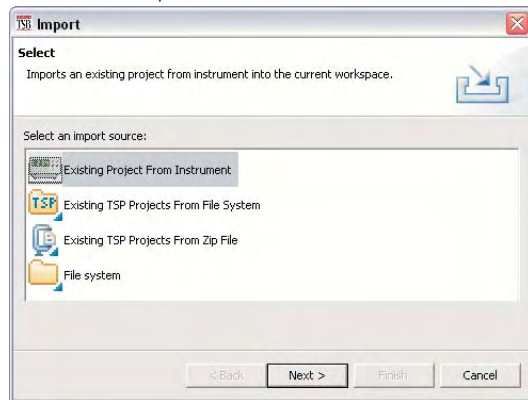

A modified script can be loaded back into the Series 2600A as a user script using the same name or a new name. An imported factory script can only be loaded back into the Series 2600A as a user script.

Figure 13-13  
**Importing a script from memory of the Series 2600A**

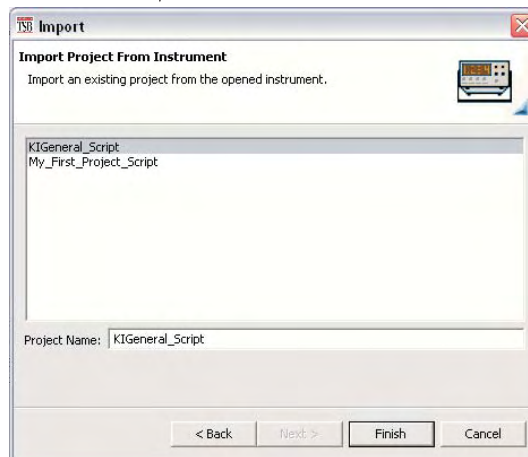

A) Click File to display the drop-down file menu and click Import to open the Import wizard.

B) In the Import Select box, click Existing Project From Instrument and then click Next.

C) In the Import Project From Instrument box, click the KIGeneral\_Script project, and then click Finish.

## Instrument console

With communications established with the SourceMeter instrument, the Instrument Console is used for the following operations:

- Execute chunks, which are individual ICL commands and TSL programming statements.
- Display returned data (readings and messages).
- Display error messages caused by erroneous code sent from the Instrument Console.

The instrument console is opened by clicking the Instrument Console tab in the lower window pane of the Test Script Builder (see [Figure 13-1](#)).

An active Instrument Console displays the TSP> prompt. Type in a command after the prompt and press Enter to execute it. For example, type in the following command:

```
TSP>reset ()
```

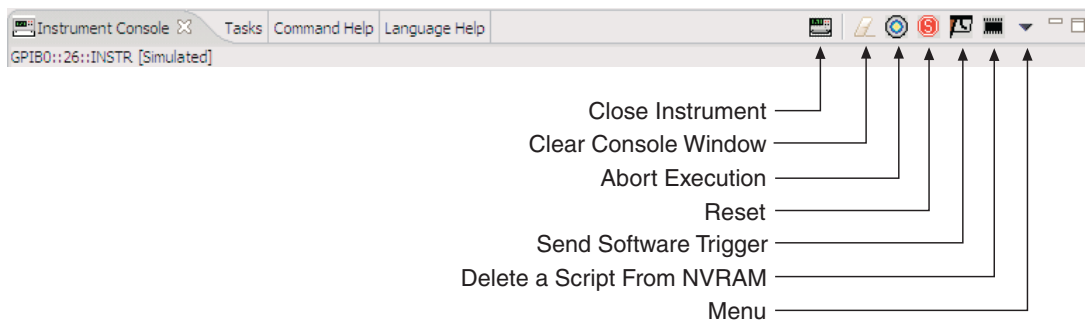

After pressing **ENTER**, the SourceMeter instrument resets to its default settings.

Code and messages in the Instrument Console can be cleared by clicking the Clear Console Window icon. It can also be cleared from the mouse menu as follows: Position the mouse pointer in the console window, right-click the mouse and then select Clear Console Window from the mouse menu.

## Instrument Console icons

After communications with the SourceMeter instrument are open, all of the icons on the Instrument Console toolbar will be active.

Figure 13-14  
Instrument Console icons

The Instrument Console icons are explained as follows:

**Close instrument:** With communications open, clicking this icon closes (disables) communications with the SourceMeter instrument.

**Clear console window:** Clicking this icon removes all code and response messages from the Instrument Console window. There are two other ways to clear the Instrument Console window:

- Place the cursor in the console window, right-click the mouse, and then select Clear Console Window from the mouse menu.
- Click the Menu icon and click the Clear Console Window item in the menu.

**Abort execution:** Clicking this icon aborts execution of a command sent from the Instrument Console.

**Reset:** Clicking this icon resets the SourceMeter instrument. It is the same as sending the `reset ( )` command.

**Send software trigger:** Clicking this icon sends a software trigger to the SourceMeter instrument (see [Section 10](#) for more information on triggering).

**Delete a script from nonvolatile memory:** Use this icon to delete a script from the nonvolatile memory of the SourceMeter instrument. After clicking this icon, select the script to be deleted from the displayed list, and click Delete.

**Menu:** Clicking this icon opens a menu with the following menu items:

- **Clear console window:** Click this menu item to clear the console window. Other ways to clear the console are explained above for the Clear Console Window icon.
- **Instrument:** Clicking this menu item opens a submenu to select items that perform the same operations as some of the other toolbar icons. Also included in the menu is the Flash

item. The Keithley Instruments Flash Programmer is used to download firmware upgrades into the Series 2600A. See [Flash programmer](#) later in this section for details on using the flash programmer.

- **Save console:** The contents (code and response messages) of the Instrument Console window can be saved as a text (.txt) file. After clicking this menu item, a browser will open to allow you to save the log. Use any text editor, such as WordPad, to open the saved text file and view the log.
- **Run:** This menu item is used to run any TSP (.tsp) file that resides in the Project Navigator or elsewhere in your computer or network (see [Running a TSP file](#) later on in this section). After selecting Run, a submenu will open with items to select Editor or Script File. Items for projects in the Project Navigator will also be listed in this submenu:
  - **Editor:** Selecting this item will open another submenu that will list all the TSP files that reside in the Project Navigator. Click a script file to run the script.
  - **Script file:** Selecting this item will open a browser that allows you to locate a TSP file stored in your computer or network. With the File Name displayed in the browser, click Open to run the TSP file.
  - **Projects:** The Run menu lists the projects that are in the Project Navigator. Select a project to display the TSP files for that project. Click a TSP file name to run the file.

The Menu icon is also displayed when the Problems, Tasks or Bookmarks tab is opened (displayed).

## Programming interaction tabs

Up to seven tabs can be displayed in the lower window pane of the Workspace to provide programming interaction between the Test Script Builder and the SourceMeter instrument.

The tabs that can be placed in the Workspace include the following: Instrument Console, Problems, Tasks, Command Help, Language Help, Browser View and Bookmarks. Tabs not presently located in the Workspace can be added by selecting them from the Window option on the toolbar at the top of the Workspace as follows:

Select **Window > Show View > Click the tab to be viewed**

A tab in the Workspace can be opened (viewed) by clicking the tab name. When a tab is opened, an “X” will appear to the right of the tab name. Clicking this “X” removes the tab from the Workspace.

### Instrument Console tab

This tab (shown in [Figure 13-1](#)) is used to send commands to the connected SourceMeter instrument. Retrieved data (for example, readings) from commands and scripts appear in the Instrument Console.

---

NOTE [Figure 13-15](#) and [Figure 13-16](#) show partial screen shots of the following tabs.

---

### Problems tab

When a script file is saved, error checking is performed. If a script error is detected, an “X” will appear in the left-hand margin of the Script Editor at or near the corrupt line of code. The Problems tab will open automatically and provide a description of the error.

If you click the problem in the Problems tab, the line code that has the “X” will be highlighted in the Script Editor. After fixing the erroneous code, the problem will clear when the script file is saved.

### Tasks tab

This tab displays user-defined tasks associated with specific files, specific lines in specific files, as well as generic tasks that are not associated with any specific file.

A task marker (✓) can be inserted for a line of code in the left-hand margin of the Script Editor. Right-click the line number for the code and select Add Task from the mouse menu. In the New Task window, type in a description of the task and click OK. The task will be added to the Task tab. If you click the task in the Tasks tab, the line of code that has the task marker will be highlighted in the Script Editor. A task can be cleared from the Script Editor by right-clicking the task marker and selecting Remove Task.

A task that is not linked to any code or file can be added to the Tasks tab. Place the mouse cursor in the Tasks tab, right-click the mouse, and then select Add Task to enter a description of the task.

### Command Help tab

This tab provides details on ICL functions and attributes (see [Section 19](#) of this manual). The first page of Command Help provides links to the major topics of the help file. Click ICL commands list to display the list of functions and attributes. Click a function or attribute to display the details.

### Language Help tab

This tab provides details on the Test Script Language (TSL); see [Test Script Language \(TSL\)](#) in [Section 19](#). The first page of Language Help provides links to the major topics of the help file.

### Browser View tab

When on-line to the internet, this tab serves as a browser for the Keithley Instruments website ([www.keithley.com](http://www.keithley.com)).

### Bookmarks tab

This tab displays bookmarks that are placed in the Script Editor by the user. A bookmark is placed for a line of code in the left-hand margin of the Script Editor. Right-click the line number for the code and select Add Bookmark from the mouse menu. In the Add Bookmark window, type in a bookmark name and click OK. The bookmark name will be added to the Bookmarks tab.

In the Bookmarks tab, clicking a bookmark displays and highlights the line of code that has the bookmark. A bookmark can be removed from the Script Editor by right-clicking the bookmark and selecting Remove Bookmark.

The Bookmarks tab in [Figure 13-16](#) shows an example of using bookmarks. Each bookmark in the tab is linked to a function for a script file that exists in the Project Navigator. When a bookmark is clicked, the first line for that function will be displayed and highlighted in the Script Editor.

Figure 13-15  
**Programming interaction tabs: Problems, Tasks, and Command Help**

**Problems tab:**

| Description             | Resource | In Folder | Location |
|-------------------------|----------|-----------|----------|
| `do' expected near `fo' | main.tsp | KIGeneral | line 47  |

**Tasks tab:**

| Description                                             | Resource | In Folder        | Location |
|---------------------------------------------------------|----------|------------------|----------|
| <input type="checkbox"/> -- TODO insert your code here. | main.tsp | My_First_Project | line 27  |

Language Help tab:

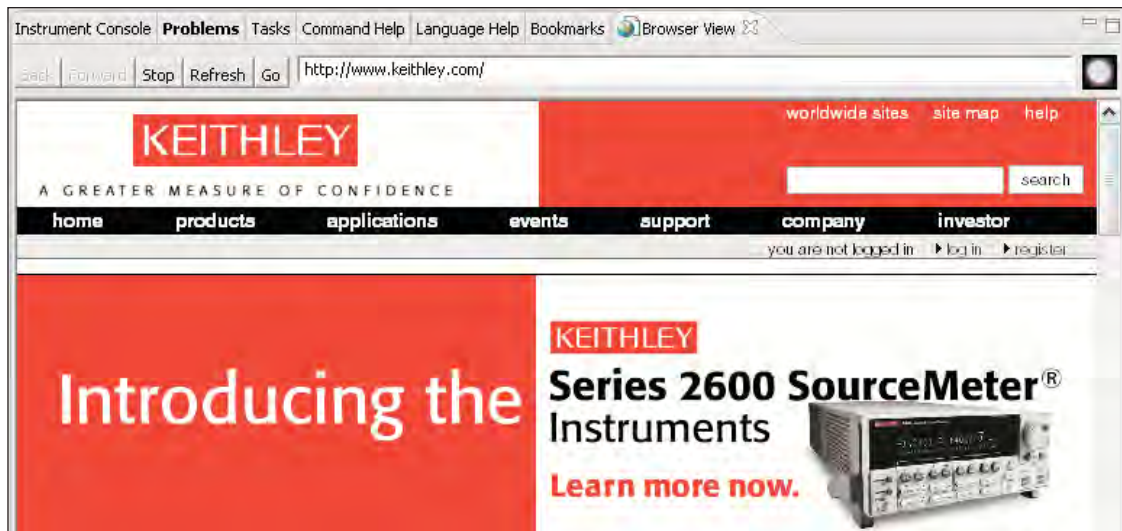

Bookmarks tab:

The screenshot shows a window titled "Bookmarks" with a tabbed interface. The active tab is "Bookmarks", and other tabs include "Instrument Console", "Problems", "Tasks", "Command Help", "Language Help", and "Browser View". Below the tabs is a search bar with "back", "forward", "stop", "refresh", and "go" buttons. The main content area displays a table with 8 items:

| Description        | Resource | In Folder | Location |
|--------------------|----------|-----------|----------|
| PulseIMeasureV     | main.tsp | KIGeneral | line 2   |
| PulseVMeasureI     | main.tsp | KIGeneral | line 74  |
| SweepLinMeasureV   | main.tsp | KIGeneral | line 147 |
| SweepVLinMeasureI  | main.tsp | KIGeneral | line 212 |
| SweepLogMeasureV   | main.tsp | KIGeneral | line 277 |
| SweepVLogMeasureI  | main.tsp | KIGeneral | line 342 |
| SweepListMeasureV  | main.tsp | KIGeneral | line 407 |
| SweepVListMeasureI | main.tsp | KIGeneral | line 467 |

Browser View tab:

**Flash programmer**

When a firmware upgrade for the Series 2600A becomes available, it can be downloaded from the Keithley Instruments website (www.keithley.com). New or enhanced factory scripts may be included in the upgrade. The file for the firmware upgrade can then be installed in the Series 2600A using the flash programmer.

---

---

**CAUTION** *Disconnect the input/output terminals before performing a flash upgrade.*

---

---

With communications between the TSB and the SourceMeter instrument opened, the flash programmer can be accessed using the Menu icon as follows:

Menu icon > Select Instrument > Flash

Use the displayed browser to select the downloaded file and click **Open** to start the upgrade. See [Upgrading the firmware](#) in [Section 21](#) for details.

## File management tasks

A project, along with its associated files (for example, script files), resides in a workspace folder. Typical file management tasks include the creation of new projects and script files (see [Creating and modifying a script](#) for details on file management tasks). A script project can also be imported from a Series 2600A into Test Script Builder, where it can be modified (for details, see [Retrieving scripts from the Series 2600A](#)).

Other typical file management tasks include [Creating a new workspace](#), [Importing a project from another workspace](#), [Switching workspaces](#), and [Deleting projects and/or script files](#). These file management tasks are explained as follows:

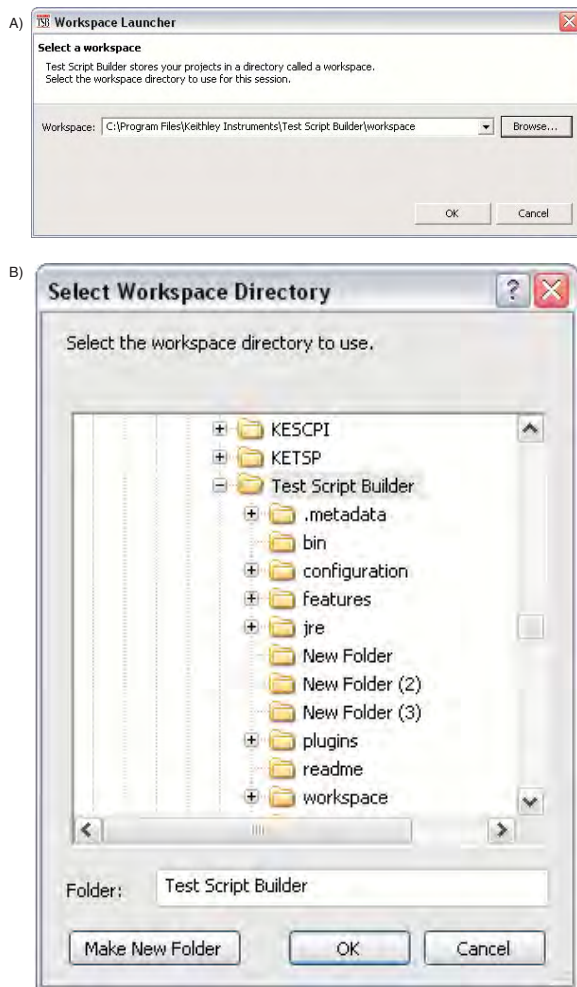

### Creating a new workspace

Additional workspaces can be created anywhere in your file system. A new workspace is simply a new folder for project files. A new folder for a workspace can be made from TSB as follows:

1. At the top of TSB, click **File** on the toolbar to open the file menu and then click **Switch Workspace** to open the Workspace Launcher ([Figure 13-17A](#)).
2. Click the **Browse** button to open the Select Workspace Directory browser and select the location for the new folder. [Figure 13-17B](#) shows the Test Script Builder folder selected as the location for the new workspace folder. Keep in mind that the workspace folder can be located anywhere in your file system.
3. In the Select Workspace Directory, click the **Make New Folder** button. A folder named New Folder will be inserted at the selected location.
4. In the browser, right-click **New Folder** and click **Rename** in the mouse menu.
5. Type in a name for the new workspace folder (for example, workspace2) and press **Enter**.
6. In the browser, click **OK**, and then click **OK** in the Workspace Launcher. Test Script Builder will close and then reopen using the new workspace.

There will not be any projects residing in the Project Navigator for the new workspace. New projects and script files can be created as explained in [Creating and modifying a script](#). A project (along with its script files) can be imported into the new workspace from another workspace folder. See [Importing a project from another workspace](#).

Figure 13-17  
**Workspace Launcher and Select Workspace Directory**

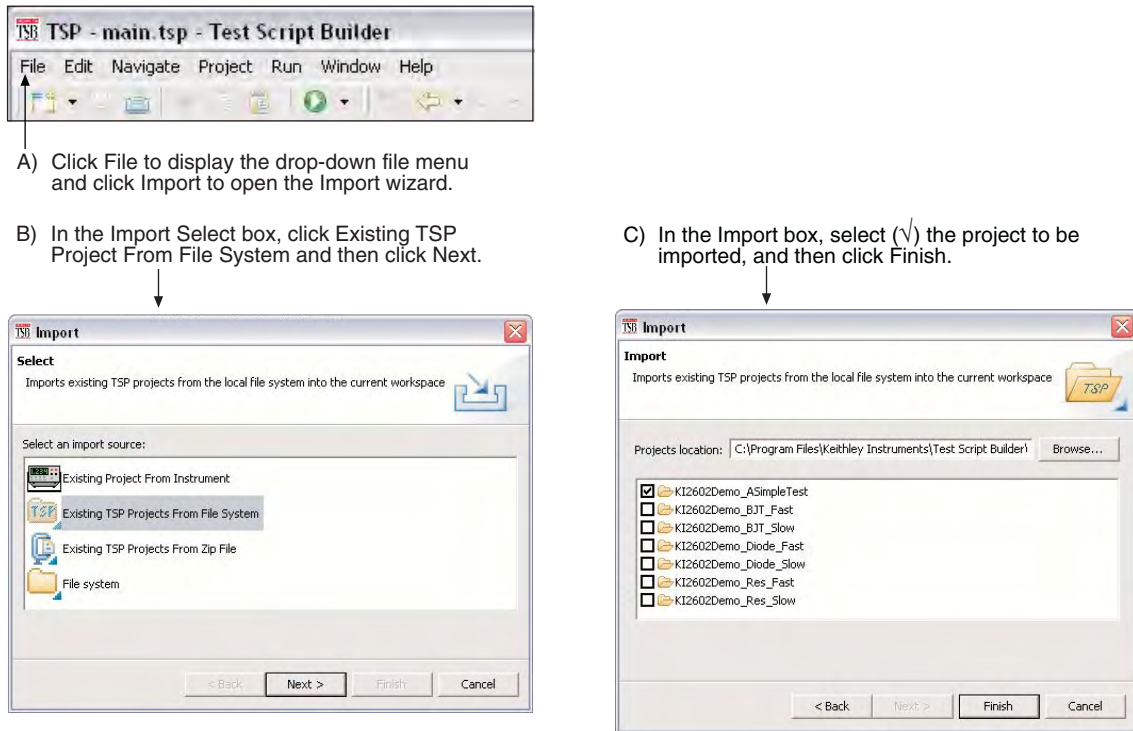

### Importing a project from another workspace

A project (along with its script files) can be imported from another workspace folder that resides in your file system. This is explained in [Figure 13-18](#), which imports a project named KI2602Demo\_ASimpleTest. In Step C, use the Browser to locate the project that you wish to import.

After clicking Finish in the Import window, the project will appear in the Project Navigator of the Test Script Builder.

Figure 13-18  
**Importing a project from another workspace folder**

## Switching workspaces

Perform the following steps to switch to another workspace:

1. At the top of TSB, click File on the toolbar to open the file menu and then click Switch Workspace to open the Workspace Launcher (Figure 13-17A).
2. Click the Browse button to open the Select Workspace Directory browser (Figure 13-17B) and select the workspace folder. TSB will shut down and then reopen using the selected workspace.

## Deleting projects and/or script files

### Deleting a project

To delete a project, right-click the project in the Project Navigator and then click Delete in the mouse menu to display the Confirm Project Delete window (see Figure 13-19).

There are two project delete options:

- **Also delete contents under...** (directory path for project): This option deletes the project from the Project Navigator and also deletes the project from the workspace folder in your file system.
- **Do not delete contents:** This option deletes the project from the Project Navigator, but does not delete it from the workspace folder. The project can later be imported back into the Project Navigator (see [Importing a project from another workspace](#) described earlier in this section).

After selecting the delete option, click Yes in the Confirm Project Delete window to perform the deletion.

Figure 13-19  
**Deleting a project**

The script file will be deleted from the Project Navigator and will also be deleted from the workspace folder for the project.

### Deleting a script file

To delete a script file from a project, right-click the script file in the Project Navigator and then click Delete in the mouse menu. The script file will be deleted from the Project Navigator and will also be deleted from the workspace folder for the project.

## Displaying custom messages

You can create custom messages that display on the front panel display of the Series 2600A. Use the code below to display “Test in Process” on the front panel display:

```
display.clear() -- Clears display of messages.
display.setText("Test in Process") -- Displays message.
```

Displayed messages and input prompts are used in scripts to prompt the operator to enter parameter values from the front panel. See [Interactive scripts](#) for more information.

This page left blank intentionally.

---

## System Expansion (TSP-Link)

### In this section:

| Topic                                                      | Page        |

## Overview

TSP-Link™ is an expansion interface that allows the Series 2600A instrument to communicate with other TSP-enabled instruments. The test system can be expanded to include up to 32 TSP-Link enabled instruments.

### Master and slaves

In a TSP-Link system, one of the nodes (instruments) is the Master and the other nodes are the Slaves.

The Master can control the other nodes (Slaves) in the system. When any node transitions from local operation to remote, it becomes the Master of the system; all other nodes also transition to remote operation, and become its Slaves. When any node transitions from remote operation to local, all other nodes also transition to local operation, and the Master/Slave relationship between nodes is dissolved. For more information about remote and local operations, see [Factory script information](#) in [Section 19](#).

### System configurations

A TSP-Link system can be used without a PC (stand-alone system) or as a PC-based system.

**Stand-alone system:** In a stand-alone system, scripts that control the system are executed from the front panel of one of the instruments. No PC connection is required. In [Figure 14-1](#), a script can be run from the front panel of any one of the instruments.

**PC-based system:** In a PC-based system, the GPIB, LAN, or RS-232 interface to any single node becomes the interface to the entire system. In [Figure 14-1](#), the system can be controlled via the GPIB, LAN or RS-232 interface of Node 1.

## Connections

Connections for an expanded system are shown in [Figure 14-1](#). As shown, one unit is optionally connected to the PC using the GPIB, LAN, or RS-232 interface. Details on these PC communication connections are covered in [Section 12](#).

As shown in [Figure 14-1](#), all the units in the system are daisy-chained together using LAN crossover cables.

Figure 14-1  
TSP-Link connections

## Initialization

Before a TSP-Link system can be used, it must be initialized. For initialization to succeed, each instrument in a TSP-Link system must be assigned a different node number.

### Assigning node numbers

At the factory, each Series 2600A instrument is assigned as Node 1. The node number for each unit is stored in its nonvolatile memory and will not be lost when the instrument is turned off.

#### Front panel operation

You can use the front panel of a instrument to assign a node number to that instrument (node). You can assign any number from 1 to 64 to the node.

Complete the following steps to assign a node number from the front panel of the instrument.

1. Press **Menu > TSPLINK > NODE**.
2. Press the **navigation wheel** and select the desired number.
3. Press **ENTER** to select the node number.

#### Remote programming

The `tsplink.node` attribute is used to set the node number for an instrument:

```
tsplink.node = N
```

Where: N = 1 to 64

The node number of an instrument can be determined by reading the `tsplink.node` attribute as follows:

```
print(tsplink.node)
```

The above `print` command will output the node number. For example, if the node number is 1, the value `1.000000e+00` will be output.

## Resetting the TSP-Link

After all the node numbers are set, you must initialize the system by performing a TSP-Link reset. For initialization to succeed, all units must be powered on when the TSP-Link reset is performed.

---

**NOTE** If you change the system topology after initialization, you must re-initialize the system by performing a TSP-Link reset. Changes that affect the system topology include powering down or rebooting any unit in the system, or rearranging or disconnecting the LAN cable connections between units.

---

#### Front panel operation

Complete the following steps to reset the TSP-Link network from the front panel.

1. Press **Menu > TSPLINK**.
2. Press **RESET**.

## Remote programming

The commands associated with TSP-Link reset are listed in [Table 14-1](#).

Table 14-1

### TSP-Link reset commands

| Command                      | Description                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>tsplink.reset()</code> | Initializes the TSP-Link network.                                                                         |
| <code>tsplink.state</code>   | Returns “online” if the most recent TSP-Link reset was successful. Returns “offline” if the reset failed. |

An attempted TSP-Link reset will fail if any of the following conditions are true:

- Two or more instruments in the system have the same node number.
- There are no other instruments connected to the unit performing the reset (only if the expected number of nodes was not provided in the reset call).
- One or more of the units in the system is not powered on.
- If the actual number of nodes is less than the expected number.

Example: The following code will reset the TSP-Link and output its state:

```
tsplink.reset()
print(tsplink.state)
```

If the reset is successful, `online` will be returned to indicate that communications with all nodes have been established.

## Using the expanded system

### Accessing nodes

A TSP-Link reset populates the node table. Each unit in the system corresponds to an entry in this table. Each entry is indexed by the node number of the unit. The variable `node[N]` (where `N` is the node number) is used to access any node in the system. For example, node 1 is represented in the node table as entry `node[1]`.

Each of these entries is, in turn, a table, holding all of the logical instruments (and associated ICL commands) shared by the corresponding unit (see [Logical instruments](#) for more details). SMU A on node 1, therefore, could be accessed as `node[1].smua`.

The variable `localnode` is an alias for `node[N]`, where `N` is the node number of the node on which the code is running. For example, if node 1 is running the code, `localnode` can be used instead of `node[1]`.

**Programming examples:** The following examples show how to access instruments in the TSP-Link system shown in [Figure 14-1](#):

- Any of the following three commands can be used to reset SMU A of node 1 (which, in this example, is the Master). The other nodes in the system are not affected.

```
smua.reset()
localnode.smua.reset()
node[1].smua.reset()
```

- The following command will reset the SMU A of node 4, which is a Slave. The other nodes are not affected.

```
node[4].smua.reset()
```

## System behavior

### Using the `reset()` command

While most TSP-Link operations target a single node in the system, the `reset()` command affects the system as a whole. The `reset()` command, by definition, resets all nodes to their default settings:

```
-- Resets all nodes in a TSP-Link system.
reset()
```

`node[N]` and `localnode` can be used with `reset` to reset only one of the nodes. The other nodes are not affected. Examples:

```
-- Resets node 1 only.
node[1].reset()
-- Resets node 1 only.
localnode.reset()
-- Resets node 4 only.
node[4].reset()
```

### Abort

An `abort` will terminate an executing script and return all nodes to local operation (REM indicators turn off), dissolving the Master/Slave relationships between nodes. An abort is invoked by either issuing an `abort` command to the Master or pressing the **EXIT** key on any node in the system.

An abort can also be performed by pressing the **OUTPUT ON/OFF** key on any node. The results are the same as above, with the addition that all SMU outputs in the system are turned off.

## Triggering with TSP-Link

TSP-Link has three synchronization lines that function similar to the Digio synchronization lines. See [Section 8](#) and [Section 10](#) for more information.

## TSP advanced features

Use the TSP advanced features to run test scripts in parallel, to manage resources allocated to test scripts running in parallel, and to use the data queue to facilitate real-time communication between nodes on the TSP-Link network.

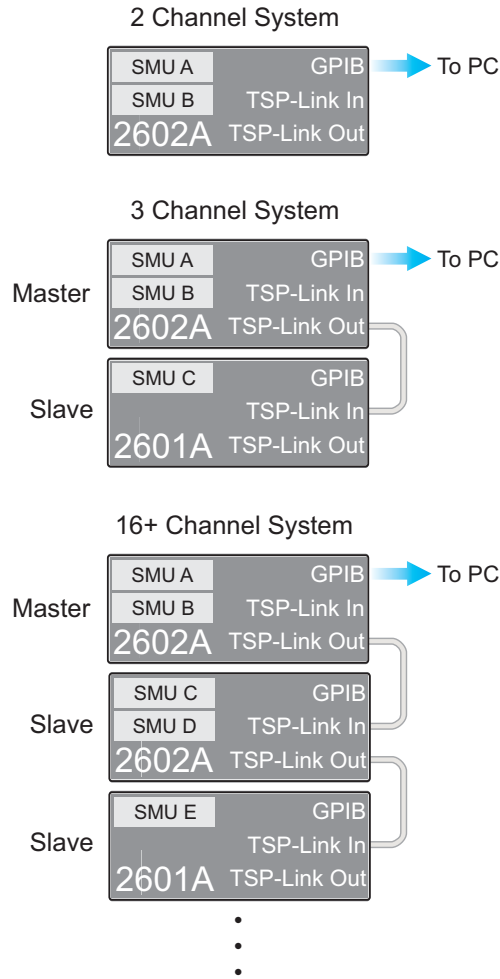

Running test scripts in parallel improves functional testing, provides higher throughput, and expands system flexibility.

There are two methods you can use to run test scripts in parallel:

- Create multiple TSP-Link networks
- Use a single TSP-Link network with groups

[Figure 14-2](#) displays the first method, which consists of multiple TSP-Link networks. Each TSP-Link network has a master node and a GPIB connection to the PC.

Figure 14-2  
**Multiple TSP-Link networks**

The second method to run parallel test scripts is to use groups with a single TSP-Link network. A group consists of one or more nodes with the same group number. Each group on the TSP-Link network can run different test scripts at the same time (in parallel).

*Figure 14-3* displays a single TSP-Link network with groups. This method requires one TSP-Link network and a single GPIB connection to the PC.

**Figure 14-3**  
Single TSP-Link network with groups

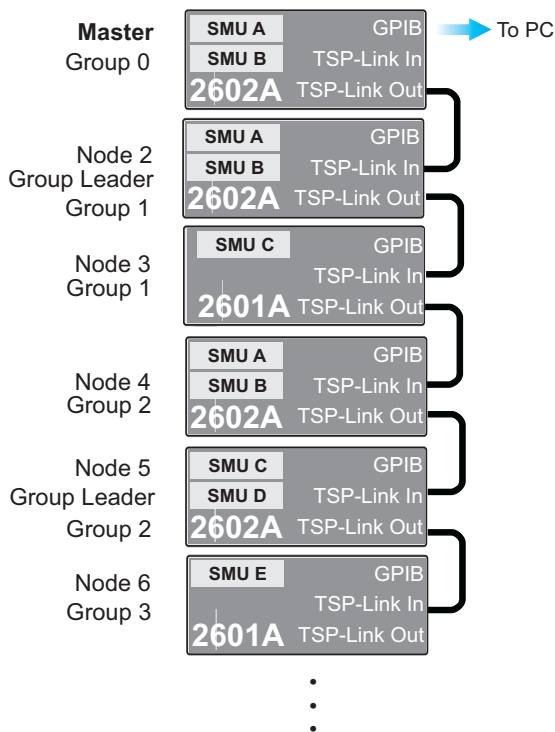

Table 14-2 describes the functions of a single TSP-Link network. Each group in this example runs multiple test scripts at the same time or in parallel.

Table 14-2  
TSP-Link network group functions

| Group number | Group members          | Current function                                                                                                                       |
|--------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Master node            | Initiates and runs a test script on Node 2<br>Initiates and runs a test script on Node 5<br>Initiates and runs a test script on Node 6 |
| 1            | Group leader<br>Node 2 | Runs the test script initiated by the master node<br>Initiates remote operations on Node 3                                             |
|              | Node 3                 | Performs remote operations initiated by Node 2                                                                                         |
| 2            | Group leader<br>Node 5 | Runs the test script initiated by the master node<br>Initiates remote operations on Node 4                                             |
|              | Node 4                 | Performs remote operations initiated by Node 5                                                                                         |
| 3            | Group leader<br>Node 6 | Runs the test script initiated by the master node                                                                                      |

## Using groups to manage nodes on the TSP-Link network

The primary reason to use a group is to assign each node to run different test scripts at the same time (in parallel). Each node must belong to a group; a group can consist of one or more nodes on the TSP-Link network. Group numbers are not assigned automatically; you must use the Instrument Control Library (ICL) commands to assign each node to a group.

### Master node overview

The master node is always the node that coordinates activity on the TSP-Link network. All nodes assigned to group 0 belong to the same group as the master node.

The following list describes the functionality of the master node:

- The only node that can issue the `execute` command to a remote node
- Cannot initiate remote operations on any node in a remote group if any node in that remote group is performing an overlapped operation
- Can use the `waitcomplete` command to wait for all overlapped operations running on the local group that the master node belongs to, and to wait for all overlapped operations running on a remote group, or to wait for all overlapped operations running on the TSP-Link network to complete

### Group leader overview

Each group has a dynamic group leader. The last node in a group running any operation initiated by the master node is the group leader.

The following list describes the functionality of the group leader:

- Runs operations initiated by the master node
- Initiates remote operations on any node with the same group number
- Cannot initiate remote operations on any node with a different group number
- Can use the `waitcomplete` command without a parameter to wait for all overlapped operations running on nodes in the same group

### Assigning groups

Group numbers can range from 0 (zero) to 64. The default group number is 0. You can change the group number at any time.

Use the following code to dynamically assign nodes to a group.

Note the following:

- Replace N with the node number
- N represents the node number that runs the test scripts and the TSL code
- Each time the node powers off, the group number for that node changes to 0
- Replace G with the group number

```
-- Assigns the node to a group.
node[N].tsplink.group = G
```

### Reassigning groups

Use the following code to change group assignment. You can add or remove a node to a group at anytime.

```
-- Assigns the node to a different group.
node[N].tsplink.group = G
```

## Running parallel test scripts

You can issue the `execute` command from the master node to initiate test script and TSL code on a remote node. The `execute` command places the remote node in the overlapped operation state. As a test script runs on the remote node, the master node continues to process other commands in parallel.

Note the following:

- Use the following code to send the `execute` command on a remote node
- N represents the node number that runs the test script

- Replace N with the node number

**To set the global variable on Node N equal to 2.5:**

```
node[N].execute("setpoint = 2.5")
```

The following code is an example of how to run a test script on a remote node.

---

NOTE For this example, `myscript` is defined on the local node.

---

**To run myscript on Node N:**

```
node[N].execute(myscript.source)
```

The following code demonstrates how to run a test script defined on a remote node.

---

NOTE For this example, `myscript` is defined on the remote node.

---

**To execute a script defined on the remote node:**

```
node[N].execute("myscript()")
```

It is recommended that you copy large scripts to a remote node to improve system performance (see [Copying test scripts across the TSP-Link network](#) for more information).

**Coordinating overlapped operations in remote groups**

Errors occur if you send a command to a node in a remote group running an overlapped operation. All nodes in a group must be in the overlapped idle state before the master node can send a command to the group.

Use the `waitcomplete` command to:

- **Group leader and master node:** To wait for all overlapped operations running in the local group to complete.
- **Master node only:** To wait for all overlapped operations running on a remote group to complete.
- **Master node only:** To wait for all groups to complete overlapped operations.

For additional information, refer to [Section 19](#) and the `waitcomplete` command.

The following code is an example on how to issue the `waitcomplete` command from the master node:

```
-- Waits for each node in group G to complete all overlapped operations.
waitcomplete(G)
-- Waits for all groups on the TSP-Link network to complete overlapped
-- operations.
waitcomplete(0)
```

The group leader can issue the `waitcomplete` command to wait for the local group to complete all overlapped operations.

The following code is an example of how to issue the `waitcomplete` command:

```
-- Waits for all nodes in a local group to complete the overlapped
-- operations.
waitcomplete()
```

## Using the data queue for real-time communication

You cannot access the reading buffers or global variables from any node in a remote group while a node in that group is performing an overlapped operation. You can use the data queue to retrieve data from any node in a group performing an overlapped operation. In addition, the master node and the group leaders can use the data queue as a way to coordinate activities.

The data queue uses the first-in, first-out (FIFO) structure to store data. Nodes running test scripts in parallel can store data in the data queue for real-time communication. Each Series 2600A has an internal data queue. You can access the data queue from any node at any time.

You can use the data queue to post numeric values, strings, and tables. Tables in the data queue consume one entry. A new copy of the table is created when the table is retrieved from the data queue. The copy of the table does not contain any references to the original table or any subtables.

To add or retrieve values from the data queue and to view the capacity, see [Section 19](#).

## Copying test scripts across the TSP-Link network

To run a large script on a remote node, it is highly recommend that you copy the test script to the remote node to increase the speed of test script initiation.

Use the code below to copy test scripts across the TSP-Link network. This example creates a copy of a script on the remote node.

Note the following:

- The copy of the test script has the same name as the source
- Replace N with the number of the node that receives a copy of the script
- Replace `myscript` with the name of the script that you want to copy from the local node

```
-- Adds the source code from myscript to the data queue.
node[N].dataqueue.add(myscript.source)

-- Creates a new script on the remote node using the source code from
-- myscript.
node[N].execute(myscript.name.." = script.new(dataqueue.next(),
[["..myscript.name.."]])")
```

## Removing stale values from the reading buffer

The node that acquires the data stores the data for the reading buffer. To optimize data access, all nodes can cache data from the node that stores the reading buffer data.

Running TSL code remotely can cause values in the reading buffer cache to become stale. If the values in the reading buffer change while the TSL code runs remotely, another node can hold stale values. Use the `clearcache` command to clear the cache.

The following code demonstrates how stale values occur and how to use the `clearcache` command to clear the reading buffer cache.

Note the following:

- Replace N with the node number
- Replace G with the group number

```
-- Creates a reading buffer on a node in a remote group.
node[N].tsplink.group = G
node[N].execute("rbremote = smua.makebuffer(20) " ..
 "smua.measure.count = 20 " ..
 "smua.measure.overlappedv(rbremote)")
waitcomplete(G)

-- Creates a variable on the local node to access the reading buffer.
rblocal = node[N].getglobal("rbremote")

-- Access data from the reading buffer.
print(rblocal[1])

-- Runs code on the remote node that updates the reading buffer.
node[N].execute("smua.measure.overlappedv(rbremote)")

-- Use the clearcache command if the reading buffer contains cached data.
rblocal.clearcache()

-- If you do not use the clearcache command, the data buffer values do
--not update. The same data buffer values will print each time the
-- print command is issued.
print(rblocal[1])
```

This page left blank intentionally.

## Overview

This section provides information on:

- [Selecting an interface](#)
- [GPIB operation](#)
- [General bus commands](#)
- [Front panel GPIB operation](#)
- [RS-232 interface operation](#)
- Ethernet communications

## Selecting an interface

The Keithley Instruments Series 2600A System SourceMeter® instrument supports three remote interfaces:

- GPIB (General Purpose Interface Bus)
- RS-232
- LAN

---

NOTE See [Section 12](#) for more information on the GPIB and RS-232 communications interfaces. See [Section 16](#) for more information on LAN interfaces.

---

The Series 2600A can only be controlled from one remote interface at a time. The unit will remote to the first interface on which it receives a message. It will ignore the other interface until the unit is taken back to local operation.

## Output queue

All interfaces share the same output queue. The output queue sets the MAV bits in the status model. The data in the output queue clears if the mode changes to local mode.

---

NOTE You must save the data from the output queue while the instrument is communicating with the remote command interface. All data in the output queue is cleared when the instrument returns to local mode.

---

## GPIB operation

This section contains information about GPIB standards, bus connections, and primary address selection.

### GPIB standards

The GPIB is the IEEE-488 instrumentation data bus with hardware and programming standards originally adopted by the IEEE (Institute of Electrical and Electronic Engineers) in 1975. The Series 2600A is IEEE-488.1 compliant and supports IEEE-488.2 common commands and status model topology.

### GPIB connections

To connect the Series 2600A to the GPIB bus, use a cable equipped with standard IEEE-488 connectors, as shown in [Figure 15-1](#).

Figure 15-1  
IEEE-488 connector

To allow many parallel connections to one instrument, stack the connectors. Two screws are located on each connector to ensure that connections remain secure. [Figure 15-2](#) shows a typical connection scheme for a multi-unit test system.

Figure 15-2  
IEEE-488 connections

To avoid possible mechanical damage, stack no more than three connectors on any one unit. To minimize interference caused by electromagnetic radiation, use only shielded IEEE-488 cables. Available shielded cables from Keithley Instruments are listed in [Options and accessories](#) in Section 1.

To connect the Series 2600A to the IEEE-488 bus, line up the cable connector with the connector located on the rear panel. Install and tighten the screws securely, making sure not to overtighten them ([Figure 15-3](#) shows the location of the connections).

Figure 15-3  
IEEE-488, RS-232, and LAN connection

Connect any additional connectors from other instruments as required for your application. Make sure the other end of the cable is properly connected to the controller. You can only have 15 devices connected to an IEEE-488 bus, including the controller. The maximum cable length is either 20 meters or two meters multiplied by the number of devices, whichever is less. Not observing these limits may cause erratic bus operation.

## Primary address

The Series 2600A ships from the factory with a GPIB primary address of 26. If the GPIB interface is enabled, it momentarily displays the primary address on power-up. You can set the address to a

value from 0 to 30, but do not assign the same address to another device or to a controller that is on the same GPIB bus (controller addresses are usually 0 or 21).

### Front panel primary address

To set or check the primary address:

1. Press **MENU** > **GPIB**, then press **ENTER** or the **navigation wheel**.
2. Set the primary address to the desired value, then press **ENTER** or the **navigation wheel**.
3. Press **EXIT** to back out of the menu structure.

### Remote primary address

Use the following command to set the primary address by remote:

```
gpib.address = address
```

For example, the following command sets the address to 20:

```
gpib.address = 20
```

Note that changing the GPIB address takes effect when the command is processed. Any response messages generated after processing this command will be sent with the new settings. If command messages are being queued (sent before this command has executed), the new settings may take effect in the middle of a subsequent command message, so care should be exercised when setting this attribute from the GPIB interface.

## Terminator

When receiving data over the GPIB, the Series 2600A terminates on any line feed character or any data byte with EOI asserted (line feed with EOI asserted is also valid). When sending data, it will append a line feed character to all outgoing messages. The EOI line will be asserted with the terminating line feed character.

## General bus commands

General commands are those commands, such as DCL, that have the same general meaning regardless of the instrument. [Table 15-1](#) lists the general bus commands.

Table 15-1

**General bus commands**

| Command  | Effect on Series 2600A                                     |
|----------|------------------------------------------------------------|
| REN      | Goes into remote when next addressed to listen.            |
| IFC      | Goes into talker and listener idle states.                 |
| LLO      | LOCAL key locked out.                                      |
| GTL      | Cancel remote; restore Series 2600A front panel operation. |
| DCL      | Returns all devices to known conditions.                   |
| SDC      | Returns Series 2600A to known conditions.                  |
| GET      | Initiates a trigger.                                       |
| SPE, SPD | Serial polls the Series 2600A.                             |

## REN (remote enable)

The remote enable command is sent to the Series 2600A by the controller to set up the instrument for remote operation. Generally, the instrument should be placed in the remote mode before you attempt to program it over the bus. Setting REN true does not place the instrument in the remote state. You must address the instrument to listen after setting REN true before it goes into remote.

## IFC (interface clear)

The IFC command is sent by the controller to place the Series 2600A in the local, talker, or listener idle states. The unit responds to the IFC command by cancelling front panel TALK or LSTN lights, if the instrument was previously placed in one of these states.

Transfer of command messages to the instrument and transfer of response messages from the instrument are not interrupted by IFC. If a response message was suspended by IFC, transfer of the message will resume when the unit is addressed to talk. If a command message transfer was suspended by IFC, the rest of the message can be sent when the unit is addressed to listen.

## LLO (local lockout)

When the unit is in remote operation, all front panel controls are disabled except the **LOCAL** and **OUTPUT OFF** keys (and of course the POWER switch). The LLO command disables the **LOCAL** key, but it does not affect **OUTPUT OFF**, which cannot be disabled.

## GTL (go to local)

Use the GTL command to put a remote-mode instrument into local mode. Leaving the remote state also restores operation of all front panel controls.

## DCL (device clear)

Use the DCL command to clear the GPIB interface and return it to a known state. Note that the DCL command is not an addressed command, so all instruments equipped to implement DCL will do so simultaneously.

When the Series 2600A receives a DCL command, it clears the Input Buffer and Output Queue, cancels deferred commands, and clears any command that prevents the processing of any other device command. A DCL does not affect instrument settings and stored data.

## SDC (selective device clear)

The SDC command is an addressed command that performs essentially the same function as the DCL command. However, since each device must be individually addressed, the SDC command provides a method to clear only selected instruments instead of clearing all instruments simultaneously, as is the case with DCL.

## GET (group execute trigger)

GET is a GPIB trigger that is used to trigger the instrument to take readings from a remote interface.

## SPE, SPD (serial polling)

Use the serial polling sequence to obtain the Series 2600A serial poll byte. The serial poll byte contains important information about internal functions. (See [Appendix C](#).) Generally, the serial polling sequence is used by the controller to determine which of several instruments has requested service with the SRQ line. The serial polling sequence may be performed at any time to obtain the status byte from the Series 2600A.

## Front panel GPIB operation

This section describes aspects of the front panel that are part of GPIB operation, including messages, status indicators, and the **LOCAL** key.

### Error and status messages

See [Appendix A](#) for a list of status and error messages associated with IEEE-488 programming. The instrument can be programmed to generate an SRQ, and command queries can be performed to check for specific error conditions.

### GPIB status indicators

The REM (remote), TALK (talk), LSTN (listen), and SRQ (service request) indicators show the GPIB bus status. Each of these indicators is described below.

#### REM

This indicator shows when the instrument is in the remote state. When the instrument is in remote, all front panel keys, except for the **LOCAL** and **OUTPUT OFF** keys, are locked out. When REM is turned off, the instrument is in the local state, and front panel operation is restored.

#### TALK

This indicator is on when the instrument is in the talker active state. Place the unit in the talk state by addressing it to talk with the correct talk command. TALK is off when the unit is in the talker idle state. Place the unit in the talker idle state by sending a UNT (Untalk) command, addressing it to listen, or sending the IFC (Interface Clear) command.

#### LSTN

This indicator is on when the Series 2600A is in the listener active state, which is activated by addressing the instrument to listen with the correct listen command. LSTN is off when the unit is in the listener idle state. Place the unit in the listener idle state by sending UNL (Unlisten), addressing it to talk, or sending IFC (Interface Clear) command over the bus.

#### SRQ

You can program the instrument to generate a service request (SRQ) when one or more errors or conditions occur. When this indicator is on, a service request has been generated. This indicator stays on until the serial poll byte is read or all the conditions that caused SRQ have been cleared.

## LOCAL key

The **LOCAL (EXIT)** key cancels the remote state and restores local operation of the instrument. Pressing the **LOCAL** key also turns off the REM indicator and returns the display to normal if a user-defined message was displayed.

If the LLO (Local Lockout) command is in effect, the **LOCAL** key is also inoperative. For safety reasons, the **OUTPUT OFF** key can be used to turn the output off while in LLO. Note that pressing **LOCAL** or **OUTPUT OFF** will also abort any commands or scripts that are being processed.

## RS-232 interface operation

### Setting RS-232 interface parameters

#### Front panel RS-232 parameters

To set interface parameters:

1. Press **MENU > RS232** and then press **ENTER** the **navigation wheel**.
2. Select and enter the following interface parameters:
  - Baud rate
  - Number of bits
  - Parity
  - Flow control  
(See the following section for details)
3. Press **EXIT** as needed to back out of the menu structure.

#### Remote RS-232 parameters

Commands to set RS-232 parameters are listed in [Table 15-2](#). See [Section 19](#) for more information.

Table 15-2

**RS-232 interface commands**

| Command                                | Description                                                                                                                                                |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>serial.baud = baud</code>        | Set baud rate (300, 600, 1200, 2400, 4800, 9600, 19200, 38400, 57600, or 115200)                                                                           |
| <code>serial.databits = bits</code>    | Set number of bits (7 or 8)                                                                                                                                |
| <code>serial.flowcontrol = flow</code> | Set flow control:<br><code>serial.FLOW_NONE</code> (no flow control)<br><code>serial.FLOW_HARDWARE</code> (hardware flow control)                          |
| <code>serial.parity = parity</code>    | Set parity:<br><code>serial.PARITY_NONE</code> (no parity)<br><code>serial.PARITY_EVEN</code> (even parity)<br><code>serial.PARITY_ODD</code> (odd parity) |

Note that changing the serial port settings take effect when the command is processed. Any response messages generated after processing these commands will be sent with the new settings. If command messages are being queued (sent before these commands have executed), the new settings may take effect in the middle of a subsequent command message, so care should be exercised when setting these attributes from the RS-232 interface.

## RS-232 programming example

Send the following commands to set the baud rate to 9600 with no flow control:

```
serial.baud = 9600
serial.flowcontrol = serial.FLOW_NONE
```

## Sending and receiving data

The RS-232 interface transfers data using 7 or 8 data bits, 1 stop bit, and no, even, or odd parity. Make sure the device you connect to the Series 2600A also uses the same settings.

## Terminator

When receiving data over the RS-232 interface the command interface terminates on line feeds. A line feed is appended to all output messages when the RS-232 interface is being used as a command interface.

Sending data using the `serial.write` function does not append a terminator. Be sure to append the appropriate terminator to the message before sending it.

## Baud rate

The baud rate is the rate at which the Series 2600A and the programming terminal communicate. Choose one of the following available rates:

- 115200
- 57600
- 38400
- 19200
- 9600
- 4800
- 2400
- 1200
- 600
- 300

The factory-selected baud rate is 9600.

Both the Series 2600A and the other device must be configured for the same baud rate. Make sure the device connected to the Series 2600A RS-232 port can support the selected baud rate.

## Data bits and parity

The RS-232 interface can be configured to send/receive data that is 7 or 8 bits long using even, odd, or no parity.

## Flow control (signal handshaking)

Signal handshaking between the controller and the instrument allows the two devices to communicate to each other regarding being ready or not ready to receive data.

The RS-232 interface provides two control lines (RTS and CTS) for this purpose (see [Figure 15-4](#) and [Table 15-3](#)). When the Series 2600A is ready to send (RTS) data, it will transmit when it receives the clear to send (CTS) signal from the computer.

Figure 15-4  
**RS-232 interface connector**

Table 15-3  
**RS-232 connector pinout**

| Pin number | Description        |
|------------|--------------------|
| 1          | Not used           |
| 2          | TXD, transmit data |
| 3          | RXD, receive data  |
| 4          | Not used           |
| 5          | GND, signal ground |
| 6          | Not used           |
| 7          | RTS, ready to send |
| 8          | CTS, clear to send |
| 9          | Not used           |

To enable or disable flow control, use the RS-232 configuration menu. Select **HARDWARE** to enable flow control, or **NONE** to disable it.

## RS-232 connections

The RS-232 serial port is connected to the serial port of a computer using a straight-through RS-232 cable terminated with DB-9 connectors. Do not use a null modem cable. The serial port uses the transmit (TXD), receive (RXD), CTS and RTS (if flow control is enabled), and signal ground (GND) lines of the RS-232 standard. [Figure 15-4](#) shows the rear panel connector for the RS-232 interface, and [Table 15-3](#) shows the pinout for the connector. The connector location is shown in [Figure 15-3](#).

If your computer uses a DB-25 connector for the RS-232 interface, you will need a standard cable or adapter with a DB-25 connector on one end and a DB-9 connector on the other. An available RS-232 cable from Keithley Instruments is listed in [Options and accessories](#) in Section 1.

[Table 15-4](#) provides pinout identification for the 9-pin (DB-9) or 25-pin (DB-25) serial port connector on the computer (PC).

Table 15-4  
**PC serial port pinout**

| Signal*                  | DB-9 pin number | DB-25 pin number |
|--------------------------|-----------------|------------------|
| DCD, data carrier detect | 1               | 8                |
| RXD, receive data        | 2               | 3                |
| TXD, transmit data       | 3               | 2                |
| DTR, data terminal ready | 4               | 20               |
| GND, signal ground       | 5               | 7                |
| DSR, data set ready      | 6               | 6                |
| RTS, request to send     | 7               | 4                |
| CTS, clear to send       | 8               | 5                |
| RI, ring indicator       | 9               | 22               |

\* The Series 2600A does not use all RS-232 signals. See [Table 15-3](#).

## Error messages

See [Appendix A](#) for RS-232 error messages.

## Ethernet communications

Ethernet provides the flexibility to build scalable and functional test or data acquisition systems with a large degree of flexibility. The Series 2600A is a Class C LXI-compliant instrument that supports TCP/IP and complies with the IEE 802.3 standard. There is one Ethernet port, (located on the back of the instrument), and supports full connectivity on a 10 Mbps or 100 Mbps network.

### Ethernet cable connection

The Series 2600A includes 2 x CA-180-3A cables. Use one cable for TSP-Link and use the other cable for LAN (for a direct instrument to PC connection).

---

NOTE Do not use the cable supplied to connect with a router or hub unless the router or hub supports Auto-MDIX.

---

1. Insert the LAN cable into the LAN port located on the back of the instrument. See [Figure 15-5](#).

Figure 15-5  
**Ethernet connection**

2. Insert the category 5 cable into the Ethernet port located on the host PC.

To configure the LAN settings, see [Connecting to the LAN](#).

## Using the LAN with remote operations

[Table 15-5](#) provides the functions available from the remote interface:

Table 15-5  
**LAN functions**

| Port Number | Function                     |
|-------------|------------------------------|
| 23          | Telnet                       |
| 1024        | VXI-11                       |
| 5025        | Raw socket                   |
| 5027        | Dead socket termination port |

---

**NOTE** You can only use one remote interface at a time. Although multiple ethernet connections to the instrument can be opened, only one can be used to control the instrument at any given time.

---

**Raw socket:** Raw socket is a basic ethernet connection that communicates similarly to RS-232 without explicit message boundaries. The instrument will always terminate messages with a line feed, but because binary data may include bytes that resemble line feed characters, it may be difficult to distinguish between data and line feed characters.

**VXI-11:** VXI-11 is similar to GPIB and supports message boundaries as well as service requests (SRQs). A VXI-11 driver or VISA software is required. Test Script Builder (TSB) uses VISA and can be used with the VXI-11 interface.

**Telnet:** Telnet is similar to raw socket and is used when the user needs to interact directly with the instrument, typically for debugging and troubleshooting. Telnet requires a separate telnet program.

**Dead socket termination port:** The dead socket termination port is used to terminate all existing ethernet connections. A dead socket is one which is held open by the instrument because it has not been properly closed. This most often happens when the PC is turned off or reboots without first closing the socket. This port cannot be used for command and control functions.

### Monitoring the LAN

The `lan.autoconnect` command configures the instrument to monitor the LAN for lost connections. All Ethernet connections are disconnected if the LAN link is disconnected for longer than the time-out value specified in the `lan.linktimeout` attribute.

This page left blank intentionally.

---

## LAN Concepts and Settings

## Overview

Keithley Instruments Series 2600A System SourceMeter® instruments are class C LXI version 1.2 compliant. The Series 2600A is a scalable test system with a direct connection to a host PC or interact with a DHCP or DNS server, and other LXI compliant instruments on a local area network (LAN).

The Series 2600A is compliant with the IEEE standard 802.3 and supports full connectivity on a 10Mbps or 100Mbps network. The LAN interface is an alternative solution to GPIB that can be used to build test systems with a large degree of flexibility and includes web accessibility.

---

**NOTE** Please read this entire chapter before you connect the Series 2600A to the LAN.

---

## Establishing a point-to-point connection

A one-to-one LAN connection to set up a static IP address between the PC and the instrument enables the use of the instrument's internal web page and TSP™ Express.

Use the instructions below to configure the instrument's IP address based on the present IP address of the host PC. Whenever there is an existing IP address configured for the network interface card's network settings, the IP address for the ethernet instruments should be configured so they are compatible.

---

---

**CAUTION** Record all network configurations before modifying any existing network configuration information on the network interface card. Once the network configuration settings are updated, the older information is lost. This may cause a problem reconnecting the PC to a corporate network if DHCP Enabled = NO (DHCP is disabled).

Be sure to return all settings to their original configuration prior to reconnecting the PC to a corporate network. Failure to do this could result in damage to the equipment and loss of data. Contact your system administrator for more information.

---

---

### Step 1: Identify and record the PC's existing IP configuration Information

1. Open the command prompt to see the existing IP configuration information:
  - In Windows 2000/XP:
    - a. Click the **Start** button and select **Run**.
    - b. Type `cmd` in the **Open** field and click **OK**.
  - In Windows Vista:
    - a. Click the **Start** button.
    - b. Select **All Programs**.
    - c. Select **Accessories**.
    - d. Select **Command Prompt**.
2. At the command prompt, type `ipconfig/all` and click **Enter** (see [Figure 16-1](#)).
  - a. If the information for the ethernet adapter displays **Media Disconnected** then close the command prompt and skip to [Step 2: Disable DHCP to use the computer's existing IP address](#).

- b. When the information is displayed, record the DHCP mode, IP address, subnet mask, default gateway, and DNS servers.

---

**CAUTION** `ipconfig/all` displays the configuration of all network connections. Be sure to record the information for the proper network card.

---

Figure 16-1  
Computer configuration using the command prompt

```

c:\ Command Prompt

C:\WINDOWS>ipconfig/all

Windows IP Configuration

 Host Name : mycomputer
 Primary Dns Suffix :
 Node Type : Hybrid
 IP Routing Enabled. : No
 WINS Proxy Enabled. : No
 DNS Suffix Search List. : mycompany.com

Ethernet adapter Wireless Network Connection:

 Connection-specific DNS Suffix . . :
 Description : Intel(R) Wireless WiFi Link 4965AG
 Physical Address. : 00-01-02-03-04-05
 Dhcp Enabled. : Yes
 IP Address. : 1.2.3.87
 Subnet Mask : 255.255.255.0
 Default Gateway : 1.2.3.1
 DNS Servers : 1.2.3.2

Ethernet adapter Local Area Connection:

 Connection-specific DNS Suffix . . :
 Description : Intel(R) 82566MM Gigabit Network Connection
 Physical Address. : 00-02-03-04-05-06
 Dhcp Enabled. : No
 IP Address. : 192.168.1.100
 Subnet Mask : 255.255.255.0
 Default Gateway : 192.168.1.1
 DNS Servers :

C:\WINDOWS>

```

3. Verify DHCP or Static IP status.
  - To determine the next step, check the DHCP Enabled setting in the IP configuration screen or in the settings recorded earlier.
    - a. If DHCP Enabled = **Yes**, proceed to [Step 2: Disable DHCP to use the computer's existing IP address.](#)
    - b. If DHCP Enabled = **No**, proceed to [Step 3: Configure the Instrument's LAN settings.](#)

---

**NOTE** When DHCP Enabled = Yes, the IP address of the PC is assigned automatically upon power up. However, if DHCP Enabled = No, the network will not recognize the PC if the original settings are changed. If at any time you are unsure how to proceed, contact your system administrator.

---

4. To exit the IP configuration screen, type `exit` at the command prompt and press **ENTER**.

---

**Step 2: Disable DHCP to use the computer's existing IP address**

---

**NOTE** Do not change the IP address at any time without talking to your system administrator first. Entering an incorrect IP address can prevent your PC from connecting to your corporate network.

---

1. Open the Internet Protocol Properties dialog box
  - In Windows 2000:
    - a. Click the **Start** button, select **Settings**, and open the **Control Panel**.
    - b. Open **Network and Dial-up Connections**.
    - c. Right-click **Local Area Connection** and select **Properties**. The Local Area Connection Properties dialog box is displayed.
    - d. Double-click **Internet Protocol (TCP/IP)** in the items list. The Internet Protocol (TCP/IP) Properties dialog box is displayed (see [Figure 16-2](#)).
  - In Windows XP:
    - a. Click the **Start** button and open the **Control Panel**.
    - b. Open **Network Connections**.
    - c. Right-click **Local Area Connection** and select **Properties**. The Local Area Connection Properties dialog box is displayed.
    - d. Double-click **Internet Protocol (TCP/IP)** in the items list. The Internet Protocol (TCP/IP) Properties dialog box is displayed (see [Figure 16-2](#)).
  - In Windows Vista:
    - a. Click the **Start** button and open the **Control Panel**.
    - b. Open **Network & Sharing Center**.
    - c. In the list, click **View Status** next to Connection. The Wireless Network Connection Status dialog box is displayed.
    - d. Click **Properties**. Windows displays a permissions message.
    - e. If you are logged in as administrator, click **Continue**. If you are not logged in as administrator, enter the administrator's password to continue.
    - f. The Network Connection Properties dialog box is displayed.
    - g. Double-click **Internet Protocol Version 6 (TCP/IPv6)** in the items list. The Internet Protocol Version 6 (TCP/IPv6) Properties dialog box is displayed (see [Figure 16-2](#)).
2. Select **Use the following IP address**. The option for **Use the following DNS server** addresses is automatically selected.
3. Set the IP Address
  - a. Are the IP address and subnet mask fields populated?
    - Yes: If populated, record the address, subnet mask, default gateway, and DNS servers to use in [Step 3: Configure the Instrument's LAN settings](#).
    - No: If blank, enter the IP address 192.168.0.3 in the IP address field and 255.255.255.0 in the subnet mask field. These will be used to configure the instrument's LAN settings.
  - b. After recording or entering the IP address, click **OK** to close the Internet Protocol (TCP/IP) Properties dialog box.
4. Close the Network Connections window.

Figure 16-2  
**Internet protocol (TCP/IP) properties dialog box**

### Step 3: Configure the Instrument's LAN settings

To configure the Series 2600A using the front panel:

1. Press the **MENU** key to display the MAIN MENU. Use the **navigation wheel** to select **LAN** to display the LAN MENU.
2. Change the IP address assignment method:
  - a. Select **CONFIG > METHOD > MANUAL**, then press the **ENTER** key.
  - b. Press the **EXIT** key once to return to the LAN MENU.
  - c. Select **APPLY\_SETTINGS > YES**, then press the **ENTER** key.
3. Enter the IP address using the LAN MENU:
  - a. Select **CONFIG > IP-ADDRESS**.
  - b. Refer to the recorded computer's IP address. A portion of the computer's IP address will be used as a base for the instrument's unique ID. Only the last three numbers (after the last decimal point) will be different between the PC and instrument. The last three digits may be anything from 1-255 for a subnet mask of 255.255.255.0.

For example, the Internet Protocol (TCP/IP) Properties dialog box in [Figure 16-1](#) shows that the computer's IP address is 192.168.1.1. A unique address for the instrument is 192.168.001.101.

---

NOTE The instrument's IP address can have leading zeros, but the computer's cannot.

---

- c. Use the **navigation wheel** to select and enter an appropriate IP address for the instrument. Be sure to record the instrument's IP address to use in [Step 5: Access the instrument's internal web page](#).
  - d. Push the **ENTER** key or **navigation wheel** to confirm the changes.
  - e. Press the **EXIT** key to return to the LAN MENU.
  - f. From the LAN MENU, select **APPLY\_SETTINGS > YES**, then press the **ENTER** key.
4. Change the subnet mask from within the LAN MENU:
- a. Select **CONFIG > SUBNETMASK**, then press the **ENTER** key. The SUBNETMASK menu item is to the right of **GATEWAY**. Use the **navigation wheel** to scroll through the options.
  - b. Modify the SUBNETMASK to match the PC settings recorded earlier or 255.255.255.000 if DHCP Enabled = YES.
  - c. Push the **ENTER** key or the **navigation wheel** when finished changing all the characters.
  - d. Press the **EXIT** key to return to the LAN MENU.
  - e. From the LAN MENU, select **APPLY\_SETTINGS > YES**, then press the **ENTER** key.

---

NOTE **APPLY\_SETTINGS** must be used before changes to the IP address or subnet mask are applied.

---

#### **Step 4: Connect the crossover cable from the instrument to the PC network interface card**

Connect the supplied crossover cable between the computer's NIC card and the ethernet connector on the instrument's rear panel. There are multiple connectors on the Series 2600A rear panel. Be sure to connect to the LAN connection port (see [Figure 16-3](#)).

---

NOTE Connect the crossover cable into the same PC ethernet port that was used during the configuration of the instrument. This will ensure that the system is using the correct network card.

---

Figure 16-3  
LAN connection

#### Step 5: Access the instrument's internal web page

1. Open a web browser on the host PC.
2. Enter the instrument's IP address in the browser's address box. For example, if the instrument's IP address is 192.168.0.3, enter 192.168.0.3 in the browser's address box.
3. Press **ENTER** on the PC keyboard to open the instrument's web page.

---

NOTE If the web page does not open in the browser, see [LAN troubleshooting suggestions](#).

---

## LAN troubleshooting suggestions

If you are unable to connect to the instrument's internal web page, check the following items:

- Verify that the crossover cable is in the correct port on the instrument. Do not connect to one of the TSP-Link® ports.
- Verify that the crossover cable is in the correct port on the PC. The side ethernet port of a laptop may be disabled while the unit is in a docking station.
- Verify that the correct ethernet card's configuration information was used during the setup procedure.
- Verify that the computer's network card is enabled.
- Verify the instrument IP address is compatible with the IP address on the computer.
- Verify the instrument Subnet mask address is the same as the computer's subnet mask address.
- Cycle the power on the instrument.
- Reboot the computer.
- Contact your system administrator for assistance.

## Connecting to the LAN

Each device on the LAN (corporate or private) requires a unique IP address. Contact your IT department for details on obtaining an IP address before you deploy the Series 2600A on a corporate or private network.

---

---

**WARNING** *It is highly recommended that you contact your corporate IT (Information Technology) department for permission before you connect the Series 2600A to a corporate network.*

---

---

There are two indicators on the LAN jack:

**ACT indicator.** The light flashes green which indicates the instrument is receiving LAN packets.

**LINK indicator.** A solid light indicates the instrument is connected to the LAN.

The following interfaces may be used to configure the LAN settings:

- Front panel
- Telnet
- RS232
- GPIB
- Virtual front panel

---

**NOTE** Reference [Section 19](#) for the Instrument Control Library (ICL) commands to configure the LAN from a remote interface.

---

It is highly recommended that the front panel be used to configure the LAN. The connection to the virtual front panel is lost if the IP address, subnet mask, or gateway is changed.

## Setting the method

There are two methods used to configure the LAN.

**Auto:** Use the Auto setting to allow the DHCP server to automatically set the LAN settings.

You do not need to set the LAN options manually. The DHCP server automatically configures the IP address, subnet mask and the default gateway. A DHCP server must be available on the LAN in order to use this option.

**Manual:** Use the Manual setting to manually configure the communication parameters.

The manual setting requires you to configure the following:

- IP Address
- Gateway
- Subnet mask

## Assigning the Method

Complete the following steps to select a method:

1. From the front panel, press **MENU > LAN > CONFIG > METHOD**.
2. Select one of the following methods and then push the **navigation wheel** to enter the desired method:
  - Press **AUTO**.
  - Press **MANUAL**. The LAN CONFIG menu is shown.
3. (Optional) Press **Exit** to return to the LAN CONFIG menu. CONFIG blinks on the front panel.
4. Turn the navigation wheel one click to the left and then push-in to select **APPLY\_SETTINGS**.
5. Select **YES**.

## Setting the IP address

Note the following:

- Contact your IT department to secure a valid IP address for the instrument when placing the instrument on a corporate network.
- The IP address does not need to be manually set if the method is set to AUTO.

A direct connection to the PC can also be configured. See [Establishing a point-to-point connection](#) for more information.

## Setting the subnet mask

Note the following:

- Contact your IT department to secure a valid subnet mask for the instrument when placing the instrument on a corporate network.
- The subnet mask does not need to be manually set if the method is set to AUTO.

A direct connection to the PC can also be configured. See [Establishing a point-to-point connection](#) for more information.

## Understanding the domain name system

The Domain Name System (DNS) lets you type a domain name in the address bar to connect to the instrument. The DNS removes the requirement to memorize the IP address, instead you only need to know the domain name.

### Example:

Series2600A.yourcompany.com

Contact your IT department to learn more about DNS.

---

**NOTE** If a DNS server is not part of the LAN infrastructure, then this setting is not used.

---

## Verify menu overview

You can use the options on the verify menu to do the following:

- **Verify:** Enables or disables the DNS feature.
- **Dynamic:** (DHCP) The Series 2600A attempts to assign a host name to the DNS server.

To configure the DNS:

1. From the front panel press, **MENU > LAN > CONFIG > DNS**. **VERIFY** flashes.
2. Push the **navigation wheel** to select the **VERIFY** option.
3. Choose one of the following:
  - **ENABLE**
  - **DISABLE**
4. Push the **navigation wheel** to return to the DNS menu.
5. Use the **navigation wheel** to select **DYNAMIC** and press the **ENTER** key or the **navigation wheel**.
6. Choose one of the following:
  - **ENABLE**
  - **DISABLE**
7. Select **DNS-ADDRESS-1** and then do the following:
  - Turn the **navigation wheel** to select the desired digit.
  - Push the **navigation wheel** and then use it to change the value.
  - Push the **ENTER** key or the **navigation wheel** to accept the value.
8. Repeat step 7 to configure **DNS-ADDRESS-2**.
9. Press **Exit** to return to the LAN CONFIG menu. **CONFIG** blinks on the front panel.
10. Turn the navigation wheel one click to the left and select **APPLY\_SETTINGS**.
11. Select **YES** and press the **ENTER** key or the **navigation wheel**.

## Understanding LAN speeds

Another characteristic of the LAN is speed. The Series 2600A negotiates with the host PC and other LXI compliant devices on the LAN to transmit data at the highest speed possible. LAN speeds must be configured to match the speed of the other instruments on the network.

## Configuring the LAN speed

To configure the LAN speed, complete the following steps:

1. From the LAN menu, turn the navigation wheel to the right and then select **SPEED** and then choose one of the following:
  - **10MBPS**
  - **100MBPS**
2. Press **Exit** to return to the LAN CONFIG menu. **CONFIG** blinks on the front panel.
3. Turn the navigation wheel one click to the left and then push-in to select **APPLY\_SETTINGS**.
4. Select **YES**.

## Duplex mode

The duplex mode is based on the LAN configuration. There are two settings:

**Half.** Only one direction is active at a time.

**Full.** Permits communications in both directions simultaneously.

### Configuring the duplex mode

Complete the following steps to configure the duplex mode:

1. Push the **navigation wheel** to return to the LAN menu.
2. Select **DUPLEX** and then choose one of the following:
  - **HALF**
  - **FULL**
3. Press the **navigation wheel** to return to the LAN CONFIG menu. DUPLEX blinks on the front panel.
4. Turn the **navigation wheel** one click to the left and then push to select **APPLY\_SETTINGS**.
5. Select **YES**.

Use the status menu to confirm the LAN configuration, communication settings, to retrieve error messages, and to change the password.

## Configuring the network settings

### CONFIG/FAULT

Use the CONFIG and FAULT menus to retrieve LAN faults and configuration messages.

There are two types of messages:

- **LAN faults:** Communicates issues related to physical connectivity.
- **LAN configurations:** Communicates issue related to configuration.

Table 16-1 displays possible fault and configuration messages.

Table 16-1

#### CONFIG/fault messages

| LAN message       | Notes                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| LAN fault         | <ul style="list-style-type: none"> <li>• Could not acquire IP address</li> <li>• Duplicate IP address detected</li> </ul>            |
| LAN configuration | <ul style="list-style-type: none"> <li>• LAN configuration closed</li> <li>• Manual Configuration started on 10.10.10.105</li> </ul> |

## Viewing LAN status messages

To view the LAN status messages, complete the following steps:

From the front panel or the virtual front panel, complete the following steps:

- Select **MENU > LAN > STATUS > CONFIG/FAULT**.  
Figure 16-4 shows a LAN status message.

Figure 16-4  
LAN CONFIG/FAULT

## Viewing the network settings

You can use the Status menu to view the active network settings.

Complete the following steps to view the active network settings.

1. From the front panel press, **MENU > LAN > STATUS**.
2. Turn the navigation wheel to the right or to the left to view one of the following network settings:
  - IP address
  - Gateway
  - Subnet-mask
  - Method
  - DNS
  - MAC address
3. Push the **navigation wheel** to view the status.
4. Press **ENTER** to return to the STATUS menu.

## Confirming the active speed and duplex negotiation

The Series 2600A automatically detects the speed and duplex negotiation active on the LAN. Once the speed and duplex negotiation is detected, the instrument automatically adjusts to match the LAN settings.

## Confirming port numbers

Use the port menu to view the ports numbers assigned to each protocol. [Table 16-2](#) displays the command interface and the required port number.

Table 16-2  
Port number

| Command Interface | Port number |
|-------------------|-------------|
| Raw socket        | 5025        |
| Telnet            | 23          |
| VXI-11            | 1024        |
| DST               | 1030        |

Complete the following steps to check the port number:

1. Select **MENU > LAN > STATUS > PORT**.
2. choose one of the following:
  - **RAW-SOCKET**
  - **TELNET**
  - **VXI-11**
  - **DST**

The port number is displayed on the front panel.

## Selecting a remote command interface

This section provides the details of how to use a remote command interface to connect to the Series 2600A.

### VXI - 11

This command interfaces provides message boundaries, supports serial poll, and serial request (SRQ). You can expect a slower connection with this protocol.

### Raw socket

Use as an alternative to VXI -11. Raw socket offers a faster connection than VXI-11. However, raw socket does not support serial poll and serial request message boundaries.

### Dead socket connection

Use the dead socket connection to manually disconnect a dead session on any open socket. This forces the connection to close when the dead socket connection is closed.

## Configuring a telnet connection

The Series 2600A supports the telnet protocol that you can use over a TCP/IP connection to issue commands to the instrument. You can use a telnet connection to interact with scripts or issue commands in real-time.

---

**NOTE** This example uses HyperTerminal available with Microsoft Windows XP. Consult the help system for your version of Microsoft Windows to identify a compatible tool.

---

To connect with the Series 2600A using HyperTerminal on a Windows XP system, complete the following steps:

1. On the host PC, click **Start > Accessories > Communications > HyperTerminal**. A dialog box similar to the one shown in [Figure 16-5](#) should open.

Figure 16-5  
**Connection description**

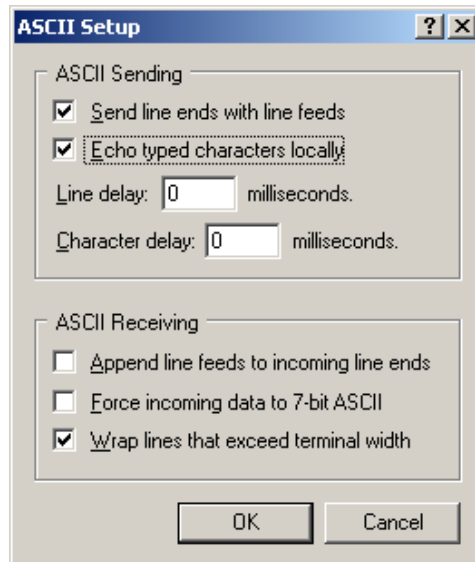

2. Type a name to identify the connection and then click **OK**.
3. Click the **Connect using** drop-down list and then select **TCP/IP (Winsock)** (see [Figure 16-6](#)).

Figure 16-6  
**Connect To dialog box**

4. In the **Host address** field, type the IP address.
5. Type **23** in the **Port number** field and then click **OK**.  
The HyperTerminal program window displays.
6. From the HyperTerminal program window, click **File > Properties**.
7. Choose the **Settings** tab and then click the **ASCII Setup** button.

Figure 16-7  
ASCII Setup window

8. Select the following options: ~~options~~ left blank intentionally.
  - Send line ends with line feeds
  - Echo typed characters locally
9. Click **OK**  
The Properties window displays.
10. Click **OK**.

---

## Web Interface and TSB Embedded

### In this section:

| Topic                                            | Page        |
|--------------------------------------------------|-------------|
| <b>Working with the web interface</b> .....      | <b>17-1</b> |
| Web browser requirements .....                   | 17-2        |
| Accessing the web interface .....                | 17-2        |
| Configuring IP addressing .....                  | 17-3        |
| <b>Password management</b> .....                 | <b>17-6</b> |
| Password overview .....                          | 17-6        |
| Accessing the virtual front panel .....          | 17-7        |
| Device identification indicator .....            | 17-8        |
| <b>Working with TSB Embedded</b> .....           | <b>17-9</b> |
| Using the Instrument Control Library (ICL) ..... | 17-9        |

## Working with the web interface

The Series 2600A has a web interface that you can use to access the following:

- Connection string
- LXI class
- Firmware version number
- MAC address
- Instrument model
- Connection string
- Virtual front panel
- TSB embedded

### Web browser requirements

The web interface uses different technologies to display information. If you cannot view the virtual front panel or other topics on the page, make sure your web browser meets the minimum requirements.

Table 17-1 displays the web browsers and the version tested with the Series 2600A.

Table 17-1

#### Web Browser Requirements

| Web browser                              | Version number |
|------------------------------------------|----------------|
| Microsoft Internet Explorer              | 6.0 or higher  |
| Mozilla Firefox                          | 1.5 or higher  |
| Java Platform Standard Edition (Java SE) | 6.0 or higher  |

### Welcome page overview

You can use the welcome web page to view the following information in read-only format:

- IP configuration
- Serial number
- LXI Class
- MAC address
- Host name
- Firmware revision number

### Accessing the web interface

Complete the following steps to log in to the web interface.

1. Open a web browser.
2. In the address bar, type the IP address for the instrument.

Figure 17-1 displays LXI welcome page.

Figure 17-1  
LXI Welcome page

**LXI Web Interface - Welcome Page**

|                            |                                                                                                                                      |

| Instrument Address String: | TCPIP[board]::192.168.0.11::5025::SOCKET<br>GPIB[board]::26::INSTR<br>ASRL[board]::INSTR<br>TCPIP[board]::192.168.0.11::inst0::INSTR |
| Smu A Calibration Date:    | Sat Jan 01 13:00:48 2005                                                                                                             |
| Smu A Calibration Due:     | Sat Jan 01 13:00:48 2005                                                                                                             |

You can use the LXI welcome page to retrieve the following information:

- LXI class
- Serial number
- Host name
- Port Number
- Instrument Address String
- IP, DNS, and gateway address
- Calibration dates

## Configuring IP addressing

Use the IP configuration page to review and to configure the Internet Protocol (IP) settings.

To modify the IP settings, complete the following steps.

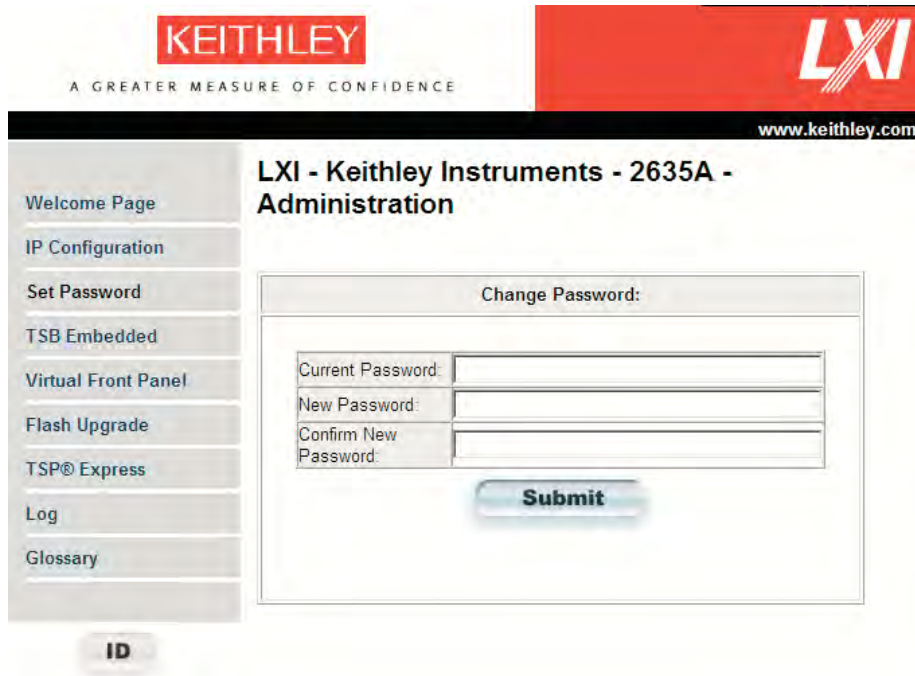

1. From the Welcome page, from the main menu click **IP Configuration**.

Figure 17-2  
IP configuration page

2. Click **Modify**.

Figure 17-3  
Password administration page

- If the unit has a password enabled, type the **Password** type the password and then click **Submit**. If password is not enabled, this page will not appear.

Figure 17-4  
**Modify IP configuration page**

The screenshot shows the 'Modify IP Configuration' page for a Keithley Instruments SMU 2636A. The page has a header with the Keithley logo and 'LXI' branding. A navigation menu on the left includes 'Welcome Page', 'IP Configuration', 'Set Password', 'TSB Embedded', 'Virtual Front Panel', 'Flash Upgrade', 'TSP® Express', 'Log', and 'Glossary'. The main form contains the following fields and options:

- Host Name: k-2636A-1175561
- Description: Keithley Instruments SMU 2636A - 1175561
- TCP/IP Configuration Mode:  Automatic,  Manual
- Static IP Address: 192.168.0.11
- Subnet Mask: 255.255.255.0
- Default Gateway: 0.0.0.0
- DNS Verify:  Enabled,  Disabled
- DDNS Enable:  Enabled,  Disabled
- DNS Servers: 0.0.0.0, 0.0.0.0
- Domain Name: (empty)
- Speed:  100 Mbs,  10 Mbs
- Duplex:  Full,  Half

A 'Submit' button is located at the bottom center of the form.

- Modify the desired field(s) and then click **Submit**.

---

**NOTE** You must reload the page if you change the gateway or subnet mask from the Modify IP configuration page.

---

---

**CAUTION** If you change the IP address, you must type the new IP address in the address bar before you can use the web interface.

---

## Password management

The Series 2600A has unique password capabilities that lets you decide how to password protect the instrument. You can enable password policies to lock the instrument which prevents unauthorized access to any remote interface and reserves the instrument exclusively for your use.

### Password overview

You can set the password to limit access to the web page and the command interface while you are away from your test area.

---

NOTE To reset the password, see "[Resetting the password](#)".

---

### Setting the password

---

NOTE Passwords can contain up to 255 characters.

---

If the password feature is enabled, a password is required to view and modify the following pages:

- IP configuration
- Set password
- TSB Embedded
- Virtual front panel
- Web page flash upgrade

Complete the following steps to set the password.

1. From the web interface, click **Set Password**.  
The LXI - Keithley Instruments -2602 - Administration page displays.
2. In the **Current Password** field, type the existing password.
3. In the **New Password** field, type the new password.
4. Retype the new password in the **Confirm Password** field.
5. Click **Submit**.  
The LXI Welcome page displays.

### Setting the password from a command interface

The attribute `localnode.passwordmode` enables passwords and sets the mode. The password mode identifies which interface to password protect.

Use one of the following attributes to set the password mode.

`localnode.PASSWORD_WEB`. Passwords are only required for the web interface.

`localnode.PASSWORD_LAN`. Enables passwords on all Ethernet and web interfaces.

`localnode.PASSWORD_ALL`. Protects the LAN, all command and web interfaces.

`localnode.PASSWORD_NONE`. Disables all passwords.

The password lock feature on Series 2600A is similar to the lock feature on your PC.

To enable the password feature, type the following from the command line:

```
localnode.password
```

---

**NOTE** You must enable passwords to use this feature.

---

To lock the instrument when you are away from the testing area, type the following command:

```
password
```

The remote interface locks. The Series 2600A does not respond to commands issued from the command line until you unlock the interface. This reserves the instrument and protects the test script running on the instrument.

### Unlocking the remote interface

If the remote interface is locked, you must enter the password before the Series 2600A responds to any command issued over a remote interface.

---

**NOTE** The password for the example below is Keithley.

---

To unlock the remote interface, type the following command

```
password Keithley
```

The Series 2600A unlocks and communicates with any remote interface.

### Resetting the password

If you forget the password, you can reset the password from the front panel. Once you enable the password feature, the Series 2600A stores this password until the LAN configuration is reset or you reset the password.

Complete the following steps to reset the password:

- From the front panel, press **MENU > RESET-PASSWORD**.

---

**NOTE** If you reset the LAN settings, you must re-enable the password feature.

---

## Accessing the virtual front panel

If the Series 2600A instrument is stored in a remote location, you can use the virtual front panel to access the features available from the front panel.

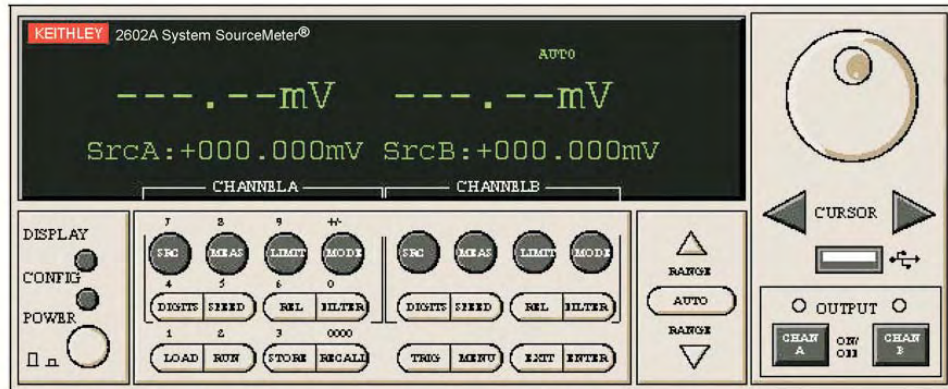

You can use the same features and functions that are available from the front panel with the exception of the following:

- Power button

Complete the following steps to access the virtual front panel.

1. From the web interface, click **Virtual Front Panel**.
2. (Optional) In the **Password** field, type the password and then click **Submit**.  
The virtual front panel displays.

Figure 17-5  
**Virtual front panel**

## Device identification indicator

You can use the ID button to physically locate the instrument that you are communicating with from the web interface. With this identification indicator enabled, the message LAN STATUS INDICATOR displays on the front panel of the instrument.

1. From the web interface, click  .  
The ID button illuminates, see [Figure 17-6](#).

Figure 17-6  
**ID Illuminated**

2. The front panel displays the LAN Status Indicator message.

Figure 17-7  
**LAN status indicator**

## Turning off the Device identification indicator

To turn off the ID indicator, Click **ID**.

The message LAN STATUS INDICATOR does not display on the front panel of the instrument.

## Working with TSB Embedded

TSB Embedded is an option to a full version of Test Script Builder (TSB) Suite. The capabilities of TSB Embedded are very similar to TSB. TSB Embedded includes a command line interface that you can use to issue ICL commands, create, modify, and save test scripts to the instrument.

### Using the Instrument Control Library (ICL)

The response from the instrument appears in the instrument output window.

Complete the following steps to issues commands from the command line.

1. To issue a ICL Command, type the command in the console and then click **Enter**.
2. (Optional) Click Clear to clear the Instrument output window.

### Creating scripts

Complete the following steps to create a new script:

1. Click in the script editor window and then type the first line of your script and then use the **Enter** key advance to line 2.
2. In the TSP Script line, type the name of the script and then click **Save script**.  
The instrument validates the syntax and then saves the script to the nonvolatile memory.

### Clearing the script editor window

- To remove the code from the script editor, click **Clear**.

### Running scripts

- To run a script, select the desired script from the User script window and then click **Run**.

### Stopping scripts

To stop a running script, click **Abort script**.

### Deleting scripts

To delete a script from TSB embedded, complete the following steps:

---

NOTE You cannot retrieve a deleted scripts

---

- Select the desired script from the user script window and then click **Delete**.

### Modifying scripts

Complete the following steps to modify a script:

1. Select the desired script from the User script window and then modify the desired code in the script editor.
2. Click **Save script** to validate the syntax and save the script.
3. The message, Script clearing will be overwritten displays, do one of the following:

- To overwrite the script, click **OK**.
- To save the script with a new name, click Cancel and then type the name of the script in the name field.

### Exporting Scripts

You can export a script to save to an external drive or to store as a back-up on your PC.

1. To export a script, click on the name of the script in the user script window and then click **Export**.  
The **Save** dialogue box displays.
2. Use the drop-down arrow to change folders, and navigate to the desired file or directory.
3. In the **File name** field, type the name of the file and then click **Save**.

## Overview

TSP-Net™ allows the Series 2600A to control Ethernet-enabled devices directly through its LAN port. This enables the Series 2600A to communicate directly with a non-TSP™-enabled device without the use of a controlling computer.

## TSP-Net capabilities

For both TSP™ and non-TSP devices, the TSP-Net library permits the Series 2600A to control a remote device through the LAN port. Using TSP-Net methods, you can transfer string data to and from a remote device, transfer and format data into Lua variables, and clear input buffers. TSP-Net is only accessible using ICL commands from a remote command interface and is not available from the front panel.

You can use TSP-Net to communicate with any Ethernet-enabled device. However, specific TSP-Net commands exist for TSP-enabled devices to allow for support of features unique to TSP. These features include script downloads, reading buffer access, wait completion, and handling of TSP prompts.

Using TSP-Net with TSP-enabled instruments, a Series 2600A can download a script to another TSP-enabled device and have both devices run scripts independently. The Series 2600A can read the data from the remote device and either manipulate the data or send the data to a different remote device on the LAN. You can simultaneously connect to a maximum of 32 devices using standard TCP/IP networking techniques through the LAN port of the Series 2600A.

## Using TSP-Net with any Ethernet-enabled device

---

NOTE Refer to [Section 19](#) for more details on the commands presented in this section.

---

To communicate to a remote Ethernet-enabled device from the Series 2600A, perform the following steps:

1. Connect to the remote device through the LAN port.

Use an Ethernet crossover cable to connect directly from the Series 2600A to an Ethernet-enabled device.

Use a straight-through Ethernet cable and a hub to connect the Series 2600A to any other device on the LAN.

2. Establish a new connection to a remote device at a specific IP address using `tspnet.connect`. For non-TSP™-enabled devices, you must also provide the port number, or the Series 2600A assumes the remote device to be TSP-capable and enables TSP prompts and error handling.

If the Series 2600A is not able to make a connection to the remote device, it generates a timeout error. Use `tspnet.timeout` to set the timeout value. The default timeout value is 20 seconds.

---

NOTE Set `tspnet.tsp.abortonconnect` to `TRUE` to abort any script currently running on a remote TSP device.

---

- Use `tspnet.write` or `tspnet.execute` to send strings to a remote device. Using `tspnet.write` sends strings to the device exactly as indicated, and you must supply any needed termination characters or other lines. Use `tspnet.termination` to specify the termination character. If you use `tspnet.execute` instead, the Series 2600A appends termination characters to all strings sent to the command.
- Retrieve responses from the remote device using `tspnet.read`. The Series 2600A suspends operation until data is available or a timeout error is generated. You can check if data is available from the remote device using `tspnet.readavailable`.

Disconnect from the remote device using `tspnet.disconnect`. Terminate all remote connections using `tspnet.reset`.

## Example script

The following example demonstrates how to connect to a remote non-TSP™-enabled device, and send and receive data from this device:

```
-- Disconnect all existing TSP-Net™ connections.
tspnet.reset()
-- Set tspnet timeout to 5 seconds.
tspnet.timeout = 5
-- Establish connection to another device with IP address 192.168.1.51
-- at port 1394.
id_instr = tspnet.connect("192.168.1.51",1394, "*rst\r\n")
-- Print the device ID from connect string.
print("ID is: ", id_instr)
-- Set termination character to CRLF. You must do this on a per
-- connection basis after connection has been made.
tspnet.termination(id_instr, tspnet.TERM_CRLF)
-- Send the command string to the connected device.
tspnet.write(id_instr,"*idn?" .. "\r\n")
-- Read the data available, then print it.
print("instrument write/read returns:: " , tspnet.read(id_instr))
-- Disconnect all existing TSP-Net sessions.
tspnet.reset()
```

## Using TSP-Net vs. TSP-Link for communication

TSP Link is the preferred communication method when communicating between the Series 2600A and another TSP™-enabled instrument. Using TSP Link has certain advantages over using TSP-Net, including:

- Error checking:** When connected to a TSP-enabled device, all errors that occur on the remote device are transferred to the error queue of the Series 2600A. The Series 2600A indicates errors from the remote device by prefacing these errors with "Remote Error".
- Digital I/O Triggering:** TSP Link connections have three TSP synchronization lines that are available to each device on the TSP Link network. You can use any one of the TSP synchronization lines to perform hardware triggering between devices on the TSP Link network.

These advantages make using TSP Link to control another TSP-enabled device the best choice for most applications. However, if the distance between the Series 2600A and the TSP-enabled device is longer than 15 feet, use TSP-Net.

To establish a remote TSP-Net connection with a TSP-enabled device, use `tspnet.connect` without specifying a port number. The Series 2600A enables TSP prompt and error handling for the remote device, which allows you to successfully use the `tspnet.tsp` set of commands to load and run scripts and retrieve reading buffers.

Abort any operation on the remote TSP-enabled device using `abort()`.

---

# Test Script Language (TSL)

## Introduction

A script is a program that the Test Script Processor (TSP) executes. A script is written using the Test Script Language (TSL). TSL is an efficient language, with simple syntax and extensible semantics. TSL is an implementation of the Lua programming language, Copyright © 1994-2004 Tecgraf, PUC-Rio. See <http://www.lua.org>, the official website for the Lua Programming Language, for more information. Also, <http://lua-users.org> internet site is created for and by users of the Lua programming language and is another source of useful information.

## Reserved words

|        |          |        |
|--------|----------|--------|
| and    | function | return |
| elseif | nil      | until  |
| for    | repeat   | else   |
| local  | true     | false  |
| then   | do       | in     |
| break  | if       | or     |
| end    | not      | while  |

## Variables and types

TSL has six basic types; nil, Boolean, number, string, function, and table. TSL is a dynamically typed language, which means variables do not need to be declared as a specific type. Instead, variables assume a type when a value is assigned to them. Therefore, each value carries its own type. If a variable has not been assigned a value, the variable defaults to the type nil. All numbers are real numbers. There is no distinction between integers and floating-point numbers in TSL.

```
-- var is nil.
var = nil
-- var is now a number.
var = 1.0
-- var is still a number.
var = 0.3E-12
-- var is still a number.
var = 7
-- var is now a string.
var = "Hello world!"
-- var is still a string.
var = "I said, Hello world!"
-- var is now a function that adds two numbers.
var = function(a, b) return(a+b) end
-- var is now a table (array) with three initialized members.
var = {1, 2., 3.00e0}
```

Nil is a type with a single value, nil, whose main property is to be different from any other value. Global variables have a nil value by default—before a first assignment—and you can assign nil to a global variable to delete it. TSL uses nil as a kind of non-value to represent the absence of a useful value.

## Operators

| Arithmetic Operators: | Relational Operators:      | Logical Operators: |
|-----------------------|----------------------------|--------------------|
| + (addition)          | < (less than)              | and                |
| - (subtraction)       | > (greater than)           | or                 |
| * (multiplication)    | <= (less than or equal)    | not                |
| / (division)          | >= (greater than or equal) |                    |
| - (negation)          | ~= (not equal)             |                    |
|                       | == (equal)                 |                    |

## Functions

TSL allows you to define functions. A function can take a predefined number of parameters and return multiple parameters if desired.

Here is an example of how to define a function and call it:

```
function add_two(parameter1, parameter2)
 return(parameter1 + parameter2)
end
print(add_two(3, 4))
```

Below is an alternate syntax for defining a function. Functions are first-class values in TSL, which means functions can be stored in variables, passed as arguments, and returned as results if desired.

```
add_three = function(parameter1, parameter2, parameter3)
 return(parameter1 + parameter2 + parameter3)
end
print(add_three(3, 4, 5))
```

Here is a function that returns multiple parameters; sum, difference, and ratio of the two numbers passed to it:

```
function sum_diff_ratio(parameter1, parameter2)
 psum = parameter1 + parameter2
 pdif = parameter1 - parameter2
 prat = parameter1 / parameter2
 return psum, pdif, prat
end
sum, diff, ratio = sum_diff_ratio(2,3)
print(sum)
print(diff)
print(ratio)
```

Output of code above:

```
7
12
5
-1
0.66666
```

## Tables/arrays

TSL makes extensive use of the data type “table,” which is essentially a very flexible array-like data type.

Define a table:

```
atable = {1, 2, 3, 4}
```

Print it:

```
-- Tables are indexed starting at one, NOT zero.
i = 1
-- atable[index] is true if there is an element at that index; nil is returned
-- otherwise. 0 does NOT evaluate to false - only nil does.
while atable[i] do
 -- Index into table using a number.
 print(atable[i])
 i = i + 1
end
```

Output of code above:

```
1
2
3
4
```

Tables can be indexed using element names instead of numeric indices. Since functions are first-class variables, tables can be used to create “pseudo-classes.” Classes are often used in object-oriented programming.

Below is a table used to create a circle pseudo-class. It has 3 elements:

clr: A string containing the color of the circle.

diam: A number containing the diameter of the circle.

setdiam: A function, or method, used to change the diameter.

```
circle = {clr = "red", diam = 1, setdiam = function(d)
 circle["diam"] = d end}
-- Index using a string; print the clr property.
print(circle["clr"])
-- Index using a string; print the diam property.
print(circle["diam"])
-- Change the diam element by calling setdiam method.
circle["setdiam"](2)
-- circle["diam"] is the same as circle.diam; simpler syntax.
print(circle.diam)
-- Change the diameter of the circle again.
circle.setdiam(3)
-- Print diam property again using simple syntax.
print(circle.diam)
```

Output of code above:

```
red
1
2
3
```

## Precedence

Operator precedence in TSL follows the table below, from higher to lower priority:

```

^
not- (unary)
* /
+ -
.. (concatenation)
< > <=>=~===
and
or

```

All operators are left associative, except for '^' (exponentiation) and '.', which are right associative. Therefore, the following expressions on the left are equivalent to those on the right:

```

a+i < b/2+1 (a+i) < ((b/2)+1)
5+x^2*8 5+((x^2)*8)
a < y and y <= z (a < y) and (y <= z)
-x^2 -(x^2)
x^y^z x^(y^z)

```

## Logical operators

The logical operators are `and`, `or`, and `not`. Like control structures, all logical operators consider `false` and `nil` as false and anything else as true. The operator `and` returns its first argument if it is false, otherwise it returns its second argument. The operator `or` returns its first argument if it is not false; otherwise it returns its second argument:

```

print(4 and 5)
print(nil and 13)
print(false and 13)
print(4 or 5)
print(false or 5)

```

Output of code above:

```

5
nil
false
4
5

```

Both `and` and `or` use short-cut evaluation, that is, they evaluate their second operand only when necessary. A useful TSL construct is `x = x or v`, which is equivalent to:

```

if not x then x = v end

```

For example, it sets `x` to a default value `v` when `x` is not set (provided that `x` is not set to `false`).

To select the maximum of two numbers `x` and `y`, use the following statement (note the `and` operator has a higher precedence than `or`):

```

max = (x > y) and x or y

```

When `x > y` is true, the first expression of the `and` is true, so the `and` results in its second argument `x` (which is also true, because it is a number), and then the `or` expression, results in the value of its first expression, `x`. When `x > y` is false, the `and` expression is false and so are the `or` results in its second expression, `y`.

The operator `not` always returns `true` or `false`:

```
print(not nil)
print(not false)
print(not 0)
print(not not nil)
```

Output of code above:

```
true
true
false
false
```

## Concatenation

TSL denotes the string concatenation operator by “.” (two dots). If any of its operands is a number, TSL converts that number to a string:

```
print("Hello " .. "World")
print(0 .. 1)
```

Output of code above:

```
Hello World
01
```

## Branching

TSL uses the “if” keyword to do conditional branching.

```
--
----- IF blocks -----
--
-- Zero IS true! This is a contrast to C where 0 evaluates false. In TSL,
-- both "nil" and false are false and everything else is true.
if 0 then
 print("Zero is true!")
else
 print("Zero is false.")
end

x = 1
y = 2
if (x and y) then
 print("' if ' expression 2 was not false.")
end

if (x or y) then
 print("' if ' expression 3 was not false.")
end

if (not x) then
 print("' if ' expression 4 was not false.")
else
 print("' if ' expression 4 was false.")
end

if x == 10 then
 print("x = 10")
elseif y > 2 then
 print("y > 2")
else
```

```
 print("x is not equal to 10, and y is not less than 2.")
end
```

Output of code above:

```
Zero is true!
' if ' expression 2 was not false.
' if ' expression 3 was not false.
' if ' expression 4 was false.
x is not equal to 10, and y is not less than 2.
```

## Loop control

TSL has familiar constructs for doing things repetitively and/or until an expression evaluates to false.

```
-- Something to iterate
list = {"One", "Two", "Three", "Four", "Five", "Six"}
--
----- FOR loop -----
--
print("Counting from one to three:")
for element = 1, 3 do
 print(element, list[element])
end
print("Counting from one to four,")
print("in steps of two:")
for element = 1, 4, 2 do
 print(element, list[element])
end
--
----- WHILE loop -----
--
print("Count elements in list")
print("on numeric index")
element = 1
-- Will exit when list[element] = nil
while list[element] do
 print(element, list[element])
 element = element + 1
end
--
----- REPEAT loop -----
--
print("Count elements in list")
print("using repeat")
element = 1
repeat
 print(element, list[element])
 element = element + 1
until not list[element]
```

Output of code above:

```
Counting from one to three:
1 One
```

```
2 Two
3 Three
Counting from one to four,
in steps of two:
1 One
3 Three
Counting elements in list
on numeric index
1 One
2 Two
3 Three
4 Four
5 Five
6 Six
Counting elements in list
using repeat
1 One
2 Two
3 Three
4 Four
5 Five
6 Six
```

## Command programming notes

### Conventions

For the following command reference, it is necessary to understand the following conventions:

#### Wild characters

Many source-measure unit (SMU) commands are expressed in a generic form using wild characters. A wild character indicates a SMU channel, function, or array index. Keep in mind that wild characters used in the generic form are NOT to be included in the command sent to the instrument.

#### X and Y

The *x* character is used for functions and attributes to indicate the SMU channel (*a* or *b*) and *y* is used to indicate the SMU function (*v*, *i*, *r*, or *p*). For example, the attribute for the source output setting is generically expressed as follows:

```
smuX.source.levelY
```

To program SMU Channel A to 5 Volts, the following command statement is to be sent to the instrument:

```
smua.source.levelv = 5.0
```

To program SMU channel B to 1 mA, the following command statement is to be sent to the instrument:

```
smub.source.leveli = 0.001
```

---

**NOTE** The wild characters *x* and/or *y* are NEVER sent to the instrument. They are used in this command reference for notational convenience only.

---

### [M] and [N]

The M and N characters, enclosed by brackets ([ ]), are used in functions and attributes anywhere an index is used in the command set.

Commands that use [M] include:

- `trigger.blender` commands use [M] for the 4 stimulus attributes.

Commands that use [N] include:

- TSP-Link lines
- Timers
- Event blenders

For example, the function to assert an output trigger is generically expressed as follows:

```
digio.trigger[N].assert
```

Where: [N] is the trigger number.

To program the Series 2600A to assert an output trigger on trigger line 5, the following command statement is sent to the instrument.

```
digio.trigger[5].assert()
```

---

**NOTE** The wild characters M and N should NOT to be sent to the instrument. However, the brackets ([ ]) must be included in the command.

---

## Functions and attributes

Commands can be function-based or attribute-based.

### Functions

Function based commands are used to control actions or activities. For example, performing a voltage measurement is a function (action) of a SMU. A function-based command is not necessarily directly related to a Series 2600A operation. For example, the `bit.bitand` function will logically AND two numbers.

Each function consists of a function name followed by a set of parenthesis (()). If the function does not have a parameter, the parenthesis set is left empty. Examples:

|                                   |                                            |
|-----------------------------------|--------------------------------------------|
| <code>digio.writeport(15)</code>  | Sets digital I/O lines 1, 2, 3 and 4 high. |
| <code>digio.writebit(3, 0)</code> | Sets line 3 low (0).                       |
| <code>smua.reset()</code>         | Returns SMU A to its default settings.     |
| <code>digio.readport()</code>     | Reads the digital I/O port.                |

The results of a function call are used by assigning the return values to variables and accessing those variables. The following code will measure SMU A voltage and return the reading:

```
reading = smua.measure.v()
```

```
print(reading)
```

```
Output: 2.360000e+00
```

The above output indicates that the voltage reading is 2.36V.

For a function that returns one value, the function call can be used in an expression. For example:

```
if smua.measure.v() > 5 then
 ...
end
```

## Attributes

An attribute is a characteristic of an instrument feature or operation. For example, some characteristics of a SMU source include the source function, range and output level.

### Assigning a value to an attribute

An attribute-based command can be used to assign a new value to an attribute. For many attributes, the value can be in the form of a discrete number or a predefined identifier. For example, filter type is an attribute. The moving average filter is selected by assigning either of the following values to the attribute:

```
0 OR smuX.FILTER_MOVING_AVG
```

Either of the following command messages will configure SMU A for the moving average filter:

```
smua.measure.filter.type = 0
smua.measure.filter.type = smua.FILTER_MOVING_AVG
```

Some attributes can take any numeric value that is within a valid range. For example, the Model 2601A/2602A voltage source can be set from -40.4V to +40.4V, while the Model 2611A/2612A voltage source can be set from -202V to +202V. The following command message sets the SMU A source level to 1.53V:

```
smua.source.levelv = 1.53
```

### Reading an attribute

Reading an attribute is accomplished by passing it to a function call as a parameter or by assigning it to another variable.

**Parameter passing example:** The following command reads the filter type for SMU A by passing the attribute to the `print` function, which outputs a value:

```
print(smua.measure.filter.type)
```

```
Output: 0.000000e+00
```

The above output indicates that the moving average filter is selected.

**Variable assignment example:** The following command reads the filter type by assigning the attribute to a variable named `filtertype`:

```
filtertype = smua.measure.filter.type
```

## Syntax rules

- Commands for functions and attributes are case sensitive. As a general rule, all function and attribute names must be in lower case, while parameters use a combination of lower and upper case characters. Upper case characters are required for attribute constants. Example:

```
smua.source.func = smua.OUTPUT_DCVOLTS
```

In the above command to select the volts source function, `OUTPUT_DCVOLTS` is the attribute constant.

- Whitespace in a function is not required. The function to set digital I/O line 3 low can be sent with or without whitespaces as follows:
 

```
digio.writebit(3,0) -- Whitespaces NOT used in string.
digio.writebit (3, 0) -- Whitespaces used in string.
```
- Some commands require multiple parameters. Multiple parameters must be separated by commas (,), as shown above for the `digio.writebit` function.

## TSP-Link nodes

Each instrument or enclosure attached to the TSP-Link bus must be uniquely identified. This identification is called a TSP-Link node number, and the enclosures are called nodes. Each node must be assigned a unique node number.

From a test script program point of view, nodes look like tables. There is one global table named `node` that contains all the actual nodes that are themselves tables. An individual node is accessed as `node[N]` where `N` is the node number assigned to the node. Each node has certain attributes that can be accessed as elements of its associated table. These are listed as follows:

- `model`            The product model number string of the node.
- `revision`        The product revision string of the node.
- `serialno`        The product serial number string of the node.

There is also an entry for each logical instrument on the node (see [Logical instruments](#)).

It is not necessary to know the node number of the node running a script. The variable `localnode` is an alias for the node entry the script is running on. For example, if a script is running on node 5, the global variable `localnode` will be an alias for `node[5]`.

## Logical instruments

You would normally refer to all instrumentation within one enclosure or node as a single instrument. For TSP and the Instrument Control Library (ICL), it is useful to think of individual SMUs as instruments. To avoid confusion, SMUs and other subdivisions of the instrumentation within an enclosure will be referred to as “logical instruments.”

Each logical instrument is given a unique identifier in a system. These identifiers are used as part of all ICL function calls that control a given logical instrument. The Series 2600A SMU has the following logical instruments in each enclosure:

|                        |                         |                     |                      |
|------------------------|-------------------------|---------------------|----------------------|
| <code>beeper</code>    | <code>errorqueue</code> | <code>serial</code> | <code>timer</code>   |
| <code>dataqueue</code> | <code>eventlog</code>   | <code>smua</code>   | <code>trigger</code> |
| <code>digio</code>     | <code>gpib</code>       | <code>smub</code>   | <code>tsplink</code> |
| <code>display</code>   | <code>lan</code>        | <code>status</code> | <code>tspnet</code>  |

Logical instruments also look like TSP tables. Each logical instrument has an element for each command that it supports. These commands are documented in this section. Note that `smua` and `smub` support the same command set and are documented jointly as `smuX`.

On any given node, the logical instrument identifiers from that node are also global variables. They can be accessed as elements of the node they belong or directly if running on that node. For example, to execute the `measure.v` command on `smua` on `node[5]`, one could use `node[5].smua.measure.v()`. If the command is being issued (executed) on `node[5]`, then `smua.measure.v()` is sufficient. Only be concerned with node numbers when controlling multiple units via the TSP-Link.

## Reading buffers

Readings can be obtained in multiple ways. Reading acquisition can be synchronous or overlapped. Furthermore, the routines that make single point measurements can be configured to make multiple measurements where only one would ordinarily be made. Also, consider that the measured value is not the only component of a reading. The measurement status (for example “In Compliance” or “Over ranged”) is also data associated with a particular reading.

All routines that return measurements can return them in reading buffers. Overlapped measurements are always returned in a reading buffer. Synchronous measurements return a single value or both a single value and a reading buffer. The more advanced user can use the reading buffer to access the additional information stored in the reading buffer.

A reading buffer is based on a TSL table. The measurements themselves are accessed by ordinary array access. If `rb` is a reading buffer, the first measurement is accessed as `rb[1]` and the 9<sup>th</sup> measurement as `rb[9]`, etc. The additional information in the table is accessed as additional members of the table. The following values are all available per reading buffer, i.e., `rb.appendmode`:

|                                  |                                                                                                                                                                                                                                                                  |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>appendmode</code>          | Off or on. If off, a new measurement to this buffer will overwrite the previous contents. If on, the first new measurement will be stored at what was formerly <code>rb[n+1]</code> . This attribute is initialized to off when the buffer is created.           |
| <code>basetimestamp</code>       | The time stamp of when the reading at <code>rb[1]</code> was stored, in seconds, since 12:00 am January 1, 1970 (UTC).                                                                                                                                           |
| <code>capacity</code>            | The total number of readings that can be stored in the reading buffer.                                                                                                                                                                                           |
| <code>collectsourcevalues</code> | When on, source values will be stored with readings in the buffer. This requires four extra bytes of storage per reading. This value, off or on, can only be changed when the buffer is empty. When the buffer is created, this attribute is initialized to off. |

The following values are available per reading, i.e., `rb.measurefunctions[3]`, as enabled. Each is actually a nested table. Related entries are stored at the same index as the relevant measurement.

|                                  |                                                                                                                                                                                                                                                                |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>collecttimestamps</code>   | When on, time stamps will be stored with readings in the buffer. This requires four extra bytes of storage per reading. This value, off or on, can only be changed when the buffer is empty. When the buffer is created, this attribute is initialized to off. |
| <code>n</code>                   | The number of readings in the reading buffer.                                                                                                                                                                                                                  |
| <code>timestampresolution</code> | The time stamp resolution, in seconds. When the buffer is created, its initial resolution is 0.000001 seconds. At this resolution, the reading buffer can store unique time stamps for up to 71 minutes. This value can be increased for very long tests.      |
| <code>measurefunctions</code>    | An array (TSL table) of strings indicating the function measured for the reading (Current, Voltage, Ohms or Watts).                                                                                                                                            |
| <code>measureranges</code>       | An array (TSL table) of full-scale range values for the measure range used when the measurement was made.                                                                                                                                                      |
| <code>readings</code>            | An array (TSL table) of the readings stored in the reading buffer. This array holds the same data that is returned when the reading buffer is accessed directly, i.e., <code>rb[2]</code> and <code>rb.readings[2]</code> are the same value.                  |
| <code>sourcefunctions</code>     | An array (TSL table) of strings indicating the source function at the time of the measurement (Current or Voltage).                                                                                                                                            |

|                                 |                                                                                                                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sourceoutputstates</code> | An array (TSL table) of strings indicating the state of the source (Off or On).                                                                                                                                                               |
| <code>sourceranges</code>       | An array (TSL table) of full-scale range values for the source range used when the measurement was made.                                                                                                                                      |
| <code>sourcevalues</code>       | If enabled (see <code>collectsourcevalues</code> above), an array (TSL table) of the sourced value in effect at the time of the reading.                                                                                                      |
| <code>statuses</code>           | An array (TSL table) of status values for all of the readings in the buffer. The status values are floating-point numbers that encode the status value into a floating-point value.                                                           |
| <code>timestamps</code>         | An array (TSL table) of time stamps, in seconds, between when the reading was acquired and when the first reading in the buffer was acquired. Adding this value to the base timestamp will give the actual time the measurement was acquired. |

For example, the number of readings the reading buffer can store is accessed as `rb.capacity`.

## Time and date values

Time and date values are represented as a number of seconds since some base. Representing time as a number of seconds is referred to as “standard time format.” There are three time bases:

1. UTC 12:00 am Jan 1, 1970. Reading buffer base timestamps, calibration dates, and the value returned by `os.time()` are all examples of UTC time.
2. When the Series 2600A is powered on. The value returned by `os.clock()` is referenced to the power-on time.
3. Time referenced to an event, such as the first reading stored in a reading buffer.

## Remote versus local state

The Series 2600A can be in either the local state or the remote state. When in the local state (REM indicator off), the instrument is operated using the front panel controls. When in the remote state (REM indicator on), instrument operation is being controlled by the PC. When the instrument is powered-on, it will be in the local state.

### Remote state

The following actions will place the instrument in the remote state:

- Sending a command from the PC to the instrument.
- Running a script (FACTORY or USER test) from the front panel. After the test is completed, the instrument will return to the local mode.
- Opening communications between the instrument and Test Script Builder.

While in the remote state, front panel controls are disabled. However, the **LOCAL** key will be active if it has not been locked out. When an interactive script is running, the front panel controls will be active to allow the operator to input parameter values.

### Local state

The following actions will cancel the remote state and return the instrument to the local state:

- Cycling power for the instrument.
- Pressing front panel **LOCAL** key (if it is not locked out).
- Sending the `abort` command from the PC.
- Clicking the Abort Execution icon on the toolbar of the Instrument Console for Test Script Builder.

- After a front panel script (FACTORY or USER test) is completed, the instrument will return to the local state.

### TSP-Link system

A test system can be expanded to include up to 32 TSP-Linked enabled instruments. The system can be stand-alone or PC-based. Details on system expansion using the TSP-Link are provided in [Section 14](#).

**Stand-alone system:** A script can be run from the front panel of any node (instrument) in the system. When a script is run, all nodes in the system go into remote operation (REM indicators turn on). The node running the script becomes the Master and can control all of the other nodes, which become its Slaves. When the script is finished running, all the nodes in the system return to local operation (REM indicators turn off), and the Master/Slave relationship between nodes is dissolved.

**PC-based system:** When using a PC, the LAN, GPIB, or RS-232 interface to any single node becomes the interface to the entire system. When a command is sent via one of these interfaces, all nodes go into remote operation (REM indicators turn on).

The node that receives the command becomes the Master and can control all of the other nodes, which become its Slaves. In a PC-based system, the Master/Slave relationship between nodes can only be dissolved by performing an abort.

## Standard libraries

In addition to the standard programming constructs above, TSL includes standard libraries that contain useful functions for string manipulation, mathematics and related functions. TSL also includes instrument control extension libraries. These libraries provide programming interfaces to the instrumentation accessible by the TSP. These libraries are automatically loaded when the TSP starts and do not need to be managed by the programmer.

| <code>print(x)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Prints the argument <code>x</code> to the active host interface, using the <code>toString()</code> function to convert <code>x</code> to a string (note that numbers are converted to scientific notation using <code>format.asciiprecision</code> ).                                                                                                                                                                                                                                                                                                                                                            |
| <code>collectgarbage([limit])</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Sets the garbage-collection threshold to the given limit (in Kbytes) and checks it against the byte counter. If the new threshold is smaller than the byte counter, then TSL immediately runs the garbage collector. If the limit parameter is absent, it defaults to 0 (thus forcing a garbage-collection cycle). See <b>Note</b> for more information.                                                                                                                                                                                                                                                         |
| <code>gcinfo()</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Returns the number of Kbytes of dynamic memory that TSP is using.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>tonumber(x [,base])</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Returns <code>x</code> converted to a number. If <code>x</code> is already a number, or a convertible string, then the number is returned; otherwise, it returns <code>nil</code> .<br>An optional argument specifies the base to interpret the numeral. The base may be any integer between 2 and 36, inclusive. In bases above 10, the letter 'A' (in either upper or lower case) represents 10, 'B' represents 11, and so forth, with 'Z' representing 35. In base 10, the default, the number may have a decimal part, as well as an optional exponent. In other bases, only unsigned integers are accepted. |
| <code>toString(x)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Receives an argument of any type and converts it to a string in a reasonable format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>type(v)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Returns the type of its only argument, coded as a string. The possible results of this function are: <code>nil</code> , <code>number</code> , <code>Boolean</code> , <code>table</code> , or <code>function</code> .                                                                                                                                                                                                                                                                                                                                                                                             |
| <p><b>NOTE:</b> TSL does automatic memory management. That means that you do not have to worry about allocating memory for new objects and freeing it when the objects are no longer needed. TSL manages memory automatically by running a garbage collector from time to time to collect all dead objects (that is, those objects that are no longer accessible from TSL). All objects in TSL are subject to automatic management: tables, variables, functions, threads, and strings. TSL uses two numbers to control its garbage-collection cycles. One number counts how many bytes of dynamic memory TSL is using; the other is a threshold. When the number of bytes crosses the threshold, TSL runs the garbage collector, which reclaims the memory of all dead objects. The byte counter is adjusted, and then the threshold is reset to twice the new value of the byte counter.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## String library functions

This library provides generic functions for string manipulation, such as finding and extracting substrings. When indexing a string in TSL, the first character is at position 1 (not 0 as in ANSI C). Indices may be negative and are interpreted as indexing backwards, from the end of the string. Thus, the last character is at position 1, and so on.

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>string.byte(s [,i])</code>            | Returns the internal numerical code of the <code>i</code> -th character of string <code>s</code> , or <code>nil</code> if the index is out of range.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>string.char(i1, i1, ...)</code>       | Receives 0 or more integers. Returns a string with length equal to the number of arguments, in which each character has the internal numerical code equal to its corresponding argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>string.format(fs, e1, e2, ...)</code> | Returns a formatted version of its variable number of arguments following the description given in its first argument, which must be a string. The format string follows the same rules as the print family of ANSI C functions. The only differences are that the options/modifiers <code>*</code> , <code>l</code> , <code>L</code> , <code>n</code> , <code>p</code> , and <code>h</code> are not supported. The options <code>c</code> , <code>d</code> , <code>E</code> , <code>e</code> , <code>f</code> , <code>g</code> , <code>G</code> , <code>l</code> , <code>o</code> , <code>u</code> , <code>X</code> , and <code>x</code> all expect a numeric argument, where <code>s</code> expects a string argument. String values to be formatted with <code>%s</code> cannot contain embedded zeros. |
| <code>string.len(s)</code>                  | Returns the length of the strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>string.lower(s)</code>                | Returns a copy of the string <code>s</code> with all uppercase letters changed to lowercase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>string.rep(s, n)</code>               | Returns a string that is the concatenation of <code>n</code> copies of the string <code>s</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>string.sub(s, i [, j])</code> | Returns the substring of <code>s</code> that starts at <code>i</code> and continues until <code>j</code> . <code>i</code> and <code>j</code> may be negative. If <code>j</code> is absent, then it is assumed to be equal to <code>-1</code> , which is the same as the string length. In particular, the call <code>string.sub(s, 1, j)</code> returns a prefix <code>s</code> with length <code>j</code> , and <code>string.sub(s, -i)</code> returns a suffix <code>s</code> with length <code>i</code> . |
| <code>string.upper(s)</code>        | Returns a copy of the string <code>s</code> with all lowercase letters changed to uppercase.                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Math library functions

This library is an interface to most of the functions of the ANSI C math library. All trigonometric functions work in radians. The functions `math.deg()` and `math.rad()` convert between radians and degrees.

|                                    |                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>math.abs(x)</code>           | Returns the absolute value of the argument <code>x</code> .                                                                                                                                                                                                                                                                                                      |
| <code>math.acos(x)</code>          | Returns the principal value of the trigonometric arc cosine function of <code>x</code> .                                                                                                                                                                                                                                                                         |
| <code>math.asin(x)</code>          | Returns the principal value of the trigonometric arc sine function of <code>x</code> .                                                                                                                                                                                                                                                                           |
| <code>math.atan(x)</code>          | Returns the principal value of the trigonometric arc tangent function of <code>x</code> .                                                                                                                                                                                                                                                                        |
| <code>math.atan2(y, x)</code>      | Returns the principal value of the trigonometric arc tangent function of <code>y/x</code> .                                                                                                                                                                                                                                                                      |
| <code>math.ceil(x)</code>          | Returns the smallest floating-point number not less than <code>x</code> whose value is an exact mathematical integer.                                                                                                                                                                                                                                            |
| <code>math.cos(x)</code>           | Returns the trigonometric cosine function of <code>x</code> .                                                                                                                                                                                                                                                                                                    |
| <code>math.deg(x)</code>           | Returns the value of <code>x</code> in degrees, where <code>x</code> is in radians.                                                                                                                                                                                                                                                                              |
| <code>math.exp(x)</code>           | Returns the exponential function of <code>x</code> ; that is, $e^x$ , where $e$ is the base of the natural logarithms.                                                                                                                                                                                                                                           |
| <code>math.floor(x)</code>         | Returns the largest floating-point number not greater than <code>x</code> whose value is an exact mathematical integer.                                                                                                                                                                                                                                          |
| <code>math.log(x)</code>           | Returns the natural logarithm function of <code>x</code> .                                                                                                                                                                                                                                                                                                       |
| <code>math.log10(x)</code>         | Returns the base-10 logarithm function of <code>x</code> .                                                                                                                                                                                                                                                                                                       |
| <code>math.max(x, y, ...)</code>   | Returns the maximum value of its numeric argument(s).                                                                                                                                                                                                                                                                                                            |
| <code>math.min(x, y, ...)</code>   | Returns the minimum value of its argument(s).                                                                                                                                                                                                                                                                                                                    |
| <code>math.mod(x, y)</code>        | Returns an approximation to the mathematical value <code>f</code> such that <code>f</code> has the same sign as <code>x</code> , the absolute value of <code>f</code> is less than the absolute value of <code>y</code> , and there exists an integer <code>k</code> such that $k*y+f = x$ .                                                                     |
| <code>math.pi</code>               | Variable containing the value of $\pi$ (3.141592654).                                                                                                                                                                                                                                                                                                            |
| <code>math.pow(x, y)</code>        | Returns $x^y$ .                                                                                                                                                                                                                                                                                                                                                  |
| <code>math.rad(x)</code>           | Returns the value of <code>x</code> in radians, where <code>x</code> is in degrees.                                                                                                                                                                                                                                                                              |
| <code>math.sin(x)</code>           | Returns the trigonometric sine function of <code>x</code> .                                                                                                                                                                                                                                                                                                      |
| <code>math.sqrt(x)</code>          | Returns the non-negative square root of <code>x</code> .                                                                                                                                                                                                                                                                                                         |
| <code>math.tan(x)</code>           | Returns the trigonometric tangent function of <code>x</code> .                                                                                                                                                                                                                                                                                                   |
| <code>math.frexp()</code>          | Splits <code>x</code> into a fraction <code>f</code> and exponent <code>n</code> , such that <code>f</code> is 0.0 or $0.5 \leq  f  < 1.0$ , and $f * 2^n$ is equal to <code>x</code> . Both <code>f</code> and <code>n</code> are returned; <code>f, n = math.frexp(x)</code> .                                                                                 |
| <code>math.ldexp(x, n)</code>      | Returns the inverse of the <code>math.frexp()</code> function; it computes the value $x * 2^n$ .                                                                                                                                                                                                                                                                 |
| <code>math.random([x], [y])</code> | When called without an argument, returns a pseudo-random real number in the range <code>[0, 1)</code> .<br>When called with number <code>x</code> , returns a pseudo-random integer in the range <code>[1, n]</code> .<br>When called with two arguments, <code>x</code> and <code>y</code> , returns a pseudo-random integer in the range <code>[x, y]</code> . |
| <code>math.randomseed(x)</code>    | Sets a "seed" for the pseudo-random generator. Equal seeds produce equal sequences of numbers.                                                                                                                                                                                                                                                                   |

## Instrument Control Library

### File I/O

Lua supports file I/O with its `io` library commands. A subset of these commands is supported for use with Series 2600A instruments. As with Lua `fs`, these commands are encapsulated as an `io` logical instrument so that the files on any given node are accessible to the entire TSP-Link system.

Lua organizes its file I/O commands into two groups:

1. Commands that reside in the `io` table, for example: `io.open`, `io.close`, `io.input`, and `io.output`. These commands are responsible for opening and closing file descriptors and performing basic I/O operations on a pair of default files, one input and one output.
2. Commands that reside in the file descriptors themselves (for example: `file.seek`, `file.write`, and `file.read`) operate exclusively on the file with which they are associated.

---

**NOTE** File descriptor command `s` for file I/O use a colon (:) to separate the command parts rather than a period (.) like the `io` commands.

---

Note that file descriptors cannot be passed between nodes in a TSP-Link system; as such, the `io.open`

command is not accessible via the TSP-Link. However, the default input and output files mentioned above allow for the execution of many file I/O operations without any reference to a file descriptor.

The following Lua I/O commands, which support basic file I/O, are included for your reference:

```
file:close
file:flush
file:read
file:seek
file:write
io.close
io.flush
io.input
io.open
io.output
io.read
io.write
io.type
```

The following standard I/O commands are not supported at this time:

```
file:lines
file:setvbuf
io.lines
io.popen
io.tmpfile
```

## beeper

The beeper generates a beep tone. It is typically used to announce the start and/or completion of a test or operation.

| <b>beeper.beep</b>     |                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Generates a beep tone.                                                                                                                                                                                                                                                                                                                             |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                         |

## bit

### Logic and bit operations

The bit functions are used to perform bitwise logic operations on two given numbers, and bit operations on one given number. Logic and bit operations truncate the fractional part of given numbers to make them integers.

**Logic operations:** The `bit.bitand`, `bit.bitor` and `bit.bitxor` functions in this group perform logic operations on two numbers. The TSP will perform the indicated logic operation on the binary equivalents of the two integers. Logic operations are performed bitwise. That is, Bit 1 of the first number is AND'ed, OR'ed, or XOR'ed with bit 1 of the second number. Bit 2 of the first number is AND'ed, OR'ed or XOR'ed with Bit 2 of the second number. This bitwise logic operation is performed on all corresponding bits of the two numbers. The result of a logic operation will be returned as an integer.

**Bit operations:** The rest of the functions in this group are used for operations on the bits of a given number. These functions can be used to clear a bit, toggle a bit, test a bit, set a bit (or bit field) and retrieve the weighted value of a bit (or field value). All of these functions use an `index` parameter to “point” to the bit position of the given number. The least significant bit of a given number has an index of 1, and the most significant bit has an index of 32.

| <b>bit.bitand</b>      |                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Performs a bitwise logical AND operation on two numbers.                                                                                                                                                                                                                                                                                                                 |
| TSP-Link accessibility | This function cannot be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                            |
| Usage                  | <pre>value = bit.bitand(value1, value2)</pre> <p> <code>value1</code>                      First number for the AND operation.<br/> <code>value2</code>                      Second number for the AND operation.<br/> <code>value</code>                         Returned result of the AND operation. </p>                                                             |
| Remarks                | <ul style="list-style-type: none"> <li>• This function performs a logical AND operation on two numbers.</li> <li>• Any fractional parts of <code>value1</code> and <code>value2</code> are truncated to make them integers. The returned <code>value</code> is also an integer.</li> <li>• See <a href="#">Logic and bit operations</a> for more information.</li> </ul> |
| Also see               | <a href="#">bit.bitor</a> , <a href="#">bit.bitxor</a>                                                                                                                                                                                                                                                                                                                   |
| Example                | <p>AND'ing decimal 10 (binary 1010) with decimal 9 (binary 1001) will return a value of decimal 8 (binary 1000):</p> <pre>value = bit.bitand(10, 9) print(value) Output: 8.000000e+00</pre>                                                                                                                                                                              |

| <b>bit.bitor</b>       |                                                                                                                                                                                                                                                                                                                                                                         |

| Usage                  | <pre>value = bit.setfield(value1, index, width, fieldvalue)</pre> <p>value1                      The given number.<br/>index                        Index position of the least significant bit of the field<br/>                                 1 to (33 – width).<br/>width                        Field width – number of bits in the field; 1 to 24.<br/>fieldvalue                   Value to write to the field.<br/>value                        Returned value of the new number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Remarks                | <ul style="list-style-type: none"> <li>This function returns <code>value</code>, which is <code>value1</code> with a field of bits overwritten, starting at the given <code>index</code> position. The <code>index</code> specifies the position of the least significant bit of the given field. The <code>width</code> bits starting at the given <code>index</code> will be set to the value given by <code>fieldvalue</code>. The least significant bit in <code>value1</code> has an index of 1 and the most significant bit has an index of 32.</li> <li>Prior to setting the field of bits, any fractional parts of <code>value1</code> and <code>fieldvalue</code> will be truncated to make them integers.</li> <li>If the <code>fieldvalue</code> is wider than the <code>width</code>, the extra most significant bits of the <code>fieldvalue</code> will be truncated. For example, assume the <code>width</code> is 4 bits, and the binary value for <code>fieldwidth</code> is 11110 (5 bits). The most significant bit of <code>fieldwidth</code> will be truncated, and a binary value of 1110 will be used as the <code>fieldvalue</code>.</li> <li>See <a href="#">Logic and bit operations</a> for more information.</li> </ul> |

| Example                | <p>The binary equivalent of decimal 10 is 1010. Toggling the bit at index position 3 will return a decimal value of 14 (binary 1110).</p> <pre>value = bit.toggle(10, 3) print(value)</pre> <p>Output: 1.400000e+01</p>                                                                                                                                                                                                                                                                                                                                                       |        |               |       |                                                    |       |                                   |

## data queue

You can use the data queue commands to share data between test scripts running in parallel and to access data from a remote group or a local node on a TSP-Link network. You can access data from the data queue even if a remote group or a local node has overlapped operations in process.

| <b>dataqueue.add</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Function               | Adds an entry into the data queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Usage                  | <pre>results = dataqueue.add(value) results = dataqueue.add(value, timeout)</pre> <p>value                                      The data item to add.</p> <p>timeout                                    The maximum number of seconds to wait for room in the data queue.</p> <p>results                                    The resulting value of <code>true</code> or <code>false</code> based on the success of the add function. Replace the word <code>results</code> with the name of the variable in which you want to store the result indicator.</p>                                                                                  |
| Remarks                | <ul style="list-style-type: none"> <li>You can only use the <code>timeout</code> value while adding data to the local data queue.</li> <li>The <code>timeout</code> value is ignored if the data queue is not full.</li> <li>The <code>dataqueue.add</code> function returns <code>false</code> if time-out expires before room is available in the data queue or if the data queue is full and a <code>timeout</code> value is not specified.</li> <li>If the value is a table, a duplicate of the table and any subtables is made. The duplicate table does not contain any references to the original table or to any subtables.</li> </ul> |
| Example                | <pre>dataqueue.add(10) dataqueue.add(10, 2) data_added = dataqueue.add(10, 3)</pre> <p>Use the following code to verify data was added to the data queue:</p> <pre>if not data_added then   print("timeout error") end</pre>                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>dataqueue.CAPACITY</b> |                                                                                                                                                                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute                 | The maximum number of entries that you can store in the data queue.                                                                                                                                                                                                |
| TSP-Link accessibility    | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                        |
| Usage                     | <pre>capacity = dataqueue.CAPACITY -- Reads dataqueue capacity dataqueue.CAPACITY = capacity -- Writes dataqueue capacity.</pre> <p>capacity                                    A custom variable that stores the maximum number of entries in the data queue.</p> |
| Remarks                   | A read only attribute.                                                                                                                                                                                                                                             |
| Example                   | <pre>print(dataqueue.CAPACITY)</pre>                                                                                                                                                                                                                               |

| <b>dataqueue.clear</b> |                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Clears the data queue.                                                                                                                                                                                                         |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                     |
| Usage                  | <code>dataqueue.clear()</code>                                                                                                                                                                                                 |
| Remarks                | <ul style="list-style-type: none"> <li>The <code>dataqueue.clear</code> command forces all <code>dataqueue.add</code> commands in progress to time-out.</li> <li>The function deletes all data from the data queue.</li> </ul> |

| <b>dataqueue.count</b> |                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | Stores the number of entries saved in the data queue.                                                                                                                                                                                                                    |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                              |
| Usage                  | <pre>count = dataqueue.count      -- Reads number of data queue entries. dataqueue.count = count     -- Writes number of data queue entries.</pre> <p><code>count</code>                      A custom variable that stores the number of entries in the data queue.</p> |
| Remarks                | This is a read-only attribute.                                                                                                                                                                                                                                           |

| <b>dataqueue.next</b>  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Removes the next entry from the data queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Usage                  | <pre>value = dataqueue.next() value = dataqueue.next(timeout)</pre> <p><code>timeout</code>                      The maximum number of seconds to wait for data in the data queue.</p> <p><code>value</code>                              The next entry in the data queue.</p>                                                                                                                                                                                                                                                                                     |
| Remarks                | <ul style="list-style-type: none"> <li>If the data queue is empty, the function waits up to the <code>timeout</code> value.</li> <li>If data is not available in the data queue before the <code>timeout</code> value expires, the return value is <code>nil</code>.</li> <li>The entries in the data queue are removed in a first in and first out order.</li> <li>If the value is a table, a duplicate of the original table and any subtables is made. The duplicate table does not contain any references to the original table or to any subtables.</li> </ul> |

## delay

This function is used to hold up system operation for a specified period of time. It is typically used to soak an instrument at a specific voltage or current for a period of time.

| <b>delay</b>           |                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Delays system operation.                                                                                                                                                                                                                                                                                                                |
| TSP-Link accessibility | This function cannot be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                           |
| Usage                  | <pre>delay(seconds)</pre> <p>seconds                                  Sets the delay in seconds (100,000 seconds maximum).</p>                                                                                                                                                                                                          |
| Remarks                | <ul style="list-style-type: none"> <li>This function will delay for the specified number of seconds. It is impossible to delay for zero seconds.</li> <li>Delay time will be at least the given number of seconds. Due to overhead, the actual delay will be 5-10 <math>\mu</math>s (typical) more than the requested delay.</li> </ul> |
| Example                | Sets SMU A output to 1V, soaks the DUT for 50ms and then turns the output off:<br><pre>smua.source.levelv = 1.0 delay(0.050) smua.source.off()</pre>                                                                                                                                                                                    |

## digio

The functions and attributes in this group are used to control read/write and trigger operations for the digital I/O port.

---

**NOTE** The digital I/O lines can be used for both input and output. If a line is being driven low, then a 0 value will be read by a command for that line. You must write a 1 to all digital I/O lines that are to be used as inputs.

---

| <b>digio.readbit</b>   |                                                                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Reads one digital I/O line.                                                                                                                                                                                                                     |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                      |
| Usage                  | <pre>data = digio.readbit(n)</pre> <p>data                                          A custom variable that stores the state of the I/O line.<br/>n                                                  Digital I/O number to be read (1 - 14).</p> |
| Remarks                | <ul style="list-style-type: none"> <li>A returned value of 0 indicates that the line is low. A returned value of 1 indicates that the line is high.</li> </ul>                                                                                  |
| Details                | See in <a href="#">Section 8</a> .                                                                                                                                                                                                              |
| Also see               | <a href="#">digio.readport</a> , <a href="#">digio.writebit</a> , <a href="#">digio.writeport</a>                                                                                                                                               |
| Example                | Assume line 4 is set high, and it is then read:<br><pre>data = digio.readbit(4) print(data)</pre> Output: 1.000000e+00                                                                                                                          |

| Remarks  | <ul style="list-style-type: none"> <li>You can express the mode as a number (0 through 8) or you can use one of the pre-defined constants.</li> <li>The custom variable <code>mode</code> stores the trigger mode as a numeric value when the attribute is read.</li> <li>The default trigger mode for a line is <code>digio.TRIG_BYPASS</code>. In this mode, the line can be directly controlled as a digital I/O line. When programmed to any other mode, the output state of the I/O line is controlled by the trigger logic and the user-specified output state of the line will be ignored.</li> <li>To control the line state, use the <code>digio.TRIG_BYPASS</code> mode with the <code>digio.writebit</code> and the <code>digio.writeport</code> commands.</li> </ul> |
| Details  | See <a href="#">Triggering</a> in <a href="#">Section 10</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Usage                  | <code>digio.writeport(data)</code><br><br><div style="display: flex; justify-content: space-between; width: 100%;"> <span><code>data</code></span> <span>Value to write to the port; 0 to 16383.</span> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Remarks                | <ul style="list-style-type: none"> <li>The binary representation of data indicates the output pattern to be written to the I/O port. For example, a data value of 170 has a binary equivalent of 00000010101010. Lines 2, 4, 6 and 8 are set high (1), and the other 10 lines are set low (0).</li> <li>Write protected lines will not be changed (see <a href="#">digio.writeprotect</a>).</li> <li>The <code>reset</code> function does not affect the present states of the digital I/O lines.</li> <li>Use the <code>digio.writebit</code> and <code>digio.writeport</code> commands to control the output state of the synchronization line while the trigger mode is set to <code>digio.TRIG_BYPASS</code>.</li> </ul> |
| Details                | See <a href="#">Controlling digital I/O lines</a> in <a href="#">Section 8</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Also see               | <a href="#">digio.readbit</a> , <a href="#">digio.readport</a> , <a href="#">digio.writebit</a> , <a href="#">digio.writebit</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Example                | Sets digital I/O lines 1 through 8 high (binary 00000011111111):<br><code>digio.writeport(255)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>digio.writeprotect</b> |                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute                 | Write protect mask that disables bits from being changed with the <code>digio.writebit</code> and <code>digio.writeport</code> functions.                                                                                                                                                                                                                      |
| Default                   | 0                                                                                                                                                                                                                                                                                                                                                              |
| TSP-Link accessibility    | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                    |
| Usage                     | <pre>mask = digio.writeprotect    -- Reads write protect mask. digio.writeprotect = mask    -- Writes write protect mask.</pre><br><div style="display: flex; justify-content: space-between; width: 100%;"> <span><code>mask</code></span> <span>Set to the value that specifies the bit pattern for write protect.</span> </div>                             |
| Remarks                   | <ul style="list-style-type: none"> <li>Bits that are set to 1 cause the corresponding line to be write protected.</li> <li>The binary equivalent of <code>mask</code> indicates the mask to be set for the I/O port. For example, a <code>mask</code> value of 7 has a binary equivalent 00000000000111. This mask write protects lines 1, 2 and 3.</li> </ul> |
| Details                   | See <a href="#">Controlling digital I/O lines</a> in <a href="#">Section 8</a> .                                                                                                                                                                                                                                                                               |
| Also see                  | <a href="#">digio.writebit</a> , <a href="#">digio.writeport</a> .                                                                                                                                                                                                                                                                                             |
| Example                   | Write protects lines 1, 2, 3 and 4:<br><code>digio.writeprotect = 15</code>                                                                                                                                                                                                                                                                                    |

## display

The functions and attributes in this group are used for various display operations, which are explained in [Section 11](#).

| <b>display.clear</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Clears all lines of the display.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Usage                  | <code>display.clear()</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Remarks                | <ul style="list-style-type: none"> <li>This function will switch to the user screen and then clear the display.</li> <li>The <code>display.clear()</code>, <code>display.setcursor()</code>, and <code>display.settext()</code> functions are overlapped, non-blocking commands. That is, the script will NOT wait for one of these commands to complete. These non-blocking functions do not immediately update the display. For performance considerations, they write to a shadow and will update the display as soon as processing time becomes available.</li> </ul> |
| Details                | See <a href="#">Clearing the display</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Usage                          | <pre>annun = display.getannunciators()</pre> <p>annun Returns the bitmap value for indicators that are active.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |             |                |                |     |                |      |   |   |      |   |     |      |   |    |     |    |     |    |   |   |     |    |      |      |   |   |      |    |      |     |   |    |      |    |      |      |   |    |     |    |      |         |   |    |      |    |       |      |   |     |     |    |       |
| Remarks                        | <ul style="list-style-type: none"> <li>This function returns a bitmap value that indicates which indicators are turned on. The 16-bit binary equivalent of the returned value is the bitmap. For example, assume the returned value is 1028. The binary equivalent for this value is as follows:<br/>0000010000000100</li> <li>The above bitmap indicates that bits 3 and 11 are set. From the chart below, bit 3 and bit 11 corresponds to the indicators that are turned on (<b>4W</b> and <b>REM</b>). Notice that the sum of the weighted values for bits 3 and 11 is the returned value (1028).</li> </ul> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>Annunciator</th> <th>Bit</th> <th>Weighted value</th> <th>Annunciator</th> <th>Bit</th> <th>Weighted value</th> </tr> </thead> <tbody> <tr> <td>FILT</td> <td>1</td> <td>1</td> <td>EDIT</td> <td>9</td> <td>256</td> </tr> <tr> <td>MATH</td> <td>2</td> <td>22</td> <td>ERR</td> <td>10</td> <td>512</td> </tr> <tr> <td>4W</td> <td>3</td> <td>4</td> <td>REM</td> <td>11</td> <td>1024</td> </tr> <tr> <td>AUTO</td> <td>4</td> <td>8</td> <td>TALK</td> <td>12</td> <td>2048</td> </tr> <tr> <td>ARM</td> <td>5</td> <td>16</td> <td>LSTN</td> <td>13</td> <td>4096</td> </tr> <tr> <td>TRIG</td> <td>6</td> <td>32</td> <td>SRQ</td> <td>14</td> <td>8192</td> </tr> <tr> <td>*(STAR)</td> <td>7</td> <td>64</td> <td>REAR</td> <td>15</td> <td>16384</td> </tr> <tr> <td>SMPL</td> <td>8</td> <td>128</td> <td>REL</td> <td>16</td> <td>32768</td> </tr> </tbody> </table> | Annunciator    | Bit         | Weighted value | Annunciator    | Bit | Weighted value | FILT | 1 | 1 | EDIT | 9 | 256 | MATH | 2 | 22 | ERR | 10 | 512 | 4W | 3 | 4 | REM | 11 | 1024 | AUTO | 4 | 8 | TALK | 12 | 2048 | ARM | 5 | 16 | LSTN | 13 | 4096 | TRIG | 6 | 32 | SRQ | 14 | 8192 | *(STAR) | 7 | 64 | REAR | 15 | 16384 | SMPL | 8 | 128 | REL | 16 | 32768 |

| <b>display.getcursor</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function                 | Reads the present position of the cursor for the user display.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| TSP-Link accessibility   | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Usage                    | <pre>row, column, style = display.getcursor()</pre> <p>row Returns the row for the present cursor position.<br/>column Returns the column for the present cursor position.<br/>style Returns the cursor style.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| Remarks                  | <ul style="list-style-type: none"><li>This function switches the display to the user screen, and then returns values to indicate row and column position, and cursor style.</li><li>The <code>row</code> value is returned as 1 (top row) or 2 (bottom row).</li><li>With the cursor in the top row, the <code>column</code> is returned as a value from 1 to 20. With the cursor in the bottom row, the <code>column</code> is returned as a value from 1 to 32. Columns are numbered from left to right on the display.</li><li>The returned value for <code>style</code> is 0 (invisible) or 1 (blink).</li></ul> |
| Details                  | See <a href="#">Cursor position</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Usage                  | <p>There are five ways to use this function:</p> <pre>text = display.gettext() text = display.gettext(embellished) text = display.gettext(embellished, row) text = display.gettext(embellished, row, column_start) text = display.gettext(embellished, row, column_start, column_end)</pre> <p>embellished                      Set to <code>false</code> to return text as a simple character string. Set to <code>true</code> to include all character codes.</p> <p>row                                Set to 1 or 2 to select which row to read text. If not included, text from both rows are read.</p> <p>column_start                    Set to starting column for reading text. Default is 1.</p> <p>column_end                      Set to ending column for reading text. Default is 20 (Row 1) or 32 (Row 2).</p>                                                                 |
| Remarks                | <ul style="list-style-type: none"> <li>The range of valid column numbers depends on which row is specified. For Row 1, valid column numbers are 1 to 20. For Row 2, valid column numbers are 1 to 32.</li> <li>Sending the command without any parameters returns both lines of the display. The <code>\$N</code> character code will be included to show where the top line ends and the bottom line begins.</li> <li>With <code>embellished</code> set to <code>true</code>, all other character codes will be returned along with the message. With <code>embellished</code> set to <code>false</code>, only the message and the <code>\$N</code> character code will be returned. See the <a href="#">display.settext</a> function for details on the character codes.</li> <li>The display will not be switched to the user screen. Text will be read from the active screen.</li> </ul> |
| Details                | See <a href="#">Displaying text messages</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Function                  | Displays a formatted input field that the operator can edit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| TSP-Link accessibility    | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| Usage                     | <p>There are four ways to use this function:</p> <pre>value = display.inputvalue(format) value = display.inputvalue(format, default) value = display.inputvalue(format, default, min) value = display.inputvalue(format, default, min, max)</pre> <table border="0"> <tr> <td style="padding-right: 20px;">format</td> <td>Defines format string for the input field using 0, the decimal point (.), polarity sign (+) and 'E' for exponent.</td> </tr> <tr> <td>default</td> <td>Set the default value for the parameter.</td> </tr> <tr> <td>min</td> <td>Set the minimum input value that can be set.</td> </tr> <tr> <td>max</td> <td>Set the maximum input value that can be set.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | format | Defines format string for the input field using 0, the decimal point (.), polarity sign (+) and 'E' for exponent. | default | Set the default value for the parameter. | min | Set the minimum input value that can be set. | max | Set the maximum input value that can be set. |
| format                    | Defines format string for the input field using 0, the decimal point (.), polarity sign (+) and 'E' for exponent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| default                   | Set the default value for the parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| min                       | Set the minimum input value that can be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| max                       | Set the maximum input value that can be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| Remarks                   | <ul style="list-style-type: none"> <li>Examples of the input field:<br/>+0.0000+00.0000E+000.00000E+0</li> <li><b>Value field:</b> <ul style="list-style-type: none"> <li>+ Include a "+" sign for positive/negative value entry. Not including the "+" sign prevents negative value entry.</li> <li>0 Defines the digit positions for the value. Up to six 0 can be used for the value (as shown above in the third and fourth examples).</li> </ul> </li> <li>.If used, include the decimal point (.) where needed for the value.</li> <li><b>Exponent field (optional):</b> <ul style="list-style-type: none"> <li>E Include the "E" for exponent entry.</li> <li>+ Include a "+" sign for positive/negative exponent entry. Not including the "+" sign prevents negative exponent entry.</li> <li>0 Defines the digit positions for the exponent.</li> </ul> </li> <li>Along with specifying the <i>format</i> for the input field, there are options to specify minimum and maximum limits for the input field. When NOT using the "+" sign for the value field, the minimum limit cannot be set to less than zero. When using the "+" sign, the minimum limit can set to less than zero (for example, -2).</li> <li>There is also an option to specify a default value. When this command is executed, the initially displayed value for the field will be the <i>default</i> value.</li> <li>The input value is limited to <math>\pm 1e37</math>.</li> </ul> |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| Remarks (cont.)           | <ul style="list-style-type: none"> <li>After sending this command, script execution waits for the operator to enter a value and press <b>ENTER</b>:</li> <li>If limits are used, the operator will not be able to input values outside the minimum and maximum limits.</li> <li>For positive and negative entry ("+" sign used for the value field and/or the exponent field), polarity of a non-zero value or exponent can be toggled by positioning the cursor on the polarity sign and turning the wheel. Polarity will also toggle when using the wheel to decrease or increase the value or exponent past zero. A zero value or exponent (for example +00) is always positive and cannot be toggled to negative polarity.</li> <li>After sending this command and pressing the <b>EXIT</b> key, <i>value</i> will return <i>nil</i>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |
| Details                   | See <a href="#">Parameter value prompting</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                   |         |                                          |     |                                              |     |                                              |

| Function                    | Adds an entry to the “USER TESTS” submenu of the “LOAD TEST” menu.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TSP-Link accessibility      | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Usage                       | <p>There are two ways to use this function:</p> <pre>display.loadmenu.add(displayname, chunk) display.loadmenu.add(displayname, chunk, memory)</pre> <p><code>displayname</code>                      Name to display in the menu.<br/> <code>chunk</code>                                      Chunk is the code to be executed.<br/> <code>memory</code>                                      Save or don't save <code>chunk</code> and <code>displayname</code> in nonvolatile memory.</p> <p>Set <code>memory</code> to one of the following values:<br/> 0 or <code>display.DONT_SAVE</code><br/> 1 or <code>display.SAVE</code><br/> The default <code>memory</code> setting is <code>display.SAVE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Remarks                     | <ul style="list-style-type: none"> <li>This function adds an entry to the “USER TESTS” submenu of the “LOAD TEST” menu. If the given item is subsequently selected via the front panel, the <code>chunk</code> will be executed when the <b>RUN</b> key is pressed.</li> <li>The <code>chunk</code> can be made up of scripts, functions, variables, and commands. With <code>memory</code> set to <code>display.SAVE</code>, commands are saved with the <code>chunk</code> in nonvolatile memory. Scripts, functions and variables used in the <code>chunk</code> are not saved by <code>display.SAVE</code>. Functions and variables need to be saved along with the script (see <a href="#">Loading and saving a user script</a> in <a href="#">Section 11</a>). If the script is not saved in nonvolatile memory, it will be lost when the Series 2600A is turned off. See <b>Example 1</b> below.</li> <li>It does not matter what order the menu items are added. They will be displayed in alphabetical order when the “USER TESTS” menu is selected.</li> </ul>                                                                                                                                                                                                              |
| Details                     | See <a href="#">Load test menu</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Also see                    | <a href="#">display.loadmenu.delete</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Examples                    | <p><b>Example 1:</b> Assume a script with a function named “DUT1” has already been loaded into the Series 2600A, and the script has NOT been saved in nonvolatile memory. Now assume you want to add a test named “Test” to the USER TESTS menu. You want the test to run the function named “DUT1” and sound the beeper. The following command will add “Test” to the menu, define the chunk, and then save <code>displayname</code> and <code>chunk</code> in nonvolatile memory:</p> <pre>display.loadmenu.add("Test", "DUT1() beeper.beep(2, 500)", display.SAVE)</pre> <p>When “Test” is run from the front panel USER TESTS menu, the function named “DUT1” will execute and the beeper will beep for two seconds.</p> <p>Now assume you cycle power on the Series 2600A. Since the script was not saved in nonvolatile memory, the function named “DUT1” is lost. When “Test” is again run from the front panel, the beeper will beep, but “DUT1” will not execute because it no longer exists in the chunk.</p> <p><b>Example 2:</b> Adds entry called “Part1” to the front panel “USER TESTS” load menu for the chunk “testpart([[Part1]], 5.0)”, and saves it in nonvolatile memory:</p> <pre>display.loadmenu.add("Part1", "testpart([[Part1]], 5.0)", display.SAVE)</pre> |

| <b>display.loadmenu.catalog</b> |                                                                                                                                                                                                                                                                         |

| Function               | Presents a menu on the front panel display.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Usage                  | <code>selection = display.menu(name, items)</code><br><br>name                                   Menu name to display on the top line.<br>items                                   Menu items to display on the bottom line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Remarks                | <ul style="list-style-type: none"> <li>The menu consists of the menu <code>name</code> string on the top line, and a selectable list of <code>items</code> on the bottom line. The menu items must be a single string with each item separated by white space. The name for the top line is limited to 20 characters.</li> <li>After sending this command, script execution waits for the operator to select a menu item. An item is selected by rotating the wheel (or using the cursor keys) to place the blinking cursor on the item, and then pressing the wheel (or <b>ENTER</b> key). When an item is selected, the text of that selection is returned.</li> <li>Pressing the <b>EXIT</b> key will not abort the script while the menu is displayed, but it will return <code>nil</code>. The script can be aborted by calling the <code>exit</code> function when <code>nil</code> is returned.</li> </ul> |
| Details                | See <a href="#">Menu</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Example                | Displays a menu with three menu items. If the second menu item is selected, <code>selection</code> will be given the value <code>Test2</code> :<br><code>selection = display.menu("Sample Menu", "Test1 Test2 Test3")</code><br><code>print(selection)</code><br>Output: Test2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>display.numpad</b>  |                                                                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | This attribute controls whether the front panel keys act as a numeric keypad during value entry.                                                                                                                                                                                                                                       |
| Default                | <code>display.ENABLE</code>                                                                                                                                                                                                                                                                                                            |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                            |
| Usage                  | <code>X = display.numpad            -- Read the numpad option.</code><br><code>display.numpad = X            -- Write the numpad option.</code><br><br>Where <code>X</code> is one of:<br>1 or <code>display.ENABLE</code> Enable the numeric keypad feature.<br>0 or <code>display.DISABLE</code> Disable the numeric keypad feature. |
| Remarks                | <ul style="list-style-type: none"> <li>The numeric keypad feature is only available when editing a numeric value and the EDIT indicator is lit.</li> </ul>                                                                                                                                                                             |
| Example                | Turn on the numeric keypad feature:<br><code>display.numpad = 1</code>                                                                                                                                                                                                                                                                 |

| Function               | Prompts the user to enter a parameter from the front panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| Usage                  | <p>There are four ways to use this function:</p> <pre>value = display.prompt(format, units, help) value = display.prompt(format, units, help, default) value = display.prompt(format, units, help, default, min) value = display.prompt(format, units, help, default, min, max)</pre> <table border="0"> <tr> <td style="padding-right: 20px;">format</td> <td>Define format string for the input field using 0, the decimal point (.), polarity sign (+) and 'E' for exponent.</td> </tr> <tr> <td>units</td> <td>Set units text string for top line (8 characters maximum).</td> </tr> <tr> <td>help</td> <td>Text string to display on the bottom line (32 characters maximum).</td> </tr> <tr> <td>default</td> <td>Set the default value for the parameter.</td> </tr> <tr> <td>min</td> <td>Set the minimum input value that can be set.</td> </tr> <tr> <td>max</td> <td>Set the maximum input value that can be set.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | format | Define format string for the input field using 0, the decimal point (.), polarity sign (+) and 'E' for exponent. | units | Set units text string for top line (8 characters maximum). | help | Text string to display on the bottom line (32 characters maximum). | default | Set the default value for the parameter. | min | Set the minimum input value that can be set. | max | Set the maximum input value that can be set. |
| format                 | Define format string for the input field using 0, the decimal point (.), polarity sign (+) and 'E' for exponent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| units                  | Set units text string for top line (8 characters maximum).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| help                   | Text string to display on the bottom line (32 characters maximum).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| default                | Set the default value for the parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| min                    | Set the minimum input value that can be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| max                    | Set the maximum input value that can be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |
| Remarks                | <ul style="list-style-type: none"> <li>This function will create an editable input field at the present cursor position, and an input prompt message on the bottom line. Example of a displayed input field and prompt:<br/>0.00V<br/>Input 0 to +2V</li> <li>The <code>format</code> configures the editable input field. Four examples for the format:<br/>+0.0000+00.0000E+000.0000E+0</li> <li><b>Value field:</b> <ul style="list-style-type: none"> <li>+ Include a "+" sign for positive/negative value entry. Not including the "+" sign prevents negative value entry.</li> <li>0 Defines the digit positions for the value. Up to six 0 can be used for the value (as shown above in the third and fourth examples).</li> <li>If used, include the decimal point (.) where needed for the value.</li> </ul> </li> <li><b>Exponent field (optional):</b> <ul style="list-style-type: none"> <li>E Include the "E" for exponent entry.</li> <li>+ Include a "+" sign for positive/negative exponent entry. Not including the "+" sign prevents negative exponent entry.</li> <li>0 Defines the digit positions for the exponent.</li> </ul> </li> <li><code>units</code> is a string that indicates the units (for example, "V" or "A") for the value and <code>help</code> provides a message prompt on the bottom line.</li> <li>Along with specifying the <code>format</code> for the input field, there are options to specify minimum and maximum limits for the input field. When NOT using the "+" sign for the value field, the minimum limit cannot be set to less than zero. When using the "+" sign, the minimum limit can set to less than zero (for example, -2).</li> <li>There is also an option to specify a default value. When this command is executed, the initially displayed value for the field will be the <code>default</code> value.</li> <li>The input value is limited to <math>\pm 1e37</math>.</li> <li>After sending this command, script execution holds and waits for the operator to enter a value and press <b>ENTER</b>.</li> <li>If limits are used, the operator will not be able to input values outside the minimum and maximum limits.</li> <li>For positive and negative entry ("+" sign used for the value field and/or the exponent field), polarity of a non-zero value or exponent can be toggled by positioning the cursor on the polarity sign and turning the wheel. Polarity will also toggle when using the wheel to decrease or increase the value or exponent past zero. A zero value or exponent (for example +00) is always positive and cannot be toggled to negative polarity.</li> <li>After sending this command and pressing the <b>EXIT</b> key, <code>value</code> will return <code>nil</code>.</li> </ul> |        |                                                                                                                  |       |                                                            |      |                                                                    |         |                                          |     |                                              |     |                                              |

| Function                 | Sets the position of the cursor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TSP-Link accessibility   | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Usage                    | <p>There are two ways to use this function:</p> <pre>display.setcursor(row, column) display.setcursor(row, column, style)</pre> <p><code>row</code>                                      Set <code>row</code> number for the cursor (1 or 2).<br/> <code>column</code>                                    Set <code>column</code> number for the cursor. For row 1, <code>column</code> can be set from 1 to 20. For row 2, it can be set from 1 to 32.<br/> <code>style</code>                                        Set cursor <code>style</code> to be invisible (0) or blink (1).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Remarks                  | <ul style="list-style-type: none"> <li>• Sending this command selects the user screen and then moves the cursor to the given location.</li> <li>• An out of range parameter for <code>row</code> will set the cursor to row 2. An out of range parameter for <code>column</code> will set the cursor to column 20 (for row 1) or 32 (for row 2).</li> <li>• An out of range parameter for <code>style</code> sets it to 0 (invisible).</li> <li>• A blinking cursor will only be visible when it is positioned over displayed text. It cannot be seen when positioned over a space character.</li> <li>• The <code>display.clear</code>, <code>display.setcursor</code>, and <code>display.settext</code> functions are overlapped, non-blocking commands. That is, the script will NOT wait for one of these commands to complete. These non-blocking functions do not immediately update the display. For performance considerations, they write to a shadow and will update the display as soon as processing time becomes available.</li> </ul> |
| Details                  | See <a href="#">Sending key codes</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Remarks  | <ul style="list-style-type: none"> <li>This function selects the user display screen, and displays the given text. The first write to the display after power on will clear the user screen.</li> <li>The text starts at the present cursor position. After the text is displayed, the cursor will be located after the last character in the display message.</li> <li>The text remains on the display until replaced or cleared.</li> <li>The following character codes can be also be included in the <code>text</code> string: <ul style="list-style-type: none"> <li><code>\$N</code>Newline – Starts text on the next line. If the cursor is already on line 2, text will be ignored after the '<code>\$N</code>' is received.</li> <li><code>\$R</code>Sets text to Normal.</li> <li><code>\$B</code> Sets text to Blink.</li> <li><code>\$D</code>Sets text to Dim intensity.</li> <li><code>\$F</code>Sets text to background blink.</li> <li><code>\$\$</code>Escape sequence to display a single "\$".</li> </ul> </li> <li>The <code>display.clear</code>, <code>display.setcursor</code>, and <code>display.settext</code> functions are overlapped, non-blocking commands. That is, the script will NOT wait for one of these commands to complete. These non-blocking functions do not immediately update the display. For performance considerations, they write to a shadow and will update the display as soon as processing time becomes available.</li> </ul> |
| Details  | See <a href="#">Displaying text messages</a> in <a href="#">Section 11</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Usage                  | <pre>key = display.waitkey()</pre> <p>key                                  The key code.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |              |          |               |          |         |          |      |    |           |    |         |    |        |    |      |    |         |    |               |     |          |    |     |    |                |     |          |    |           |    |            |    |      |    |           |    |            |    |          |    |         |    |         |    |          |    |         |    |       |    |            |    |       |    |      |    |            |    |      |    |            |    |              |    |               |    |            |    |            |    |              |     |           |    |        |    |               |     |
| Remarks                | <ul style="list-style-type: none"> <li>After sending this function, script execution will hold up until a front panel key or the wheel is pressed, or the wheel is turned. After pressing a control or turning the wheel, the key code value for that key will be returned. The chart shown below lists the key code value for each front panel control. The controls are listed alphabetically.</li> <li>If the <b>EXIT</b> key is pressed while this function is waiting for a keystroke, the script will not be aborted.</li> <li>A typical use for this function is to prompt the user to press <b>EXIT</b> to abort the script or press any other key to continue. If key code value 75 is returned (<b>EXIT</b> key pressed), then the <code>exit()</code> function can be called to abort the script. Sample code for this process is provided in <a href="#">Capturing key-press codes</a> in <a href="#">Section 11</a>.</li> </ul> <table border="1"> <thead> <tr> <th>Control</th> <th>Key code</th> <th>Control</th> <th>Key code</th> <th>Control</th> <th>Key code</th> </tr> </thead> <tbody> <tr> <td>AUTO</td> <td>73</td> <td>LIMIT (B)</td> <td>90</td> <td>REL (A)</td> <td>70</td> </tr> <tr> <td>CONFIG</td> <td>80</td> <td>LOAD</td> <td>95</td> <td>REL (B)</td> <td>67</td> </tr> <tr> <td>CURSOR (left)</td> <td>401</td> <td>MEAS (A)</td> <td>86</td> <td>RUN</td> <td>71</td> </tr> <tr> <td>CURSOR (right)</td> <td>103</td> <td>MEAS (B)</td> <td>83</td> <td>SPEED (A)</td> <td>94</td> </tr> <tr> <td>DIGITS (A)</td> <td>87</td> <td>MENU</td> <td>68</td> <td>SPEED (B)</td> <td>91</td> </tr> <tr> <td>DIGITS (B)</td> <td>84</td> <td>MODE (A)</td> <td>69</td> <td>SRC (A)</td> <td>79</td> </tr> <tr> <td>DISPLAY</td> <td>72</td> <td>MODE (B)</td> <td>66</td> <td>SRC (B)</td> <td>76</td> </tr> <tr> <td>ENTER</td> <td>82</td> <td>OUTPUT (A)</td> <td>88</td> <td>STORE</td> <td>78</td> </tr> <tr> <td>EXIT</td> <td>75</td> <td>OUTPUT (B)</td> <td>96</td> <td>TRIG</td> <td>92</td> </tr> <tr> <td>FILTER (A)</td> <td>77</td> <td>RANGE (down)</td> <td>84</td> <td>WHEEL (press)</td> <td>97</td> </tr> <tr> <td>FILTER (B)</td> <td>74</td> <td>RANGE (up)</td> <td>65</td> <td>WHEEL (left)</td> <td>107</td> </tr> <tr> <td>LIMIT (A)</td> <td>93</td> <td>RECALL</td> <td>85</td> <td>WHEEL (right)</td> <td>114</td> </tr> </tbody> </table> <ul style="list-style-type: none"> <li>The above chart lists the numeric key code values for the front panel controls. The key code value identifiers are listed in the documentation for <a href="#">display.sendkey</a> (for example, <code>display.KEY_RUN</code> is the identifier for the <b>RUN</b> key).</li> </ul> | Control      | Key code | Control       | Key code | Control | Key code | AUTO | 73 | LIMIT (B) | 90 | REL (A) | 70 | CONFIG | 80 | LOAD | 95 | REL (B) | 67 | CURSOR (left) | 401 | MEAS (A) | 86 | RUN | 71 | CURSOR (right) | 103 | MEAS (B) | 83 | SPEED (A) | 94 | DIGITS (A) | 87 | MENU | 68 | SPEED (B) | 91 | DIGITS (B) | 84 | MODE (A) | 69 | SRC (A) | 79 | DISPLAY | 72 | MODE (B) | 66 | SRC (B) | 76 | ENTER | 82 | OUTPUT (A) | 88 | STORE | 78 | EXIT | 75 | OUTPUT (B) | 96 | TRIG | 92 | FILTER (A) | 77 | RANGE (down) | 84 | WHEEL (press) | 97 | FILTER (B) | 74 | RANGE (up) | 65 | WHEEL (left) | 107 | LIMIT (A) | 93 | RECALL | 85 | WHEEL (right) | 114 |

| Example                | <p>The following code will hold up script execution and wait for the operator to press a key or the wheel, or rotate the wheel:</p> <pre>key = display.waitkey() print(key)</pre> <p>Output: 8.600000e+01</p> <p>The above output (86) indicates that the <b>MEAS (A)</b> key was pressed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |              |          |               |          |         |          |      |    |           |    |         |    |        |    |      |    |         |    |               |     |          |    |     |    |                |     |          |    |           |    |            |    |      |    |           |    |            |    |          |    |         |    |         |    |          |    |         |    |       |    |            |    |       |    |      |    |            |    |      |    |            |    |              |    |               |    |            |    |            |    |              |     |           |    |        |    |               |     |

## errorqueue

The functions and attribute in this group are used to read the entries in the error/event queue.

| errorqueue.clear       |                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------|
| Function               | Clears all entries out of the error/event queue.                                                                |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                      |
| Usage                  | <code>errorqueue.clear()</code>                                                                                 |
| Remarks                | <ul style="list-style-type: none"> <li>This function removes all entries from the error/event queue.</li> </ul> |

| Example                | <p>Reads number of entries in the error/event queue:</p> <pre>count = errorqueue.count print(count)</pre> <p>Output:<br/>4.000000e+00</p> <p>The above output indicates that there are four entries in the event/error queue.</p>                                                                                               |

| errorqueue.next        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Reads an entry from the error/event queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Usage                  | <pre>errorcode, message, severity, node = errorqueue.next()</pre> <p style="margin-left: 40px;"> <code>errorcode</code>                                      Returns the error code number for the entry.<br/> <code>message</code>                                              Returns the message that describes the entry.<br/> <code>severity</code>                                              Returns the severity level (0, 10, 20, 30 or 40).<br/> <code>node</code>                                                      Returns the node number where the error originated. </p> |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remarks  | <ul style="list-style-type: none"> <li>• Entries are stored in a first-in, first-out (FIFO) queue. This function reads the oldest entry and removes it from the queue.</li> <li>• Error codes and messages are listed in <a href="#">Table A-2</a> in <a href="#">Appendix A</a>.</li> <li>• If there are no entries in the queue, code 0, "Queue Is Empty" is returned.</li> <li>• Returned <i>severity</i> levels include the following: <ul style="list-style-type: none"> <li>• <b>0 Informational:</b> Indicates no error: "Queue is Empty".</li> <li>• <b>10 Informational:</b> Indicates an event or a minor error. Examples: "Reading Available" and "Reading Overflow".</li> <li>• <b>20 Recoverable:</b> Indicates possible invalid user input. Operation will continue but action should be taken to correct the error. Examples: "Exponent Too Large" and "Numeric Data Not Allowed".</li> <li>• <b>30 Serious:</b> Indicates a serious error and may require technical assistance. Example: "Saved calibration constants corrupted".</li> <li>• <b>40 Fatal:</b> Indicates that the Series 2600A is non-operational and will require service. Contact information for service is provided in <a href="#">Section 1</a>. Examples: "Bad SMU AFPGA image size", "SMU is unresponsive", and "Communication Timeout with DFPGA".</li> </ul> </li> <li>• In an expanded system, each TSP-Link enabled instrument is assigned a node number. <i>node</i> returns the node number where the error originated.</li> </ul> |
| Details  | See <a href="#">Appendix A</a> (Error and Status Messages) and <a href="#">Appendix C</a> (Status Model).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Example  | <p>Reads the oldest entry in the error/event queue:</p> <pre>errorcode, message = errorqueue.next() print(errorcode, message)</pre> <p>Output: 0.000000e+00 Queue Is Empty</p> <p>The above output indicates that the queue is empty.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## event log

You can use the event log to view specific details about LAN triggering events.

| <b>eventlog.all</b>    |                                                                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Returns all entries from the event log as a single string and then clears the event log.                                                                                                                                                                   |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                 |
| Usage                  | <pre>logstring = eventlog.all()</pre> <p>logstring                                      The returned string that includes all entries.</p>                                                                                                                 |
| Remarks                | Clears the event log after returning all entries as a single string.                                                                                                                                                                                       |
| Example                | <pre>print(eventlog.all())</pre> <p>Output:</p> <pre>17:26:35.690 10 Oct 2007, LAN0, 192.168.1.102, LXI, 0, 1192037132, 1192037155.733269000, 0, 0x0 17:26:39.009 10 Oct 2007, LAN5, 192.168.1.102, LXI, 0, 1192037133, 1192037159.052777000, 0, 0x0</pre> |

| <b>eventlog.clear</b>  |                                                                           |
|------------------------|---------------------------------------------------------------------------|
| Function               | Removes all entries from the event log.                                   |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                |
| Usage                  | <code>eventlog.clear()</code>                                             |
| Remarks                | <ul style="list-style-type: none"> <li>• Clears the event log.</li> </ul> |
| Example                | <code>eventlog.clear()</code>                                             |

| <b>eventlog.count</b>  |                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | Indicates the number of entries in the event log.                                                                                                                                                                                                             |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                   |
| Usage                  | <pre>count = eventlog.count                      -- Reads the count. eventlog.count = count                      -- Writes the count.</pre> <p>count                                                              The number of entries in the event log.</p> |
| Remarks                | <ul style="list-style-type: none"> <li>• Indicates the number of entries in the event log.</li> </ul>                                                                                                                                                         |
| Example                | <pre>print(eventlog.count)</pre> <p>Output:</p> <pre>3.000000000e+000</pre>                                                                                                                                                                                   |

| <b>eventlog.enable</b> |                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | The enabled or disabled status of the event log.                                                                                                                                                                                                                                               |
| Default                | eventlog.ENABLE                                                                                                                                                                                                                                                                                |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                    |
| Usage                  | <pre>enable = eventlog.enable    -- Reads event log status. eventlog.enable = enable    -- Writes event log status.</pre> <p>Set <code>enable</code> to one of the following values:</p> <pre>1 or eventlog.ENABLE      Event log enabled. 0 or eventlog.DISABLE     Event log disabled.</pre> |
| Remarks                | <ul style="list-style-type: none"> <li>When the event log is disabled, no new events will be logged, but existing events may be read and removed.</li> <li>When the event log is enabled, new events will be logged.</li> </ul>                                                                |
| Example                | <code>eventlog.enable = 0</code>                                                                                                                                                                                                                                                               |

| <b>eventlog.next</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Returns the next entry from the event log and removes it from the log.                                                                                                                                                                                                                                                                                                                                                         |

## format

The format attributes are used to configure the output formats used by the `print`, `printnumber`, and `printbuffer` functions. These attributes are used to set the data format (ASCII or binary), ASCII precision (number of digits) and binary byte order (normal or swapped).

| <b>format.asciiprecision</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The precision attribute is only used with the ASCII format. The precision must be a number between 1 and 16.</li> <li>Note that the precision is the number of significant digits printed. There will always be one digit to the left of the decimal point. Be sure to include this digit when setting the precision.</li> <li>The default (<code>reset</code>) precision is 6.</li> </ul> |

| Example                         | Selects the ASCII data format:<br><code>format.data = format.ASCII</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                |               |                                |                                          |                                 |                                          |                               |                                          |                                 |                                          |

## file system

You can use the file system functions to access files saved on the USB flash drive. A compatible non-Keithley application may be required to navigate in the file system or to view a list the files available.

These commands interact as an fs logical instrument on the TSP Platform to share a file system from any node over the entire TSP-Link network.

To allow for future enhancements, the root folder of the USB memory stick has the absolute path `"/usb1/"`. Both the forward slash (/) and backslash (\) are supported as directory separators.

| <b>fs.chdir</b>        |                                                                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Sets the current working directory.                                                                                                                                                           |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                    |
| Usage                  | <pre>fs.chdir(path)</pre> <p><code>path</code>                      The path of the new working directory. This path may be either absolute or relative to the current working directory.</p> |
| Remarks                | <ul style="list-style-type: none"> <li>• An error is logged to the error queue if the given path does not exist.</li> </ul>                                                                   |

## gpib

The following attribute is used to set the GPIB address.

| <b>gpib.address</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | GPIB address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Default                | 26                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Usage                  | <pre>address = gpib.address      -- Reads address. gpib.address = address      -- Writes address.</pre> <p>address                      Set from 0 to 30.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Remarks                | <ul style="list-style-type: none"> <li>• A new GPIB address takes effect when the command is processed. If there are response messages in the output queue when this command is processed they must be read at the new address.</li> <li>• The user should allow ample time for the command to be processed before attempting to communicate with the instrument again. After sending this command, make sure to use the new address to communicate with the instrument.</li> <li>• The GPIB address is stored in nonvolatile memory. The <code>reset</code> function has no effect on the address.</li> </ul> |
| Details                | See <a href="#">GPIB operation</a> in <a href="#">Section 15</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Example                | Sets the GPIB address of the Series 2600A to 26 and then reads the address: <pre>gpib.address = 26 address = gpib.address print (address) Output: 2.600000e+01</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## io

| <b>io.close</b>        |                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Closes a file.                                                                                                                                                                              |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                  |
| Usage                  | <pre>io.close() io.close(file)</pre> <p>file                              The descriptor of the file to close.</p>                                                                          |
| Remarks                | <ul style="list-style-type: none"> <li>• If a file is not specified, the default output file closes.</li> <li>• Only <code>io.close()</code> can be accessed from a remote node.</li> </ul> |

| <b>io.flush</b>        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Saves buffered data to a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Usage                  | <code>io.flush()</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Remarks                | <ul style="list-style-type: none"> <li>It is important to note that you must use the <code>io.flush</code> or <code>io.close()</code> commands to write data to the file system.</li> <li>Note: Data is not automatically written to a file when you use the <code>io.write</code> function.</li> <li>The <code>io.write</code> function will buffer data and it may not be written to the USB drive immediately while <code>io:flush</code> forces any buffered data to be written to the drive.</li> <li>This function only flushes the default output file.</li> </ul> |
| Also see               | <code>file:write</code> , <code>io.write</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## localnode

Use the attributes and functions in this section to set the power line frequency, control prompts (on and off), control error messages, (show and hide), to access global variables, and to run test scripts.

There are two different ways to use the `localnode` object.

- Send commands from the local node.
- Send commands from a remote node.

To send commands from the local node, use the `localnode` element:

```
localnode.linefreq = 50
```

---

**NOTE** Use the node reference to send commands from a remote node, do not use the `localnode` element.

---

```
node[n].linefreq = 50
```

---

**NOTE** Some `localnode` commands cannot be run on the local node. They must be run from a remote node.

---

| <b>localnode.autolinefreq</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Default                   | 60                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TSP-Link accessibility    | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Usage                     | <pre>frequency = localnode.linefreq --Reads line frequency. localnode.linefreq = frequency --Writes line frequency.</pre> <p>frequency                                  Set to 50 or 60.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Remarks                   | <ul style="list-style-type: none"> <li>• To achieve optimum noise rejection when performing measurements at integer NPLC apertures, the line frequency setting must match the frequency (50Hz or 60Hz) of the AC power line.</li> <li>• When used in an expanded system (TSP-Link), <code>localnode.linefreq</code> is sent to the remote master node only. Use <code>node[n].linefreq</code> (where <code>n</code> is the node number) to send the command to any node in the system. See <a href="#">Section 14</a> for details on TSP-Link.</li> <li>• When this attribute is set, the <code>localnode.autolinefreq</code> attribute is automatically set to false.</li> </ul> |
| Also see                  | <a href="#">localnode.autolinefreq</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Example                   | Sets the line frequency to 60Hz:<br><code>localnode.linefreq = 60</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>localnode.model</b> |                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | The instrument model.                                                                                                                                 |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                           |
| Usage                  | <pre>model = localnode.model -- Reads the node model.</pre> <p>model                                          The model number of the instrument.</p> |
| Remarks                | <ul style="list-style-type: none"> <li>• This is the model number of the instrument.</li> </ul>                                                       |

| Attribute                | Prompting mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Default                  | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TSP-Link accessibility   | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Usage                    | <pre>prompting = localnode.prompts -- Reads prompting state. localnode.prompts = prompting -- Writes prompting state.</pre> <p style="text-align: center;"><code>prompting</code>                      Set to 0 to disable or 1 to enable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Remarks                  | <ul style="list-style-type: none"> <li>• This attribute controls prompting. When it is set to 1, prompts are issued after each command message is processed by the instrument. When it is set to 0, prompts are not issued.</li> <li>• The command messages do not generate prompts. The Series 2600A generates prompts in response to command messages.</li> <li>• When the prompting mode is enabled, the Series 2600A generates prompts in response to command messages. There are three prompts that might be returned: <ul style="list-style-type: none"> <li>• "TSP&gt;" is the standard prompt. This prompt indicates that everything is normal and the command is done processing.</li> <li>• "TSP?" is issued if there are entries in the error queue when the prompt is issued. Like the "TSP&gt;" prompt, it indicates the command is done processing. It does not mean the previous command generated an error, only that there are still errors in the queue when the command was done processing.</li> <li>• "&gt;&gt;&gt;&gt;" is the continuation prompt. This prompt is used when downloading scripts or flash images. When downloading scripts or flash images, many command messages must be sent as a unit. The continuation prompt indicates that the instrument is expecting more messages as part of the current command.</li> </ul> </li> <li>• Test Script Builder (TSB) requires prompts. It sets the prompting mode automatically. If you disable prompting, use of the TSB will freeze because it will be waiting for the prompt that lets it know that the command is done executing. DO NOT disable prompting with the use of the TSB.</li> <li>• When used in an expanded system (TSP-Link), <code>localnode.prompt</code> is sent to the remote master node only. Use <code>node[n].prompt</code> (where <code>n</code> is the node number) to send the command to any node in the system. See <a href="#">Section 14</a> for details about TSP-Link.</li> </ul> |

| Function                     | Sets the local time zone.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TSP-Link accessibility       | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Usage                        | <pre>localnode.settimezone(offset) localnode.settimezone(offset, dst_offset, dst_start, dst_end)</pre> <p> <code>offset</code>                                 String representing offset from UTC.<br/> <code>dst_offset</code>                             String representing daylight savings offset from UTC.<br/> <code>dst_start</code>                             String representing when daylight savings time starts.<br/> <code>dst_end</code>                                String representing when daylight savings time ends. </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Remarks                      | <ul style="list-style-type: none"> <li>The time zone is only used when converting between local time and UTC time when using the <code>os.time</code> and <code>os.date</code> functions.</li> <li>If only one parameter is given, the same time offset is used throughout the year. If four parameters are given, time is adjusted twice during the year for daylight savings time.</li> <li><code>offset</code> and <code>dst_offset</code> are strings of the form "[+ -]hh[:mm[:ss]]" that indicate how much time must be added to the local time to get UTC time. <code>hh</code> is a number between 0 and 23 that represents hours, <code>mm</code> is a number between 0 and 59 that represents minutes, and <code>ss</code> is a number between 0 and 59 that represents seconds. The minutes and seconds fields are optional.</li> <li>The UTC-5 time zone would be specified with the string "5" because UTC-5 is 5 hours behind UTC and one must add 5 hours to the local time to get UTC time. The time zone UTC4 would be specified as "-4" because UTC4 is 4 hours ahead of UTC and 4 hours must be subtracted from the local time to get UTC.</li> <li><code>dst_start</code> and <code>dst_end</code> are strings of the form "MM.w.dw/hh[:mm[:ss]]" that indicate when daylight savings time begins and ends respectively. <code>MM</code> is a number between 1 and 12 that represents the month, <code>w</code> is a number between 1 and 5 that represents the week within the month, <code>dw</code> is a number between 0 and 6 that represents the day of the week where 0 is Sunday. The rest of the fields represent the time of day that the change takes effect. <code>hh</code> represents hours, <code>mm</code> represents minutes, and <code>ss</code> represents seconds. The minutes and seconds fields are optional.</li> <li>The week of the month and day of the week fields are not specific dates.</li> </ul> |

| Remarks | <ul style="list-style-type: none"> <li>• If this attribute is set to 1, the unit will automatically display any generated errors stored in the error queue, and then clear the queue. Errors will be processed at the end of executing a command message (just prior to issuing a prompt, if prompts are enabled).</li> <li>• If this attribute is set to 0, errors will be left in the error queue and must be explicitly read or cleared.</li> <li>• When used in an expanded system (TSP-Link), <code>localnode.showerrors</code> is sent to the remote master node only. Use <code>node[n].showerrors</code> (where <code>n</code> is the node number) to send the command to any node in the system. See <a href="#">Section 14</a> for details about TSP-Link.</li> </ul> |
| Details | See <a href="#">errorqueue</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## makegetter and makesetter

These functions are used create functions that set and retrieve the value of an attribute.

| makegetter                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                    |                                                 |                            |                                   |                     |                                                   |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|-------------------------------------------------|----------------------------|-----------------------------------|---------------------|---------------------------------------------------|
| Function                   | Creates a function to set the value of an attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                 |                            |                                   |                     |                                                   |
| TSP-Link accessibility     | This function cannot be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                    |                                                 |                            |                                   |                     |                                                   |
| Usage                      | <pre>getter = makegetter(table, attributename)</pre> <p> <table> <tr> <td><code>table</code></td> <td>Read-only table where the attribute is located.</td> </tr> <tr> <td><code>attributename</code></td> <td>The string name of the attribute.</td> </tr> <tr> <td><code>getter</code></td> <td>Function that returns the value of the attribute.</td> </tr> </table> </p>                                                                                                                                                                                            | <code>table</code> | Read-only table where the attribute is located. | <code>attributename</code> | The string name of the attribute. | <code>getter</code> | Function that returns the value of the attribute. |
| <code>table</code>         | Read-only table where the attribute is located.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                    |                                                 |                            |                                   |                     |                                                   |
| <code>attributename</code> | The string name of the attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                 |                            |                                   |                     |                                                   |
| <code>getter</code>        | Function that returns the value of the attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                 |                            |                                   |                     |                                                   |
| Remarks                    | <ul style="list-style-type: none"> <li>• This function creates a function that when called returns the value of the attribute. This function is useful for aliasing attributes to improve execution speed. Calling the <code>getter</code> function will execute faster than accessing the attribute directly.</li> <li>• Creating a <code>getter</code> function is only useful if it is going to be called several times. Otherwise the overhead of creating the <code>getter</code> function outweighs the overhead of accessing the attribute directly.</li> </ul> |                    |                                                 |                            |                                   |                     |                                                   |
| Example                    | <pre>Creates a getter function called getlevel: getlevel = makegetter(smua.source, "levelv") ... v = getlevel() When getlevel is called, it returns the value of smua.source.levelv.</pre>                                                                                                                                                                                                                                                                                                                                                                             |                    |                                                 |                            |                                   |                     |                                                   |

| makesetter                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                 |                            |                                   |                     |                                                |

| Usage                      | <pre>setter = makesetter(table, attributename)</pre> <p> <table> <tr> <td><code>table</code></td> <td>Read-only table where the attribute is located.</td> </tr> <tr> <td><code>attributename</code></td> <td>The string name of the attribute.</td> </tr> <tr> <td><code>setter</code></td> <td>Function that sets the value of the attribute.</td> </tr> </table> </p>                                                                                                                                                                                            | <code>table</code> | Read-only table where the attribute is located. | <code>attributename</code> | The string name of the attribute. | <code>setter</code> | Function that sets the value of the attribute. |
| <code>table</code>         | Read-only table where the attribute is located.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                 |                            |                                   |                     |                                                |
| <code>attributename</code> | The string name of the attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                 |                            |                                   |                     |                                                |
| <code>setter</code>        | Function that sets the value of the attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                 |                            |                                   |                     |                                                |
| Remarks                    | <ul style="list-style-type: none"> <li>• This function creates a function that when called sets the value of the attribute. This function is useful for aliasing attributes to improve execution speed. Calling the <code>setter</code> function will execute faster than accessing the attribute directly.</li> <li>• Creating a <code>setter</code> function is only useful if it is going to be called several times. Otherwise the overhead of creating the <code>setter</code> function outweighs the overhead of accessing the attribute directly.</li> </ul> |                    |                                                 |                            |                                   |                     |                                                |

|         |                                                                                                                                                                                                                                           |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | <pre>Creates a setter function called setlevel: setlevel = makesetter(smua.source, "levelv") for v = 1, 10 do   setlevel(v) end Using setlevel in the loop sets the value of smua.source.levelv, thereby performing a source sweep.</pre> |

## opc

This function sets the OPC bit in the status register when all overlapped commands are completed.

| opc                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Usage                  | <p>There are multiple ways to use this function, the use depends on the number of tables or reading buffer subtables that are specified:</p> <pre>printbuffer(start_index, end_index, st_1) printbuffer(start_index, end_index, st_1, st_2) printbuffer(start_index, end_index, st_1, st_2, ..., st_n)</pre> <p>start_index                      Starting index of values to print.<br/> end_index                          Ending index of values to print.<br/> st_1, st_2, ... st_n              Tables or reading buffer subtables from which to print.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Remarks                | <ul style="list-style-type: none"> <li>• Correct usage when there are no outstanding overlapped commands to acquire data:</li> <li>• <math>1 \leq \text{start\_index} \leq \text{end\_index} \leq n</math></li> <li>• Where <math>n</math> refers to the index of the last entry in the tables to be printed.</li> <li>• If <math>\text{end\_index} &lt; \text{start\_index}</math> or <math>n &lt; \text{start\_index}</math>, no data will be printed. If <math>\text{start\_index} &lt; 1</math>, 1 will be used as the first index. If <math>n &lt; \text{end\_index}</math>, <math>n</math> will be used as the last index.</li> <li>• When any of the given reading buffers are being used in overlapped commands that have not yet completed at least to the desired index, this function will return data as it becomes available.</li> <li>• When there are outstanding overlapped commands to acquire data, <math>n</math> refers to the index that the last entry in the table will have after all the measurements have completed.</li> <li>• If you do not specify a subtable in a reading buffer, default subtables are automatically used. The readings subtable is the default for the Series 2600A reading buffers.</li> <li>• At least one table or subtable must be specified.</li> <li>• This command generates a single response message that contains all data. The response message is stored in the output queue.</li> <li>• The <code>format.data</code> attribute controls the format of the response message.</li> </ul> |

| Function               | Reads data from the serial port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Usage                  | <pre>data = serial.read(maxchars)</pre> <p><code>maxchars</code>                      The maximum number of characters to read.<br/> <code>data</code>                                Returns a string consisting of all data read from the serial port.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Remarks                | <ul style="list-style-type: none"> <li>• This function will read available characters from the serial port. It will not wait for new characters to arrive. As long as <code>maxchars</code> is a relatively small number (less than several hundred characters), all characters received by the serial port prior to the call will be returned. This might be less than <code>maxchars</code>. If too many characters are received in between calls to this function, the RS-232 buffers will overflow and some characters may be lost.</li> <li>• This function can be called as many times as necessary to receive the required number of characters. For optimal performance, it is suggested that a small delay be used between repeat calls to this function.</li> <li>• The data returned is the raw data stream read from the port. Control characters, terminator characters, etc. will not be interpreted nor will the data stream be altered in any way.</li> <li>• This function cannot be used if the serial port is enabled as a command interface. A settings conflict error will be generated if the serial port is enabled as a command interface when this function is called.</li> </ul> |

| Example                | <p>Reads data from the serial port:</p> <pre>data = serial.read(200) print(data)</pre> <p>Output: John Doe<br/> The above output indicates that the string "John Doe" was read from the serial port.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>serial.write</b>    |                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Writes data to the serial port.                                                                                                                                                                                                                                          |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                               |
| Usage                  | <pre>serial.write(data)</pre> <p><code>data</code>                                Specify the data string to write.</p>                                                                                                                                                  |
| Remarks                | This function will write the given string to the serial port where it can be read by equipment (for example, a component handler) connected to the other end of the serial port. No terminator characters are added to the data. The data will be written exactly as is. |
| Also see               | <a href="#">serial.read</a>                                                                                                                                                                                                                                              |
| Example                | <p>Writes data string "1 2 3 4" to the serial port:</p> <pre>serial.write("1 2 3 4")</pre>                                                                                                                                                                               |

## setup

The functions and attribute in this group are used to save/recall setups and to set the power-on setup.

| <b>setup.poweron</b>   |                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute              | The saved setup to recall when the unit is turned on.                                                                                                                                                                             |
| Default                | 0                                                                                                                                                                                                                                 |
| TSP-Link accessibility | This attribute can be accessed from a remote TSP-Link node.                                                                                                                                                                       |
| Usage                  | <pre>n = setup.poweron          -- Reads the power-on setup. setup.poweron = n          -- Writes the power-on setup.  n                          Setup number to recall on power up (0 to 5).</pre>                              |
| Remarks                | <ul style="list-style-type: none"> <li>For an <code>n</code> setting of 0, the unit powers up to the factory default (reset) setup. For an <code>n</code> setting of 1 to 5, the unit powers up to a user saved setup.</li> </ul> |
| Details                | See <a href="#">Power-up</a> in <a href="#">Section 1</a> .                                                                                                                                                                       |
| Example                | Sets unit to power on to the factory defaults:<br><code>setup.poweron = 0</code>                                                                                                                                                  |

| <b>setup.recall</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function               | Recalls settings from a saved setup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| TSP-Link accessibility | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Usage                  | <pre>setup.recall(id)  id                          The setup ID.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Remarks                | <ul style="list-style-type: none"> <li>If a number (<code>n</code>), this parameter is interpreted as a setup number, and the setup is restored from internal memory. If it is a string, this parameter is interpreted as a path and file name, and the setup is restored from the corresponding file on the memory stick. The path may be absolute or relative to the current working directory.</li> <li>For an <code>n</code> setting of 0, the unit recalls the factory default (reset) setup. For an <code>n</code> setting of 1 to 5, the unit recalls a user saved setup from the internal nonvolatile memory.</li> <li>Saved setup settings can also be loaded from a USB memory stick. If <code>id</code> is a string, the setup will be recalled from the memory stick and <code>id</code> is the file name as described above.</li> </ul> |
| Details                | See <a href="#">User setup</a> in <a href="#">Section 3</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Remarks                                                                              | <ul style="list-style-type: none"> <li>This attribute controls which polarity calibration constants are used to make all subsequent measurements. This attribute does not affect the <code>smuX.measure.calibrateY</code> or the <code>smuX.source.calibrateY</code> function. The polarity for those commands are dictated by the range parameter given to the command.</li> <li>The measurement calibration commands require the measurements provided to have been made using the polarity being calibrated. When the calibration points are sufficiently far away from zero the desired polarity constants are inherently used when making those measurements. When measuring near zero, it is possible for the measurement to be made using the calibration constants from either polarity without knowing which was used. Setting this attribute to positive or negative forces measurements to be made using the calibration constants for a given polarity rather than basing the choice on the raw measurement data.</li> <li>This attribute can only be set to positive or negative when calibration is unlocked. This attribute will automatically be set back to CAL_AUTO when calibration is locked.</li> </ul> |

An autozero is performed when needed.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                          |
| Remarks                      | <ul style="list-style-type: none"> <li>• The Series 2600A uses a ratio metric A/D conversion technique. To ensure accuracy of readings, the instrument must periodically obtain fresh measurements of its internal ground and voltage reference. The time interval between needing to update these reference measurements is determined by the integration aperture being used for measurements. Separate reference and zero measurements are used for each aperture.</li> <li>• By default, the instrument automatically checks these reference measurements whenever a signal measurement is made. If the reference measurements have expired when a signal measurement is made, the instrument will automatically take two more A/D conversions, one for the reference and one for the zero, before returning the result. Thus, occasionally, a measurement takes longer than normal.</li> <li>• This extra time can cause problems in sweeps and other test sequences in which measurement timing is critical. To avoid the extra time for the reference measurements in these situations, the <code>smuX.measure.autozero</code> attribute can be used to disable the automatic reference measurements. Keep in mind that with automatic reference measurements disabled, the instrument may gradually drift out of specification.</li> <li>• To minimize the drift, a reference and zero measurement should be made just prior to the critical test sequence. The <code>smuX.AUTOZERO_ONCE</code> setting can be used to force a refresh of the reference and zero measurements used for the current aperture setting.</li> <li>• Autozero reference measurements for the last 10 used NPLC settings are stored in a reference cache. If an NPLC setting is selected and an entry for it is not in the cache, the oldest (least recently used) entry will be discarded to make room for the new entry.</li> </ul> |                          |
| Example                      | Perform autozero once for SMU A:<br><code>smua.measure.autozero = smua.AUTOZERO_ONCE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                          |

| range                          | The measurement range to calibrate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                  |       |                                     |             |                                                         |              |                                                                           |             |                                                         |              |                                                                |
| cp1measured                    | The value measured by this SMU for calibration point 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                  |       |                                     |             |                                                         |              |                                                                           |             |                                                         |              |                                                                |
| cp1reference                   | The reference measurement for calibration point 1 as measured externally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                  |       |                                     |             |                                                         |              |                                                                           |             |                                                         |              |                                                                |
| cp2measured                    | The value measured by this SMU for calibration point 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                  |       |                                     |             |                                                         |              |                                                                           |             |                                                         |              |                                                                |
| cp2reference                   | The reference measurement for calibration measured externally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                  |       |                                     |             |                                                         |              |                                                                           |             |                                                         |              |                                                                |
| Remarks                        | <ul style="list-style-type: none"> <li>This function generates and activates new calibration constants for the given range. The positive and negative polarities of the instrument must be calibrated separately. Use a positive value for <code>range</code> to calibrate the positive polarity and a negative value for <code>range</code> to calibrate the negative polarity.</li> <li>Typically the two calibration points used will be near zero for calibration point 1 and 90% of full-scale for calibration point 2.</li> <li>All four measurements (<code>cp1measured</code>, <code>cp1reference</code>, <code>cp2measured</code>, and <code>cp2reference</code>) <b>must</b> be made with the active calibration set. Corruption of the calibration constants may result if this is not heeded.</li> <li>The new calibration constants will be activated immediately but they will not be written to nonvolatile storage. Use <code>smuX.cal.save</code> to commit the new constants to nonvolatile storage. The active calibration constants will stay in effect until the instrument is power cycled or a calibration set is loaded from nonvolatile storage with the <code>smuX.cal.restore</code> function.</li> <li>This function will be disabled until a successful call to <code>smuX.cal.unlock</code> is made.</li> </ul> |                                                                                                  |       |                                     |             |                                                         |              |                                                                           |             |                                                         |              |                                                                |

| Remarks                                                  | <ul style="list-style-type: none"> <li>• There are two averaging filter types to choose from: repeating and moving. For the repeating filter (which is the power-on default), the stack (filter count) is filled, and the conversions are averaged to yield a reading. The stack is then cleared, and the process starts over.</li> <li>• The median filter uses a first-in, first-out stack. When the stack (filter count) becomes full, the “middle-most” reading is returned. For each subsequent conversion placed into the stack, the oldest reading is discarded. The stack is then re-sorted, yielding a new reading. If the filter count is an even number, the reading returned is the average of the two middle readings.</li> <li>• The moving average filter uses a first-in, first-out stack. When the stack (filter count) becomes full, the measurement conversions are averaged, yielding a reading. For each subsequent conversion placed into the stack, the oldest conversion is discarded. The stack is re-averaged, yielding a new reading.</li> <li>• The <code>reset</code> function selects the repeat filter.</li> </ul> |                                          |                                    |                                          |                            |                                      |                            |

| Function                        | Starts an asynchronous (background) measurement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                             |
| TSP-Link accessibility          | This function can be accessed from a remote TSP-Link node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                             |
| Usage                           | <p>There are several ways to use this function:</p> <pre>smuX.measure.overlappedv(rbuffer) smuX.measure.overlappedi(rbuffer) smuX.measure.overlappedr(rbuffer) smuX.measure.overlappedp(rbuffer) smuX.measure.overlappediv(ibuffer, vbuffer)</pre> <p><code>rbuffer</code>                      A reading buffer object where the reading(s) will be stored.<br/> <code>ibuffer</code>                      A reading buffer object where current reading(s) will be stored.<br/> <code>vbuffer</code>                      A reading buffer object where voltage reading(s) will be stored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                             |
| Remarks                         | <ul style="list-style-type: none"> <li>This function will start a measurement and return immediately. The measurements, as they are performed, are stored in a reading buffer (along with any ancillary information also being acquired). If the instrument is configured to return multiple readings where one is requested, the readings will be available as they are made.</li> <li>The <code>smuX.measure.overlappediv</code> function stores both current and voltage readings in respective buffers (current and then voltage are stored in separate buffers).</li> <li>This function is an overlapped command. Script execution will continue while the measurement(s) is made in the background. Attempts to access result values that have not yet been generated will cause the script to block and wait for the data to become available. The <code>waitcomplete</code> function can also be used to wait for the measurement(s) to complete before continuing.</li> <li>If a given reading buffer contains any data, it will be cleared prior to taking any measurements, unless the reading buffer has been configured to append data.</li> </ul> |                                                                                                                                                                             |
| Details                         | See <a href="#">Reading buffer options</a> in <a href="#">Section 7</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                             |

| Remarks                    | <ul style="list-style-type: none"> <li>Reading this attribute returns the positive full-scale value of the measure range the SMU is currently using.</li> <li>Assigning to this attribute sets the SMU on a fixed range large enough to measure the given value. The instrument will select the best range for measuring a value of rangeval.</li> <li>This attribute is primarily intended to eliminate the time required by the automatic range selection performed by a measuring instrument. Because selecting a fixed range will prevent auto-ranging, an over-range condition can occur, for example, measuring 10.0V on the Model 2601A/2602A 6V range or measuring 5.0V on the Model 2611A/2612A 2V range will cause an over-range. The value 9.91000E+37 is returned when this occurs.</li> <li>If the source function is the same as the measurement function (for example, sourcing voltage, and measuring voltage), the measurement range is locked to be the same as the source range. However, the setting for the voltage measure range is retained and used when the source function is changed to current, and the present voltage measurement range will be used.</li> <li>Model 2601A/2602A example: Assume the source function is voltage. The source range is 1V and you set the measure range for 6V. Since the source range is 1V, the SMU will perform voltage measurements on the 1V range. If you now change the function to current, measurements will be performed on the 6V range.</li> <li>Explicitly setting either a source or measurement range for a function will disable auto ranging for that function. Auto ranging is controlled separately for each source and measurement function: source voltage, source current, measure voltage and measure current. Auto ranging is enabled for all four by default.</li> <li>Changing the range while the output is off will not update the hardware settings, but querying will return the range setting that will be used once the output is turned on. Setting a range while the output is on will take effect immediately.</li> <li>With source auto ranging enabled, the output level controls the range. Querying the range after the level is set will return the range the unit chose as appropriate for that source level.</li> <li>With measure auto ranging enabled, the range will be changed only when a measurement is taken. Querying the range after a measurement will return the range selected for that measurement.</li> </ul> |                                                                                                  |
