Title: Factorial Analysis (Fixed Point)
Author: Richard A. Lamm
Date: January 25, 1961
Installation: Lederle Laboratories, Pearl River, N. Y.
Classification: F4-222

Abstract

The program performs the analysis of variance for data from complete factorial experiments with one to five main factors and 'r' observations per cell. The program is in fixed point and it uses double precision arithmetic. Since the effects to be computed are completely arbitrary, the program may be used for hierarchial designs with equal numbers of observations per cell, split plot designs and others.

3. Description

The program, which operates in the fixed point mode with double precision arithmetic, computes the analysis of variance of complete factorial designs. There may be from 1 to 5 factors labeled a, b, c, d and e with r observations per cell. The number of levels for the factors may be of any magnitude provided that the number of data and the maximum number of partial sums to be generated are, together, less than 2369 (2497 if the logarithmic transformation is not used). If r is greater than one and the highest order interaction is desired, the restriction becomes $abcde(r+1) < 2369$ (or 2497). The number of data, abcder, may not exceed 2048. The total sum of squares (corrected for the mean) must be less than 2^{30} .

The program requires the use of the flexowriter for input and output. It uses constants as delays. The α -numeric code word in location 0105 will function only with the flexowriter.

The program contains its own data input routine. Since all data are entered at a q of 30, scaling of the numbers is generally required. The program provides for two kinds of scaling.

Prescaling: The factor by which data must be multiplied in order to make all numbers integers. In some cases, it may be necessary to reduce the size of the data numbers by a power of 10 in order to satisfy the restriction on the total sum of squares.

Postscaling: Usually it is possible to have four digits or more per datum without encountering difficulty with the size of the total sum of squares. The program provides for the internal multiplication of the entered data by 10 or 100 in order to avoid the typing of additional zeroes on the data tape. It is desirable to have the numbers as large as possible in order to minimize the effect of rounding errors.

The choice of effects to be computed is completely arbitrary. The program computes only those effects which have positive codewords (effect selectors). The adjustment of the effect selectors to positive or negative is done during data tape input (see Input). The effect selectors (locations 1500-1530 of the program) have the additional feature of being codewords for a special five character per word α -numeric routine which is included in the program.

By use of this selection, it is possible to perform the analysis of hierarchical designs with equal numbers of observations per cell at each level. For example, for a design with four levels of hierarchy, the selection of the a, ab and abc effects only (exclude b, c, ac and bc) will give the desired analysis. The "error" line will give the lowest level effect.

The table of means is printed if and only if the sum of squares for the effect is selected for computation. The printing of the means may be omitted by depressing the Transfer Control switch. The heading for the means will not be excluded by this procedure.

If r is 1, it is recommended that the highest order interaction be omitted from computation so that the error line is non zero. If the recommendation is not followed two stops will occur; the first at 0908 when it is attempted to obtain $abcd/abcd$ at 0; the second at 1301 when it is attempted to compute $1/ems$ (error mean square) = $1/0$ at 0. If the recommendation is followed, the "error" line will contain the highest order interaction.

The input routine provides for an optional transformation of the data to $1000 \log$ (scaled datum). Branching to the log routine is accomplished if the transformation read from tape after the printing of "TRANSFORM:" leaves at least a 25 at 29 in the accumulator. If this information is "y" for untransformed and " $1000 \log y$ " for transformation the input will function correctly.

Input:

The data tape should contain:

1. A carriage return (optional) and the Job Number, problem description or the like followed by a conditional stop.
2. A carriage return, the number of levels of each factor a, b, c, d and e and the number of observations for each cell, r, as: a'b'c'd'e'r'. If all five factors are not present a 1 is used for those not present. Those present appear first. If possible, it is suggested that factors be ordered so that those with the fewest (non-singular) levels appear first, since the operating time will be minimized in this way (e.g., less time is required to compute the analysis of a 2 x 3 x 4 factorial than for a 4 x 3 x 2 factorial). However, if this will make the typing of the data more difficult, the suggestion should be disregarded.
3. A carriage return and a 0 or 1 followed by a conditional stop. A 0 is used if the effect selectors are to be altered. A 1 is used if the selected effects are not altered from the previous computation. The program tape contains the code words such that all effects are computed.

If the previous character is 0, the tape should contain $2^F - 1$ effect selectors with a condition stop after each selector (F is the number of non-singular factors). The selectors should be entered for the standard order of effects, namely, a, b, ab, c, ac, bc, abc, etc. The selector should be 1 if the effect is desired, 0 if it is not. If r is 1, the last selector should always be 0.

4. A carriage return followed by:
 - a. Lo data, conditional stop (provide abcder consecutive locations)
 - b. Lo partial sums, conditional stop (provide consecutive locations as required by design)
 - c. Prescaling factor (e.g. 100x where x is the original datum), conditional stop
 - d. Post scaling factor (1, 10 or 100), conditional stop
 - e. Transformation (y or 1000 log y), conditional stop.

5. A carriage return followed by the data in standard factorial order, that is, for a 2^3 experiment enter $a_1b_1c_1$, $a_1b_1c_2$, $a_1b_2c_1$, $a_1b_2c_2$, $a_2b_1c_1$, $a_2b_1c_2$, $a_2b_2c_1$ and $a_2b_2c_2$. For most problems the majority of the final scaled numbers should contain four decimal digits. Negative numbers must be entered with a minus sign and seven digits. Leading zeroes are required for negative numbers only.

Output:

1. Means: The program prints 10 times the scaled mean for each level of each selected effect. The means for each effect are preceded by the designation of the effect. The means are printed in the standard factorial order (see Input 5). If the Transfer Control switch is depressed the means will not be printed but the effect designation will be printed. If any selected effect contains more levels than are printable on one line an automatic carriage return (ACR) must be used. The ACR should be placed to allow at least 5 entries per line and preferably more. (If only 5 entries per line are provided, the analysis of variance will be double spaced.)

2. Analysis of Variance: Under the appropriate headings of "Effect", "d.f." (degrees of freedom), "S O S" (Sum of Squares), "M S" (Mean Square) and "100 ms/ems" (scaled mean square divided by error mean square), the program prints:
- a. total, total d.f. and total S O S.
 - b. For each selected effect, the effect designation, d.f., S O S, M S as well as 100 ms/ems unless the M S exceeds 5,368,709, in which case the latter will be omitted.
 - c. The word "error" (residual), d.f., S O S, M S. This line will contain the effects of all interactions of order higher than the highest computed as well as the variation within individual cells.

Method:

A standard computational procedure is used by the program [1].

In particular, for any effect the S O S is computed as:

$$\Sigma [(P\Sigma)^2/n] - (\text{Tot } \Sigma)^2/abcd\text{er} - (\text{S O S for Main Effects and Lower ordered interactions in effect})$$

where $P\Sigma$ is the partial sum for a level

and n is the number of observations in the partial sum.

Determination of the S O S for other effects to be subtracted from the first two terms of the above expression is made by the masks contained in 1532-1562 of the program. If any of these effects have not been computed, a zero is subtracted in place of them. For example, if the S O S for a is computed and the S O S for b is omitted, the S O S for ab contains the effect of b as well as ab. In this case the ab represents a "b within a" effect.

Since each $(\Sigma)^2/n$ may be subject to a round-off error of 1 in the last place, the accuracy of the output is limited only by these errors.

4. Operating Procedure

With the Program Input routine (10.4) in 0000-0263, store the subroutines as follows:

<u>Routine</u>	<u>Location</u>
$\text{Log}_k x$ (18.0) if required	1700 - 1857
α -numeric (19.0)	1900 - 1957
Integer Printout (J4-172)	1000 - 1058
Data Output 30 (J4-173)	2500 - 2651
Double Precision Sum of Squares or Products (F1-164)	6000 - 6263
Factorial Analysis	Lo - Lo + 1662

If it is desired to relocate the subroutines 18.0, 19.0, J4-172 and J4-173 because of space requirements for data and partial sums or because of other storage requirements of the user, fill the appendix program in Lo + 1663 to Lo + 1739 by pressing "start compute" at the completion of the filling of the program tape. At the completion of filling the appendix program, depress the manual input switch on the flexowriter and press "start compute". Type and fill:

xz (Lo Output 30)	J4-173
xz (Lo Integer Printout)	J4-172
xz (Lo α -numeric)	19.0
xz (Lo $\text{Log}_k x$)	18.0 if required.

(Note that provision is not made for the change of location of F1-164.)
 Halt and transfer to Lo + 1700. When the computer stops at Lo + 1737
 the appendix program may be destroyed.

In addition to the storage requirements of the program (17 tracks) and
 the subroutines (less than 9 tracks) the program also uses 6300 - 6331
 for the storage of d.f. for the analysis of variance and 6332 - 6363
 for the storage of Sums of Squares. The order of storage is the same
 as that of the codewords (1500 - 1531). The program uses the binarization
 routine of 10.4 to binarize Lo (data) and Lo (PΣ) (see 0055 and 0062 of
 the program).

The Transfer Control switch should be up unless the means are not desired.

The Breakpoint 16 switch should be up unless more than one problem is
 to be run. If Breakpoint 16 is depressed, the program automatically
 returns to Lo of the program to receive another problem.

To perform an analysis, place the data tape in the reader and halt and
 transfer to Lo of the program.

Tab stops should be placed at intervals of at least 6 with an ACR at the
 end if the problem requires it (see Output).

Program Stops:

0238 - α + 5 of DPSOSOP (F1-164) calling sequence. The total sum of
 squares exceeds $2^{30}-1$. Do not continue. If the start is pressed,
 the program will continue with an incorrect total S O S and hence
 an incorrect error sum of squares. If this stop does occur, enter

the modification (see below) and continue by transferring to Lo + 0238.

0908 - Divide check - abcdcr/abcdcr at 0. The recommendation for effect selection was not followed. Action: go to manual input on the console, type 7wwwwwq and return to normal operation and start.

1301 - Following stop at 0908: error mean square is 0. Press start to continue. 100 ms/ems will be incorrect. Other: error mean square is 0 or 1. Press start to continue. If error mean square is 1, the results will be correct. If 0, 100 ms/ems will be incorrect.

1454 - Breakpoint 16. The problem is completed.

Modification

If the program stops at Lo + 0238 because the total S O S exceeds $2^{30}-1$ or to guard against this stop, make the following modifications. (Lo = initial location of program; Mo = initial location of modification.)

1. Change Lo + 0238 to xu(Mo)
2. Add:

<u>Location</u>	<u>Program Input Code</u>	<u>Instruction</u>	<u>Note</u>
Mo	/0000000	b(Lo + 0236)	Lo data
Mo + 1		y(Mo + 5)	
Mo + 2		y(Mo + 8)	
Mo + 3		a(Lo + 0237)	abcdcr at 29
Mo + 4		y(Mo + 26)	
Mo + 5		b[]	datum at 30

<u>Location</u>	<u>Program Input Code</u>	<u>Instruction</u>	<u>Note</u>
Mo + 6		a(Mo + 23)	5 at 30
Mo + 7		m(Mo + 24)	1/10 at 0
Mo + 8		c[]	datum
Mo + 9		b(Mo + 5)	
Mo + 10		a(Mo + 25)	1 at 29
Mo + 11		y(Mo + 5)	
Mo + 12		y(Mo + 8)	
Mo + 13		s(Mo + 26)	
Mo + 14		t(Mo + 5)	
Mo + 15		r { 19.0 }	
Mo + 16		u { }	
Mo + 17	,0000005'	201f4f7f	Print:
Mo + 18		6f720j4f	"rescale y by 1/10"
Mo + 19		0612060f	
Mo + 20		12060j26	
Mo + 21		0j0420vq	
Mo + 22		u(Lo + 0233)	
Mo + 23	,0000004'	0000000f	5 at 30
Mo + 24		0jjjjjjj	1/10 at 0
Mo + 25		00000004	1 at 29
Mo + 26		000b0000	Test for Loop

Descaling Output

If the data have not been transformed and they have been prescaled by 10^p and postscaled by 10^q , then the output is descaled by dividing by 10^n where

$\frac{n}{p + q + 1}$	for means
$\frac{n}{2(p + q)}$	for S O S, M S
$\frac{n}{0}$	for d.f. and
$\frac{n}{2}$	for ms/ems (F)

If the logarithmic transformation is used

<u>divide by</u>	<u>and subtract</u>	
10,000	$p + q$	for means
1,000,000	0	for S O S, M S
1	0	for d.f.
100	0	ms/ems

Timing:

The sample problem (3 x 3 x 3) required 4 minutes 20 seconds.

Reference

- [1] Snedecor, George. Statistical Methods 5th Ed. Iowa State University Press, Ames, Iowa (1957). Sections 12.6, 12.11

Sample Problem

The sample problem is a 3 x 3 x 3 factorial for which the complete analysis is desired. The data is:

		A ₁	A ₂	A ₃
B ₁	C ₁	1.59	2.60	1.46
	C ₂	3.95	4.54	4.17
	C ₃	1.49	1.12	1.50
B ₂	C ₁	0.25	0.98	1.03
	C ₂	2.55	4.22	4.55
	C ₃	2.51	2.70	1.72
B ₃	C ₁	1.84	2.37	1.95
	C ₂	3.63	3.62	4.92
	C ₃	3.78	3.63	2.78

Since r is 1, it is necessary to alter the effect selectors. In order to eliminate the decimal places, it is necessary to prescale by 100, and since it is desirable to have at least four digit numbers, the data may be postscaled by 10. If the data is to be stored from 3000 on, and the partial sums from 3100 on, the data tape contains:

```
Sample Problem'
3'3'3'1'1'1'1'
0'1'1'1'1'1'1'1'0'
3000'3100'100x'10'y'
159'395'149'25'255' ... 195'492'278'
```

The results are as shown on page 14.

If, in the same data, it is assumed that the B's are subclasses within A₁ and the C's are multiple observations within the B's, the appropriate analysis is a hierarchial as shown on page 15.

For this example the data tape contains:

```
Sample Problem'
3'3'1'1'1'1'3'
0'1'0'1'
3000'3100'100x'10'y'
159'395' ... 492'278'
```
