WARRANTY

All TEKTRONIX instruments are warranted against defective materials and workmanship for one year. Any questions with respect to the warranty should be taken up with your TEKTRONIX Field Engineer or representative.

All requests for repairs and replacement parts should be directed to the TEKTRONIX Field Office or representative in your area. This will assure you the fastest possible service. Please include the instrument Type Number or Part Number and Serial Number with all requests for parts or service.

Specifications and price change privileges reserved.

Display Generator Board

P7001

DISPLAY GENERATOR

CIRCUIT DESCRIPTION

The Display Generator converts digital data from the Address and Data Buses to analog signals for the X, Y, and Z axes of a Display Unit. The X output signal is derived from the nine least significant bits of the address, the Y signal from bits five through fourteen of the Data Bus, and Z information from bits three and four of the Data Bus.

LOGIC CIRCUITS

The Display Generator logic is initialized by the POWER FAIL line (B16) diagram 9B. The Status Register (U32A) is set when B16 goes low, and the Bus Controller (U53) is set to its idle state. When B16 goes high, a pulse is generated by U22D and U42E which loads a "0" into the Shift Register (U50). These initial states cause Waveform A to be displayed as soon as the POWER FAIL line goes high. Thereafter, new status words may be entered by pulling the STATUS STROBE line (A17) low or by addressing the Display generator and supplying MASTER SYNC to the bus. The Data Bus information is then loaded into the Status Register and the Shift Register.

Either of two modes of operation, Y-T or X-Y, may be commanded via the coded Status Word and stored in the Status Register. In addition, the STORE command is recognized by the Store Multi (U30), which causes the Display Generator to set all locations of the designated waveforms in Memory to 00. Locations containing no data (00) are ignored during Y-T display mode.

In the Y-T (normal) display mode, the Display Generator examines, in sequence, each memory location of the designated waveform and converts the non-zero points for display. The address information is counted through all displayed waveforms. However, memory access exists only during the display time of the designated waveforms in memory. Counters U10, U20, and U21B, C, & D advance one count each time Memory is interrogated, or every 8 μ s during WAVEFORM.

The Shift Register (U50) is synchronized to the Address Counter, and shifts once for every 512 addresses. The Shift Register output indicates if the waveform is to be displayed, and enables the appropriate path for the Address Counter input.

The 512th address sets the End-of-Trace Register (U21A). This produces Z axis blanking during retrace by presetting the Z Axis Buffer Register (U23). U21A is cleared by the LOAD DISPLAY and Z AXIS signals at U22B.

The Display Generator logic for the X-Y mode is essentially the same as the Y-T mode. Data is stored by U24 (X), U26 (Y), and U23 (Z) Buffer Registers. After the Inhibit Multi (U51A) times out (\approx 400 ns), the data is applied to OR gates, U05B, U36, and U14. If the data is non-zero or the X-Y mode is set, the data is held (or stored) until the next display cycle. Then it is shifted into the X, Y, and Z Registers (U44, U46, and U33) for conversion to display information. The X and Y Buffer Registers (U24 and U26) are cleared when the data is loaded into the corresponding display register. The resulting zero data initiates another memory request via U43A when in Y-T mode, or enables new data to be loaded for X-Y display mode.

If only zeros are available when the display cycle starts, the Z Axis Register (U33) is cleared, loading of the Display Registers is inhibited and the Z axis is blanked. The previous data point is therefore held, but not displayed. During Y-T display mode, the Z Buffer Register (U23) is set each time data is entered (except as described for retrace logic), so Z axis information is not required for a display.

During readout, the display is inhibited by the action of the Character Logic stage (U16). U16A is triggered by the READOUT TRIGGER signal. Then, when U16A runs out (approximately 60 μ s), if the Display Skip line (A36) is low, U16B is triggered. (DISPLAY SKIP is low when a character is to be displayed). After U16B is triggered, its output disables new data displays by holding the clear input of the Z Register (U33) low (via U14C).

BUS CONTROLLER DIAGRAM 9B

Memory requests are generated by clearing the Bus Controller (U53B) after inputs to U40A provide a logic output. U53A is cleared by the preceding memory cycle. Therefore, a 00 state exists that will pull the DATA CHANNEL REQUEST line (A14) low. When DATA CHANNEL GRANT is received, the high level on the D input is clocked

into U53A and the SELECT ACKNOWLEDGE line (B15) is pulled low.

When the DATA CHANNEL GRANT line goes low and BUS BUSY and SYNC ACKNOWLEDGE go high, a "1" is clocked into U53B. The Bus Controller now shifts to its master state. This sets the appropriate address information (via U53, U00, U01, & U11) on the Address Bus, and pulls the CONTROL SYNC line (A11) low approximately 50 ns later. The 50 ns delay is provided by the RC network R31/C31 in the Control Sync Generator (U32B).

When SYNC ACKNOWLEDGE goes low, the data on the buses is shifted into the X, Y, and Z Buffer Registers. The Inhibit Multi (U51A) diagram 9A is triggered to provide a settling time before the data is examined, and time for the next address to ripple through the Address Counter.

The REQUEST INHIBIT command is coupled through OR gate U43D diagram 9B to the clear input of U53A and the set input of U53B. This returns the Bus Controller to the idle state, and BUS BUSY is terminated, freeing the bus. C02 (at pin 13, U43D) serves to hold the REQUEST INHIBIT line low for a short period until the state of DATA REQUEST (pin 5, U40A) is established by the X and Y Buffer Registers (U24 and U26). This prevents U53B from being inadvertently cleared, which would have resulted in setting the Bus Controller to the Bus Request state.

ANALOG CIRCUITS DIAGRAM 9B

The description to this point has covered the access of data from memory (or the Data Bus) and the subsequent transfer of this data to the Display Registers. Each register feeds a D/A Converter, which converts the data to analog information for application to the Display Unit.

The D/A Converter for the Z axis consists of circuits (Q243, Q245, and resistor networks diagram 9A) that pull down the emitter of Q03, 5C on the Z Axis/Front Panel board and established four current levels proportional to the contents of U33B and U33C.

A jumper arrangement is provided to permit selection of either a DOT display or a VECTOR (normal) display. In the DOT display mode, gating signals at the inputs to Q243 and Q245 turn the Z axis off during the first half of each display cycle (to allow settling time).

The normal VECTOR display is a linear interpolation mode that integrates the difference between input and feedback current between successive data points in the X

and Y axes. RC networks in the collector circuits of Q243 and Q245 provide integration of the Z Axis signal for the VECTOR mode.

VECTOR GENERATORS DIAGRAM 9B

The X and Y Axis Vector Generators are identical in operation. The following description of operation of the X Axis may be applied to the Y Axis when corresponding part numbers are substituted.

The vector generator is a sampled feedback system with an 8 μ s period. A 2-MHz Clock (U62D & E) diagram 9A is divided by U52 to 125 kHz and applied to U51B. U51B generates STROBE pulses which load new data (if required) into the X Display Register (U44) to drive the X Axis D-A Converter (U55) and turn on sampling gate CR 151, 153, 155, and 157 diagram 9B through Q133 and T150 at the beginning of each 8 μ s period. C150 and VR150 provide a reverse bias to the sampling gate diodes when the gate is off.

When the sampling gate is closed (on), the voltage on C185/C186 is applied to C184, where it is stored while the gate is open. This stored voltage is applied to the gate of Q180A. Q180 operates in conjunction with Q161 and Q163 to hold the voltage (across R186 and R190) at the gate of Q180B essentially equal to that at Q180A. This action steers a portion of the current from Q93 (set by U92B, establishing equal voltages across R93 and R95) through Q163. The remainder of the current from Q93 passes through Q161 to the junction of C185, C186, and Q171. R185, R187, and C187 provide positive ac feedback to C184 to establish a voltage on C184 equal to that on C185 despite sampling gate losses.

Since the current through Q93 is fixed, and the current through Q163 proportional to the voltage at C185, the current through Q161 is inversely proportional to the voltage across C184. If the current through Q171 is held constant, the current through Q161 will be adjusted (at 8 μ s intervals) to an equal value, so the change in charge on C185 causes increased current through Q163 and reduced current through Q161.

If the current through Q171 (supplied by the X Axis D-A, U55) is changed simultaneously with the sampling of the voltage across C185, a difference current will be supplied by C185/C186. This constant current will result in a linear voltage change across C185/C186 until the next sample is taken. The values of C185/C186, R186 and R190 are adjusted so that the voltage change during each display cycle results in a precisely compensating change in current through Q161 at the end of the cycle. This results in an equilibrium voltage across C185/C186 proportional to the D-A output current, and linear changes from one equilibrium value to the next.

Q214 serves to reduce the impedance at the emitter of Q171, while R173 and R175 provide an adjustable standing current for horizontal centering.

The voltage across C185/C186 is supplied through a low-pass filter (R70 and C70) to the input of a voltage follower (U86). The output of U86 is applied to a differential transconductance amplifier (Q225 and Q219) resulting in a differential current output at J15 and J16.

In the DOT mode of operation, the sampling gate is disabled by disconnecting C184, C185/C186 and bypassing the diode bridge. The feedback loop operates much as before, but on a continuous basis. The Z axis is turned off each time new data is applied to the D-A (U55), and remains off for 4 μ s. The new level at the input of U86 will be established in a relatively short time (since the time constant is reduced), and will follow an exponential curve due to the continuous feedback. After the voltage at U86 is settled, the Z axis is turned on for 4 μ s to display the point.

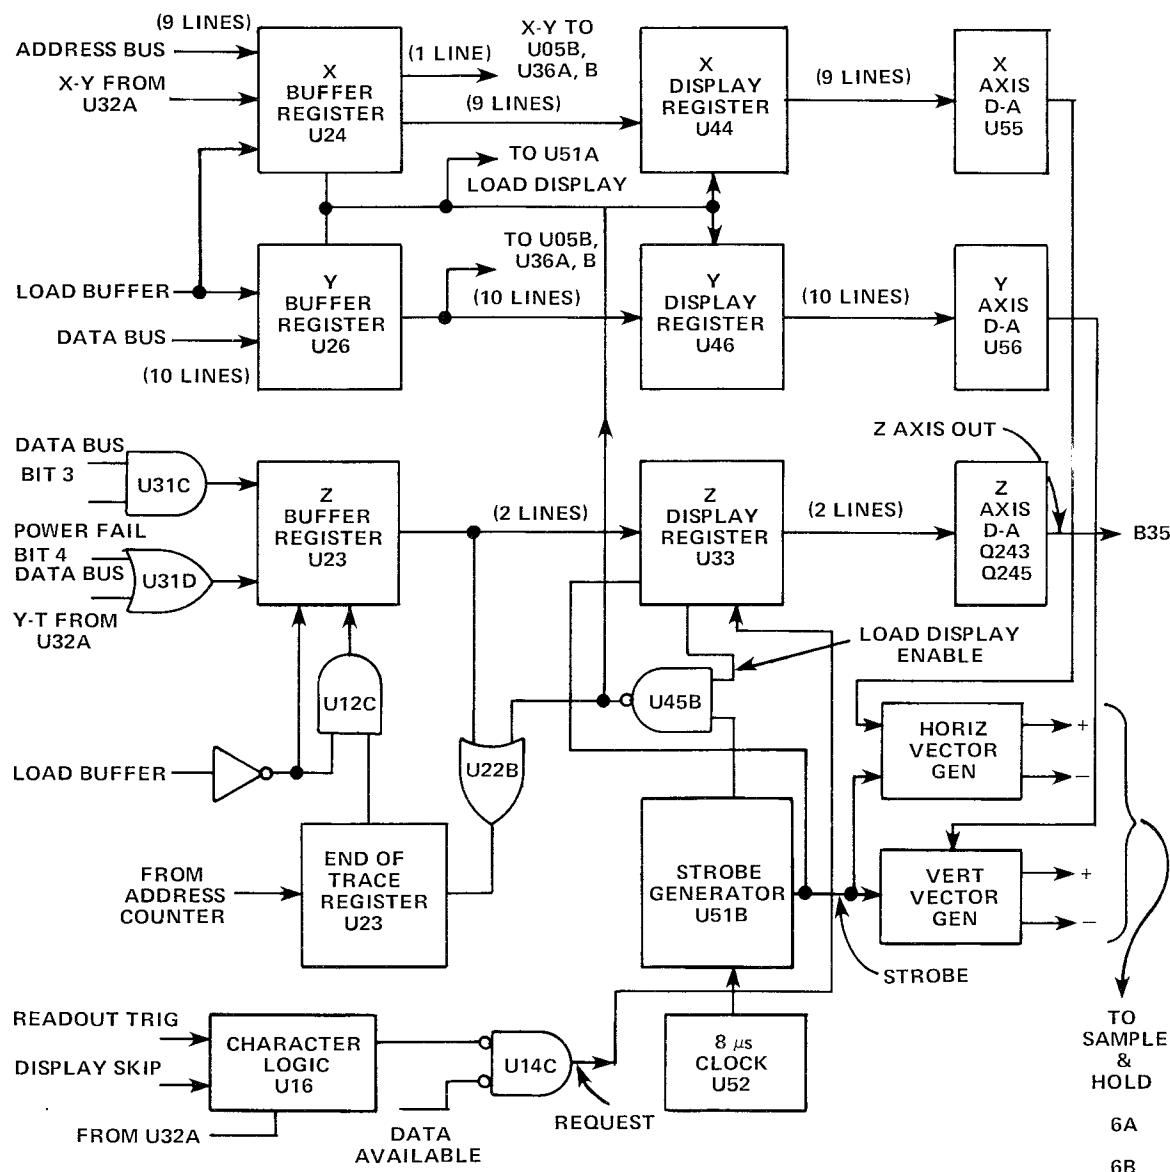

Fig. 1(B). Display Generator Block Diagram (Partial)

CALIBRATION PROCEDURE

Calibration of the Display Generator board involves the adjustment of six potentiometers, labeled VERT BAL (R115), VERT COMP (R109), VERT GAIN (R205), and HORIZ BAL (R175), HORIZ COMP (R190), HORIZ GAIN (R225) on the schematic 9B. The procedure requires the use of Tektronix P7001 Checkout Software for use with PDP-11.

Two test waveforms will be used, Calibrate Waveform (CAL), and X-Y Display Waveform (XYD). The Zero Display Generator Test (ZDG) may then be applied as a performance check on the Display Generator.

All adjustments are easily reached by swinging out the Front Panel (see procedure in Front Panel & Z Axis/Front Panel manual). Location of the adjustments is shown in Fig. 2.

1. With the P7001 Checkout Software, load the CAL waveform in MEMORY LOCATION A.

2. Allow at least 20 minutes warm-up time for the P7001 before making any adjustments. Set the P7001 front-panel buttons as follows:

DISPLAY SOURCE:	MEMORY
DATA HANDLING:	HOLD
MEMORY LOCATION:	A
PROGRAM CALL:	none

3. With the P7001 Checkout Software, select the XYD waveform as the display. The waveform is computer-generated, and the Display Generator is in the X-Y mode. The waveform is not stored in memory upon completion of the test.

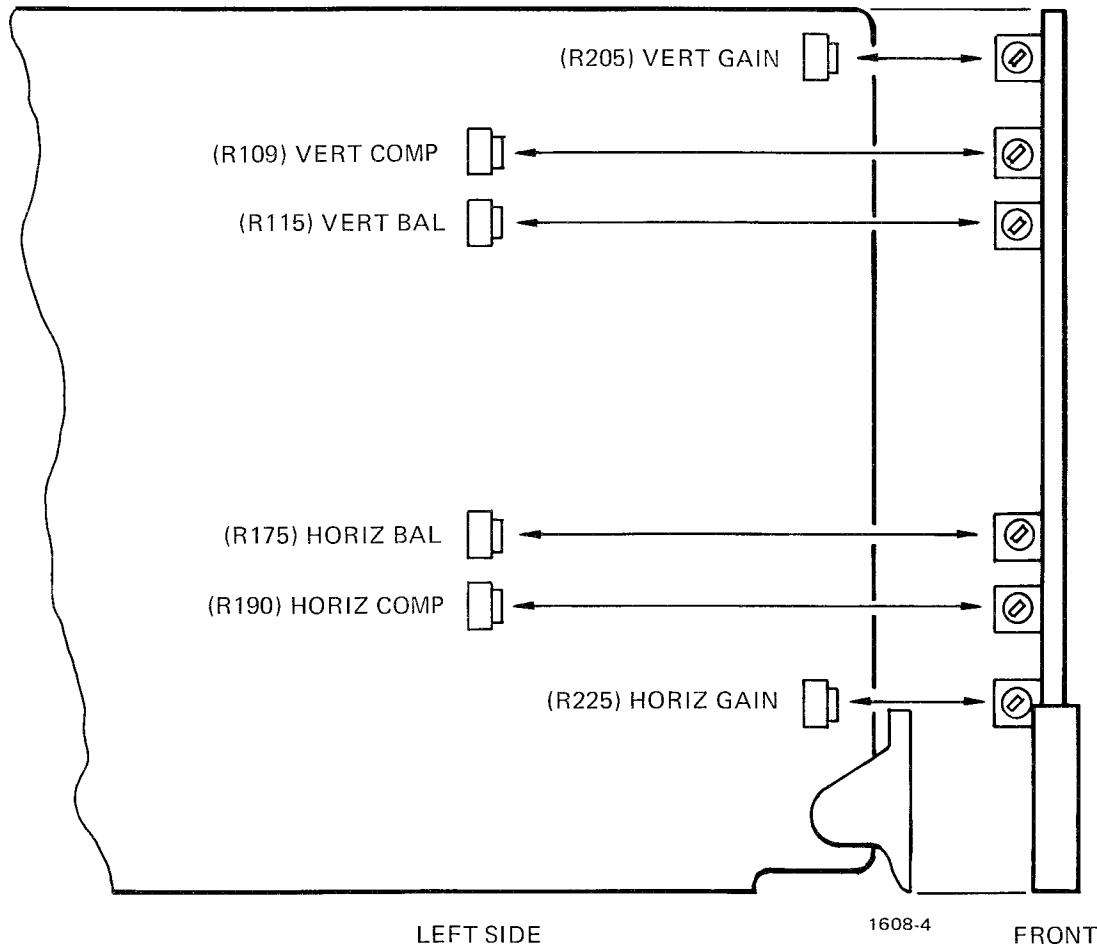

Fig. 2. Location of adjustments on the Display Generator board.

Observing the Display Unit Screen, adjust HORIZ COMP (R190) so that the crossing-line pattern gives the best approximation of an "X". Fig. 3 shows a properly adjusted display.

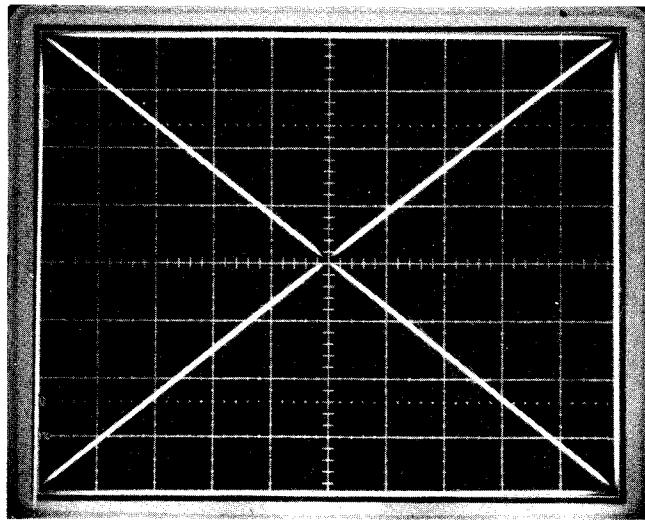

Fig. 3. XYD waveform display with HORIZ COMP (R190) properly adjusted.

4. Cancel the XYD waveform and observe the CAL waveform in MEMORY LOCATION A.

Adjust HORIZ BAL (R175) and HORIZ GAIN (R225) for horizontal alignment of the CAL waveform with the center 8 divisions of the graticule. The CAL display left-most and right-most crt divisions may have up to 0.1 division of compression or expansion while the display matches all other graticule lines. Note that HORIZ BAL affects horizontal position, while HORIZ GAIN affects spacing between the CAL waveform steps.

5. Adjust VERT COMP (R109) so that the first two (brightened) steps of the CAL waveform are flat.

6. Adjust VERT BAL (R115) and VERT GAIN (R205) for vertical alignment of the CAL waveform with the graticule. The top and bottom steps may have up to 0.1 division of compression or expansion when all other levels match their respective graticule lines.

7. Readjust HORIZ BAL and HORIZ GAIN as necessary, following the procedure outlined in Step 4. Take care not to disturb settings of the compensation controls, R109 and R190. Fig. 4 shows the CAL waveform with a properly adjusted Display Generator.

If a performance check of the Display Generator is desired, please refer to the P7001 Checkout Software manual (070-1612-00) for procedures.

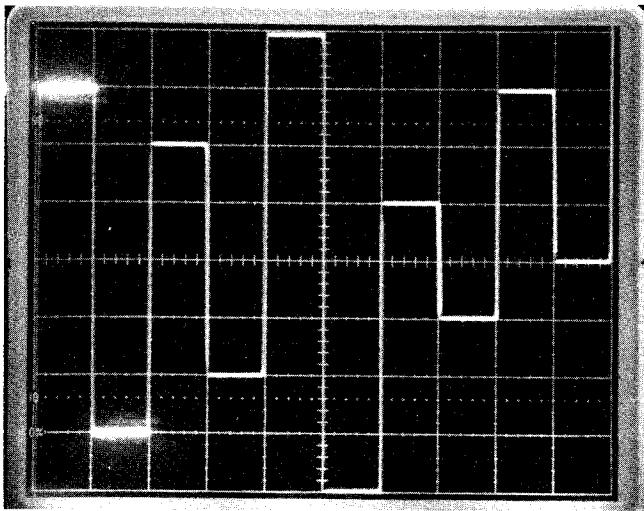

Fig. 4. CAL waveform display with a properly adjusted Display Generator.

REPLACEABLE PARTS

PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

SPECIAL NOTES AND SYMBOLS

X000 Part first added at this serial number

00X Part removed after this serial number

ITEM NAME

In the Parts List, an Item Name is separated from the description by a colon (:). Because of space limitations, an Item Name may sometimes appear as incomplete. For further Item Name identification, the U.S. Federal Cataloging Handbook H6-1 can be utilized where possible.
