## LG4 System Module

#### Introduction

This is the module specification of LG4 which is the main electronics module in NHL-2NA GSM dual band phone. NHL-2NA phone is also nick named as Nokia 7650. The sales name is Nokia 7650.

### Technical overview

#### LG4 features

- Dual band GSM tranceiver. EGSM900 and GSM1800 bands with GPRS class 6 and HSCSD data capability
- BB release is Galaxy WD2, main ASIC UPP\_WD2
- RF release is Gemini premium release for Lilly (but shrinked)
- Bluetooth, based on BT102 module
- IR, HW capable for 1Mbit data speed
- Proximity sensor for controlling integrated handsfree feature (IHF)
- Handsfree, headset and earpiece audio connections
- VGA camera module connected with spring connector to LG4
- Ambient light sensor for controlling display and keyboard backlights
- Color display interface
- Flex cable interface to LS4 Grip module

#### **Component placement and PWB outline**

Components are placed only on one side of the LG4 module.

Figure 1 shows LG4 module from component side, main components are listed.

#### **CCS** Technical Documentation

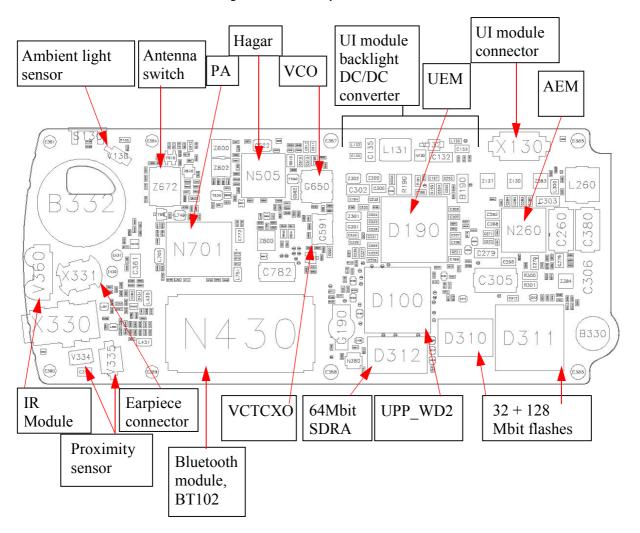

Figure 1: Main components on LG4

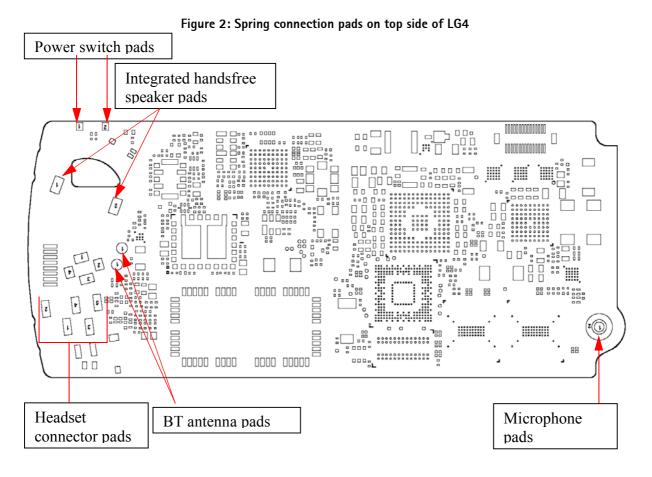

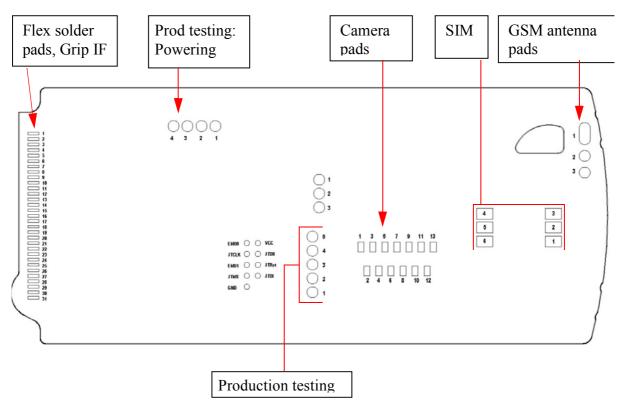

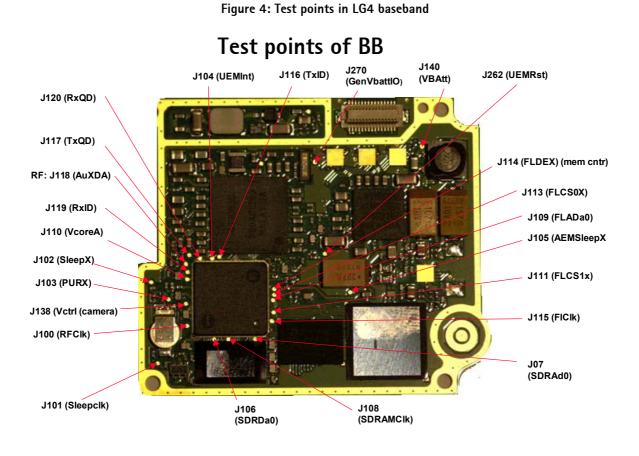

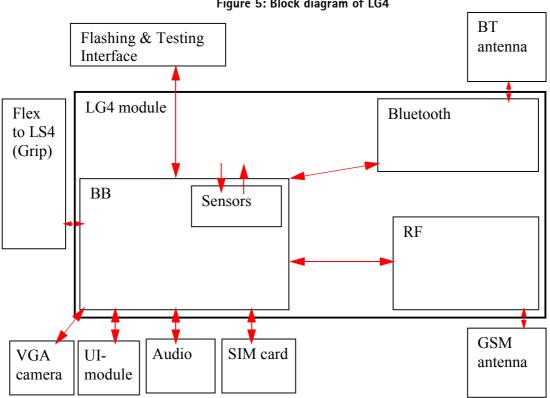

Figure 3: Spring connection pads on back side of LG4 and flex cable solder pads

## **Block diagram**

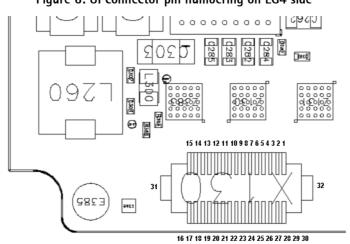

Below is the block diagram of LG4 module. External interfaces are drawn as arrows crossing LG4 border.

#### Figure 5: Block diagram of LG4

#### **UI Interface**

UI module interface pin numbering is presented in figure below. UI interface details are in UI-module specification.

#### Figure 6: UI connector pin numbering on LG4 side

## **Baseband Technical Summary**

The heart of the BB is UPP\_WD2, which includes MCU, DSP and Digital Control Logic. Powering handled by Using AEM ASIC and UEM ASIC. There is Flash Memory 128Mbit + 32Mbit Flashes (20 Mbytes) and 64 Mbit (8 Mbytes) SDRAM. So there is a total of 28 Mbytes of Memory Capacity.

In BB there is an integrated Handsfree Audio Amplifier In AEM. There are two Audio Elements (Earpiece 8 mm and Speaker 16 mm) and External Galvanic Headset (DCT4) interface. IHF Speaker is also used to handle the Ringing tone. For IHF automated off function there is proximity Sensor. In NHL-2NA there is only one microphone for both modes HS and IHF.

For Data connectivity there is 1Mbit IR Module (IrDA compatible) and Bluetooth.

Display is MD-TFD type Color Display with 4096 Colors and 176x208 pixels with Backlight. Keyboard is partially in UI-Module and Partially in Grip-Module. Also there is This Navigation Key Feature in UI-Module.

For imaging purposes BB supports VGA camera via CCP interfaces, which are integrated in UPP\_WD2.

## **Functional Description**

#### **BB** Description

Core is based on UPP\_WD2 CPU, which is a special version of the DCT4 UPP ASIC. UPP\_WD2 takes care of all the signal processing and operation controlling tasks of the phone as well as all PDA tasks.

For Power management there are two Asics for controlling energy management and supplying current and different voltages; UEM and AEM. UEM and SW have the main control of the system voltages and operating modes and AEM acts as an auxiliary source of voltages and current. The main reset for the system is generated by the UEM.

The interface from the RF and audio sections is handled also by UEM. This ASIC provides A/D and D/A conversion of the in-phase and quadrature receive and transmit signal paths and also A/D and D/A conversions of received and transmitted audio signals. Data transmission between the UEM, AEM and RF and the UPP\_WD2 is implemented using different serial connections (CBUS, DBUS and RFBUS). Digital speech processing is handled by UPP\_WD2 ASIC. Internal HF with proximity sensor functionality is implemented inside the AEM ASIC.

A real time clock function is integrated into UEM, which utilizes the same 32kHz-clock source as the sleep clock. A rechargeable battery provides backup power to run the RTC when the main battery is removed. Backuptime is 20 Hours.

#### Memory Configuration

NHL-2NA uses two kinds of memories, Flash and SDRAM. These Memories have their own Dedicated buses in UPP\_WD2.

Synchronous DRAM is used as working memory. Interface is 16 bit wide data and 14 bit Address. Memory clocking speed is 104 MHz. The SDRAM size 64Mbits (4Mx16).

SDRAM I/O is 1.8 V and core 2.78 V supplied by AEM's regulators VIOA and VMEMA. All memory contents are lost if the supply voltage is switched off.

Multiplexed Flash Memory Interface is used to store the MCU program code and User Data. The memory interface is a burst type FLASH with multiplexed address/data bus.

Both I/O and core voltage are 1.8 V supplied by AEM's VMEMB.

#### **Energy Management**

The master of EM control is UEM and with SW they have the main control of the system voltages and operating modes. AEM (Auxiliary Energy Management) acts as an auxiliary source of voltages and current.

**CCS** Technical Documentation

#### Modes of Operation

NHL-2NA employs several hardware & SW controlled operation modes. Main Modes are described below.

- NO\_SUPPLY mode means that the main battery is not present or its voltage is too low (below UEM master reset threshold) and back-up battery voltage is too low.
- In BACK\_UP mode the main battery is not present or its voltage is too low but back-up battery has sufficient charge in it.
- In PWR\_OFF mode the main battery is present and its voltage is over UEM master reset threshold. All regulators are disabled.
- RESET mode is a synonym for start-up sequence and contains in fact several modes. In this mode regulators and oscillators are enabled and after they have stabilized system reset is released and PWR\_ON mode entered.
- In PWR\_ON mode SW is running and controlling the system.
- SLEEP mode is entered from PWR\_ON mode when the system's activity is low (SLEEPX and AEMSLEEPX controlled by SW).
- FLASHING mode is for production SW download.

#### Voltage limits

In the following the voltage limits of the system are listed. These are also controlling system states.:

Parameter	Description	Value
V <sub>MSTR+</sub>	Master reset threshold (rising)	2.1 V (typ.)
V <sub>MSTR-</sub>	Master reset threshold (falling)	1.9 V (typ.)
V <sub>COFF+</sub>	Hardware cutoff (rising)	3.1 V (typ.)
V <sub>COFF-</sub>	Hardware cutoff (falling)	2.8 V (typ.)
V_BU <sub>COFF+</sub>	Back-up battery cutoff (rising)	2.1 V (typ.)
V_BU <sub>COFF-</sub>	Back-up battery cutoff (falling)	2.0 V (typ.)
SW <sub>COFF</sub>	SW cutoff limit (> regulator drop-out limit) MIN!	3.15 V SW changeable

The master reset threshold controls the internal reset of UEM. If battery voltage is above  $V_{MSTR}$ , UEM's charging control logic is alive. Also, RTC is active and supplied from the main battery. Above  $V_{MSTR}$  UEM allows the system to be powered on although this may not succeed due to voltage drops during start-up. SW can also consider battery voltage

too low for operation and power down the system.

#### **Clocking Scheme**

A 26 MHz VCTCXO is used as system clock generator in GSM. During the system start-up, UEM and AEM use their own RC-oscillators to generate timing for state machines. All clock signals of the engine are illustrated in following figure.

In PWR\_ON mode, SW must configure CBUS clock (1MHz) to be active all the time, as this clock is used in AEM as digital clock and for the SMPS. Bluetooth uses 26 MHz analog clock.

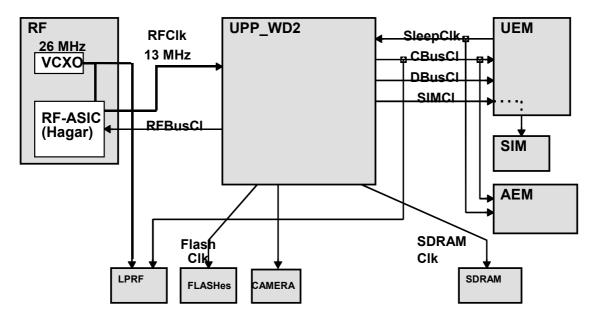

Figure 7: NHL-2NA Clocking.

In SLEEP mode the VCTCXO is off. UEM generates low frequency clock signal (32.768 kHz) that is fed to UPP\_WD2, Bluetooth and AEM.

#### UPP\_WD2 voltage/clock frequency adjusting

The systems of the BB make it possible to adjust both clock frequency and the core voltage of the main ASIC. Here is a rough description of the Clocking Scheme.

No external clock is available for UPP\_WD2 before VCTCXO starts. As reset is released, the VCTCXO is running and MCU uses the 13 MHz clock while DSP is in reset. There are three identical DPLL's, for MCU, for DSP and for accessory interfaces, which can be controlled independently. The clock for MCU can be up to 104 MHz and 117 MHz is maximum clock Frequency for the DSP. These clock signals are used either directly (SDRAM IF) or divided down for the interfaces (e.g. flash IF).

#### Power Distribution, Control and Reset

All power (except backup battery power) is drawn from BLB-2 Li-lon battery located in the Grip part of the phone. Power goes through LM3822 current gauge which is used for current measurement and thus for remaining operating time estimation.

LG4 board contains two power ASIC's UEM and AEM which contain the regulators needed for generating the different operating voltages. In addition there is a SMPS in LG4 generating the operating voltage for display module backlighting. In LS4 keyboard the backlight is powered with a current pump.

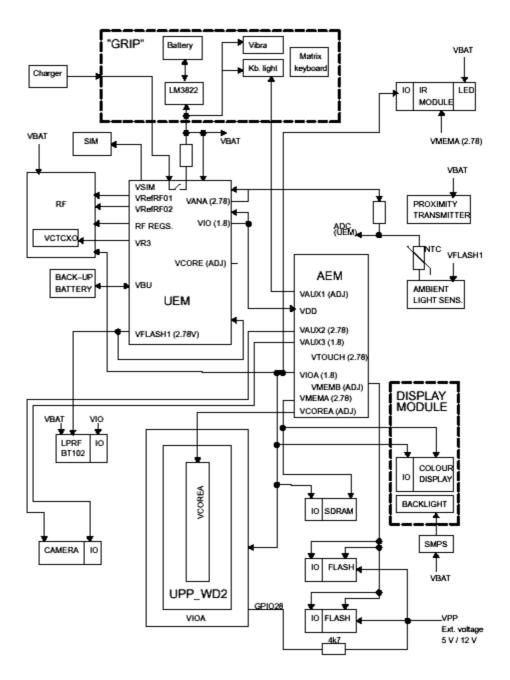

Figure 8: Power distribution diagram

#### Power-up sequence (Reset mode)

RESET mode can be entered in four ways: by inserting the battery or charger, by RTC alarm or by pressing the power key. After voltage appearing at UEM's pin UEMRSTX (connected to AEM's pin REFENA) is used as indication for AEM to start up HW regulators. Also VCTXO is Powered up by using VR3 (UEM). After the 220 ms delays regulator are configured and UEM enters PWR\_ON mode and system reset PURX is released.

During system start-up, in RESET state, the regulators are enabled, and each regulator charges the capacitor(s) at the output with the maximum current (short circuit current) it can deliver. This results in battery voltage dropping during the start-up. When a battery with voltage level just above the hardware cutoff limit is inserted, the system may not start due to excessive voltage dipping. Dropping below 2.8 V for longer than 5 us forces the system to PWR\_OFF state.

#### Powering off

Controlled powering off is done when the user requests it by pressing power-key or when the battery voltage is falling too low. Uncontrolled powering off happens when battery is suddenly removed or if over-temperature condition is detected in regulator block while in RESET mode. Then all UEM's regulators are disabled immediately and AEM's regulators are disabled as VDD supply disappears.

#### Controlled powering off

For NHL-2NA powering off is initiated by pressing the power key and Power off sequence is activated in UEM and SW. Basically Power key cause UEM Interrupt to UPP\_WD2 and SW sets Watchdog time value to zero and as this happens, PURX is forced low and all regulators are disabled.

If the battery voltage falls below the very last SW-cutoff level, SW will power off the system by letting the UEM's watchdog elapse.

If thermal shutdown limit in UEM regulator block is exceeded, the system is powered off. System reset PURX is forced low. AEM has its own thermal limit for regulators. Whenever the limit is exceeded, an interrupt is given to UPP\_WD2 and SW should immediately power off the whole system. AEM will disable its regulators in any case by itself after 10 ms delay (uncontrolled powering off).

#### Uncontrolled powering off

This happens when the battery is suddenly removed and is problematic as data may corrupt in memories. UEM's state machine notices battery removal after battery voltage has been below  $V_{COFF-}$  for 5 us and enters PWR\_OFF mode. PURX is set low and all UEM's regulators are disabled. AEM's regulators except for VCOREA, VIOA, VMEMA and VMEMB are disabled as PURX goes low. These regulators stay enabled as long as there is voltage present at pin VDD (from UEM's VIO).

#### Watchdogs

There are three watchdogs in UEM. First one is for controlling system power-on and power-down sequences. The initial time for this watchdog after reset is 32 s and the

watchdog can not be disabled. The time can be set using a register. This watchdog is used for powering the system off in a controlled manner. The other one is for security block and is used during IMEI code setting. The third one is a power key watchdog. It is used to power off the system in case SW is stuck and the user presses the power key. This WD is SW configurable.

There is also a "soft watchdog" in UPP\_WD2. It is used to reset the chip in case software gets stuck for any reason. The Bluetooth module also contains a watchdog.

#### Charging

Charging controls and charge switch is in UEM. There are three different charging modes; charging empty battery (start-up charge mode), PWM charging mode (without SW control) and SW controlled charging.

UEM digital part takes care of charger detection (generates interrupt to UPP\_WD2), pulse width modulated charging control (for internal charge switch and external performance charger) and over voltage and current detection. SW using registers controls all these.

#### Chargers

NHL-2NA BB is supporting a standard charger (two wires) or fast (performance) charger (three wires), Chargers ACP-7, ACP-8 and ACP-9 and ACP-12, Cigarette Charger LCH-8 are supported.

With the standard version the PWM signal is set to 1 Hz, while with fast charger it is set to 32 Hz. Also PWM signal is connected from UEM pin to the charger's control input.

Due to high current consumption of the NHL-2NA BB, a performance charger ACP-8 is needed.

#### Battery

NHL-2NA Battery is a detachable, semi-fixed Lithium-Ion BLB-2 battery. Other batteries are allowed to use but NOT charged. Nominal voltage is thus 3.6-3.7 V (max charging voltage 4.1-4.2 V).

The interface consists of four pins: VBAT, GND, BSI and BTEMP. Pull-down resistor inside of the batteries (BSI signal) recognizes the battery types. Voltage level at BSI line is measured with using Em's AD-converter.

#### Back-up battery and real time clock

Real time clock (RTC), crystal oscillator and back-up battery circuitry reside in UEM. A register in UEM controls back-up battery charging and charging is possible only in POWER\_ON State.

#### Baseband Measurement A/D Converter

The UEM contains 11 channels A/D converter, which is used for different Baseband measurement purposes. The resolution of A/D converter is 10 bits. Converter uses the CBUS interface clock signal for the conversion. An interrupt will be given to the MCU at the end of the all measurement. Converter is used for following purposes.

- Battery Voltage Measurement A/D Channel (Internal)
- Charger Voltage Measurement A/D Channel (Internal)
- Charger Current Measurement A/D Channel (Internal)
- Battery Temperature Measurement A/D Channel (External)
- Battery Size Measurement A/D Channel (External)
- Light Sensor Measurement A/D Channel (External)
- PA Temperature measurement A/D Channel (External)
- VCTCXO Temperature measurement A/D Channel (External)

There is also auxiliary AD converter in UEM, which is used to monitor RF functions. Converter is controlled directly by UPP DSP. Converter can be used for following purposes:

VCXO Temperature measurement A/D Channel (if not used in normal AD)

PA Temperature measurement A/D Channel (if not used in normal AD)

## NHL-2NA BB Features & HW interfaces

#### NHL-2NA BB User interface

#### **UI-Module Interface**

Interface is for Color Display 176 x 208 (X3) resolution and backlight is white LED with lightguide. Also Part of Keyboard is locating in module with Navigation Key. Display is connected to LG4 by 30-pin Board-to-Board connector. Interface includes also power rails for UI and Backlight. Interface uses GPIO pins of UPP\_WD2.

#### **Power Key**

PWROnx of UEM is pulled up to battery voltage by a current source inside UEM. Pressing PWR-Key connects UEM PWRONX-pin to ground via resistor. The power key has also a reset function: while removing battery is difficult, a reset can be accomplished by pressing this key for longer time. Power key is connected to main PCB via spring contacts.

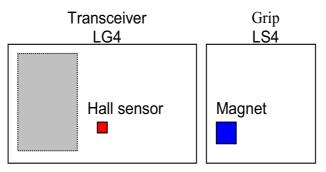

#### **Grip Interface**

Grip Interface includes Matrix Keyboard & Backlight, Battery interface, Vibra Interface, Charger interface, Current Gauge interface.

Hall Sensor and Magnet

NHL-2NA is using Hall sensor TLE 4917 (NMP code 4341087) and magnet to find out the open/close position of the grip. The hall sensor component is in the LG4 BB area and the magnet is in the grip module. See Locations of the sensor and magnet below.

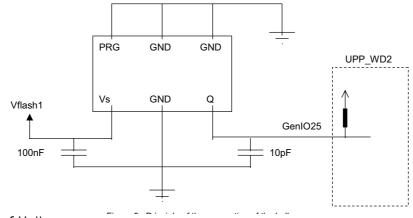

#### Figure 9: Locations of the sensor and magnet

As the grip is closed, the hall sensor and magnet are against each other. At this position the output of the hall sensor is high. As the grip is open and sensor and magnet are separated, the output is low. This low level gives the information to processor that grip is open.

Sensor needs 2.7V for operation and that's why Vflash1 voltage is needed to be connected to Vs pin. PRG pin is needed to connected GND that output is zero as magnet and sensor are separated. See Principle of the connection of the hall sensor below.

#### Figure 10: Principle of the connection of the hall sensor

Pins list of Hall sensors:

Pin	Min	Nom	Max	Pin number
Vs	2.4 V	2.7 V	3.5 V	1
GND	0 V			2, 4, 5
Q	0 V	1.8 V		3
PRG	0 V		3.7 V	6

**NOKIA** CCS Technical Documentation

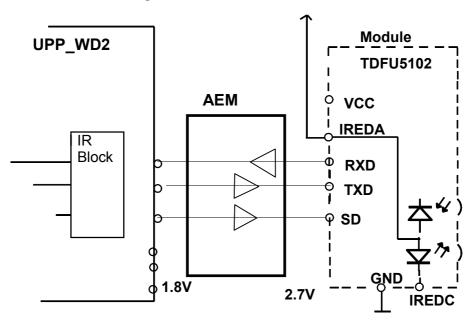

#### Bluetooth

Bluetooth provides a fully digital link for communication between a master unit and one or more slave units. The system provides a radio link that offers a high degree of flexibility to support various applications and product scenarios. Data and control interface for a low power RF module is provided. The transmission is half-duplex. Air bit rate is 812.5 kbit/s.

#### IR

NHL-2NA BB uses TDFU5102 1Mbit IrDA 1.1 compatible module. Module interface signals are Tx (Transmitted Data), Rx (Received Data) and SD (ShutDown). IR transmission data speed can be from 9.6 kbit/s to 1.15 Mbit/s. The communication over the IR is always started using bit rate 9.6 kbit/s.

Digital part is powered with 2.78 V by VMEMA and the LED by VBAT (nom. 4.2 V). VMEMA is fully SW-controlled regulator. More details of the module can be found out from IR specification under EDMS. See figure 11 for

#### Figure 11: IR connected to UPP\_WD2

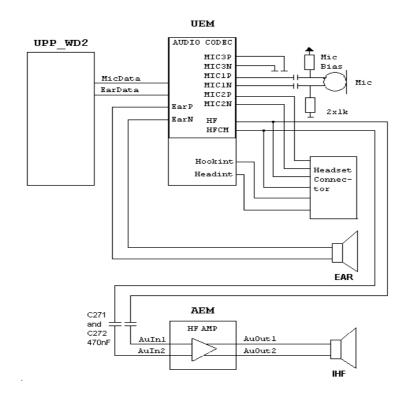

#### SIM Interface

The SIM interface is located in two chips (UPP\_WD2 and UEM). In UEM there is only support for one SIM card. The interfaces support both 1.8 V and 3 V SIM cards. Adjust-able SIM regulator (1.8V/3.0V) is located in UEM and can be controlled by SW.

The data communication between the card and the phone is asynchronous half duplex. The clock supplied to the card is in GSM system 1.083 MHz or 3.25 MHz. The data baudrate is SIM card clock frequency divided by 372 (by default), 64, 32 or 16.

#### NHL-2NA Audio Concept

NHL-2NA Audio's includes Earpiece, microphone, and headset connector, Integrated Handsfree (IHF) with proximity sensing. IHF have high quality Audio with DCT4 Enchantments. Headset is DCT4 monoheadset with/-out button. For IHF versus Earpiece function there is proximity sensor option, which detects if close to head, it switches IHF off. It can be turned ON Manually. In NHL-2NA Audio Blocks there is NHL-2NA BB Audio block diagram. Audio's are based on ASIC's UPP\_WD2 and UEM.

This Asic's readily support normal audio functionality. Between UPP\_WD2 and UEM the audio signals are transferred in digital format using signals MICDATA and EARDATA. The microphone is connected to UEM and the headset output of UEM is fed also to AEM audio amplifier. So actual IHF situation the signal is also existing in Headset signals. NHL-2NA audio SW controls IHF amplifier power off when uses headset because both use same audio lines (HF and HFCM). Ringing tones and warning/info tones are to be produced with the IHF speaker also.

#### Earpiece

The earpiece to be used in NHL-2NA is an 8-mm Pico earpiece. It has  $32\Omega$  continuous impedance and continuos power 8 mWatts. It Contacts to PWB Special adapter via springs. It's driven by differential signals from UEM (EARP & EARN)

#### Microphone

The microphone capsule for NHL-2NA is a WM64MN capsule. Its sensitivity is -41db Nominal and it's provided encapsulated in housing of neoprene. Contacts are done by springs.

Two inputs are used from UEM, one for normal internal microphone and a second for headset. The third microphone input is not used, so it must connected to ground. Microphone bias block in UEM generates bias voltages for handportable and HandsFree/headset microphones. For both microphone bias outputs (MICB1 & MICB2) the minimum output voltage is 2.0 Volts and maximum output current is 600  $\mu$ A. Microphone bias block also includes a low pass filter for the reference voltage used as an input for the MICB1&2 amplifiers.

#### IHF Amplifier and Speaker

The speaker to be used in NHL-2NA is a 16mm 8 $\Omega$  speaker. It can handle 0.2 Watts nominal Power and Peak power 0.4 Watts. Component has molded neoprene gasket and its contact to PWB via springs.

HF and HFCM lines of UEM are use to drive AEM IHF amplifier. IHF amplifier consists of four blocks: gain setting stage, power amplifier, and comparator and Bias VCM generation. There is also some digital logic, which is integrated to other digital parts of AEM.

Power amplifier is a differential opamp. The differential output is intended to HandsFree speaker. HandsFree amplifier load impedance is 8 ohm.

The outputs go into a high impedance state when powered down. The amplifier can be enabled and shut down by control register.

SW realizes IHF and earpiece volume control mainly in AEM. For maximum signal-tonoise performance it is preferable to set the gain of UEM's earpiece driver to some fixed, close-to-maximum value and use lower gain setting for AEM audio amplifier. Gain setting can be done in 2 dB steps, from -40 to +6 dB. Output sound pressure level of the internal HandsFree speaker is controlled by the proximity sensor and SW (CBus is used for controlling). Proximity sensor activity changes the gain automatically.

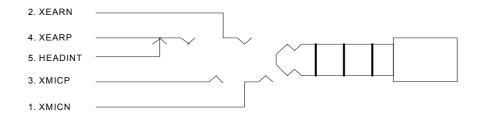

The schematic around the AEM IHF amplifier is presented in NHL-2NA schematics. The schematic shows all the filtering needed and also protection components against ESD and EMC.EMC and ESD Filtering component must be as near as possible to earphone pads of the phone. Audio input lines components DC decoupling capacitors and EMC capacitor must be located near to AEM.

The supply voltage for the IHF amplifier is filtered directly from the battery voltage. The size of the capacitance needed for smoothing the voltage is High-Pass filter consist of two parallel 220uF capacitors to ground with 2x2.20hm parallel in Series in VBAT line.

#### **External Audio interface**

In NHL-2NA there is Headset Connector which is fully differential 4-wire connection.

#### Figure 13: External Audio Connector

The Handsfree (HF) driver in UEM is meant for headset. In NHL-2NA case the output is driven in fully differential mode. In the fully differential mode HF pin is the negative output and HFCM pin is the positive output. The gain of the Handsfree driver in the differential mode is 6 dB. The earpiece (EARP, EARN) and headset (HF, HFCM) signals are multiplexed so that the outputs can not be used simultaneously. Minimum resistive and maximum capacitive loading between HF and HFCM outputs are 30ohm and 10nF. The HF and HFCM amplifiers include a transient suppression circuitry, which prevents unwanted spikes in HF and HFCM outputs when switching on and off the amplifiers.

The plug opens a mechanical switch inside the connector between HF and HeadInt lines. The HeadInt line will be pulled up to 2.7V by internal resistor when the switch is open. When not having the plug inserted the voltage in the HeadInt line will be <0.8 V caused by internal pull down resistor in the HF line.

#### Camera Interface

NHL-2NA camera type is a Still camera with viewer option. Camera resolution is VGA. The Camera module is connected by springs to PWB.

Camera interface is serial CCP, which is unidirectional interface; the control information to camera is transmitted through I2C bus. The I2C is implemented purely by SW using general purpose I/Os.

CCP interface consists of differential type of clock signal and one data signal. CCP enables the use of high data rates with low EMI; maximum transfer capacity is 104 Mbit/ s, which means that transferring VGA (640x480) images at 15 fps is possible. CCP has three image data operating modes: 8-bit, 10-bit and 12-bit ones.

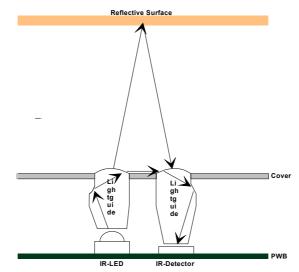

AEM includes two dedicated regulators for powering internal camera, 2.78V for logic and sensor and 1.8V for I/O.

More about camera module later in this section.

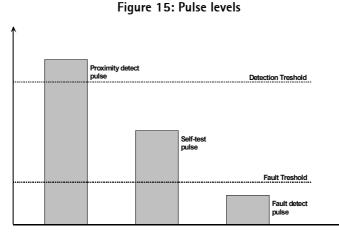

#### **Proximity Sensor**

Proximity Detector is used to deactivate IHF when something is close to the phone. Proximity detection is based on detecting level of reflected IR radiation. Detection distance varies depending on the reflecting surface. System is calibrated to detect 20% diffuse reflectance targets, parallel to the phone, at 50mm distance. Detection distance may change due to wearing; minimum detection distance allowed is 30mm.

#### Figure 14: Proximity Detector Principle

Proximity Detector has also a self-monitoring feature, which is used to detect possible failures in the Proximity Detector. Proximity Detector Principle figure describes the mechanical concept of the Proximity Detector, Pulse levels shows signal levels.

Proximity detector interface is in AEM (Auxiliary Energy Management ASIC), other components of the proximity detector are optoelectrical components and optics.

The proximity detector block on AEM consists of digital and analog part. Digital logic is included in digital part of AEM, and it is controlled through proximity detector control register.

Analog part includes a current source for the emitter and a transinpedance amplifier, high pass filter to filter off up to 2mA DC-current, gain-controllable amplifier and two

comparators with adjustable thresholds in the receiver.

Proximity detector block enables several pulse width and pulse frequency selections and emitter current can be controlled with a current sensing resistor. In NHL-2NA emitter current is 100mA, pulse width  $8\mu$ s and pulse frequency 500/2000Hz.

#### **Proximity Detector components**

#### Lightguides

Lightguides are needed to guide emitted IR radiation outside the phone as well as to guide the reflected pulses into the phone to the photodiode. Half angle of the emitted radiation is 10°. This means, that most of the emitted radiation is reflected from a circle that has diameter 20mm, when the target is at 50mm distance. Receiver lightguide collects radiation and guides it to the photodiode. Optical insulator, made of black rubber, surrounds the photodiode so that it cannot receive any radiation that is reflected inside the phone.

Self-monitoring signal is created with small reflector areas and curved top surfaces in the lightguides. Reflectors are placed inside the phone, so that they are subject to as little wearing as possible.

#### IRED

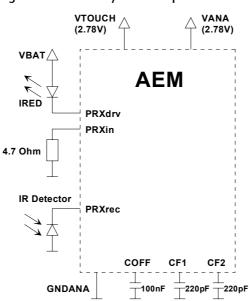

The IRED type is CL-200-IR-X-TU (NMP CODE 4860009), which has high radiant intensity and relatively small half angle (28°). Maximum forward current is 100mA (pulsed 1A) and  $V_f = 1.3V$ . Rise Time is 2µs, total radiant intensity 12mW (at 50mA current) and peak radiant intensity at 950nm.

#### Photodiode

The photodiode is BPW34FS (NMP CODE 486J830). It has peak sensitivity at 950nm and filtering for visible light. Photodiode receives radiation from 60° half angle and its rise time is 20ns.

#### **HW Implementation**

The implementation of the proximity sensor is described in figure 16. Note that VTOUCH is connected externally to VANA.

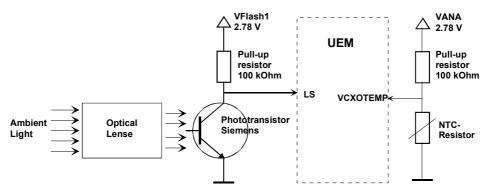

#### Figure 16: Proximity sensor implementation

#### Ambient Light Sensor

Ambient Light Detector (ALD) is used as a power saving feature.

Ambient Light Detector (ALD) measures illuminance on the display (ambient light). User can select the limit, above which display backlight is not needed. In practice, two limits are used in software to produce hysteresis. Hysteresis is needed to prevent backlight from blinking. Backlight can be switched ON only when ambient light level is below lower limit. Backlight is switched OFF, when ambient light level exceeds higher limit.

CCS Technical Documentation

#### Flashing

NOKIA

SW download in service is impelemented by custom tools and SW, kindly refer to Service Software Instructions and Service Tool section of the manual.

#### Connections to Baseband

NHL-2NA type flash programmer FPS-8 is connected to the baseband directly in Production Tester, by using service cable and FLA-21 or Module jig to connect to test pads. With assembled devices the testpads can be accessed by opening the grip with a special tool.

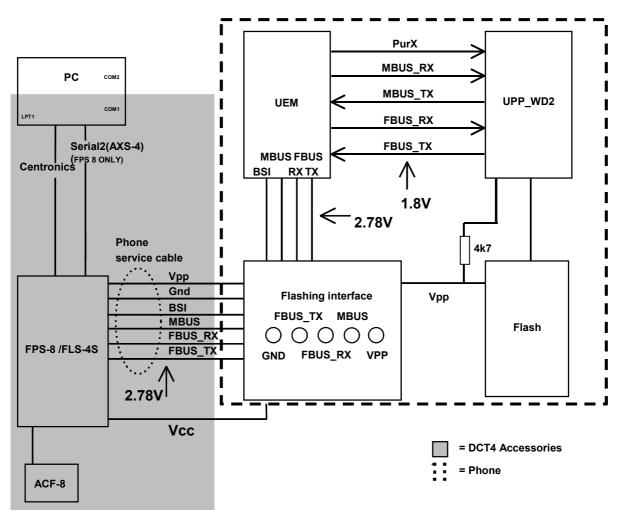

Figure 18: Flash programming connections

FPS-8 can also supply Vcc during flash programming i.e. service box's or service battery's Vcc can be connected to FPS-8 by banana plugs but external power supply can be also used during flash programming. shows how flash programming equipment is connected. Note that Vcc connected to FPS-8/FLS-4S is preferred.

The flash programming interface uses following external signals:

- 1 FBUS RX (accessed from test pad pattern)
- 2 FBUS TX (accessed from test pad pattern)
- 3 MBUS (accessed from test pad pattern)

- 4 BSI (accessed from battery connector)
- 5 Vcc (accessed from battery connector)
- 6 Ground (accessed from test pad pattern and battery connector)
- 7 Vpp (accessed from test pad pattern)

In HDB15 BB Vpp routing is based on common DCT4 solution. In this solution the use of higher Vpp voltage is enabled at FLALI phase in production and in after sales if so wanted.

External voltage (Vpp) is used during flash programming in production and possibly in aftersales to speed up the process. In production, the usage of external programming voltage is a necessity but in after sales the usage of external programming voltage does not necessarily bring any noticeable improvement to flash programming time.

#### **Testing interfaces**

In NHL-2NA BB Interfaces Because of Camera, larger memory, sensors there are some specific testing done and also because of flagship concept there is difference of physical Interfaces

Note 1: VAna & VFlash1 = 2.78 +/-3%

#### **Extreme Voltages**

Lithium-Ion battery BLB-2 (1 cell):

- Nominal voltage is 3.6V
- Lower extreme voltage is 2.8V (cut off voltage)
- Higher extreme voltage is 4.2V (charging high limit voltage)

#### **Temperature Conditions**

Specifications are met within range of -10C to +55C ambient temperature. Reduced operation between [-25] and [+60]. Storage temperature range is of -40C to +85C according to Nokia specifications.

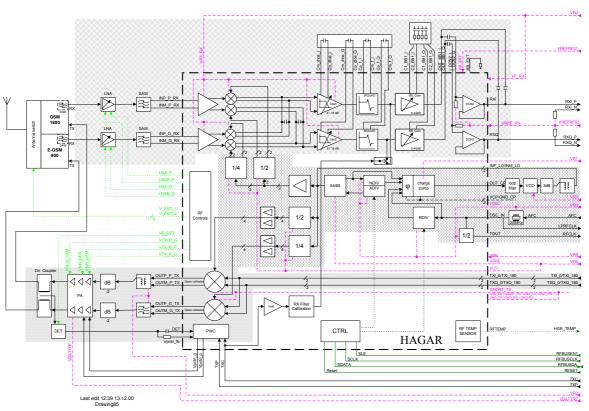

#### Humidity and Water Resistance

Relative humidity range is 5 ... 95%. Condensed or dripping water may cause intermittent malfunctions. Protection against dripping water have to be implemented in (enclosure) mechanics. Continuous dampness will cause permanent damage to the module.

#### **RF Module**

#### Functional block descriptions

The block diagrams of direct-conversion receiver and transmitter RF section are described in the following figure. The illustration shows the RF-IC ( both RX and TX functions ), power amplifier ( PA ), TX-SAW filter, VCO, VCTCXO module, discrete LNA stages and SAW-filters for receive bands.

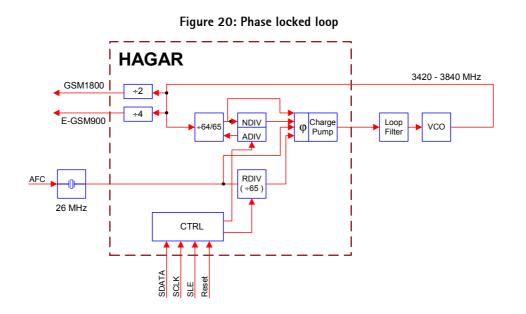

#### Figure 19: RF block description

#### The Frequency synthesizer

The VCO frequency is locked using a PLL to a stable frequency source, which is a VCTCXO. The VCTCXO is running at 26 MHz. The Temperature effect is controlled with AFC. The AFC is generated with a 11 bit conventional DAC in UEM.

The physical PLL is located inside the HAGAR RF-IC and is controlled via serial bus. The PLL synthesizer consists of the following blocks :

- 64/65 CML prescaler
- Programable R-, N- and A-dividers,
- Phase detector and charge pump

The SHF local signal generated by a VCO module is fed into prescaler. The prescaler is a dual-modulus divider. The output of the prescaler is fed to N- and A- divider which produce the input to phase detector. The phase detector compares this signal to the reference signal (400 kHz) which is obtained by dividing the VCTCXO output by reference Rdivider. The output of the phase detector is connected to the charge pump which charges or discharges integrator capacitor in the loop filter, depending on the phase of the measured frequency compared to the reference frequency.

The loop filter, VCO and VCTCXO are all external synthesizer building blocks.

The loop filter performs filtering of the pulses and generates DC control voltage to the VCO. The loop filter also defines the step response of the PLL (settling time) and effects the stability of the loop. That's why integrator capacitor has got a resistor for phase compensation. The other filter components are for sideband rejection.

The dividers are controlled via serial bus: SDATA is for data, SCLK is serial clock for the bus and SLE is latch enable, which enables new data storage into dividers.

The transceiver LO signal is generated by VCO module. The VCO generates double frequency in GSM1800 and times four frequency in E-GSM900 compared to the actual RF channel frequency. LO signal is divided by two or four in HAGAR (depending on system mode).

This RF module comprises all RF functions of the engine. RF circuitry is located on one side (B-side) of the PCB.

EMC leakage is prevented by using a metal B-shield, which screens the whole RF side (included FM radio) of the engine. The conductive (silicon or metal) gasket is used between the PCB and the shield. The metal B-shield is separated to three blocks. The first one include the FM radio. The second block include the PA, antenna switch, LNAs and dual RX SAW. The last block include the Hagar RF IC, VCO, VCTCXO, baluns and balanced filters.

The baseband circuitry is located on the A-side of the board, which is shielded with a metallized frame and ground plane of the UI-board.

Maximum height inside on B-side is 1.8 mm. Heat generated by the circuitry is conducted out via the PCB ground planes and metallic B-shield

# Receiver

Figure 24: NHL-2NA Receiver chain

The receiver is a direct-conversion, dual-band linear receiver. RF signal energy gathered by the antenna is fed via the antenna switch module to the 1<sup>st</sup> RX bandpass SAW filters and MMIC LNAs. The RF antenna switch module provides for upper- and lower-band operation. The signal having been amplified by the LNA is then fed to 2<sup>nd</sup> RX bandpass SAW filters. Both of these 2<sup>nd</sup> RX bandpass SAW filters have UNBAL/BAL configuration to achieve the balanced feed for HAGAR. The discrete LNAs have three gain levels. The first one is maximum gain, the second one is about -30dB (GSM1800) and -25dB (E-GSM900) below maximum gain and the last one is off state. The LNA gain selection is controlled directly by HAGAR.

The performance of the RX bandpass SAW filters are mainly responsible for defining the receiver's blocking characteristics against spurious signals outside passband and the protection against spurious responses.

The differential RX signal is amplified and mixed directly down to BB frequency in HAGAR. The LO signal is generated with external VCO. This VCO signal is divided by 2 (GSM1800) or by 4 (E-GSM900). The PLL and dividers are internal to the HAGAR IC. From the mixer output to ADC input RX signal is divided into I- and Q-signals. Accurate phasing is generated in LO dividers. After the mixer DTOS amplifiers convert the differential signals to single ended.

The DTOS has two gain stages. The first one has constant gain of 12dB and 85kHz cut off frequency. The gain of second stage is controlled with control signal g10. If g10 is high (1) the gain is 6dB and if g10 is low (0) the gain of the stage is -4dB. The active channel filters in HAGAR provide selectivity for channels (-3dB  $@ \pm 91$  kHz typ.). The integrated baseband filter inside HAGAR is an active-RC-filter with two off-chip capacitors. Large RC-time constants are needed in the channel select filter of the direct-conversion receiver and are achieved with large off-chip capacitors because the impedance levels could not be increased due to the noise specifications.

The baseband filter consists of two stages, DTOS and BIQUAD. DTOS is differential to single-ended converter having 8dB or 18dB gain. BIQUAD is modified Sallen-Key Biquad. Integrated resistors and capacitors are tunable. These are controlled with a digital control word. The correct control words that compensate for the process variations of integrated resistors and capacitors and of tolerance of off chip capacitors are found with the calibration circuit.

The next stage in the receiver chain is AGC-amplifier, also integrated into HAGAR. AGC has digital gain control via serial mode bms. AGC-stage provides gain control range (40 dB, 10 dB steps) for the receiver and also the necessary DC compensation. Additional 10 dB AGC step is implemented in DTOS stages.

DC compensation is made during DCN1 and DCN2 operations (controlled via serial bus). DCN1 is carried out by charging the large external capacitors in AGC stages to a voltage which effect a zero dc-offset. DCN2 set the signal offset to constant value ( $V_{ref}RF_02$  1.35 V). The  $V_{ref}RF_02$  signal is used as a zero level to RX ADCs.

Single ended filtered I/Q-signal is then fed to ADCs in BB. Input level for ADC is 1.45  $V_{pp}$  max.

Rf-temp port is intended to be used for compensation of RX SAW filters thermal behavior. This phenomena will have impact to RSSI reporting accuracy. The current information is -35ppm/C for center frequency drift for all bands. This temperature information is a voltage over two diodes and diodes are fed with constant current.

### Transmitter

Transmitter chain consists of two final frequency IQ-modulators for upper and lower band, a dual power amplifier and a power control loop.

I- and Q-signals are generated by baseband. After post filtering (RC-network) they go into IQ-modulator in HAGAR. There are separate outputs one for EGSM and one for GSM1800.

In EGSM branch there is a SAW filter before PA to attenuate unwanted signals and wideband noise from the Hagar IC.

The final amplification is realized with dual band power amplifier. It has two different power chains: one for EGSM and one for GSM1800. PA is able to produce over 2 W (0 dBm input level) in EGSM band and over 1 W (0 dBm input level) in upperband band into 50 ohm output. Gain control range is over 45 dB to get desired power levels and power ramping up and down.

Power control circuitry consists of discrete power detector (common for lower and upperband) and error amplifier in HAGAR. There is a directional coupler connected between PA output and antenna switch. It is a dual band type and has input and outputs for both systems. Directional coupler takes a sample from the forward going power with certain ratio. This signal is rectified in a schottky-diode and it produces a DC-signal after filtering.

#### AGC strategy

The AGC-amplifier is used to maintain the output level of the receiver in within a certain range. The AGC has to be set before each received burst with pre-monitoring or without pre-monitoring. In pre-monitoring, the receiver is switched on roughly 130 $\mu$ s before the burst begins, DSP measures received signal level and adjusts AGC-amplifiers via serial bus.

With this particular receiver architecture, there is 50 dB of accurate gain control in 10 dB steps and large LNA step ( approximately 25dB for E-GSM900 and 30 for GSM1800). **LNA AGC step size depends on channel to some extent.** 

In practice, this results in 6 accurate AGC steps and 2/3 non-accurate steps available to the UPP depending on the band.

Because of the requirement from the GSM specifications that each MS should be able to measure and report it's RSSI accurately when receiving levels below –48dBm, and due to the fact that the LNA step is not accurate, the LNAs should always be in the ON state in this situation. For all signals in excess of –48dBm the MS will report a constant value.

Step no.	AGC Step value	AGC Gain	Front-end LNA state	Front-end LNA gain	
				E-GSM900	GSM1800
1	0	-4	OFF	-7	-11
2	1	+6	OFF	-7	-11
3	2	+16	OFF	-7	-11
4	3	-4	ON	+18	+19
5	4	+6	ON	+18	+19
6	5	+16	ON	+18	+19
7	6	+26	ON	+18	+19
8	7	+36	ON	+18	+19
9	8	+46	ON	+18	+19

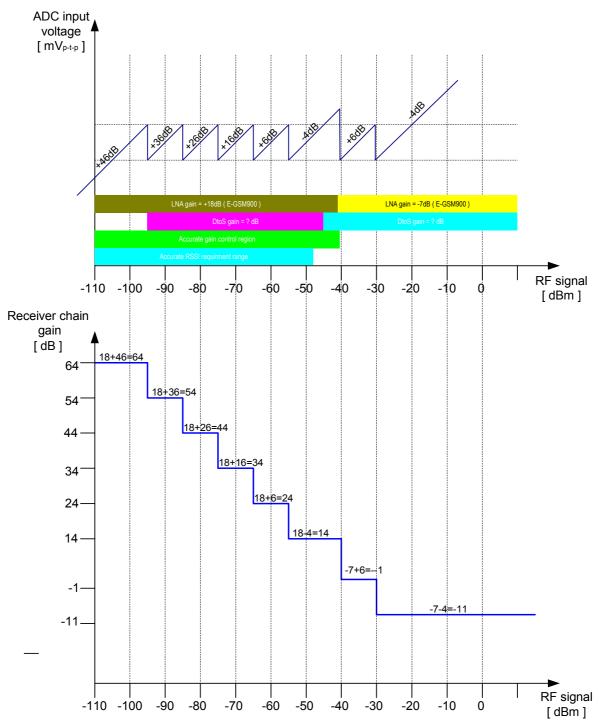

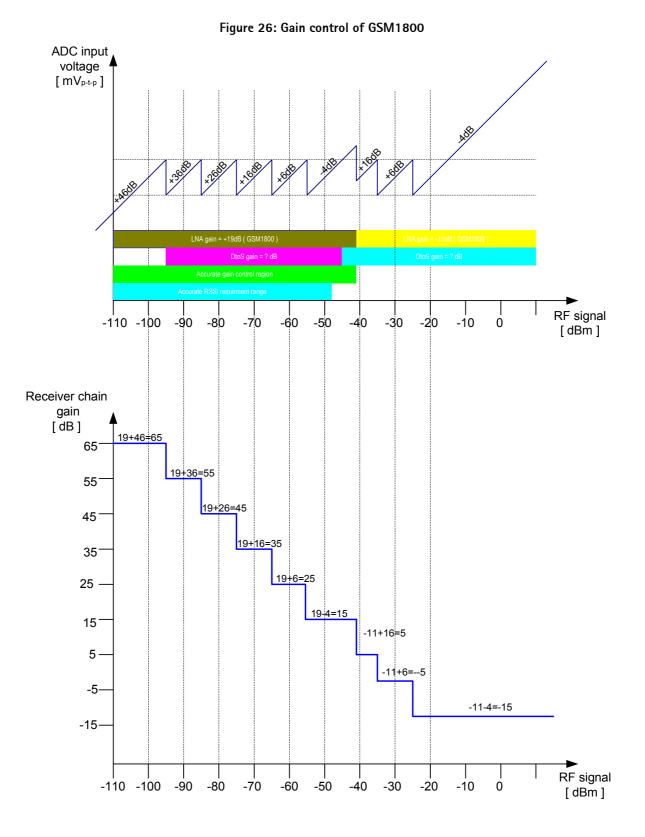

Figure 25: Gain control of E-GSM900

#### **AFC function**

The AFC is used to lock the transceivers clock to frequency of the base station. The AFC voltage is generated in baseband using an 11 bit DAC where an RC-filter is placed on the AFC control line to reduce the noise from the converter. The settling time requirement

for the RC-network comes from signaling, i.e. how often PSW slots occur. They are repeated after 10 frames. The AFC tracks the base station frequency continuously which enables the transceiver to have a stable frequency reference.

The settling time requirement is also determined from the allowed start up-time. When the transceiver is in sleep mode and "wakes-up" to receive mode, there is only about 5 ms for the AFC voltage to settle. When the first burst is received, the system clock has to be settled into  $\pm$  0.1 PPM frequency accuracy. The VCTCXO module also requires 5 ms to settle into the final frequency. The amplitude rises into full swing in 1 to 2 ms, but the frequency settling time is higher so this oscillator must be powered up early enough.

#### **DC-compensation**

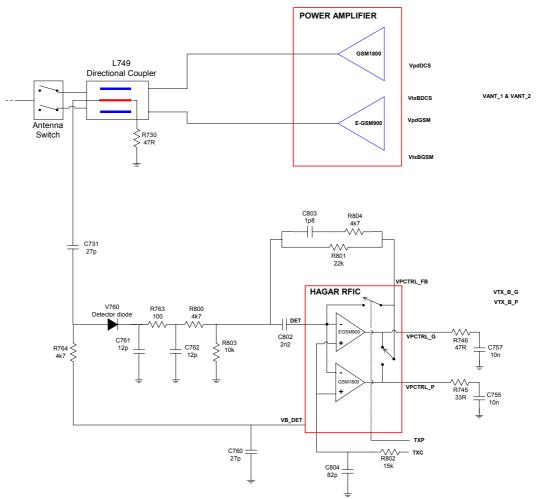

DC compensation is made during DCN1 and DCN2 operations (controlled via serial bus). DCN1 is carried out by charging the large external capacitors in AGC stages to a voltage which cause a zero dc-offset. DCN2 set the signal offset to constant value (RXREF 1.35 V). The RXREF signal is used as a zero level to RX ADCs.

#### Power control with analog temperature compensation scheme

The detected voltage level is compared by the HAGAR internal error-amplifier to the current TXC voltage level, which is generated by a DAC in BB. The TXC line is a so-called 'raised cosine' shaped function, the effect of which is to minimize the switching transients during the power ramp/decay phase. Because the dynamic range of the detector is not wide enough to control the power (more precisely, RF output voltage) over the whole range, there is an additional control line named TXP to work below detectable levels. The burst is enabled and set to rise with TXP until such time as the output level is high enough for feedback loop to kick-in.

The feedback loop controls the output level via a control pin in PA to the desired output level and burst has got the waveform of TXC-ramps. Because feedback loops could be unstable, this loop is compensated with a dominating pole. This pole serves firstly to decrease gain of the error amplifier at higher frequencies which in turn increases the phase margin (stability). Secondly, it also provides for noise filtering on the TXC line.

Before power ramp the temperature information from detector is stored to  $C_{temp}$ . This temperature information is used during the burst to compensate power levels at different temperatures. The TXP signal enables the antenna switch module to TX mode. There are two separate power control loops in HAGAR, one for E-GSM900 and the other GSM1800.

# **Grip Keyboard**

The grip keyboard interface requires 8 programmable GPIO pins, Figure 6. Construction of a GPIO in UPP\_WD2. These pins can be configured as Inputs (ROW), Outputs (COLUMN). NHL-2NA is supporting 4x4 = 16 keys (ROWS X COLUMNS). NHL-2NA's grip uses 16 keys. The interface has a 4-bit row common I/O port (P1) and a 4-bit column common I/O port (P0) to fulfill the keyboard interface functions. The transceiver keyboard interface can be connected to UPP\_WD2 with these 4+4 I/O-pins.

MCU performs the keyboard scanning.

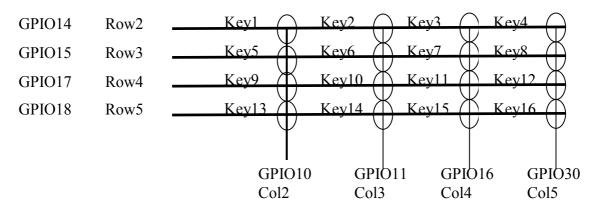

Note: Two keys can be pressed and noticed in any case.

### **Electrical implementation**

#### Figure 34: NHL-2NA's Grip keyboard implementation

Key16	End

### Unit limits

Table 6: Unit limits

Unit	Min.	Nom.	Max.
Pull up voltage, in UPP_WD2 (Measured from RowXX in)	1.65 V	1.8 V	1.95 V

### Vibra

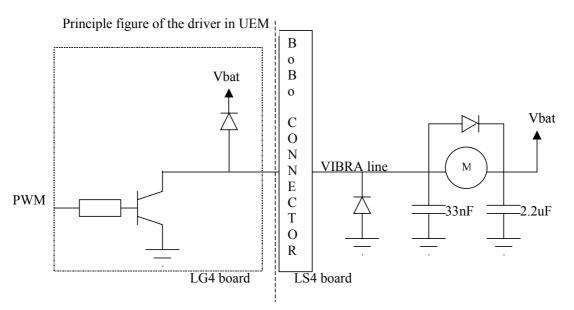

The NHL-2NA grip module includes a vibra. The Nokia code is available in the spare part list.

# **Electrical interface**

Vibra needs one line from flex for operating. The line is VIBRA.

The VIBRA line is also connected to BATGND via 33nF and 2.2uF capacitors for filtering the interference. Capacitors locate near to the vibra. Vibra driver has also protective diodes (see Electrical interface of Vibra) because of inductive characteristic of the vibra.

The vibra component is controlled by UEM vibra driver.

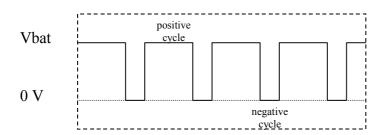

#### Figure 35: Electrical interface of Vibra

#### Table 7: Electrical properties of the VIBRA signal

Unit	Min	Nom	Мах
Current via vibra	50 mA	80 mA	135 mA
Vbat	3.0 V	3.7 V	4.2 V
Possible VIBRA signal frequency	64Hz, 129Hz, 258Hz a	ind 520Hz	
VIBRA pulse duty cycle	3%	47%	97%

#### Figure 36: Principle figure of the VIBRA signal

## Current Gauge

The current gauge is placed to the positive battery line terminal so that all current flow in either direction is registered. See Electrical-implementation of the current gauge.

The LM3822 component is well suited for the purpose since its serial resistance is only 3 mW and it has a PWM output. The current value and direction are indicated by the duty cycle of the PWM signal. Shutdown is controlled with a specific pin.

Unit	Min	Nom	Max
Resistance (between pins 1 and 8)		3 mΩ	
Current Range (average)	- 1.0 A		+1.0 A
Supply Voltage	2.5 V		5.5 V (Absolute Max)
Current consumption		2.5 uA (shut down) 90 uA (active)	
Cycle length (average)		52 ms	
Package	MSOP-8		
BATGND		0 V	
Peak Current (200ms)			10A (Absolute Max)

Note: External components (2x100nF capacitors) are needed.

### Interfacing the current gauge

AEM (locates on LG4) receives the PWM signal and calculates average duty cycle values to a register. SW can define how many PWM cycles are averaged, whether or not to give an interrupt to UPP\_WD2 after averaging is done. The PWM value for the last PWM cycle can also be found out. The shutdown control is also through AEM. AEM gives an interrupt to UPP\_WD2 indicating that current measurement is ready.

Note: Shutdown control is used to disable and enable the gauge.

Signal	Level	Polarity	1/0	to / from	Pin
Sense + / Vdd				Vbat	1
BATGND				Ground	2
Filter +				ext. capacitor	3
Filter -				ext. capacitor	4
ISD	Vbat	active Low	Input	AEM	5

#### Table 9: Signal properties

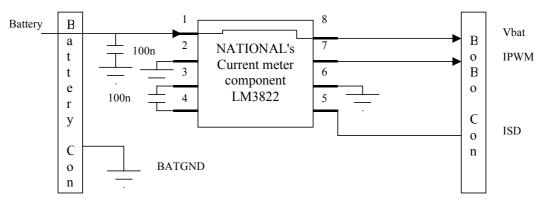

# NHL-2NA System Module LG4 and Grip Module LS4

#### **CCS** Technical Documentation

TEST				Ground	6
IPWM	Vbat	active HIGH	Output	AEM	7
Sense -		-lectrical-implementa		Transceiver Vbat	8

Figure 37: Electrical-implementation of the current gauge

Note: BATGND is the ground of the grip, not charger ground

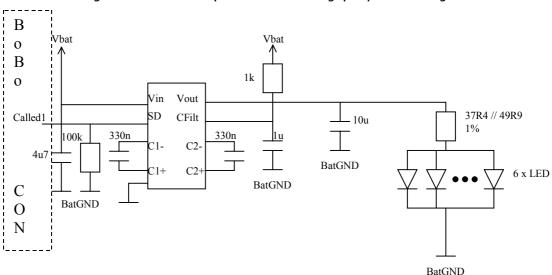

# Backlight

NHL-2NA grip keyboard uses six white backlight LEDs. These LEDs are "smart LEDs" (0.6mm height). The LED type is LWL88S, NMP code 4860331. NHL-2NA grip uses brightness groups M1-M2, N1-N2 and P1. There is only one brightness group in one grip-module.

### **Electrical interface**

The idea is to connect these six LEDs parallel. LEDs are using current that is taken from battery voltage. The voltage is controlled by charge pump (NMP code 4341137) and the current by serial resistor. The idea of the charge pump is to keep the supply voltage of the LEDs constant although Vbat changes. Serial resistors limit the current that goes to LEDs. Current for one LED is ~4mA. The circuit and LEDs consume ~52mA current.

LEDs need one line of flex (Called1). Called1 controls the charge pump SD pin. Called1 signal rises close to Vbat voltage (required for the SD signal in specification of the current pump). The output of the current pump is 4.1V (@Vbat 3.0V to 4.2V).

#### Figure 38: Electrical implementation of the grip keyboard backlight

# Hall Sensor and Magnet

NHL-2NA uses the Infineon Hall sensor TLE 4917 (NMP code 4341087) and magnet to find out the open/close position of the grip. The hall sensor component is in the transceiver unit and the magnet is in the grip module. See figure 9 for more information.

#### Magnet

NHL-2NA magnet (NMP code 6490201) locates on grip module.

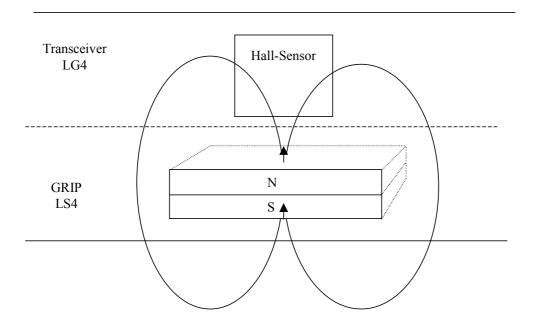

Figure 39: Basic principle of the hall-sensor implementation

Note: Hall sensor is independent on magnet flow direction, i.e. the magnet can be assembled in two ways; North-pole up or down.

# DC Jack and Battery Connector

Grip has battery connector (NMP code 5400255), DC-jack (NMP code 5400251) and board to board connector (NMP code 5460059). Signals of the battery connector and DC jack are described in table below. See also Signals between LG4 and LS4. NHL-2NA uses BLB-2 battery.

NOTE: Table below is for your convenience.

Connector	Signal	То	From	Value (BLB-2)
Battery	Vbat (sense)	Current Gauge	Battery con.	3.2 V - 4.2 V
	Btemp	ВоВо	Battery con.	1979kΩ - 4.26 kΩ (- 40°C - + 90°C)
	BSI	ВоВо	Battery con.	68kΩ
	BATGND	ВоВо	Battery con.	0 V

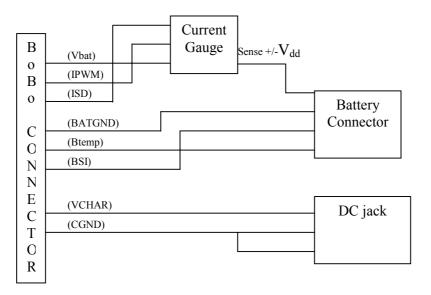

Table	10:	Batterv	connector	signals.
rauic	10.	Dattery	connector	signals.

Connector	Signal	То	From	Value (accepted charger)
DC jack	CGND	ВоВо	DC jack.	0 V
	VCHAR	ВоВо	DC jack.	5.0 V – 9.8 V
	CGND	ВоВо	DC jack.	0 V

### Electrical interface

The basic principle of connections between connectors are described below.

#### Figure 40: Figure 15. Electrical implementation of the connectors
