Getting Started

Getting Started

You can write computer programs that remotely set the analyzer front panel controls or that take measurements and read those measurements for further analysis or storage. To help you get started with programming the analyzer, this section includes the following subsections:

- *Overview of the Manual*
Summarizes each major section of this manual.
- *Connecting the Interface*
Describes how to physically connect the analyzer to a controller.
- *Using GPIB Ports*
Describes how to use the GPIB port.
- *Setting the GPIB Address*
Describes how to set the GPIB parameters from the front panel.
- *Using TekVISA*
Describes how to use the TekVISA communication protocol.

Overview of the Manual

The information contained in each major section of this manual is described below.

Syntax and Commands

Section 2, *Syntax and Commands*, describes the structure and content of the messages your program sends to the analyzer. Figure 1-1 shows command parts as described in the *Command Syntax* subsection.

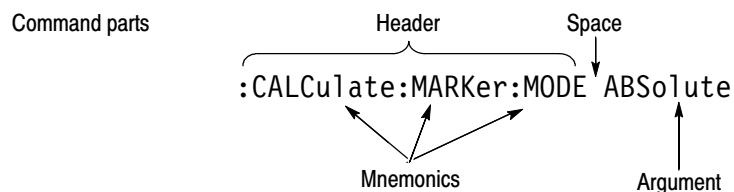

Figure 1-1: Command parts

Section 2 also describes the effect of each command and provides examples of how you might use it. The *Command Groups* subsection provides lists by functional areas. The *IEEE Common Commands* and the subsequent subsections arrange commands alphabetically (Figure 1-2).

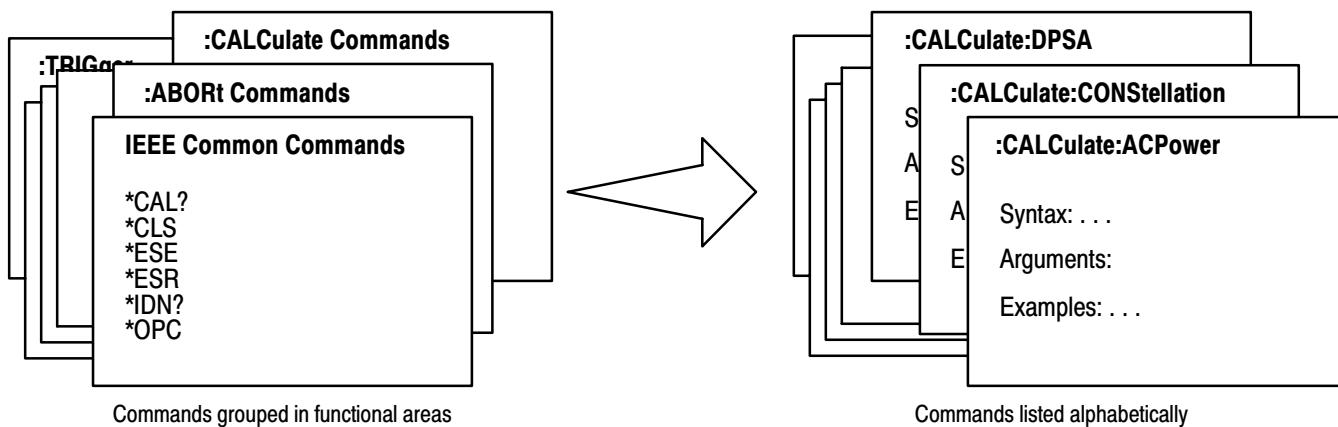

Figure 1-2: Functional groupings and an alphabetical list of commands

Status and Events

The program may request information from the instrument. The instrument provides information in the form of status and error messages. Figure 1-3 illustrates the basic operation of this system. Section 3, *Status and Events*, describes how to get status or event information from the program and details the event and error messages.

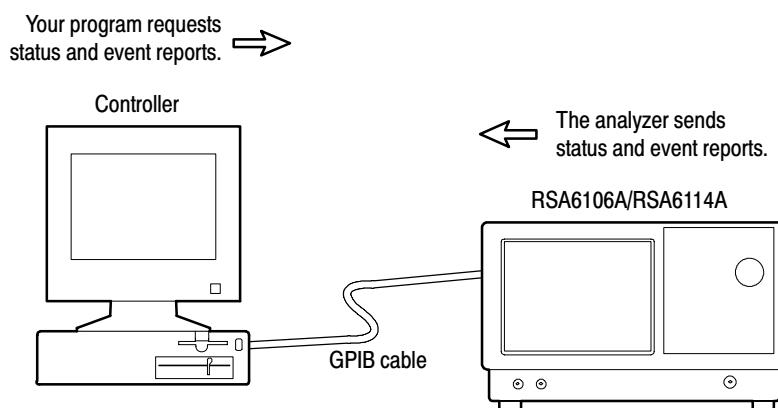

Figure 1-3: Event-driven program

Connecting the Interface

The instrument has a 24-pin GPIB connector on its rear panel, as shown in Figure 1-4. This connector has a D-type shell and conforms to IEEE Std 488.1-1987. Attach an IEEE Std 488.1-1987 GPIB cable (Tektronix part number 012-0991-00) to this connector.

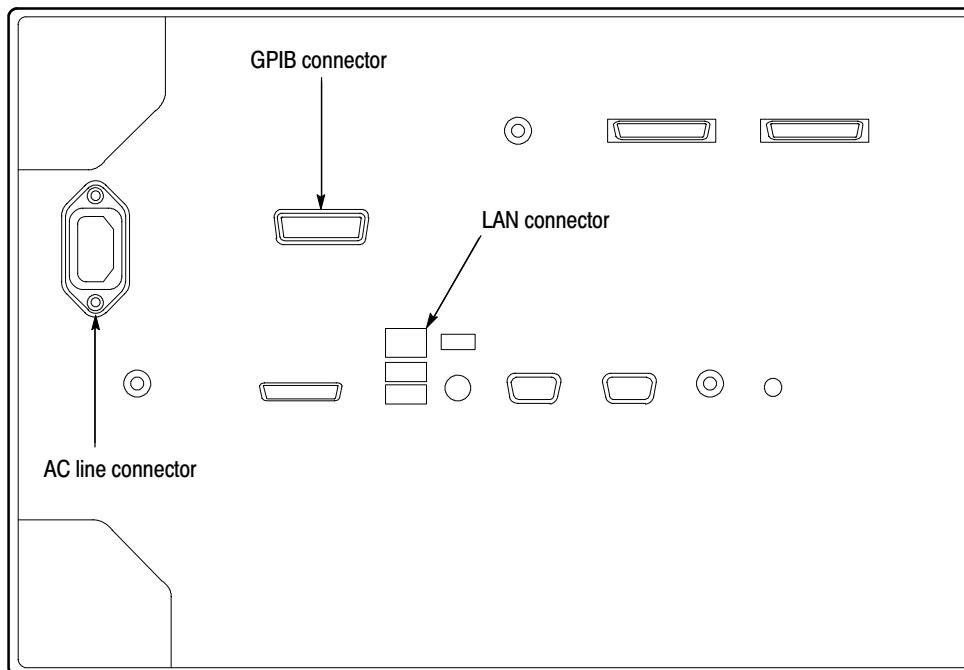

Figure 1-4: GPIB connector (rear panel)

Appendix B: GPIB Interface Specifications gives more information on the GPIB configuration of the analyzer. For the other interfaces, refer to the *RSA6100A Series Quick Start User Manual*.

Using the GPIB Port

The analyzer has Talker/Listener functions through which it can communicate with other devices, as well as the external controller, located on the bus.

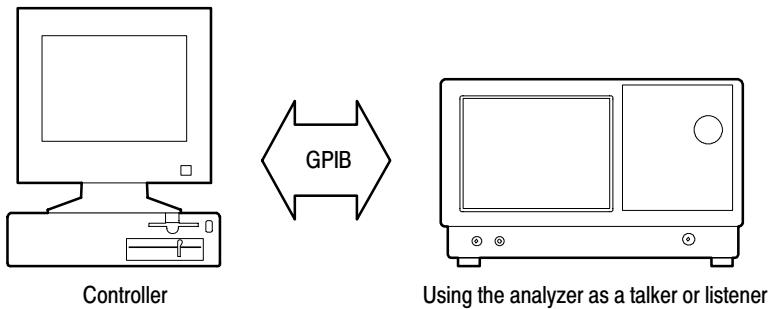

Figure 1-5: GPIB connection

GPIB Requirements

Observe the following rules when you use your analyzer with a GPIB network:

- Assign a unique device address to each device on the bus. No two devices can share the same device address.
- Do not connect more than 15 devices to any one bus.
- Connect one device for every 2 m (6 ft) of cable used.
- Do not use more than 20 m (65 ft) of cable to connect devices to a bus.
- Turn on at least 2/3 of the devices on the network while using the network.
- Connect the devices on the network in a star or linear configuration, as shown in Figure 1-6. Do not use loop or parallel configurations.

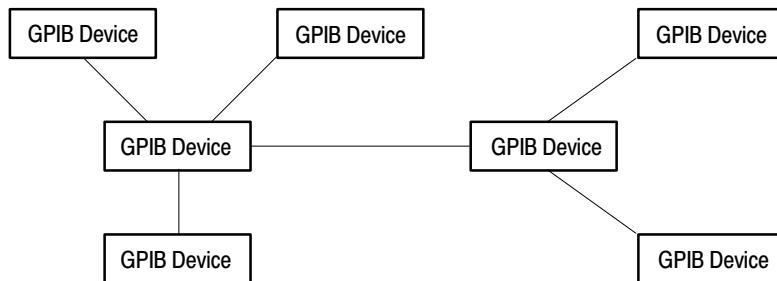

Figure 1-6: Typical GPIB network configurations

Setting the GPIB Address

When you use the GPIB port to communicate with an external controller, follow these steps to set the address of the analyzer.

1. From the **Tools** menu, select **Options** to open the Options control panel.

2. Click the **GPIB** tab and set the primary address. Range: 0 to 30 (default: 1)

NOTE. The GPIB address cannot be initialized by the *RST command.

Using TekVISA

TekVISA is Tektronix implementation of VISA (Virtual Instrument Software Architecture), an industry-standard communication protocol. VISA provides a common standard for software developers so that software from multiple vendors, such as instrument drivers, can run on the same platform. TekVISA is industry-compliant software, available with selected Tektronix instruments. You can use this software to write (or draw) interoperable instrument drivers in a variety of Application Development Environments (ADEs). It implements a subset of Version 2.2 of the VISA specification for controlling GPIB and serial (RS-232) instrument interfaces locally or remotely via an Ethernet LAN connection.

- Installation** Use an internet browser to access the Tektronix web site (www.tektronix.com) and download the current TekVISA to your PC. Unzip the downloaded file in a temporary directory of your choice and run *Setup.exe*.

NOTE. *The details on TekVISA concepts and operations are explained in the TekVISA Programmer Manual that can be also found on the Tektronix web site.*

Syntax and Commands

Command Syntax

This section contains information on the Standard Commands for Programmable Instruments (SCPI) and IEEE 488.2 Common Commands you can use to program your RSA6106A/RSA6114A analyzer. The information is organized in the following subsections:

- Backus-Naur Form Definition
- SCPI Commands and Queries
- IEEE 488.2 Common Commands
- Constructed Mnemonics

Backus-Naur Form Definition

This manual may describe commands and queries using the Backus-Naur Form (BNF) notation. Table 2-1 defines the standard BNF symbols.

Table 2-1: BNF symbols and meanings

Symbol	Meaning
< >	Defined element
::=	Is defined as
	Exclusive OR
{ }	Group; one element is required
[]	Optional; can be omitted
. . .	Previous element(s) may be repeated
()	Comment

SCPI Commands and Queries

SCPI is a standard created by a consortium that provides guidelines for remote programming of instruments. These guidelines provide a consistent programming environment for instrument control and data transfer. This environment uses defined programming messages, instrument responses, and data format across all SCPI instruments, regardless of manufacturer. The analyzer uses a command language based on the SCPI standard.

The SCPI language is based on a hierarchical or tree structure (see Figure 2-1) that represents a subsystem. The top level of the tree is the root node; it is followed by one or more lower-level nodes.

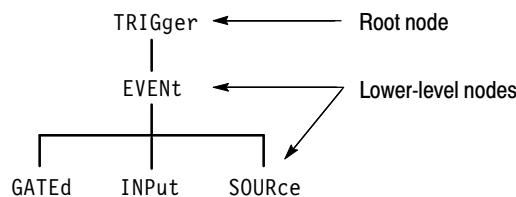

Figure 2-1: Example of SCPI subsystem hierarchy tree

You can create commands and queries from these subsystem hierarchy trees. Commands specify actions for the instrument to perform. Queries return measurement data and information about parameter settings.

Creating Commands

SCPI commands are created by stringing together the nodes of a subsystem hierarchy and separating each node by a colon.

In Figure 2-1, TRIGger is the root node and EVENT, GATed, INPut, and SOURce are lower-level nodes. To create a SCPI command, start with the root node TRIGger and move down the tree structure adding nodes until you reach the end of a branch. Most commands and some queries have parameters; you must include a value for these parameters. If you specify a parameter value that is out of range, the parameter will be set to a default value. The command descriptions, which start on page 2-47, list the valid values for all parameters.

For example, TRIGger:EVENT:SOURce EXTRear is a valid SCPI command created from the hierarchy tree in Figure 2-1.

Creating Queries

To create a query, start at the root node of a tree structure, move down to the end of a branch, and add a question mark. TRIGger:EVENT:SOURce? is an example of a valid SCPI query using the hierarchy tree in Figure 2-1.

Query Responses

The query causes the analyzer to return information about its status or settings. When a query is sent to the analyzer, only the values are returned. When the returned value is a mnemonic, it is noted in abbreviated format, as shown in Table 2-2.

Table 2-2: Query response examples

Query	Response
:CALCulate:SPECtrum:MARKer:X?	7.50E+9
:SENSe:SPECtrum:FFT:WINDOW?	BH4B

A few queries also initiate an operation action before returning information. For example, the *CAL? query runs a calibration.

Parameter Types

Every parameter in the command and query descriptions is of a specified type. The parameters are enclosed in brackets, such as <value>. The parameter type is listed after the parameter and is enclosed in parentheses, for example, (boolean). Some parameter types are defined specifically for the RSA6100A Series command set and some are defined by ANSI/IEEE 488.2-1987 (refer to Table 2-3).

Table 2-3: Parameter types used in syntax descriptions

Parameter type	Description	Example
arbitrary block ¹	A specified length of arbitrary data	#512234xxxx . . . where 5 indicates that the following 5 digits (12234) specify the length of the data in bytes; xxxx . . . indicates the data
boolean	Boolean numbers or values	ON or 1; OFF or 0
binary	Binary numbers	#B0110
octal	Octal numbers	#Q57, #Q3
hexadecimal ²	Hexadecimal numbers (0-9, A, B, C, D, E, F)	#HAA, #H1
NR1 ^{2,3} numeric	Integers	0, 1, 15, -1
NR2 ² numeric	Decimal numbers	1.2, 3.141516, -6.5
NR3 ² numeric	Floating point numbers	3.1415E-9, -16.1E5
NRf ² numeric	Flexible decimal number that may be type NR1, NR2 or NR3	See NR1, NR2, and NR3 examples
string ⁴	Alphanumeric characters (must be within quotation marks)	“Testing 1, 2, 3”

¹ Defined in ANSI/IEEE 488.2 as “Definite Length Arbitrary Block Response Data.”

² An ANSI/IEEE 488.2-1992-defined parameter type.

³ Some commands and queries will accept an octal or hexadecimal value even though the parameter type is defined as NR1.

⁴ Defined in ANSI/IEEE 488.2 as “String Response Data.”

Special Characters

The Line Feed (LF) character (ASCII 10), and all characters in the range of ASCII 127-255 are defined as special characters. These characters are used in arbitrary block arguments only; using these characters in other parts of any command yields unpredictable results.

Abbreviating Commands, Queries, and Parameters

You can abbreviate most SCPI commands, queries, and parameters to an accepted short form. This manual shows these short forms as a combination of upper and lower case letters. The upper case letters indicate the accepted short form of a command. As shown in Figure 2-2, you can create a short form by using only the upper case letters. The accepted short form and the long form are equivalent and request the same action of the instrument.

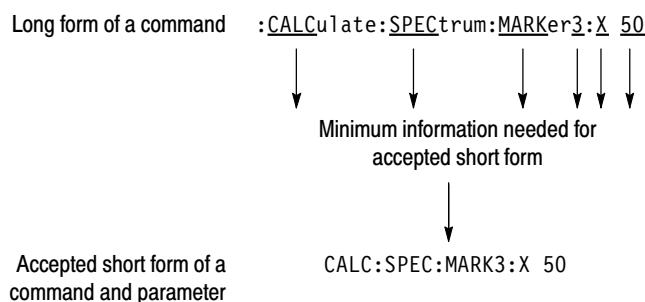

Figure 2-2: Example of abbreviating a command

NOTE. *The numeric suffix of a command or query may be included in either the long form or short form; the analyzer will default to “1” if no suffix is used. In Figure 2-2, the “3” of “MARKer3” indicates that the command is directed to Marker 3.*

Chaining Commands and Queries

You can chain several commands or queries together into a single message. To create a chained message, first create a command or query, add a semicolon (;), and then add more commands or queries and semicolons until the message is complete. If the command following a semicolon is a root node, precede it with a colon (:). Figure 2-3 illustrates a chained message consisting of several commands and queries. The single chained message should end in a command or query, not a semicolon. Responses to any queries in your message are separated by semicolons.

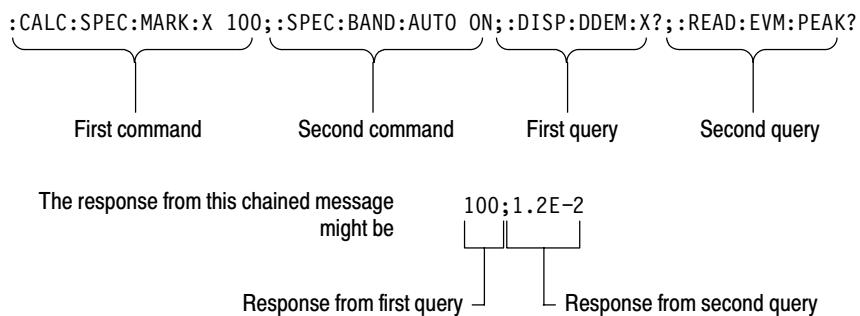

Figure 2-3: Example of chaining commands and queries

If a command or query has the same root and lower-level nodes as the previous command or query, you can omit these nodes. In Figure 2-4, the second command has the same root node (TRIGger:EVENt) as the first command, so these nodes can be omitted.

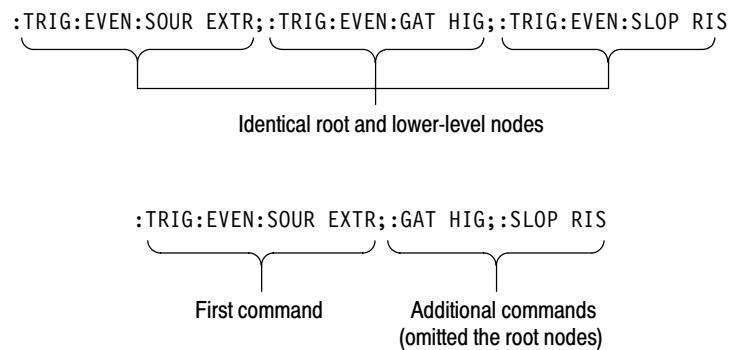

Figure 2-4: Example of omitting root and lower-level nodes in a chained message

Unit and SI Prefix

If the decimal numeric argument refers to amplitude, frequency, or time, you can express it using SI units instead of using the scaled explicit point input value format <NR3>. (SI units are units that conform to the Systeme International d'Unites standard.) For example, you can use the input format 200 mV or 1.0 MHz instead of 200.0E-3 or 1.0E+6, respectively, to specify voltage or frequency.

Table 2-4 lists the available units.

Table 2-4: Available units

Symbol	Meaning
dB	decibel (relative amplitude)
dBm	decibel (absolute amplitude)
DEG	degree (phase)
Hz	hertz (frequency)
PCT	percent (%)
s	second (time)
V	volt

The available SI prefixes are shown in Table 2-5 below.

Table 2-5: Available SI prefixes

SI prefix	A	F	P	N	U	M	K	MA¹	G	T	PE	EX
Corresponding power	10 ⁻¹⁸	10 ⁻¹⁵	10 ⁻¹²	10 ⁻⁹	10 ⁻⁶	10 ⁻³	10 ⁺³	10 ⁺⁶	10 ⁺⁹	10 ⁺¹²	10 ⁺¹⁵	10 ⁺¹⁸

¹ When the unit is "Hz", "M" may be used instead of "MA" so that the frequency can be represented by "MHz".

You can omit a unit in a command, but you must include the unit when using a SI prefix. For example, frequency of 15 MHz can be described as follows:

15.0E6, 1.5E7Hz, 15000000, 15000000Hz, 15MHz, etc.
("15M" is not allowed.)

Note that you can use either lower or upper case units and prefixes. The following examples have the same result, respectively.

170mhz, 170mHz, 170MHz, etc.
250mv, 250mV, 250MV, etc.

General Rules

Here are three general rules for using SCPI commands, queries, and parameters:

- You can use single (‘ ’) or double (“ ”) quotation marks for quoted strings, but you cannot use both types of quotation marks for the same string.
 - correct: “This string uses quotation marks correctly.”
 - correct: ‘This string also uses quotation marks correctly.’
 - incorrect: “This string does not use quotation marks correctly.”
- You can use upper case, lower case, or a mixture of both cases for all commands, queries, and parameters.

SENSE:SPECTRUM:FFT:LENGTH 1024

is the same as

sense:spectrum:fft:length 1024

and

SENSE:spectrum:FFT:length 1024

NOTE. Literal strings (quoted) are case sensitive, for example, file names.

- No embedded spaces are allowed between or within nodes.

correct: SENSE:SPECTRUM:FFT:LENGTH 1024

incorrect: SENSE: SPECTRUM: FFT: LEN GTH 1024

IEEE 488.2 Common Commands

Description	ANSI/IEEE Standard 488.2 defines the codes, formats, protocols, and usage of common commands and queries used on the interface between the controller and the instruments. The analyzer complies with this standard.
Command and Query Structure	<p>The syntax for an IEEE 488.2 common command is an asterisk (*) followed by a command and, optionally, a space and parameter value. The syntax for an IEEE 488.2 common query is an asterisk (*) followed by a query and a question mark. All of the common commands and queries are listed in the last part of the <i>Syntax and Commands</i> section. The following are examples of common commands:</p> <ul style="list-style-type: none"> ■ *ESE 16 ■ *CLS <p>The following are examples of common queries:</p> <ul style="list-style-type: none"> ■ *ESR? ■ *IDN?

Constructed Mnemonics

Some header mnemonics specify one of a range of mnemonics. For example, a channel mnemonic can be either TRACe1, TRACe2, TRACe3, or TRACe4. You use these mnemonics in the command just as you do any other mnemonic. For example, there is a :TRACe1:SPECTrum:FUNCTION command, and there is also a :TRACe2:SPECTrum:FUNCTION command. In the command descriptions, this list of choices is abbreviated as TRACe<x>. The value of <x> is the upper range of valid suffixes. If the numeric suffix is omitted, the analyzer uses the default value of “1”.

Table 2-6: Constructed mnemonics

Symbol	Meaning
MARKer<x>	A marker specifier where <x> = 0, 1, 2, 3, or 4. Refer to <i>Marker Mnemonics</i> on page 2-60.
TRACe<x>	A trace specifier where <x> = 0, 1, 2, 3, 4, or 5. Refer to <i>TRACe Commands</i> on page 2-591 for details.

Command Groups

This section lists the RSA6100A Series analyzer commands in two ways. It first presents them by functional groups. It then lists them alphabetically. The functional group list starts below. The alphabetical list provides more detail on each command and starts on page 2-47.

The RSA6100A Series analyzers conform to the Standard Commands for Programmable Instruments (SCPI) 1999.0 and IEEE Std 488.2-1987 except where noted.

Items followed by question marks are queries; items without question marks are commands. Some items in this section have a question mark in parentheses (?) in the command header section; this indicates that the item can be both a command and a query.

For the conventions of notation in this manual, refer to *Command Syntax* on page 2-1 and following pages.

Measurement Views

The measurement views in the RSA6100A Series analyzers are categorized into the following four groups:

- General signal viewing
- General purpose digital modulation (Option 21 only)
- RF measurements
- Pulsed RF (Option 20 only)

Each group contains the measurement views as shown in Table 2-7.

Each command works in particular measurement view(s) which are specified in the **Measurement Views** item in the command descriptions.

NOTE. If you send a command for the measurement view that is not displayed on screen, an execution error will occur.

Programming Hints

Here are some basic tips for using the RSA6100A Series GPIB commands:

- *Selecting a measurement item*
Use DISPlay commands to select or display the measurement view.
[Example] :DISPlay:GENeral:MEASview:NEW SPECtrum
Displays the spectrum view on the screen.
- *Setting measurement parameters*
Use SENSe commands to set conditions for the measurement session.
[Example] :SENSe:SPECtrum:FREQuency:CENTER 1.5GHz
Sets the center frequency to 1.5 GHz in the spectrum view.
- *Acquiring an input signal*
Use an INITiate or ABORT command to start or stop data acquisition.
[Example] :INITiate:CONTinuous ON;:INITiate:IMMEDIATE
Starts data acquisition in the continuous mode.
- *Processing waveforms arithmetically*
Use TRACe commands for math operation on waveforms.
[Example] :TRACe1:SPECtrum:FUNCTION AVERage
Averages the spectrum waveform.
- *Measuring with the markers*
Use CALCulate commands to measure some quantity using the markers.
[Example] :CALCulate:SPECtrum:MARKer1:MAXimum
Positions the marker at the highest peak signal on the spectrum.
- *Obtaining the measurement results*
Use a FETCh or READ command to get the results.
[Example] :FETCh:SPECtrum:TRACe1?

Command Groups

IEEE Common Commands

This section details the IEEE common commands.

Command Tree

Header	Parameter
*CAL	
*CLS	
*ESE	
*ESR?	
*IDN?	
*OPC	
*OPT?	
*RST	
*SRE	
*STB?	
*WAI	

*CAL? (Query Only)

Instructs the analyzer to perform an internal self-alignment and return its status.

NOTE. *The self-alignment can take several minutes to respond. No other commands will be executed until alignment is complete.*

Syntax *CAL?

Returns <NR1> = 1 indicates that the alignment was successful.

<NR1> = 0 indicates that the alignment was unsuccessful.

Measurement Views All

Examples *CAL?

performs an internal self-alignment and will return 1 if the alignment is successful.

*CLS (No Query Form)

Clears the analyzer status data structures. Refer to Section 3, *Status and Events*, for the register information.

The *CLS command clears the following:

- the Event Queue
- the Standard Event Status Register (SESR)
- the Status Byte Register (except the MAV bit; see below)

If the *CLS command immediately follows an <E0I>, the Output Queue and MAV bit (Status Byte Register bit 4) are also cleared. MAV indicates information is in the output queue. The device clear (DCL) GPIB control message will clear the output queue and thus MAV. *CLS does not clear the output queue or MAV. (A complete discussion of these registers and bits, and of event handling in general, begins on page 3-1.)

*CLS can suppress a Service Request that is to be generated by an *OPC. This will happen if a hardcopy output or single sequence acquisition operation is still being processed when the *CLS command is executed.

Syntax *CLS

Arguments None

Measurement Views All

Examples *CLS
clears the analyzer status data structures.

Related Commands *ESE, *ESR, *SRE, *STB?

*ESE(?)

Sets or queries the bits in the Event Status Enable Register (ESER). The ESER prevents events from being reported to the Status Byte Register (STB). Refer to Section 3, *Status and Events*, for the register information.

Syntax *ESE <value>

*ESE?

Arguments <value> ::= <NR1> is a value in the range from 0 through 255.
The binary bits of the ESER are set according to this value.

Measurement Views All

Examples *ESE 145

sets the ESER to binary 10010001, which enables the PON, EXE, and OPC bits.

*ESE?

might return the string *ESE 184, showing that the ESER contains the binary value 10111000.

Related Commands *CLS, *ESR, *SRE, *STB?

*ESR? (Query Only)

Returns the contents of the Standard Event Status Register (SESR). *ESR? also clears the SESR (since reading the SESR clears it). Refer to Section 3, *Status and Events*, for the register information.

Syntax *ESR?

Arguments None

Returns <NR1> representing the contents of the SESR by a 0 to 255 decimal number.

Measurement Views All

Examples *ESR?
might return the value 213, showing that the SESR contains binary 11010101.

Related Commands *CLS, *ESE?, *SRE, *STB?

*IDN? (Query Only)

Returns the analyzer identification code.

Syntax *IDN?

Arguments None

Measurement Views All

Returns The analyzer identification code in the following format:

TEKTRONIX,RSA61XXA,<serial_number>,<firmware_version>

Where

TEKTRONIX indicates that the manufacturer is Tektronix.

RSA61XXA is the model number (RSA6106A or RSA6114A).

<serial_number> is the serial number.

<firmware_version> is the firmware version.

Examples *IDN?

might return the response TEKTRONIX,RSA6114A,B000111,FV:1.0.1500.

*OPC(?)

Generates the operation complete message in the Standard Event Status Register (SESR) when all pending operations finish. The *OPC? query places the ASCII character “1” into the output queue when all pending operations are finished. The *OPC? response is not available to read until all pending operations finish.

The *OPC command allows you to synchronize the operation of the analyzer with your application program. Refer to *Synchronizing Execution* on page 3-12 for the details.

Syntax *OPC

*OPC?

Arguments None

Measurement Views All

*OPT? (Query Only)

Returns a list of options installed in your analyzer.

Syntax *OPT?

Arguments None

Returns The numbers of all the options installed in the analyzer, separated by commas. If no options have been installed, 0 is returned.

Table 2-24 lists the options for the RSA6100A Series analyzers.

Table 2-24: Instrument options

STATus Commands

The STATus commands control the SCPI-defined status reporting structures. In addition to those in IEEE 488.2, the analyzer has questionable and operation registers defined in SCPI. These registers conform to the IEEE 488.2 specification and each is comprised of a condition register, an event register, an enable register, and negative and positive transition filters.

NOTE. For details on the registers, refer to Status and Events beginning on page 3-1.

Examples :TRIGger:SEQUence:TIME:POSITION 20
sets the trigger position to 20% of the acquisition record.

Retrieving Response Message

When receiving a query command from the external controller, the analyzer puts the response message on the Output Queue. This message cannot be retrieved unless you perform retrieval operations through the external controller. (For example, call the IBRD subroutine included in the GPIB software of National Instruments.)

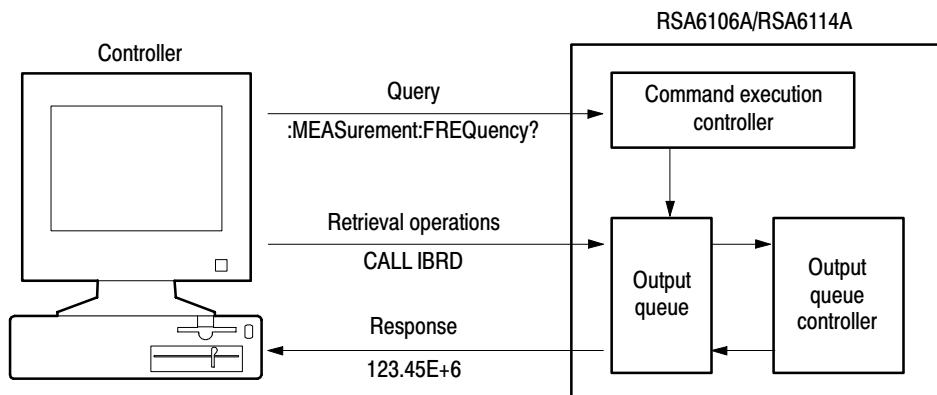

Figure 2-6: Retrieving response message

When the Output Queue contains a response message, sending another command from the external controller before retrieving this message deletes it from the queue. The Output Queue always contains the response message to the most recent query command.

You can use the MAV bit of the Status Byte Register (SBR) to check whether the Output Queue contains a response message. For details, refer to *Status Byte Register (SBR)* on page 3-4.

Status and Events

Status and Events

The SCPI interface in the analyzer includes a status and event reporting system that enables the user to monitor crucial events that occur in the instrument. The analyzer is equipped with four registers and one queue that conform to IEEE Std 488.2-1987. This section will discuss these registers and queues along with status and event processing.

Status and Event Reporting System

Figure 3-1 outlines the status and event reporting mechanism offered in the RSA6100A Series analyzers. It contains three major blocks:

- Standard Event Status
- Operation Status
- Questionable Status (fan-out structure)

The processes performed in these blocks are summarized in the Status Byte. The three blocks contain four types of registers as shown in Table 3-1.

Table 3-1: Register type

Register	Description
Condition register	Records event occurrence in the instrument. Read only.
Transition register (positive/negative)	A positive transition filter allows an event to be reported when a condition changes from false to true. A negative filter allows an event to be reported when a condition changes from true to false. Setting both positive and negative filters true allows an event to be reported anytime the condition changes. Clearing both filters disables event reporting.
Event register	Records events filtered by the transition register. Read only.
Enable register	Masks the event register to report in the summary bit. User-definable.

- * The use of Bit 15 is not allowed in SCPI.
The value of this bit is always zero.

CR: Condition Register
TR: Transition Register
EVR: Event Register
ENR: Enable Register

Status Byte

The Status Byte contains the following two registers:

- Status Byte Register (SBR)
 - Service Request Enable Register (SRER)

Status Byte Register (SBR)

The SBR is made up of 8 bits. Bits 4, 5 and 6 are defined in accordance with IEEE Std 488.2-1987 (see Figure 3-2 and Table 3-2). These bits are used to monitor the output queue, SESR and service requests, respectively. The contents of this register are returned when the *STB? query is used.

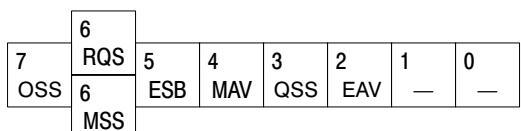

Figure 3-2: Status Byte Register (SBR)

Table 3-2: SBR bit functions

Bit	Function
7	Operation Summary Status (OSS). Summary of the operation status register.
6	<p>Request Service (RQS)/Master Status Summary (MSS). When the instrument is accessed using the GPIB serial poll command, this bit is called the Request Service (RQS) bit and indicates to the controller that a service request has occurred (in other words, that the GPIB bus SRQ line is LOW). The RQS bit is cleared when serial poll ends.</p> <p>When the instrument is accessed using the *STB? query, this bit is called the Master Status Summary (MSS) bit and indicates that the instrument has issued a service request for one or more reasons. The MSS bit is never cleared to 0 by the *STB? query.</p>
5	Event Status Bit (ESB). This bit indicates whether or not a new event has occurred after the previous Standard Event Status Register (SESR) has been cleared or after an event readout has been performed.
4	Message Available Bit (MAV). This bit indicates that a message has been placed in the output queue and can be retrieved.
3	Questionable Summary Status (QSS). Summary of the Questionable Status Byte register.
2	Event Quantity Available (EAV). Summary of the Error Event Queue.
1-0	Not used

Service Request Enable Register (SRER)

The SRER is made up of bits defined exactly the same as bits 0 through 7 in the SBR (see Figure 3-3). This register is used by the user to determine what events will generate service requests.

The SRER bit 6 cannot be set. Also, the RQS is not maskable.

The generation of a service request with the GPIB interface involves changing the SRQ line to LOW and making a service request to the controller. The result is that a status byte for which an RQS has been set is returned in response to serial polling by the controller.

Use the *SRE command to set the bits of the SRER. Use the *SRE? query to read the contents of the SRER. Bit 6 must normally be set to 0.

Standard Event Status Block

Reports the power on/off state, command errors, and the running state. It consists of the following registers:

- Standard Event Status Register (SESR)
- Event Status Enable Register (ESER)

These registers are made up of the same bits defined in Figure 3-4 and Table 3-3. Use the *ESR? query to read the contents of the SESR. Use the *ESE(?) command to access the ESER.

Bit	Description
7	Power On (PON). Indicates that the power to the instrument is on.
6	Not used.
5	Command Error (CME). Indicates that a command error has occurred while parsing by the command parser was in progress.
4	Execution Error (EXE). Indicates that an error occurred during the execution of a command. Execution errors occur for one of the following reasons: <ul style="list-style-type: none"> ■ When a value designated in the argument is outside the allowable range of the instrument, or is in conflict with the capabilities of the instrument ■ When the command could not be executed properly because the conditions for execution differed from those essentially required
3	Device-Dependent Error (DDE). An instrument error has been detected.
2	Query Error (QYE). Indicates that a query error has been detected by the output queue controller. Query errors occur for one of the following reasons: <ul style="list-style-type: none"> ■ An attempt was made to retrieve messages from the output queue, despite the fact that the output queue is empty or in pending status. ■ The output queue messages have been cleared despite the fact that they have not been retrieved.
1	Not used.
0	Operation Complete (OPC). This bit is set with the results of the execution of the *OPC command. It indicates that all pending operations have been completed.

When an event occurs, the SESR bit corresponding to the event is set, resulting in the event being stacked in the Error/Event Queue. The SBR OAV bit is also set. If the bit corresponding to the event has also been set in the ESER, the SBR ESB bit is also set. When a message is sent to the Output Queue, the SBR MAV bit is set.

Operation Status Block

The operation status block contains conditions that are part of the instrument's normal operation. It consists of the following registers:

- Operation Condition Register (OCR)
- Operation Positive/ Negative Transition Register (OPTR/ONTR)
- Operation Event Register (OEVR)
- Operation Enable Register (OENR)

These registers are made up of the same bits defined in Figure 3-5 and Table 3-4. Use the :STATus:OPERation commands to access the operation status register set.

0	Aligning (ALIG). Indicates that the instrument is currently performing an alignment. When the alignment ends after this bit is set in alignment, it is reset.

When the specified state changes in the OCR, its bit is set or reset. This change is filtered with a transition register, and the corresponding bit of the OEVR is set. If the bit corresponding to the event has also been set in the OENR, the SBR OSS bit is also set.

Questionable Status Block

The questionable status register set contains bits which give an indication of the quality of various aspects of the signal together with the fanned out registers as described in the next subsections. It consists of the following registers:

- Questionable Condition Register (QCR)
- Questionable Positive/Negative Transition Register (QPTR/QNTR)
- Questionable Event Register (QEVR)
- Questionable Enable Register (QENR)

These registers are made up of the same bits defined in Figure 3-6 and Table 3-5. Use the :STATus:QUEStionable commands to access the questionable status register set.

Queues

There are two types of queues in the status reporting system used in the analyzer: output queues and event queues.

Output Queue

The output queue is a FIFO (first in, first out) queue and holds response messages to queries, where they await retrieval. When there are messages in the queue, the SBR MAV bit is set.

The output queue will be emptied each time a command or query is received, so the controller must read the output queue before the next command or query is issued. If this is not done, an error will occur and the output queue will be emptied; however, the operation will proceed even if an error occurs.

Event Queue

The event queue is a FIFO queue and stores events as they occur in the analyzer. If more than 32 events occur, event 32 will be replaced with event code -350 (“Queue Overflow”). The error code and text are retrieved using the :SYSTem:ERRor queries.

Status and Event Processing Sequence

Figure 3-9 shows an outline of the sequence for status and event processing.

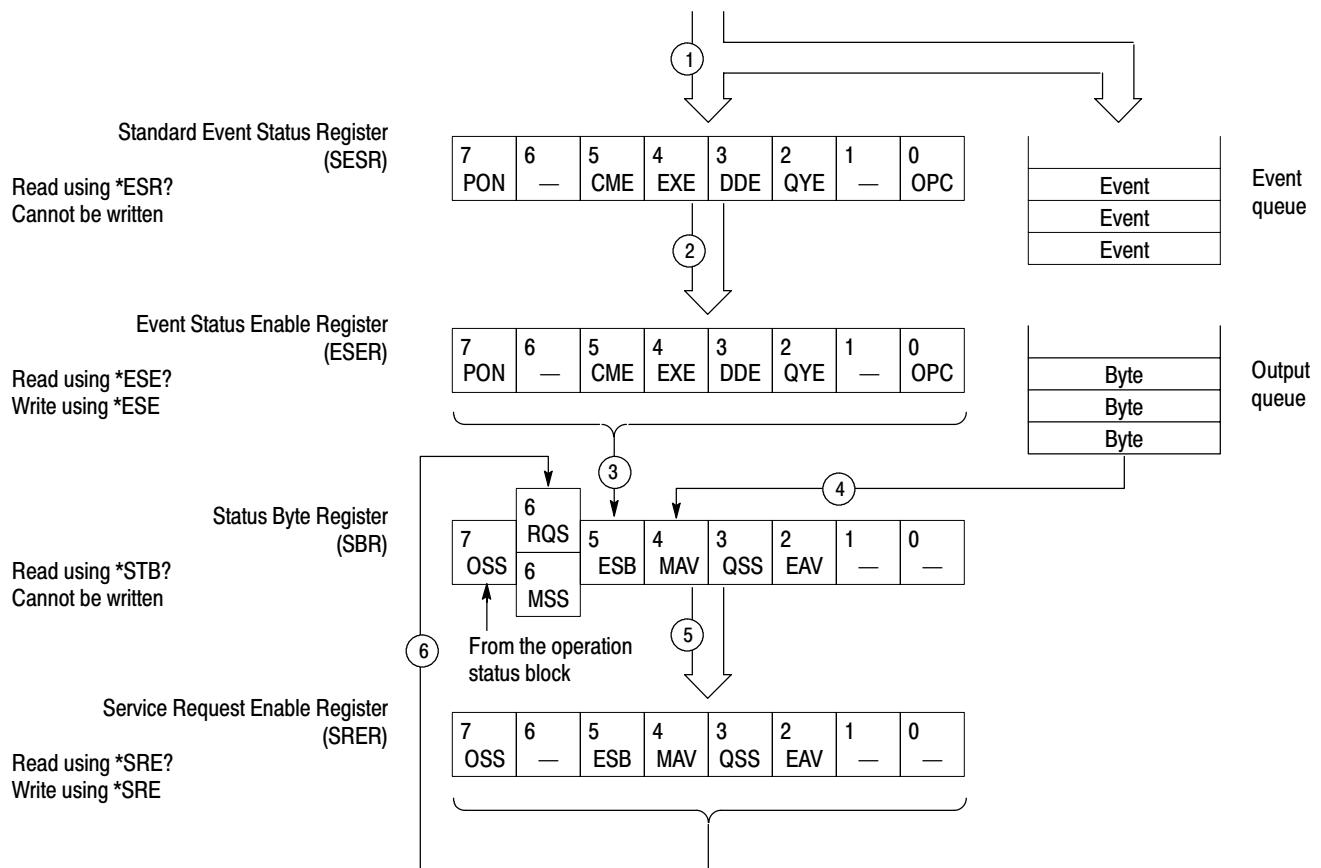

Figure 3-9: Status and event processing sequence

1. If an event has occurred, the SESR bit corresponding to that event is set and the event is placed in the event queue.
2. A bit corresponding to that event in the ESER has is set.
3. The SBR ESB bit is set to reflect the status of the ESER.
4. When a message is sent to the output queue, the SBR MAV bit is set.
5. Setting either the ESB or MAV bits in the SBR sets the respective bit in the SRER.
6. When the SRER bit is set, the SBR MSS bit is set and a service request is generated when using the GPIB interface.

Synchronizing Execution

Almost all commands are executed in the order in which they are sent from the controller, and the execution of each command is completed in a short period of time. However, the following commands perform data analysis in another thread, and another command can thus be executed concurrently:

- INITiate commands
- READ commands
- [:SENSe]:REANalyze

These commands are designed so that the next command to be sent is executed without waiting for the previous command to be completed. In some cases, a process executed by another command must first be completed before these commands can be executed; in other cases, these commands must be completed before the next command is executed.

You have two options to achieve command synchronization:

- Using the status and event reporting function
- Using synchronizing commands

Using the Status and Event Reporting Function

In the following example, a :READ command is used to obtain the measurement results while the Operation Condition Register (OCR) is being used to provide synchronization.

```
:STATus:OPERation:NTRansition 16          // Set the filter of the OCR MEASuring bit  
:STATus:OPERation:ENABLE 16                // Enable the filter of the OCR MEASuring bit  
*SRE 128        // Set the SRER OSS bit  
:READ:SPECTrum:TRACe? // Obtain the measurement results
```

The command waits for generation of SRQ.

Using Synchronizing Commands

The IEEE-488.2 common commands include the following synchronizing commands:

```
*OPC  
*OPC?  
*WAI
```

Using the *OPC Command. The *OPC command sets the SESR OPC bit when all the operations for which it is waiting are completed. If the GPIB interface is in use, you can synchronize the execution by using this command together with the serial polling or service request function.

The following is a command sequence example:

```
*ESE 1      // Enable the ESER OPC bit  
*SRE 32     // Enable the SRER ESB bit  
:ABORT;INITiate:IMMEDIATE;*OPC  
                  // Wait for SRQ to provide synchronization
```

Using the Query *OPC? The query *OPC? writes ASCII code “1” into the Output Queue when all operations for which it is waiting are completed. You can provide synchronization using the command string as the following example:

```
:ABORT;INITiate:IMMEDIATE;*OPC?
```

The command waits until “1” is written into the Output Queue. When the command goes to the Output Queue to read the data, a time-out may occur before the data is written into the queue.

Using the *WAI Command. After the process of the preceding command is completed, the *WAI command begins to execute the process of the next command as the following example:..

```
:ABORT;INITiate:IMMEDIATE;*WAI  
                  // Wait for the *WAI process to provide  
                  synchronization
```

Error Messages and Codes

Error codes with a negative value are SCPI standard error codes; errors with a positive value are unique to the RSA6100A Series Real-Time Spectrum Analyzers.

Event codes and messages can be obtained by using the queries :SYSTem:ERRor? and :SYSTem:ERRor:ALL? These are returned in the following format:

```
<event code>, "<event message>"
```

Appendix B: GPIB Interface Specification

This appendix lists and describes the GPIB functions and messages the instrument can implement.

Interface Functions

Table B-1 lists the GPIB interface functions this instrument implements. Each function is briefly described on page B-2.

Table B-1: GPIB interface function implementation

Interface function	Implemented subset	Capability
Source Handshake (SH)	SH1	Complete
Acceptor Handshake (AH)	AH1	Complete
Talker (T)	T6	Basic Talker, Serial Poll Unaddress if my-listen-address (MLA) No Talk Only mode
Listener (L)	L4	Basic Listener Unaddress if my talk address (MTA) No Listen Only mode
Service Request (SR)	SR1	Complete
Remote/Local (RL)	RL0	None
Parallel Poll (PP)	PP0	None
Device Clear (DC)	DC1	Complete
Device Trigger (DT)	DT0	None
Controller (C)	C0	None
Electrical Interface	E2	Three-state driver

- **Source Handshake (SH).** Enables a talking device to support the coordination of data transfer. The SH function controls the initiation and termination of data byte transfers.
- **Acceptor Handshake (AH).** Enables a listening device to coordinate data reception. The AH function delays data transfer initiation or termination until the listening device is ready to receive the next data byte.
- **Talker (T).** Enables a device to send device-dependent data over the interface. This capability is available only when the device is addressed to talk, and uses a one-byte address.
- **Listener (L).** Enables a device to receive device-dependent data over the interface. This capability is available only when the device is addressed to listen, and uses a one-byte address.
- **Service Request (SR).** Enables a device to assert an SRQ (Service Request) line to notify the controller when it requires service.
- **Remote/Local (RL).** Enables a device to respond to both the GTL (Go To Local) and LLO (Local Lock Out) interface messages.
- **Parallel Poll (PP).** Enables a device to respond to the following interface messages: PPC, PPD, PPE, and PPU, as well as to send out a status message when the ATN (Attention) and EOI (End or Identify) lines are asserted simultaneously.
- **Device Clear (DC).** Enables a device to be cleared or initialized, either individually, or as part of a group of devices.
- **Device Trigger (DT).** Enables a device to respond to the GET (Group Execute Trigger) interface message when acting as a listener.
- **Controller (C).** Enables a device that has this capability to send its address, universal commands, and addressed commands to other devices over the interface.
- **Electrical Interface (E).** Identifies the electrical interface driver type. The notation E1 means the electrical interface uses open collector drivers, E2 means the electrical interface uses three-state drivers.

Interface Messages

Table B-2 shows the standard interface messages that are supported by the analyzer.

Table B-2: Standard interface messages

Message	Type	Implemented
Device Clear (DCL)	UC	Yes
Local Lockout (LLO)	UC	No
Serial Poll Disable (SPD)	UC	Yes
Serial Poll Enable (SPE)	UC	Yes
Parallel Poll Unconfigure (PPU)	UC	No
Go To Local (GTL)	AC	Yes
Selected Device Clear (SDC)	AC	Yes
Group Execute Trigger (GET)	AC	No
Take Control (TCT)	AC	No
Parallel Poll Configure (PPC)	AC	No

UC: Universal command; **AC:** Address command

- **Device Clear (DCL).** Will clear (initialize) all devices on the bus that have a device clear function, whether or not the controller has addressed them.
- **Local Lockout (LLO).** Disables the return to local function.
- **Serial Poll Disable (SPD).** Changes all devices on the bus from the serial poll state to the normal operating state.
- **Serial Poll Enable (SPE).** Puts all bus devices that have a service request function into the serial poll enabled state. In this state, each device sends the controller its status byte, instead of its normal output, after the device receives its talk address on the data lines. This function may be used to determine which device sent a service request.
- **Go To Local (GTL).** Causes the listen-addressed device to switch from remote to local (front-panel) control.
- **Select Device Clear (SDC).** Clears or initializes all listen-addressed devices.
- **Group Execute Trigger (GET).** Triggers all applicable devices and causes them to initiate their programmed actions.
- **Take Control (TCT).** Allows the controller in charge to pass control of the bus to another controller on the bus.
- **Parallel Poll Configure (PPC).** Causes the listen-addressed device to respond to the secondary commands Parallel Poll Enable (PPE) and Parallel Poll Disable (PPD), which are placed on the bus following the PPC command. PPE enables a device with parallel poll capability to respond on a particular data line. PPD disables the device from responding to the parallel poll.

Appendix C: Factory Initialization Settings

The factory initialization settings provide a known state for the analyzer. The *RST command returns the instrument settings to the factory defaults. Factory initialization sets values as shown in Table C-1 through C-9.

Glossary

ASCII

Acronym for the American Standard Code for Information Interchange. Controllers transmit commands to the instrument using ASCII character encoding.

ASK

Acronym for Amplitude Shift Keying. The process, or result of a process, in which the amplitude of the carrier is varied in accordance with the state of a digital input signal.

BNF (Backus-Naur Form)

A standard notation system for command syntax diagrams. The syntax diagrams in this manual use BNF notation.

Controller

A computer or other device that sends commands to and accepts responses from the analyzer.

EVM (Error Vector Magnitude)

The magnitude of an error of an actual signal relative to an ideal signal in a constellation display.

GPIB

Acronym for General Purpose Interface Bus, the common name for the communications interface system defined in IEEE Std 488.

IEEE

Acronym for the Institute for Electrical and Electronic Engineers.

IS95

Acronym for Interim Standard-95. The standards name for first-generation CDMA cellphone technology.

Modulation

The process of varying some characteristic of a signal with a second signal.

PSK

Acronym for Phase Shift Keying. The process, or result of a process, in which the carrier phase is varied discretely in accordance with a digital code.

QAM

Acronym for Quadrature Amplitude Modulation. The process, or result of a process, in which the amplitude and phase of the carrier are varied concurrently by synthesizing two orthogonal ASK waves (see ASK).
