Disassembly of NSB-6

Remove battery.

1.

Step 1. Press the button on the side.
Step 2. Slide the cover downwards and the cover will be released.

2.

Step 3. Lift the battery first from the lower end.
Step 4. Remove the battery.

3.

Remove the SIM card from its location.

4.

Remove the slide cover.

Step 1. Open the slide cover.

Step 2. Push the slide edge outwards.

NOTE: Use only numbered side 2 to release the slide.

Step 3. Lift the slide up simultaneously and the slide will be released.

Remove the antenna.

5.

NOTE: Pull out the whip antenna first.

Step 1. To remove the antenna, push with the thin spike of SRT-3 (Battery Connector Extractor Tool) forward to release the snaps.

Step 2. Release snap fixing using screw driver.

Step 3. Lift up the antenna.

NOTE: Be careful not brake the middle frame.

6.

Remove the frame screws (4 pcs). Screws are numbered according to the tightening order.

NOTE: When assembling the screws, use 15 Ncm torque.

7.

Remove A-cover, speaker and power button.

8.

Remove keymat module screws (2 pcs).

NOTE: When assembling the screws, use 17 Ncm torque.

9.

Push SW/slide switch before removing the keymat module. Now remove the keymat module and RTC-battery. **NOTE:** Be careful not to damage the SW/slide switch on the PCB.

10.

Parts can be separated:

- lcd module
- PCB
- buzzer rubber
- metal gasket
- bottom connector
- SIM connector
- Twin Rip
- vibra

Turn the phone around.
Press down battery connector springs
using Battery Connector Extractor Tool.
Battery connector will be released.

Release the latch snap.
Remove the latch and latch spring.

Transceiver Troubleshooting

Baseband Troubleshooting

Because of the underfilling of the MAD and combo memory, it is impossible to change those.

Testing

The MCU software enters a local mode at start-up if suitable resistors are connected to the BTEMP and BSI lines.

NOTE! Baseband doesn't wake up automatically when the battery voltage is connected. Power must be switched on by

- pressing the Power key or
- inserting a waking pulse BTEMP line or
- connecting a charger

In the local mode the baseband can be controlled through MBUS or FBUS connections by a PC-locals software. Baseband internal connections are tested with selftests if possible.

Parameters cannot be set accurate enough by design because of component tolerances. Due to use of 5% resistor values, the channels of the CCONT A/D converters need to be aligned in the production phase. Within battery voltage tuning the MCU software reads the A/D reading from CCONT at 4.1V and stores this reading to emulated EEPROM memory as a reference point. Another reference point is created by assuming that while the input voltage is zero, A/D reading is also zero. Now the slope is known and A/D readings can be calibrated. Calibration is included in VBATT A/D reading task.

Troubleshooting

Troubleshooting instructions are divided into following sections:

How to check/fix the system/sleep clock.

How to check/fix the power supplies.

Contact service case.

How to check/fix the SIM faults.

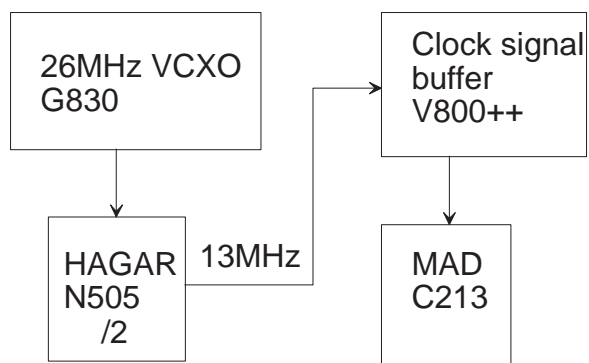

How to check/fix the Audio faults.

How to check/fix the charger faults.

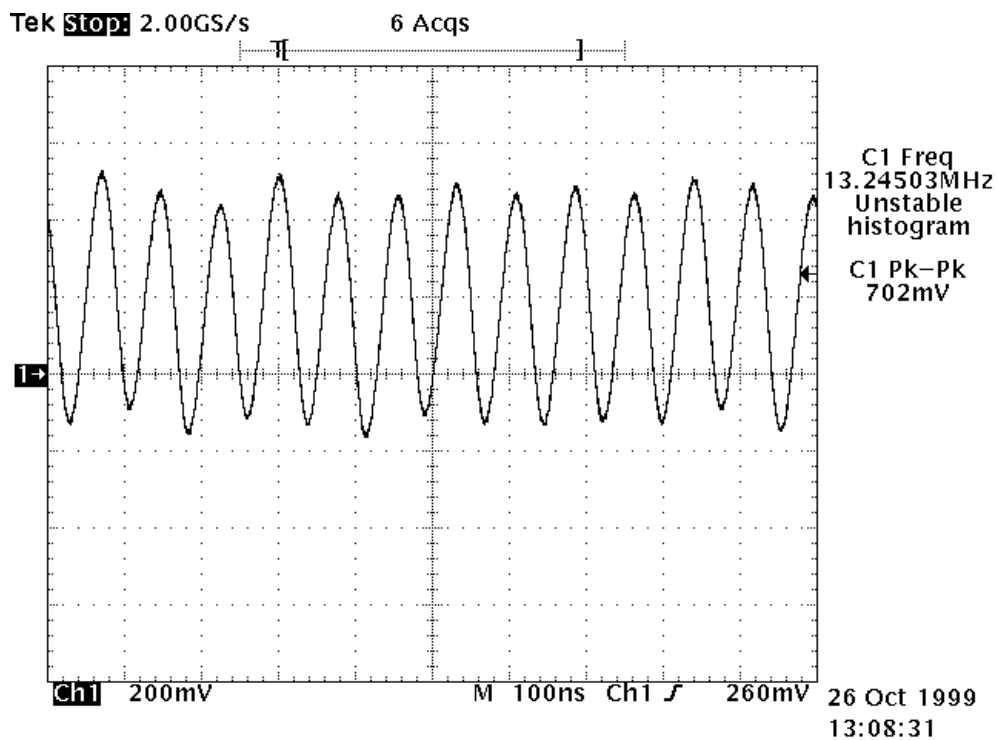

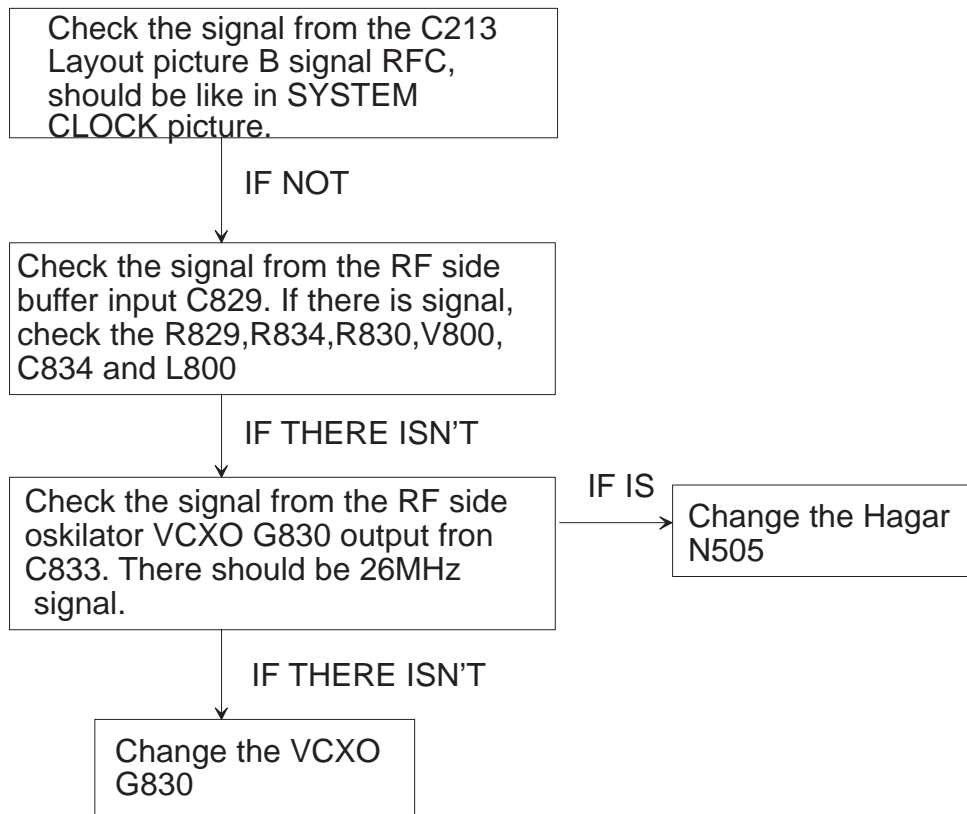

The first thing to do is to carry out a thorough visual check of the module.
Make sure that:

- there are no mechanical damages
- solder joints are OK

Before changing anything ALL SUPPLY VOLTAGES AND SYSTEM
CLOCK / SLEEP CLOCK should be checked.

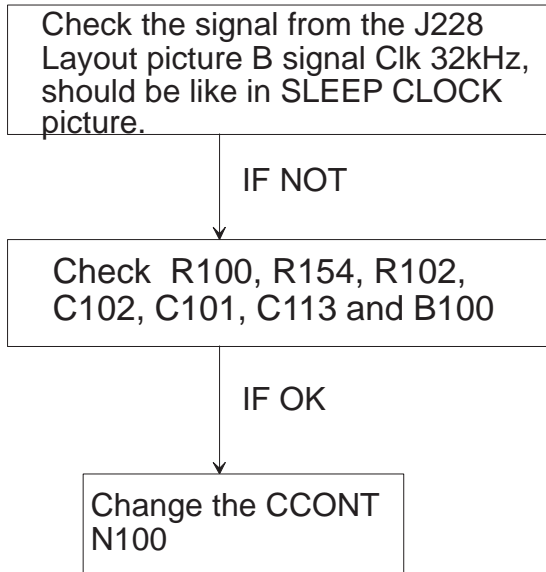

System Clock

System clock picture.

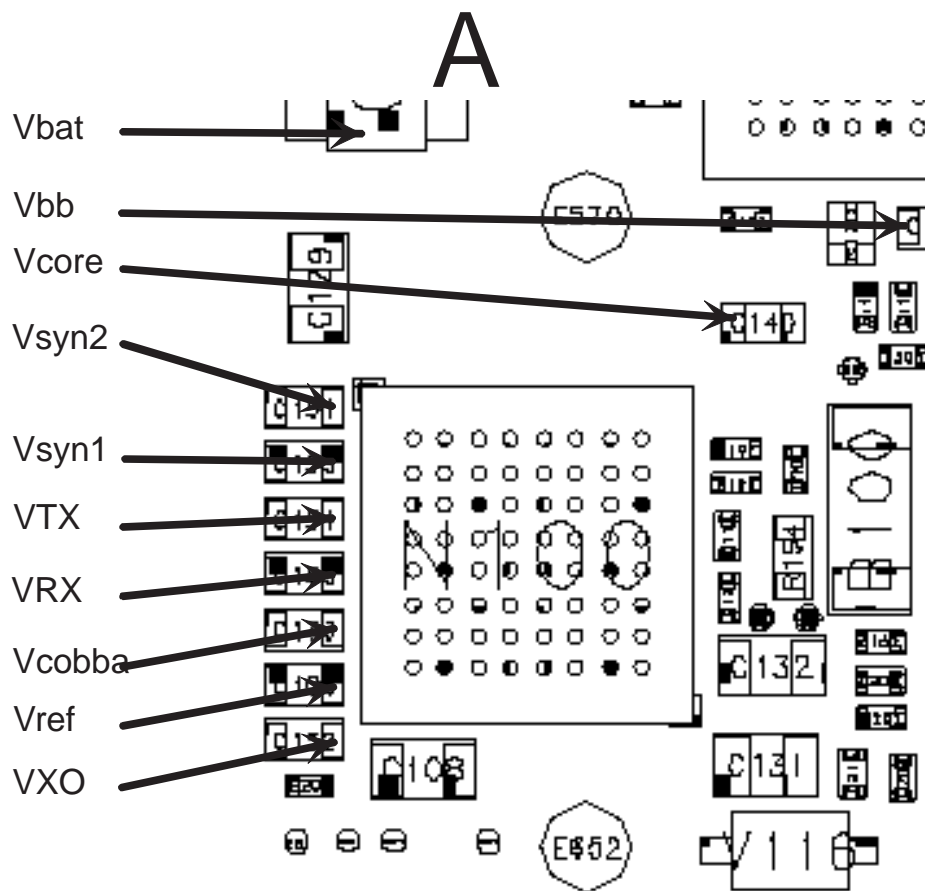

Sleep Clock

Sleep clock picture.

Power Supplies

Measure power supplies. Test points are shown in layout picture A.
Layout example shown here is NSM-2.

Vbb	= 2.7V – 2.87V
Vcore	= 1.3V – 2.65V
Vcobba	= 2,67V – 2.85V
Vref	= 1.48V – 1.523V
Vbat	= 3.11V – 4.2V
VXO	= 2,67V – 2.85V
VRX	= 2,67V – 2.85V
VTX	= 2,67V – 2.85V
Vsyn1	= 2,67V – 2.85V
Vsyn2	= 2,67V – 2.85V

Power up sequence test:

Ccounts digital parts keep MAD in reset by keeping PURX down for a delay of 62ms.

Here is shown the start up sequence picture.

- Ch1 = Vbb
- Ch2 = VXO
- Ch3 = SleepClk
- Ch4 = PURX (see picture B)

B

Phone is totally dead

The phone doesn't take current at all when the power switch is pressed or when the watchdog disable pin (X001 pin 11) is grounded. Make sure that the battery voltage you use is within the specification, i.e. 3.11 .. 4.2 V. If the voltage is lower, hardware of CCONT (N100) prevents power on.

IF battery voltage is inside the specification Change the Ccont.

Flash programming fails

The flash programming can be done via panel connector X001 or via dedicated PCB pads. In production, the first programming is done via panel connector. After this, the panel connector is cut away, thus the programming must be done via PCB pads visible through the shield under the battery. The main difference between these is that FLASH-programming voltage is produced differently. The fault finding diagrams for flash programming is shown in the start up sequence picture.

In flash programming error cases the flash prommer can give some information about a fault. The fault information messages could be:

- MCU doesn't boot
- Serial clock line failure
- Serial data line failure
- External RAM fault
- Algorithm file or alias ID not found
- MCU flash Vpp error

Power doesn't stay on or phone is jammed

If this kind of fault has come after flash programming, there are most probably open joints in ICs. Solder the joints of ICs. Normally the power will be switched off by CCONT (N100) after 30 seconds if the watchdog of the CCONT can not be served by software. This updating can be seen with an oscilloscope at CCONTCSX (J104). In normal case there is a short pulse from "1" to "0" every 8 seconds. The power off function can be prevented by connecting WDDIS (R118 edge side head) to ground.

Because of the underfill, check the supply voltages, clock signals and power up sequence. If power on sequence fails, there are some open connections under MAD or compomemory. If all seems to be correct, it is best way to erase the flash memory and try to put new software to phone.

Contact Service on the phone display

This fault means that software is able to run and thus the watchdog of CCONT (N100) can be served. Selftest functions are run when power is switched on and software is executed from flash. If any of the selftests fails, a "contact service" text is shown on display.

MCU self tests are divided to those executed while power up (start up tests) and ones that can be executed with connected PC. The tests and included items are as follows:

1. MCU ROM checksum

Calculates 16 bit checksum out of Flash code and compares it to one found in Flash.

Items being checked are:

MAD2 <—> Flash data and address lines, CE0,CE1, WE, BYTE, Vcc, GND, Flash internal functionality

2. MCU RAM interface

3. MCU RAM component

4. MCU EEPROM interface

5. MCU EEPROM component

6. RTC battery

7. CCONT interface

8. A/D converter

9. SW reset

A. Power off

B. Security data

C. EEPROM tune checksum

D. PPM checksum

E MCU download DSP

F. DSP alive

G. COBBA serial

H COBBA parallel

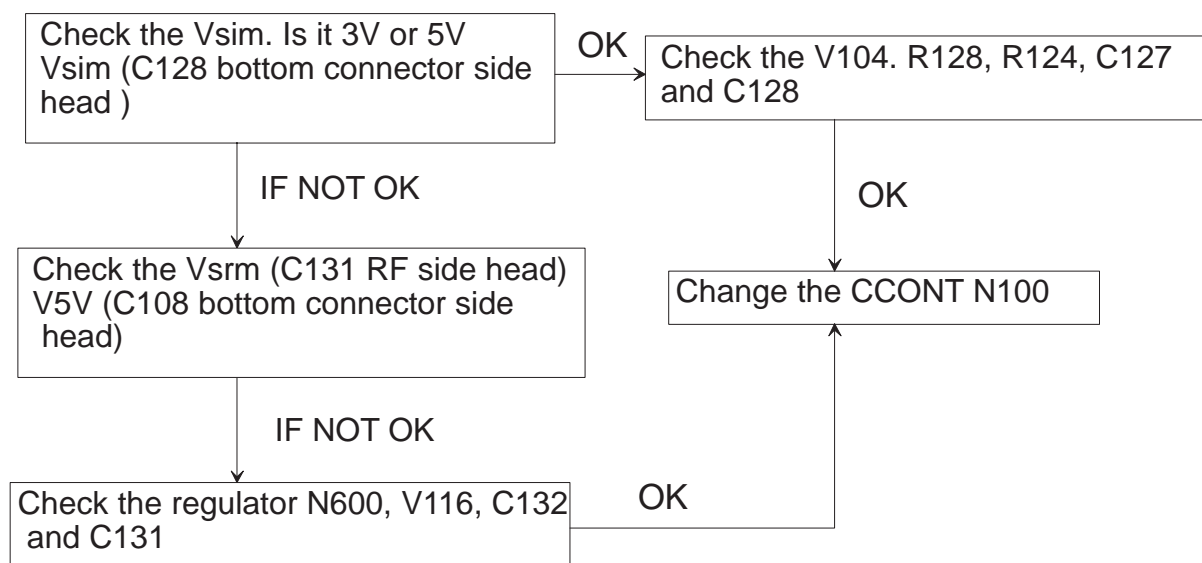

I. EEPROM checksum

K. PPM validity

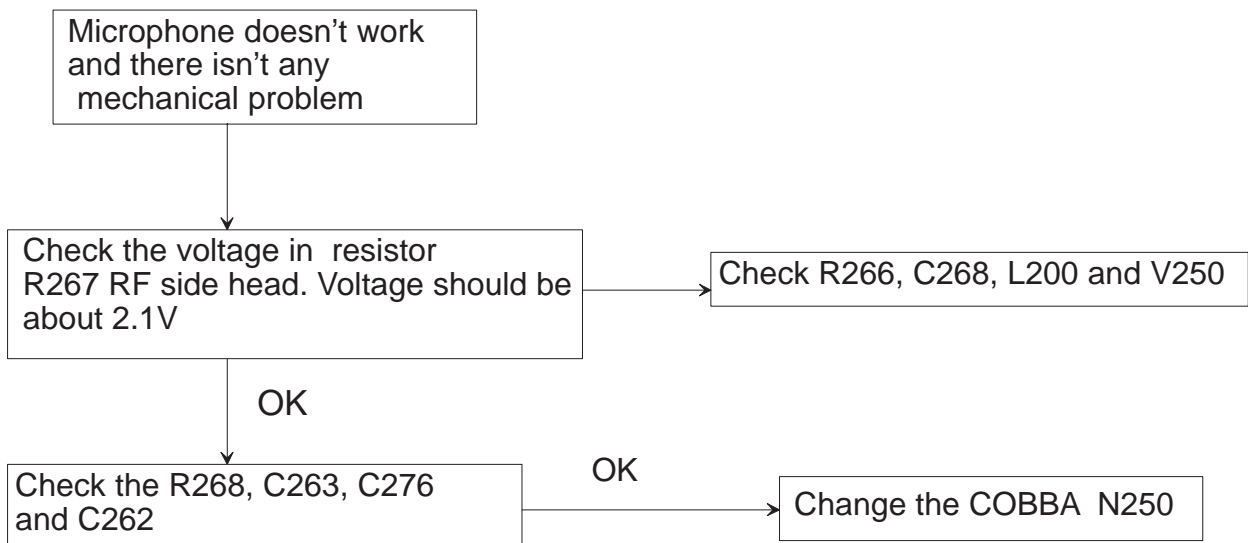

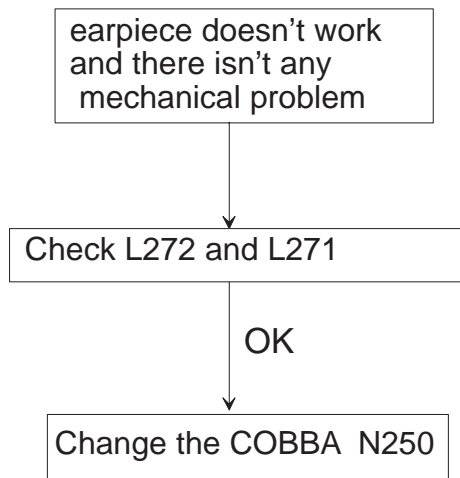

SIM related faults

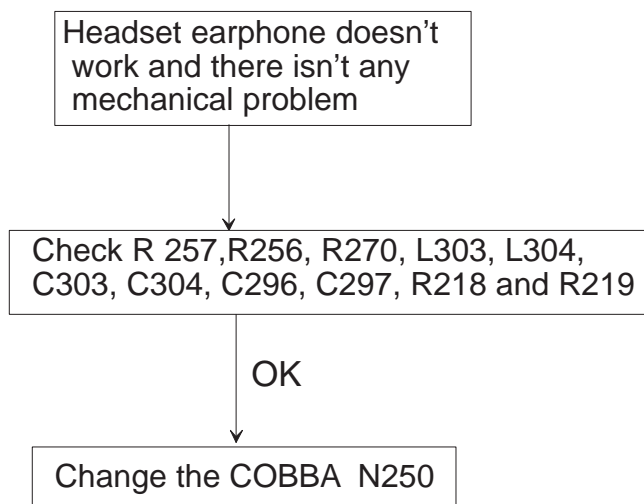

The hardware of the SIM interface from MAD2 (D200) to the SIM connector (X302) can be tested without a SIM card. When the power is switched on and the BSI line is grounded by a resistor, all the used lines (VSIM, RST, CLK, DATA) rise up to 5 V four times. Thus "Insert SIM card" faults can be found without SIM card.

The fault information "Card rejected" indicates that ATR message (the first message is always sent from card to the phone) is sent from card but the message is somehow corrupted, data signal levels are wrong etc. or factory set values (stored to the emulated EEPROM) are not correct.

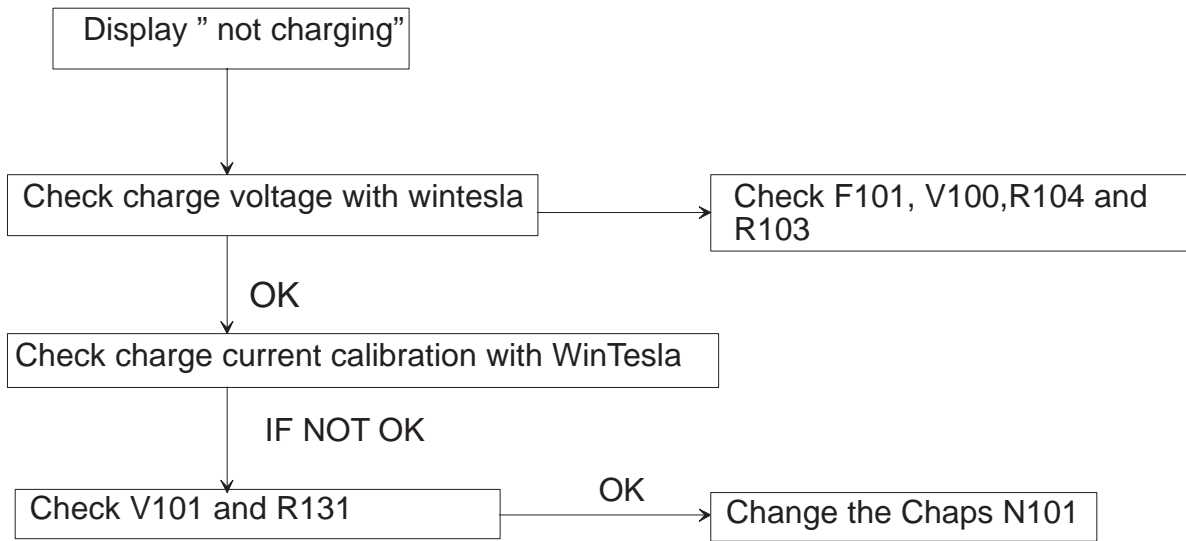

Audio faults

Charging fault

RF Testpoints (reference pictures at the back of the binder after schematics diagrams)

RX

DC levels (oscilloscope)

Point	Signal	Component	Comment	Picture
RX1	RXIP and RXQP	R530	I/Q signals (67 kHz) from Hagar to COB-BA.	1
