

Program No. K2-71

REPOSITIONAL DECIMAL MEMORY PUNCH (RDMP)

Western Electric

PURPOSE:

To punch out a decimal tape of any area of memory. This tape may then be read in by PIR and repositioned in memory.

INPUT:

- (1) L_o L_f = The boundary addresses of the area to be punched. Area may contain instructions and hex words inter-mixed.
- (2) M = The modifier or the amount to be subtracted from each absolute address that is to be de-modified.
- (3) Loh Lfh = The boundary addresses of any special area within the punch area to be punched in hex regardless of contents of words. This does not control the normal punching of Hex words.

OUTPUT:

A repositional decimal tape of the punch area including Hex load code words and Hex words. The operand address of instructions is "demodified" if the operand address, A_w , of the word w in location, L_w is:

$$M \leq A_w \leq L_f$$

By "de-modification" we mean that if the above condition is true, the modifier, M , is subtracted from the operand address; $A_w - M$ = relative address.

If $M \leq A_w \leq L_f$ the punched command will be preceded by an X.

P and I instructions are not de-modified, and are always preceded by an X.

Hex words are printed out in groups of a maximum of 9. The Hex load code for the PIR ,000000H' is punched preceding each Hex word load, The H may vary from 1 to 9.

For example, 11 sequential Hex words will be punched as follows:

----, 0000009' Hex 1' Hex 2'-----Hex 9'
,0000002' Hex 10' Hex 11' -----

SUMMARYENTRANCE:

At first location of this program.

INPUT:

- (1) L_o L_f = Area to be punched

THIS PROGRAM IS AVAILABLE TO
MEMBERS OF POOL ONLY. DISTRIBUTION
TO NON MEMBERS OF POOL IS PROHIBITED.

REPOSITIONAL DECIMAL MEMORY PUNCH (RDMP)

Summary (continued)

LO Lf = XXXXYYYY
Press start compute

(2) M = modifier
M = XXXX
Press start compute

(3) Loh Lfh = Area to be punched in Hex
LOh Lfh = XXXXYYYY
(Note: If Lo Lf = 0000 0800, 0000 would be punched in hex unless 0000 < Loh Lfh)
Press start compute

Carriage will now return and computer will stop. Turn on punch, enter whatever heading is necessary, run a few inches of blank tape,* and press start compute. Punch out will now proceed.

OUTPUT:

A decimal tape which may be entered and repositioned by the PIR.

STOP:

No programmed stops except as noted above.

T-C:

T-C up, 8 words/line; T-C down, 10 words/line

NOTES:

The modifier, M, will be subtracted from any address A_w when $M \leq A_w \leq L_f$ and the de-modified or relative address punched.

If L_w is not as above, the instruction is preceded by an X and the absolute address will be punched. No P or I instructions are demodified.

In case there are several constants within the area to be punched, the A_w 's which are $M \leq A_w \leq L_f$, these constants may be placed in a group and the area of this group given as $Loh\ Lfh$. Then that area will be punched as Hex.

*If High-Speed tape punch is used, refer to page 5.

Any word resembling a (-TXXXX) instruction will be punched as such, unless given the proper $Loh\ Lfh$. No other (-) instructions will be punched in decimal

EXAMPLES:

Suppose we wish to punch this R.D.M.P. which we have developed in the area 4000 to 4563.

To punch this entire area in relative form, we give:

Lo Lf = 4000 4563'
M = 4000'
Loh Lfh = 0000' or just'

Program No. K2-71

REPOSITIONAL DECIMAL MEMORY PUNCH
Western Electric Company

EXAMPLES:

Here is a sample of the punch:

```
xp1650'xz0007'r0517'u0463'a0540'c0225'r0517'u0548'
c0310'r0517'u0463'y0204'y0309'r0517'u0463'a0029'
c0135'40517'u0548'xp1605'a0540'c0147'b0225's0204'
xz0001'y0206'b0135's0147'c0135'xz0002'u0104'b0411'
```

and so on until Lf is reached.

Notice that XZ0000' is punched for zero words.

Note also that the P orders are not de-modified. P and I orders are never de-modified and are always preceded by an X.

Now let us punch from the same area:

```
Lo Lf = 4000 4009
Lm = 4000'
Loh Lfh = 0'
```

```
xp1650'xz0007'xr4517'xul463'xal4540'xcl4225'xr4517'xul4548'
xcl4310'xr4517'.0000000'
```

Notice that no instructions are de-modified because no

$$M \leq Aw \leq Lf$$

Notice also that the stop and transfer code .0000000' is punched after the last word to be punched.

Again, from the same area:

```
Lo Lf = 4000 4009'
M = 4000' (not really needed)
Loh Lfh = 4005 4007'
```

This means that the words 4005, 4006 and 4007 will be punched in hex.

```
Hex load word
xp1650'xz0007'xr4517'xul463'xal4540', 0000003'k2f64'32kl44'
f2kjo'xcl4310'xr4517'.0000000'
```

Notice the hex load word, 0000003' is not counted in the words/line count

Now, we punch from the same area a group containing hex words.

```
LoLf = 4532 4537'
M = 0'
Loh Lfh = 0
```

```
xt4340'xul4529', 0000002'3wwwj'3j3jo'xz6000'xp0254'.0000000'
```

Program No. K2-71

REPOSITIONAL DECIMAL MEMORY PUNCH
Western Electric Company

With the T - C up 8 words/line are printed, and with the T - C down 16 words/line are printed. One must be careful in using the 16 word count because it is conceivable that the Flexowriter, while printing, would run into the automatic carriage return and stop if several Hex words were to be printed out. Therefore, it seems best to punch out an unknown area as 8 words/line, then if necessary, upon inspection of the print out, the area may be re-punched 16 words/line.

Now a word of caution about the placement of programs to be punched out by this routine, Let us suppose that we have this R.D.M.P. routine in 1500 to 2063, and we give:

Lo Lf = 1500 2063
M = 1500
Loh Lfh = 0

(We are punching the R.D.M.P. out by the R.D.M.P. but this condition could occur while punching out any program.)

All goes well until we punch the contents of Lo + 0563 or 2063

Loc	Contents	Notes
2063	Z2000	20 at 23

Now when 2063 is punched, we get Z0500:

Aw - M
(Z2000 - 1500 = Z0500)

This is okay if we load this punch back into 1500 2063 with a Set Modifier of 1500, but suppose we load this punch into 1000 by the PIR with a modifier of 1000.

Location Lo + 0563 or 1563 will now appear as

Loc	Contents	Notes
1563	Z1500	15 at 23 instead of 20 at 23

Therefore one must be sure that there are no constants within the punch out area that will be de-modified by the R.D.M.P.

We state again that any operand address Aw where $M \leq Aw \leq Lf$ will be de-modified by M

This routine will punch out about 50 to 60 w/m.

If the High Speed punch is used for punch-out, follow this write-up normally down to the halt to turn on the punch, then connect the high-speed punch and Push Down Break-point 32. Then give a "start compute" and punching will commence.

Program No. K2-71

REPOSITIONAL DECIMAL MEMORY PUNCH
Western Electric CompanyComments by POOL Reviewer

1. Programs written for certain interpretive systems will be punched incorrectly since P and I instructions are never "demodified" by this routine. For example, P 3807 in memory will be punched as xp3807' in every case even when it is intended as a "Place" pseudo-instruction, referring to a location, rather than a "Print" order. Similarly, 800X pseudo-instructions in which X is an order letter other than T, will be treated as hex constants, and no modifier would be subtracted from their addresses.
2. Hex constants may happen to have the form of instructions, and as such they may happen to have an address part which falls between the modifier and Lf. In this case they will be "demodified" by the program. For this reason the routine can not be relied on absolutely. The Leh-Lfh provision allows the user to protect a single group of locations as containing hex words. In non-optimized programs the hex constants may indeed be in one block; then there is no problem. In case of doubt, the user should check that all hex constants outside the protected hex block were indeed punched as hex words. (Unless the user knows and can indicate which locations contain hex constants, no punchout program could possibly produce a foolproof result.)
3. 16 word typeout lines will be longer than the width of the paper used at many installations. These users may prefer to have a choice of between, say, 6 and 8 words/line, rather than the 8 and 16 words/line alternatives provided. A 6 words/line printout could be compared line-for-line with a hex-print-or-punch printout.

Flow Chart for RDMP

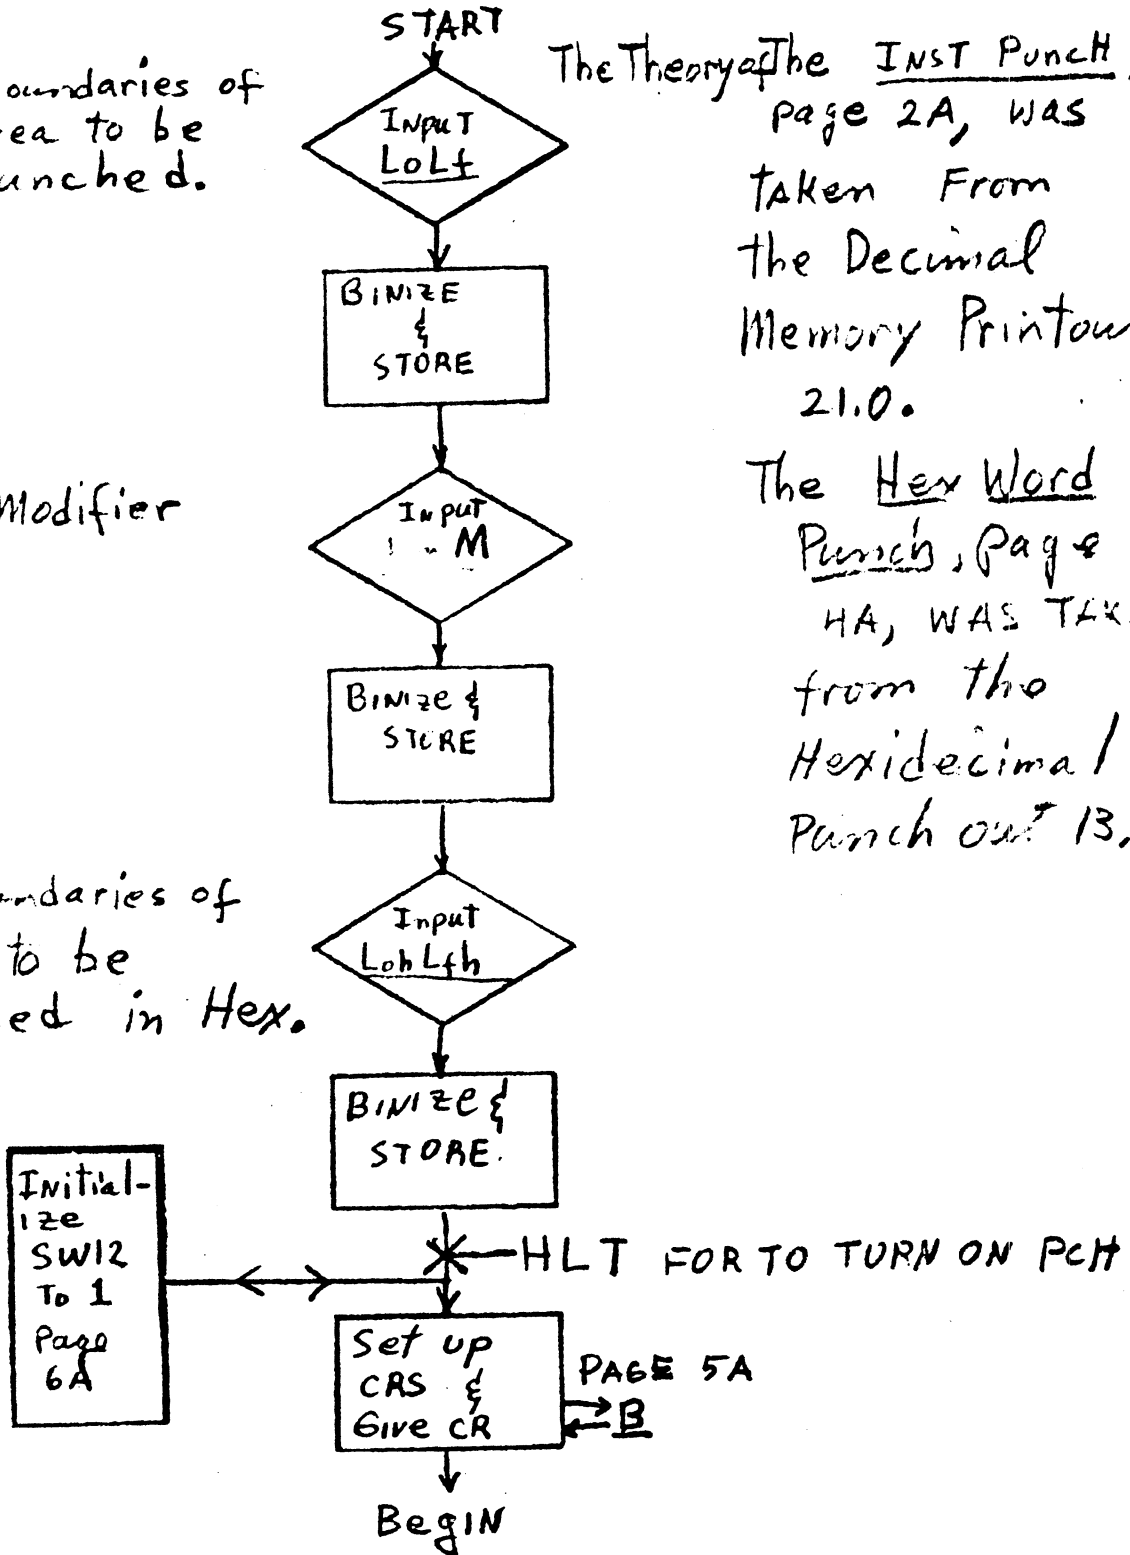

Boundaries of Area to be punched.

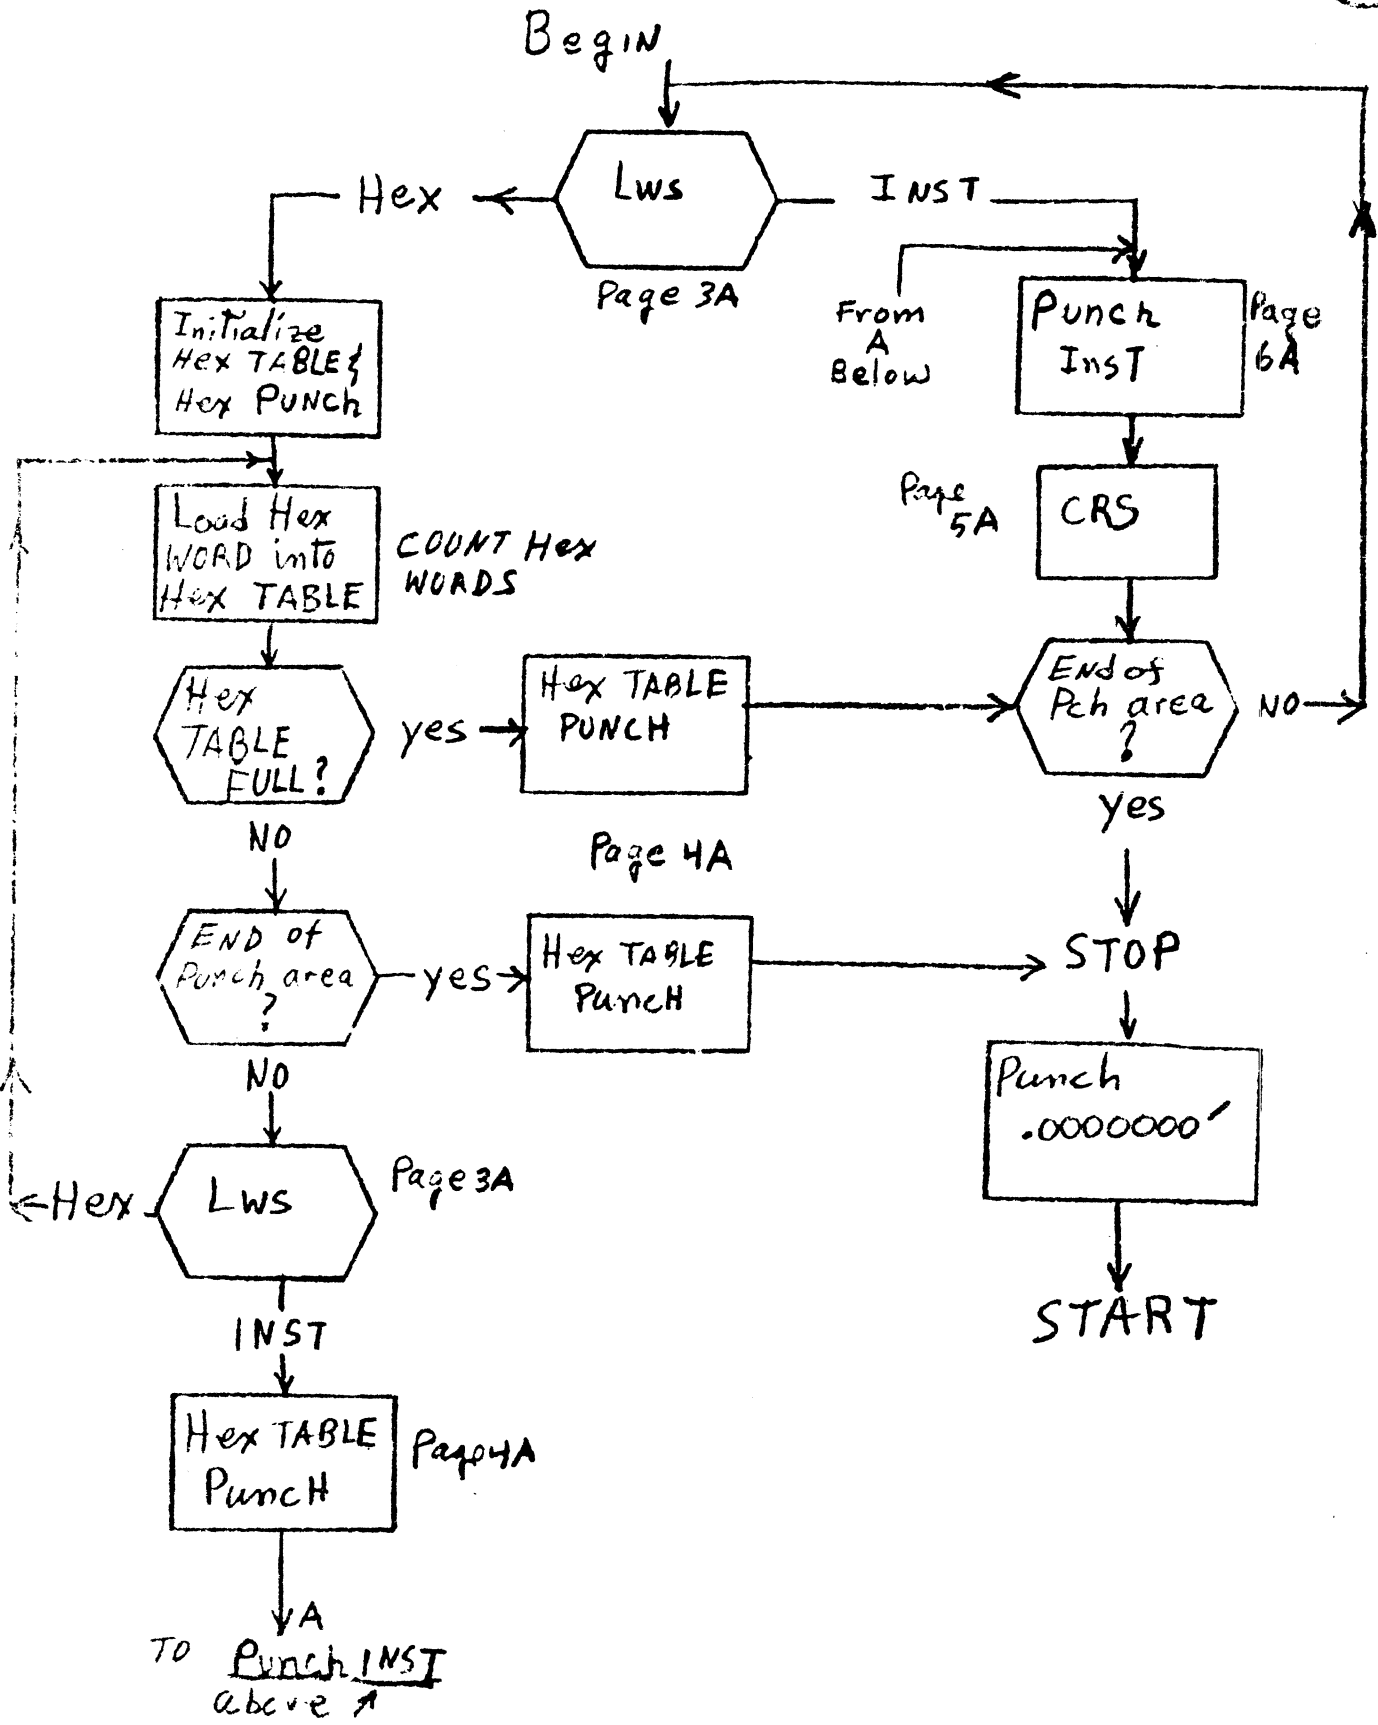

The Theory of The INST Punch, Page 2A, was taken from the Decimal Memory Printout 21.0.

Modifier

The Hex Word Punch, Page 4A, was taken from the Hexidecimal Punch out 13.0.
