WARRANTY

All TEKTRONIX instruments are warranted against defective materials and workmanship for one year. Any questions with respect to the warranty should be taken up with your TEKTRONIX Field Engineer or representative.

All requests for repairs and replacement parts should be directed to the TEKTRONIX Field Office or representative in your area. This will assure you the fastest possible service. Please include the instrument Type Number or Part Number and Serial Number with all requests for parts or service.

Specifications and price change privileges reserved.

P7001 FRONT PANEL & Z AXIS/FRONT PANEL

CIRCUIT DESCRIPTION

FRONT PANEL CIRCUIT BOARD [4A, 4B] and Z AXIS/FRONT PANEL [5A, 5B, and 5C] CIRCUIT CARD

There are many interconnections between the five circuit diagrams in this description, and references will be made to stages located on each diagram. To facilitate locating the mentioned stage, the diagram number, [4A] for example, will be noted after the stage name each time there is a change to another diagram. To simplify composition, diagram numbers are enclosed in brackets in text, rather than a diamond. Stage names are indicated by initial letter capitals, while signal line names are fully capitalized.

Several simplified block diagrams are included that should prove helpful in understanding the description.

GENERAL DESCRIPTION

The Front Panel board and Z Axis/Front Panel card contain circuits for system control and status indication, display switching, Z Axis Valid sensing, and Bus termination.

The FRONT PANEL board includes 28 pushbuttons with their coding and debounce logic and 15 status indicator lamps with decoding and lamp driver logic. The Z AXIS/FRONT PANEL card contains the status latches, data bus interface and control logic, Z Axis Valid sensing, Z axis switching circuits, and P7001 Bus terminations.

Data and power are transmitted between the two boards via three 10-conductor ribbon cables and one 3-conductor ribbon cable. The P7001 Processor may be operated through an I/O device (for example, by a computer) with the Front Panel not installed; however, the Z Axis/Front Panel card is required, as it contains functions essential for processor operation.

DETAILED DESCRIPTION

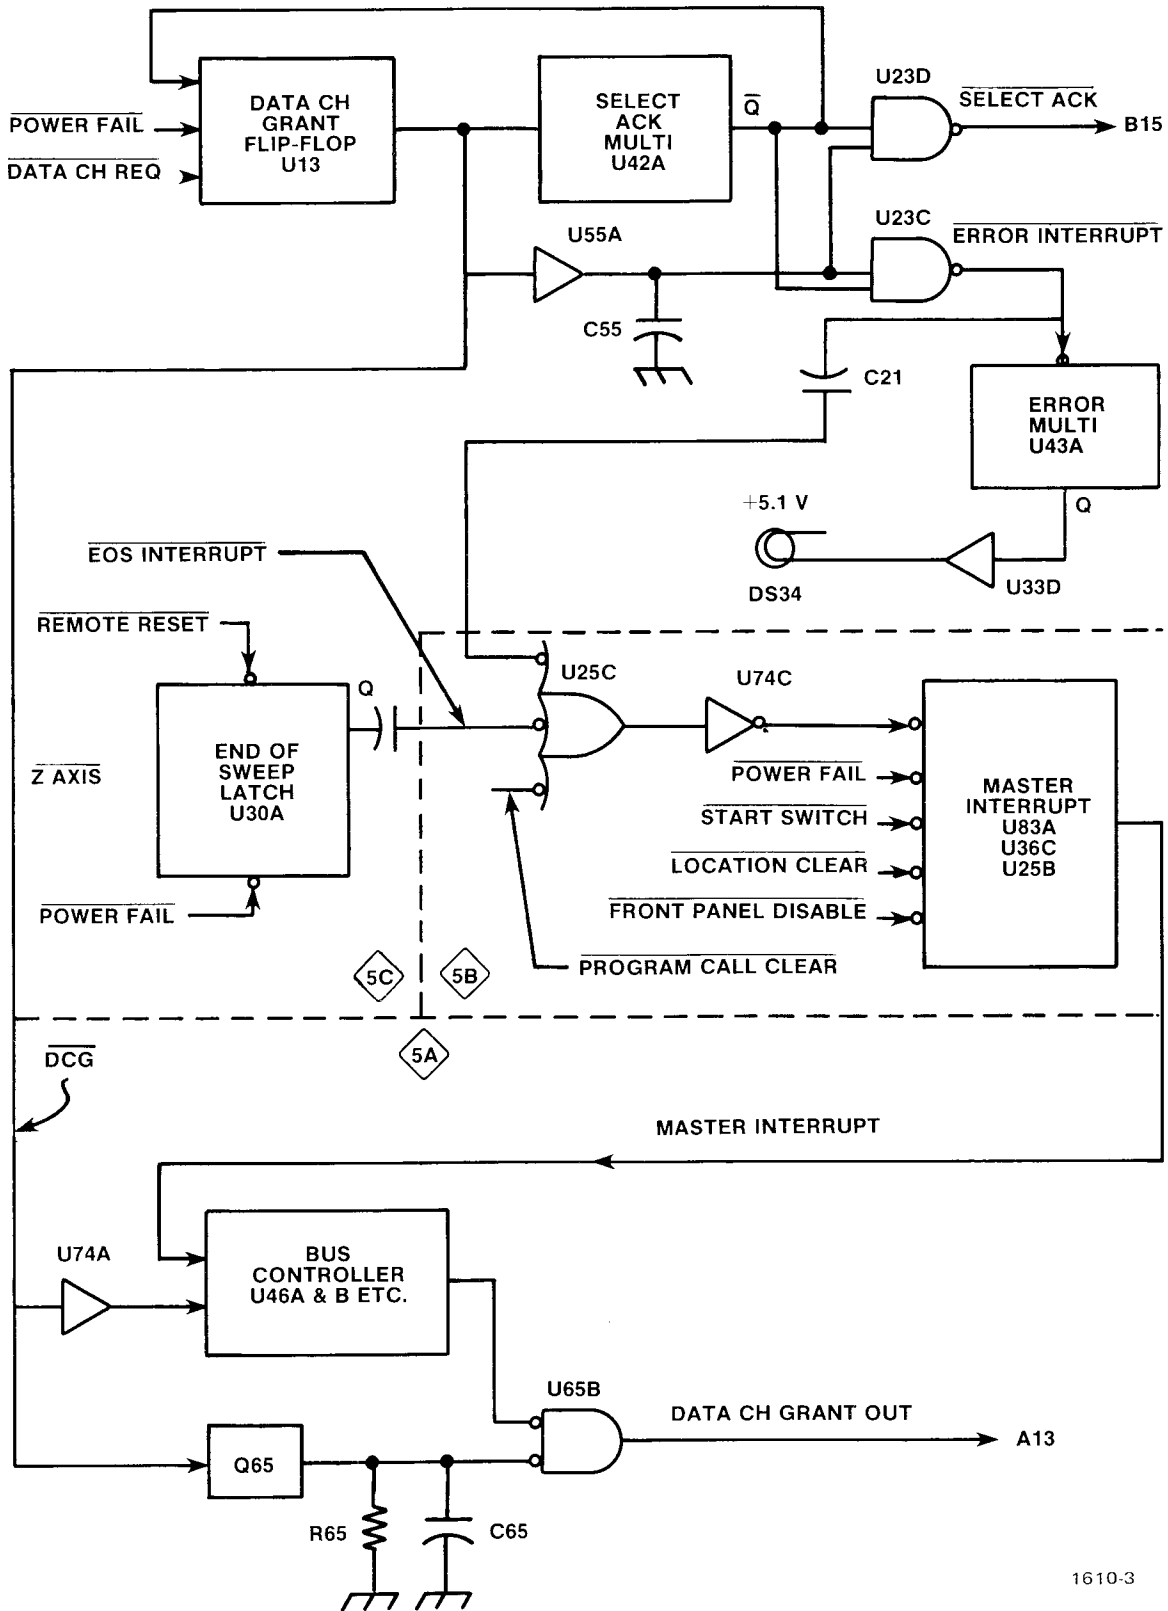

DATA CHANNEL GRANT SCHEMATIC 5

For the following description, please refer to the simplified block diagram, Fig. 1.

Priority of Data Bus usage within the P7001 is determined by a DATA CHANNEL GRANT (DCG) pulse which originates on the Z Axis/Front Panel card and is transmitted through each card in a "daisy chain" sequence. A \overline{DCG} pulse is generated by the Data CH Grant Flip-Flop (U13) [5C] whenever $\overline{DATA\ CH\ REQ}$ is low and $\overline{POWER\ FAIL}$ and $\overline{SELECT\ ACK}$ are high. The output of U13 is applied to the base of Q65 [5A] and to U74A. The delay provided by R65 and C65 allows time for the Bus Controller (U46, etc.) to inhibit DCG Out by pulling high on the input to U65B if it is a requesting controller. Otherwise, DCG is passed on to the next card in the daisy chain by U65B. When the requesting device receives DCG, it pulls down on $\overline{SELECT\ ACK}$ [5C], causing DCG to be removed until the requesting device advances to the MASTER state. When $\overline{SELECT\ ACK}$ is removed, DCG will again be generated.

The Select Ack Multi (U42A) along with U55A and U23D ensure that a $\overline{SELECT\ ACK}$ signal is generated within 3.5 μs after DCG is issued. \overline{DCG} triggers U42A and is inverted and delayed by U55A and C55. If U42A times out and \overline{DCG} is still low, U23D is enabled and pulls down on $\overline{SELECT\ ACK}$. U42A is retriggered each time \overline{DCG} is initiated, restarting the timing interval.

U23C triggers the Error Multi (U43A) if a DCG error occurs, turning on DS34 through U33D to provide a visual error indication. C21 couples an $\overline{ERROR\ INTERRUPT}$ to U25C [5B] as U43A is triggered, in order to alert the I/O device that a data transfer error has occurred.

1610-3

Fig. 1. DATA CH GRANT & SELECT ACKNOWLEDGE GENERATION.

SYNC ACKNOWLEDGE ERROR DETECTION SCHEMATIC 5C

If an address not assigned within the P7001 is called by any device, a $\overline{\text{SYNC ACK}}$ signal is not normally generated, and the Bus Controller logic will hang, preventing further bus usage. To prevent this, U42B, U51B, and U23A operate in a similar manner to the Select Ack Multi (U42A) (previously described) to generate a $\overline{\text{SYNC ACK}}$ signal whenever $\overline{\text{CONT SYNC}}$ remains low for more than 3.5 μs , clearing the Bus for continued operation. U23B triggers the Error Multi and generates an $\overline{\text{ERROR INTERRUPT}}$ as described above for DCG.

STATUS LOGIC SCHEMATIC 5B

The status word latches (U60, U62, U63, U64, U70, and U84A) may be set by any of three methods. Status words may be set by the Front Panel pushbuttons, by a normal data transfer to the Front Panel address (15600 to 15777), or via an $\overline{\text{I/O STROBE}}$. The contents of the latches are decoded and then displayed by the indicator lamps regardless of the data entry method.

For this description, please refer to the simplified block diagram, Fig. 2.

The status latches are initialized to Hold A, Program Call O, by the application of $\overline{\text{POWER FAIL}}$ through U73A, U73C, and U73D. The Bus Controller (U46, etc.) [5A] is set to the request state by $\overline{\text{POWER FAIL}}$ through U25B [5B] and U74B [5A]. This causes the first Bus operation after $\overline{\text{POWER FAIL}}$ goes high to transmit the status word "HOLD A" to the remainder of the system.

The status latches may be either loaded or examined via the Data Bus, depending on the state of $\overline{\text{DATA MODE O}}$. In either case, the latches are addressed by applying address 15600 through 15777 to the Address Bus or by asserting $\overline{\text{I/O STROBE}}$. The board address is decoded by the Address Decoder (U14 and U25A), and a $\overline{\text{SYNC ACK}}$ is generated by U51A and U34D to answer the sending device. $\overline{\text{I/O STROBE}}$ disables U14 via U85A & B, simulating the receipt of the board address, and the remainder of the process is identical to addressing the board via the Address Bus. U45A, C42, R72, C72, U45E, and U75A disable $\overline{\text{I/O STROBE ADDRESSING}}$ for about 2 μs after the Front Panel asserts $\overline{\text{I/O STROBE}}$, to prevent the board from answering itself (unless no I/O device is installed).

When the address is decoded, U25A output goes low and this signal is combined (with the state of $\overline{\text{DATA MODE O}}$) by either U53B or U53D and U55D to indicate SEND DATA or LOAD STATUS. If the command is SEND DATA, U53A and U74D generate a LOAD BUS signal which is applied to U24, U75B, and U75C [5B]. The contents of Status Latches U60 and U70 are then applied

to the Data Bus via the Data Gates (U24A, B, C, & D). The contents of U62 are applied to the Data Bus via Data Gates (U35B & C) if the Start Latch (U84B) is set, and the contents of U63 and U64 are applied via Data Gates (U26A, B, C, & D) if the Program Call Latch (U84A) is set. The SEND DATA signal is applied directly to U33B & C [5C] to load the contents of the End Of Sweep Latch (U30A) and the Error Multi (U43A) onto the Data Bus.

If $\overline{\text{DATA MODE O}}$ is asserted (low) when the address is received, the Disable Multi (U43B) [5A] will be triggered via U53D and a Load Status command will be applied to the status latches via U55D and U55C. The Data Bus information at the D inputs will then be loaded into U60, U62, U63, U64, and U70 [5B]. U53C decodes $\overline{\text{HOLD}}$ to set or reset the Start Latch (U84B), according to the status word. Additional Data Bus bits are used to set the Display Source Latch (U30B) [5C] and to generate $\overline{\text{REMOTE RESET}}$ and set the End Of Sweep Latch (U30A).

The Disable Multi (U43B) generates a FRONT PANEL DISABLE pulse for approximately 0.5 second after Load Status is generated to prevent status latch override by the Data Handling, Memory Location, or Start pushbuttons. The Program Call pushbuttons are not affected by FRONT PANEL DISABLE. FRONT PANEL DISABLE is applied to the Master Interrupt Detector [5B] to prevent interrupts from being generated by status word changes entered via the Data Bus.

FRONT PANEL BOARD SCHEMATIC 4

The Front Panel pushbuttons are divided logically into three groups plus the Start and Display Source buttons. Each switch closure to ground generates a $\overline{\text{CLEAR}}$ associated with its group and $\overline{\text{SETS}}$ as required by the individual switch function. The component values are chosen so that the $\overline{\text{SET}}$ is removed from the latches last, leaving the appropriate latches set. Additional logic generates a Master Interrupt whenever a switch operation indicates a change in system status.

When one of the Data Handling switches is pushed, U50A, U70A, and C73 [4A] generate a $\overline{\text{MODE CLEAR}}$ at U73C [5B] to clear the Mode Latches (U62A & B) and at U73B to set the Start Latch (U84B) and clear the Program Call Latch (U84A). When the Start Latch is set, the transition at pin 8 pulls U83A pin 4 low (in Master Interrupt Detector) via C37, generating an interrupt. Since the Start Latch is set, the status word will be HOLD regardless of which Data Handling button was pushed. The $\overline{\text{START}}$ output of U84B, which is at the logic high state of time, is applied to U20A [4A] to light the HOLD lamp. U40A & B generate a two bit code ($\overline{\text{M0}}$ & $\overline{\text{M1}}$) to set the Mode Latches (U62A & B) [5B] to the desired state. U703 & F, U20B & C, and U30D [4A] light the lamp under the button pushed.

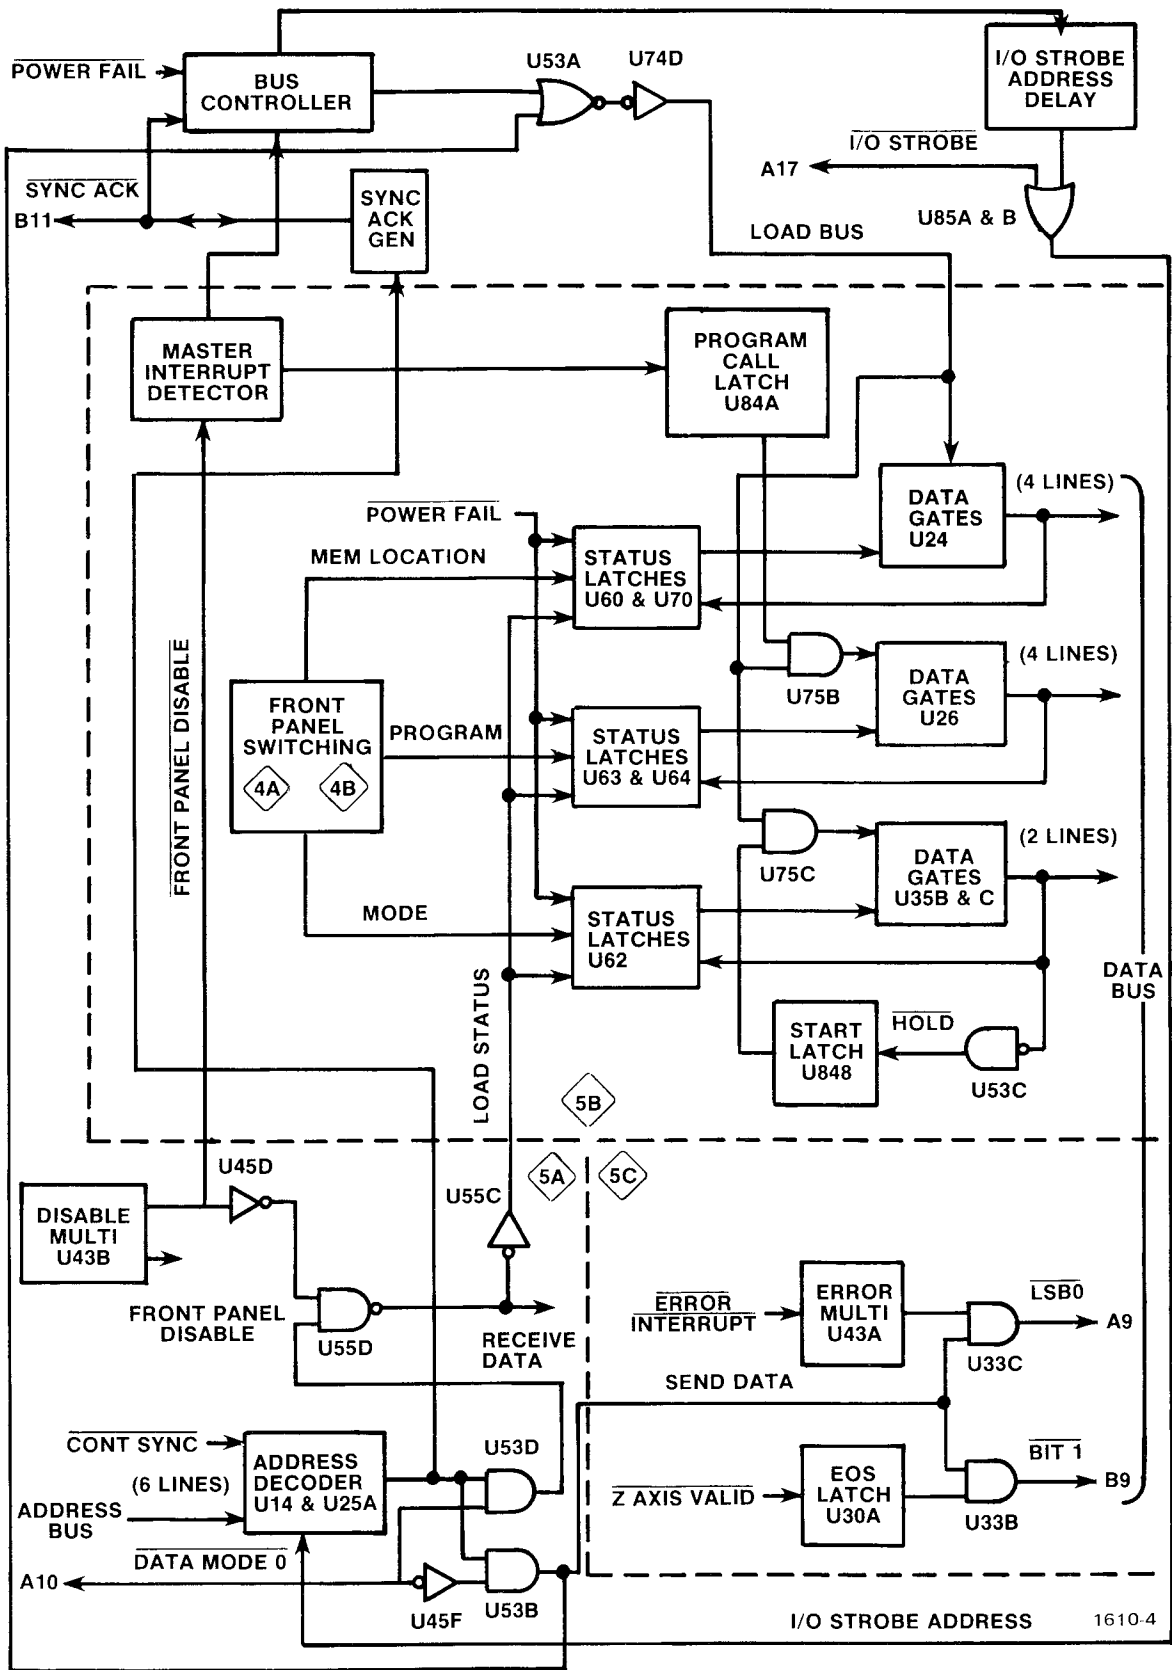

Fig. 2. Simplified block diagram of Front Panel Data Handling.

U94A and U54A form an oscillator to drive the debounce multi U94B, U34A, and U34B [4B] with a retrigger pulse every 3 ms. The timeout of the multi then starts every 3 ms as long as the appropriate switch is depressed, and runs out after the switch is released. This action allows only one transition for each switch operation.

The Start switch (SW55) triggers the Start Multi (U94B) [4A] each time it is depressed, providing that U54B has not decoded a Hold to disable U94B. The output of the Start Multi is coupled to the Start Latch (U84B) [5B] to clear the latch and to the Master Interrupt Detector to generate an interrupt each time the Start switch is pushed.

Pressing any of the Memory Location buttons generates a set at \bar{A} , \bar{B} , \bar{C} , or \bar{D} , and via U33B triggers the Location Clear Multi (U34A) [4A] to generate a clear for latches U60 [5B] and U70 via U73D, and an interrupt via U83A (in Master Interrupt Detector). The Location Clear Multi has a period of approximately 500 ms, so new clear pulses are not generated if another button is pushed within this time. New set pulses (during the timeout) are coupled to the appropriate latch, and the latch output coupled to U72B through a capacitor. These capacitors serve to

generate an interrupt if any of the latches are set while the Location Clear Multi [4A] is timing out. Fig. 3 is a simplified block diagram showing the major logic in selection of Memory Location A.

Program Call button operation triggers U34B [4B] via U33A, generating an interrupt which is coupled to the Master Interrupt Detector [5B]. This same signal also sets the Program Latches (U63 & U64) via U75D and sets the Program Call Latch (U84A) via U25C and U74C. Each Program Call switch completes a circuit to ground when pushed, either directly or via the bases of Q04 [4B], Q14, or Q23. The low generated at the pull-up resistors is encoded by U23A & B to encode the two LSBs of the Program Call status word; the low at the transistor collectors (base drive supplied by pull-up resistors R22) is encoded by U23C & D to form the two MSBs. The outputs of U23 are passed by U53 until the output of U34B, delayed by U40C, C54, and U54C, disables U53. The outputs of U53 are low long enough to set the Program Latches (U63 and U64) [5B], then are inhibited (to allow Data Bus entry of data) until the Program Call button is released. If any of the program call bits are set, U83B is enabled, and the CPU BUSY lamp is lighted by U72A [4B].

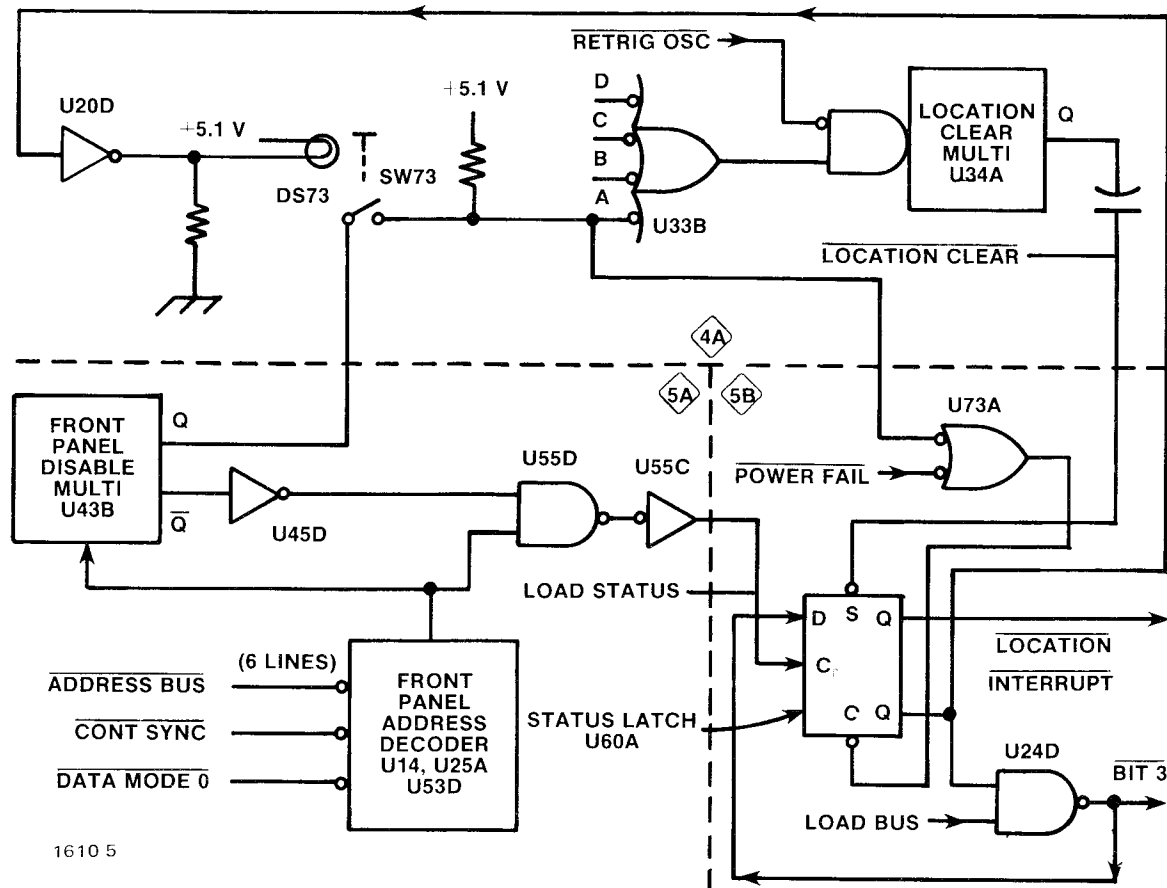

Fig. 3. Simplified Partial Front Panel Logic, showing selection of Memory Location "A" and Indicator Lamp Logic.

DISPLAY SOURCE SWITCHING

The Display Source may be programmed via the Data Bus in a manner similar to the other status latches, or the source may be selected by front-panel pushbuttons. The Data Bus programming is assertive only. If both bits are zero, the Display Source will remain unchanged. No interrupts are generated by the Display Source pushbuttons, and their state may not be read via the Data Bus. If the Display Source is PLUG-INS and one of the Data Handling buttons is pushed, U80D [4B] is enabled by the MODE CLEAR signal and sets the Display Source to BOTH. Otherwise, the Display Source is independent of the operation of the remainder of the front panel controls.

Operation of the Display Source pushbuttons directly sets the tri-flop (U92A & B and U50B) to one of three states. The appropriate lamp is turned on by U70D and U72B, C, & D. In the case of Data Bus programming, the status word is applied to U70B & C and U80A, B, & C via the Display Source Gates (U65C & D) [5A] to set the tri-flop.

The outputs of U92A and U50B [4B] are applied to the clear and set inputs of the Display Source Latch (U30B) [5C] to control the display source drive, and through U50A to U31A. U31B, U51F, C31, and U51E (Processor Chop Oscillator) trigger U31A at a 600 kHz rate whenever U50A is enabled (Display Source is BOTH). HUSH disables the oscillator whenever it is low. Each time U31A is triggered, the Z axis is turned off through U50C & D, Q03, and Q11. After a delay generated by U51D, R52, C52, and U51C, the Display Source Latch (U30B) is clocked to switch the display source. U31A times out somewhat later and enables the Z axis, and U30B determines which Z axis input is routed to the Z AXIS OUT line. The Q output of U30 is used by the channel switches to control the source of crt display.

Z AXIS VALID DETECTION SCHEMATIC 5C

The Z axis current from the Acquisition Unit is routed through Q02 (Z Axis Valid Logic) to cause a similar current through Q01 and R70. This current reduces the current supplied to R70 by Q11, and thereby the voltages at the input to the comparator, U10. Circuit constants at the comparator input are chosen so both inputs follow the Acquisition Unit Z axis output, but at differing gains. If the Z axis current is greater than approximately 1 mA, pin 1 voltage will be higher than pin 2, and the output at pin 5 will be low, indicating Z Axis Valid. Conversely, if the Z axis current is less than 1 mA, pin 1 voltage will be lower than pin 2 and pin 5 will be high, indicating Z AXIS VALID (labeled as Z AXIS at terminal B33).

SWEEP RESET SCHEMATIC 5C

If Data Bus $\overline{\text{BIT 1}}$ is low when $\overline{\text{RECEIVE DATA}}$ is present, U85D is enabled and triggers a monostable

composed of U85C, U55B, C57, and R57. The output of U55B is applied to U33A to generate a $\overline{\text{REMOTE RESET}}$ to actuate the single-sweep reset in a horizontal (time-base) plug-in unit, and set the End Of Sweep Latch (U30A). The next time $\overline{\text{Z AXIS}}$ goes high, a zero is clocked into U30A, resetting it and generating an END OF SWEEP INTERRUPT, which is coupled to the Master Interrupt Detector [5B] via U25C.

BUS CONTROLLER SCHEMATIC 5A

The Bus Controller for the Front Panel circuit card is similar to those on other cards in the P7001, except that $\overline{\text{CONTROL SYNC}}$ is never asserted. Also, this controller is always set to the Bus Request state when power is first applied to the instrument so that Memory Location A and Hold are established as initial operating conditions.

The Bus Controller circuitry consists of the D-type flip-flops (U46A and U46B) plus associated inverters and gates. The function of the controller is to allow use of the Bus by other requesting devices (circuit cards) or use of the Bus by the Front Panel card to communicate front-panel switching status (Memory Location, Mode, and Program). The Bus Controller sequences through four states, as indicated by the truth table for U46A and U46B. The four states, IDLE, BUS REQ, SEL ACK, and MASTER will be described as they occur in a normal operation.

IDLE

In this mode, the Q outputs of U46A and U46B are both at the high state. It is assumed that the instrument has been in operation previous to this cycle of operation. The last mode for the controller before IDLE is MASTER. The $\overline{\text{Q}}$ output of U46B is high, as is the Q output of U46A. These highs enable gate U36B, generating $\overline{\text{MASTER}}$ at its output (pin 6). $\overline{\text{SYNC ACK}}$ (terminal B11) would have been asserted due to previous use of the Bus by one of the circuit boards. $\overline{\text{MASTER}}$ and $\overline{\text{SYNC ACK}}$ enable gate U56B, and the resulting output (via U56A) sets U46B so that Q is high. The Q output of U46A is still high from the MASTER mode, so we are now in the IDLE mode.

BUS REQ

Note that in the IDLE mode, the $\overline{\text{Q}}$ outputs of both U46A and U46B are low, enabling gate U56D. The high from pin 13 of U56D is coupled to one input (pin 12) of U36D. When MASTER INTERRUPT occurs due to use of Front Panel pushbuttons, END OF SWEEP INTERRUPT, or by ERROR INTERRUPT, U36D is enabled and U46A is thus cleared. The $\overline{\text{Q}}$ output of U46A goes to high, and the Q of U46B is high. Gate U35A is enabled, generating the $\overline{\text{DATA CH REQ}}$ signal. The controller is now in the BUS REQ mode.

SEL ACK

The $\overline{\text{DATA CH REQ}}$ signal, as previously described under Data Channel Grant [5A or B], cause the $\overline{\text{DATA CH}}$

$\overline{\text{GRANT}} (\overline{\text{DCG}})$ to be generated. During BUS REQ mode, the $\overline{\text{Q}}$ output had gone to high, disabling gate U56D and thus setting the D input of U46B to low. $\overline{\text{DCG}}$, via U74A, clocks U46B so that its Q output goes to low. The highs at $\overline{\text{Q}}$ of both U46A and U46B enable gate U35D and disabling U35A, generating the $\overline{\text{SELECT ACK}}$ signal and removing $\overline{\text{DATA CH REQ}}$. The controller is now in the SEL ACK mode.

MASTER

$\overline{\text{SELECT ACK}}$ resets the DATA CH GRANT flip-flop (previously described), and $\overline{\text{DCG}}$ goes to high. If the Bus is not busy, $\overline{\text{BUS BUSY}}$ and $\overline{\text{SYNC ACK}}$ are high. The $\overline{\text{Q}}$ output of U46A is high, so gate U72A is enabled, generating a clock pulse for U46A. In the meantime the $\overline{\text{Q}}$ output of U46B had set the D input of U46A to high. U46A is clocked and its Q output goes high, setting the controller to the MASTER mode. In this mode, U36B is enabled and $\overline{\text{MASTER}}$ is asserted at pin 6 of U36B.

$\overline{\text{MASTER}}$ is inverted by U36A and U50B to generate $\overline{\text{BUS BUSY}}$, indicating to other units that the bus is in use. The output of U36A is also coupled through U53A and U74D to form the LOAD BUS signal, which enables the Data Gates for the Front Panel Latches [5B].

$\overline{\text{MASTER}}$, coupled through inverters U45A, U45B, U45C, and U45E enables gate U34A (after a delay due to charging C42), asserting $\overline{\text{I/O STROBE}}$ at terminal B17.

If the Program Call Latch (U84A) [5B] is not set, PROGRAM CALL at pin 8 of U56C [5A] will be at the low state, and along with $\overline{\text{I/O STROBE}}$, will enable U56C. The resulting high at pin 5 of U34B and the high at pin 4

from the inverted $\overline{\text{MASTER}}$ signal (via U36A) cause $\overline{\text{STATUS STROBE}}$ to be asserted at terminal A17.

When $\overline{\text{SYNC ACK}}$ is received, U56B is satisfied (since $\overline{\text{MASTER}}$ is low), U46B is reset (via U56A), and the controller returns to its IDLE state. $\overline{\text{MASTER}}$ is coupled through U45E, U45A, R72, and U75A, and delayed approximately 2 μs by C42 and C72 to disable U14A & B. When U14A & B are disabled, U25A is satisfied and $\overline{\text{SYNC ACK}}$ is generated via U51A and U34D. This action occurs only if no other device generates $\overline{\text{SYNC ACK}}$ within 2 μs .

In order to establish initial operating conditions when the instrument is first turned on, the Front Panel Bus Controller is always set to the BUS REQ mode at that time. This is accomplished as follows:

When instrument power is first applied, $\overline{\text{POWER FAIL}}$ is low (see Power Fail Signal in Mainframe Manual Circuit Description). Via U74B and U56A, this signal sets U46B so that Q is high. Simultaneously, $\overline{\text{POWER FAIL}}$ via U25B [5B] generates a MASTER INTERRUPT signal, which is coupled into U36D [5A]. If U46A is in the wrong state (this is, with Q high), gate U56D is enabled by the Q outputs of U46A and B. The output of U56D, along with the MASTER INTERRUPT signal, enables U36D which clears U46A so that its Q output is low. This establishes the BUS REQUEST mode of the controller. Operation of the controller is now the same as described for a normal cycle.

$\overline{\text{POWER FAIL}}$, via U73D [5B] clears Memory Location Latches U60B, U70A, and U70B. Via U73A, this signal sets latch U60A, asserting Memory Location A. The Mode Latches, U62A and U62B, are cleared by the $\overline{\text{POWER FAIL}}$ signal via U73C, establishing HOLD as the mode.

ACCESS TO FRONT PANEL CIRCUIT BOARD AND THE Z AXIS/FRONT PANEL CIRCUIT CARD

Easy access to these and most other circuit cards in the P7001 is provided by means of a hinged front panel. To release the front-panel hinge, refer to Fig. 4 and follow these steps:

1. Remove the 4 Phillips-head screws located in the corners of the front panel.

2. Hold the Front-Panel Pull located at the left side of the panel and carefully pull straight out until the stop is

reached. The front panel should now be approximately 2½ inches out from the instrument.

3. Pull the right-hand edge of the front panel out and to the left (rotating) to open.

NOTE

When re-closing the front panel, make certain that the ribbon-cable leads are tucked back into the instrument and do not get squeezed between the front panel and the frame.

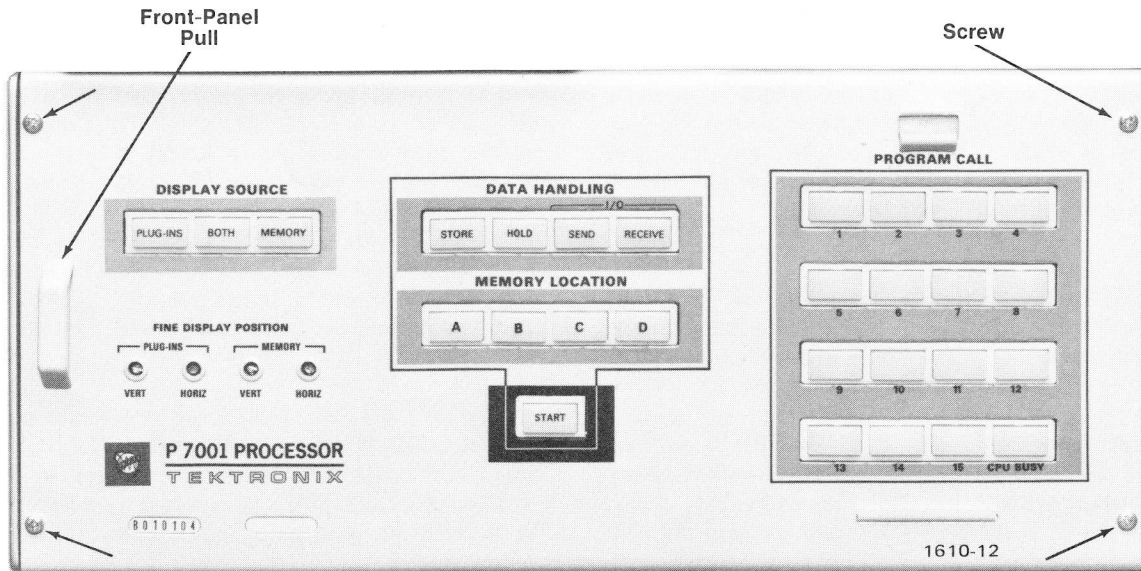

Fig. 4. Access to circuit cards.

SERVICING THE Z AXIS/FRONT PANEL CARD

To service the Z Axis/Front Panel card, a Card Extender (Part No. 067-0683-00) is required. The ribbon-cable leads are long enough to permit operation of the card while it is mounted outboard of the instrument on the card extender.

To install the card extender, first turn the instrument power off. Then, release the Z Axis/Front Panel card by pressing down on the nylon release, (located on the front lower edge of the board). Carefully pull the card out and free of its slide track. Install the card extender in place of the card and plug the card into the extender. Fig. 5 shows the card mounted on the extender.

1610-6

Fig. 5. Z Axis/Front Panel card mounted on a card extender for servicing.

CALIBRATION PROCEDURE

FRONT PANEL BOARD

Calibration of the Front Panel Board consists of adjusting the four front-panel FINE DISPLAY POSITION potentiometers.

Since these controls are operational adjustments, a procedure for setting them is covered in the DPO Operators Manual (070-1599-00). If the controls are too far out of range to use that procedure, please refer to the Sample & Hold and Display Generator calibration procedures in the individual manuals.

Z AXIS/FRONT PANEL CARD

The Z Axis/Front Panel card has only one Calibration adjustment, labeled OFFSET (R30) on schematic [5C]. This control adjusts the Z AXIS signal for proper operation with all settings for the Acquisition Unit A or B INTEN controls. Misadjustment of the Z AXIS signal typically causes loss of the ability to store waveforms in the P7001, so its adjustment should be checked whenever difficulty of this nature is encountered.

Equipment Required:

1. Test Oscilloscope – Tektronix 7704A with 7B70 or 7B71 Time Base and 7A16A Amplifier recommended.
2. 10X Probe – P6053A.

3. Screwdriver – 3" to 5" shaft, narrow, with small blade tip.

Proceeds as follows:

1. With Front Panel swung open, mount the Z Axis/Front Panel card on a card extender.
2. Connect the test oscilloscope probe tip to TP2. This test point is located at the upper edge of the card near the edge-connector. Fig. 6 shows the test probe attached.
3. Turn the power on and allow the DPO to warm up, at least 20 minutes, meanwhile presetting the controls:

P7001

DISPLAY SOURCE – PLUG-INS
 DATA HANDLING – HOLD
 MEMORY LOCATION – A

Acquisition Unit

TIME BASE 1 μ s/DIV – Free running
 AMPLIFIER Center trace without waveform

1610-13

Fig. 6. R30 and TP2, Z Axis/Front Panel card.

Test Oscilloscope

TIME BASE 5 μ s/DIV – AUTO Trigger
 AMPLIFIER 2 V/DIV (.2 V/DIV + 10X Probe)

4. Obtain a sweep (trace) on the screen of the DPO Display Unit.

5. Turn the A & B INTEN controls on the Acquisition Unit fully ccw (off).

6. Locate R30, at the top edge of the Z Axis/Front Panel card (Fig. 6).

Observing the test oscilloscope screen, adjust R30 slowly cw and then ccw between the points where the Z Axis blanking pulses disappear and the trace becomes a steady high or a steady low. This indicates range of the adjustment. Set R30 midway between these two points, where the waveform is steady and free of jitter. Fig. 7 shows the proper waveform.

7. Change the P7001 DISPLAY SOURCE to BOTH.

8. Adjust R30 carefully until the test oscilloscope display is the same as that seen when the DISPLAY SOURCE is set to PLUG-INS. The waveform should be stable and free of jitter.

9. Rotate the INTEN control (A or B), which is selected by the Acquisition Unit HORIZONTAL MODE, through its range and check for the same waveform obtained in Step 8. If jitter is encountered at any setting of the INTEN control, R30 must be re-adjusted.

10. Change the Time Base plug-in unit to the other horizontal compartment (A or B HORIZ), change the HORIZONTAL MODE to match, and repeat Step 9, rotating the now-selected INTEN control through its range.

Fig. 7. Z AXIS signal at TP2, Z Axis/Front Panel card.

REPLACEABLE PARTS

PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

SPECIAL NOTES AND SYMBOLS

- X000 Part first added at this serial number
00X Part removed after this serial number

FIGURE AND INDEX NUMBERS

Items in this section are referenced by figure and index numbers to the illustrations.

INDENTATION SYSTEM

This mechanical parts list is indented to indicate item relationships. Following is an example of the indentation system used in the description column.

```

1 2 3 4 5           Name & Description
Assembly and/or Component
Attaching parts for Assembly and/or Component
    - - - * - - -
Detail Part of Assembly and/or Component
Attaching parts for Detail Part
    - - - * - - -
Parts of Detail Part
Attaching parts for Parts of Detail Part
    - - - * - - -
  
```

Attaching Parts always appear in the same indentation as the item it mounts, while the detail parts are indented to the right. Indented items are part of, and included with, the next higher indentation. The separation symbol - - - * - - - indicates the end of attaching parts.

Attaching parts must be purchased separately, unless otherwise specified.

ITEM NAME

In the Parts List, an Item Name is separated from the description by a colon (:). Because of space limitations, an Item Name may sometimes appear as incomplete. For further Item Name identification, the U.S. Federal Cataloging Handbook H6-1 can be utilized where possible.
