## WARRANTY

All Tektronix instruments are warranted against defective materials and workmanship for one year. Tektronix transformers, manufactured in our plant, are warranted for the life of the instrument.

Any questions with respect to the warranty mentioned above should be taken up with your Tektronix Field Engineer.

Tektronix repair and replacement-part service is geared directly to the field, therefore all requests for repairs and replacement parts should be directed to the Tektronix Field Office or representative in your area. This procedure will assure you the fastest possible service. Please include the instrument Type and Serial or Model Number with all requests for parts or service.

Specifications and price change privileges reserved.

Fig. 1-1. Type 355 Programmable Sampling Unit.

# SECTION 1

## SPECIFICATION

Change information, if any, affecting this section will be found at the rear of the manual.

### General Information

The Type 3S5 Programmable Sampling Unit is a dual-channel vertical amplifier plug-in unit designed for operation in any one of the Tektronix Type 560-series oscilloscopes except the Type 561 (it will operate in a Type 561A). The Type 3S5 accepts S-series sampling heads. The sampling heads determine the input characteristics of the sampling unit and the availability of trigger pickoff for internal triggering from Channel A.

The Type 3S5 will operate with any Tektronix 3T-series sampling unit. It is recommended that it normally be used with a Type 3T5 Programmable Sampling Sweep. External programming of the Type 3S5 (and Type 3T5) can be accomplished through either a front panel external program connector, or a connector at the rear of the Type 568 or R568 Oscilloscope. The Type 3S5 rear program connector is J214 of the Type 568/R568 (the Type 3T5 rear program connector is J224 of the Type 568/R568). The Type 3T2 Random Sampling Sweep unit is recommended for non-programmed operation, because it can display the triggering event by the random sampling process, when externally triggered in time-coincidence with the displayed pulse. (Do not use random process sampling when internally triggered.) Conventional or real-time time-base plug-in units do not operate with the Type 3S5. The Type 3S5 provides the vertical signal information for voltage measurements by Tektronix digital readout systems, such as the Type 568-Type 230, or the Type 567-Type 6R1A. Decimal and units-of-measure control of the digital unit readout is also provided by the Type 3S5, including a sampling head deflection factor multiplier for sampling heads with sensitivities requiring the numbers around the Type 3S5 Units/Div control to have a decimal shift.

One or two S-series sampling heads can be plugged into the Type 3S5 front panel, or used remotely on an optional extender cable unit. The Type 3S5 provides the power for the sampling heads.

Interconnections for the sampling head circuits are provided by connectors in the sampling head compartments of the Type 3S5.

If a trigger pickoff is provided in the sampling head, the pickoff signal passes through the Type 3S5 (Channel A only) to a rear panel connector for connection to the sampling sweep unit through the oscilloscope interconnections.

Sampled signals are presented to both the oscilloscope CRT vertical deflection plates and to the front panel SIG OUT jacks. Front panel signals are useful with auxiliary equipment such as pen recorders, or for duplicate (slave) display by a conventional oscilloscope. The two Type 3S5 channels may be displayed either individually, simultaneously, or in a combined mode, A + B, producing algebraic addition of two input signals. External programming of the Type 3S5 pro-

duces only simultaneous displays (Dual-Trace) of the two channels. Individual channel displays are possible by offsetting the unused channel just outside the graticule area by external programming of DC Offset to the unused channel. A + B displays are not possible when externally programming the Type 3S5.

### ELECTRICAL CHARACTERISTICS

#### Digital Unit Compatibility

The Type 3S5 is compatible for operation with all Type 230 (or R230) Digital Units and all Type 6R1A Digital Units. It is compatible with all Type 6R1 Digital Units SN695 and up. Type 6R1 Digital Units SN101-694 require the installation of Tektronix Field Modification Kit No. 040-0342-00 when operated with a Type 3S5. (Some Type 6R1 units were modified out of sequence in advance of SN694. Check with your Tektronix Field Engineer or Representative if in doubt about the unit to be used.)

#### Characteristics

The following characteristics apply over an ambient temperature range of 0°C to +50°C and after a five minute warmup providing the instrument was calibrated at a temperature between +20°C and +30°C.

Characteristics listed below apply for either front panel operation or external programming only after the Type 3S5 front panel GAIN control has been properly adjusted for the particular oscilloscope in which the unit is operating.

For particular system warmup requirements, refer to the main frame oscilloscope instruction manual.

A procedure for mating the Type 3S5 to the oscilloscope can be found in the Operating Instructions section of this manual.

### ELECTRICAL CHARACTERISTICS

Characteristics	Performance Requirement
Deflection Factor Units/Div Range	2 to 200 in seven steps in a 1-2-5 sequence with Units/Div labeled on the sampling head directly under the control.
Accuracy	Within 3% when NORMAL-SMOOTH function is NORMAL, including sequential and random sampling. Within 4% when NORMAL-SMOOTH function is SMOOTH. (Not used with random sampling.)

**ELECTRICAL CHARACTERISTICS Cont'd**

Characteristics	Performance Requirement
Units/Div Variable Range	Increases any display deflection at least 2.5 times when control is turned fully CW from CAL position. (Control also alters signal sent to digital unit. Control is inoperative when Vertical Mode switch is at EXT PROG.)
B DELAY Range	≥ 10 ns
Interchannel Delay Range	At least +5 to -5 ns, with two of same type sampling heads; either both in Type 355 or both on identical length extender cables, and only when using time-coincident signals.
Loop Gain At Normal At SMOOTH	Can be set to <0.90 to >1.10 using the DOT RESPONSE control. ≤ 0.3. (DOT RESPONSE control inoperative.)
Low Frequency Trigger Rate Dot Slash	Vertical dot drift is ≤ 0.1 div when sampling sweep unit is triggered at 20 Hz.
Vertical GAIN control	Adjusts a post Memory amplifier gain so all deflection factors match the oscilloscope CRT deflection factors.
DC OFFSET External Program controlled: Range Accuracy	-995 mV to +995 mV in 5 mV steps, programmed by a modified BCD code. Within 2% of the programmed value, or 5 mV, whichever is greater.
Front Panel (Internal) Dial Control: Range Accuracy, expressed as relationship between dial number and the same voltage when externally programmed	+1 V to -1 V. Within 10 mV of the same offset voltage that is obtained in the external program mode.
Voltage at OFFSET out jacks Range Relation to internal offset voltage	+10 V to -10 V Internal offset voltage is equal to 0.1 times OFFSET voltage, within 1%.
Source resistance	10 kΩ, within 1%.
Signal at SIG OUT jacks: Amplitude in Volts (Referred to Input)	(Signal Input in Volts)* times $\frac{200}{\text{Units/Div setting}}$ *or Amperes for a current-measuring head.
Accuracy (referred to Input)	Within 2% at NORMAL. Within 3% at SMOOTH.
Deflection Factor (Referred to CRT)	200 mV per displayed division, within 3% at both positions of INVERT switch.

**ELECTRICAL CHARACTERISTICS Cont'd**

Characteristics	Performance Requirement
Source resistance	10 kΩ, within 0.5%.
Accuracy of Vertical Signal to Digital Unit	Within 2% at NORMAL (typically 1%). Within 3% at SMOOTH. When Units/Div VARIABLE is at its CAL detent position.
Position Control Range	Control can move free-run trace at least +2 to -2 divisions from graticule centerline.
Position Indicator Lamps	One indicator lamp will be on and the other off when CRT dot is more than 4 divisions away from graticule centerline.
Programmable Functions	Both Channel Units/Div, DC Offset, and Smoothing.
Units/Div Multiplier	A digital unit readout decimal and units multiplier (milli) automatically responds to any sampling head multiplier of ×0.1, ×1 or ×10 that may require the numbers around the Units/Div switches to have a decimal shift.
Type of Units	The Type 355 automatically controls a digital unit readout to indicate the Volts and Amps units of either channel sampling head.
External Programming Logic	Negative
Logical 1 (True)	Ground, or a voltage from 0 V to +2 V. See the operating instructions for current value required of the external closure circuit (Fig. 2-10).
Logical 0 (False)	Open circuit, or a voltage from +6 V to +15 V. See the operating instructions for leakage current values allowable when external closure circuit is a cut-off transistor (Fig. 2-10).

**ENVIRONMENTAL CHARACTERISTICS**

- Storage
  - Temperature— -40° C to +65° C
  - Altitude—to 50,000 feet.
- Operating
  - Temperature—As stated above Electrical Characteristics table.
  - Altitude—to 15,000 feet.

**MECHANICAL CHARACTERISTICS**

- Dimensions—Height 6¼ inches  
Width 4¼ inches  
Length 14½ inches
- Approximate dimensions including knobs and connectors.
- Construction—Aluminum alloy chassis with epoxy laminated circuit boards. All circuit boards are removable without using a soldering iron. Two center located circuit cards are of the plug-in type. The front panel is anodized aluminum.
- Accessories—An illustrated list of the accessories supplied with the Type 355 is at the end of the Mechanical Parts List pullout pages.

## SECTION 2

# OPERATING INSTRUCTIONS

Change information, if any, affecting this section will be found at the rear of the manual.

### General Information

This section covers installation, first time operation, function of the front panel controls and connectors, general operation and application of the Type 3S5 Programmable Sampling Unit. If you are unfamiliar with sampling, it may be helpful to read Section 3, Tektronix Basic Sampling Principles, before proceeding with this section.

The Type 3S5 is a special purpose dual-channel sampling unit designed to operate with the following indicator oscilloscopes: Type 561A, RM561A, Type 564, RM564, Type 567, RM567, Type 568 and R568. The Type 3S5 accepts S-series sampling heads which determine the input characteristics of the sampling system. For equivalent time sampling, the sampling system consists of an indicator oscilloscope, Type 3S5 with sampling head (or heads), and a sampling sweep unit. The Type 3S5 is not intended for use with real-time time-base units. The Type 3S5 may be used with all Type 230 and Type 6R1A Digital Units.

The vertical deflection factors of 2 to 200 are calibrated to the units labeled on the sampling head. Sampling head extender cable units are available to operate the S-series head remotely up to 6 feet away. Three-foot sampling head extender cable is Tektronix Part No. 012-0124-00. Six-foot sampling head extender cable is Tektronix Part No. 012-0125-00. Contact your local Tektronix Field Engineer or Representative for price and availability of these optional accessories.

### Installing the Type 3S5 In the Oscilloscope

The Type 3S5 is designed to drive the vertical deflection plates of the oscilloscope CRT, and therefore is installed in the left-hand compartment of the oscilloscope.

To insert the Type 3S5 into the oscilloscope compartment, turn the aluminum knob (at the front panel bottom center) counterclockwise several turns until it stops. Then slide the Type 3S5 completely into the compartment. Once the plug-in unit is seated, turn the aluminum knob a few turns clockwise until it is hand-tight.

The Type 3S5 requires at least one sampling head in order to operate. The sampling head (or heads) can be plugged into the Type 3S5 or used remotely by use of an extender cable.

To insert a sampling head into one of the Type 3S5 compartments, slide the unit completely into the compartment, leaving the latch at the bottom of the unit free to move. Once the sampling head is seated, push the latch to lock the head in place. To remove, pull the latch knob away from the panel, then pull the unit from the compartment. See Fig. 2-1. The same system of connection applies when using the sampling head extender cable. It is not necessary to turn the power off when inserting or removing the Type 3S5 or S-series

Fig. 2-1. Installation of S-series sampling heads.

sampling heads, provided the sampling head cover is in place.

### Mating

The Type 3S5 Vertical Output Amplifier gain must be matched to the indicator oscilloscope CRT deflection factor for accurate signal amplitude measurements. The GAIN control, a screwdriver adjustment on the front panel adjusts the Vertical Output Amplifier gain of the Type 3S5. The Type 284 Pulse Generator is used as a signal source when adjusting the GAIN control in the Equivalent-Time Sampling Operation which follows. Changing the Gain control does not affect the amplitude of the signal sent to the digital unit. For further gain setting information, refer to the Gain Adjustment instructions later in this section.

## FIRST TIME OPERATION

### Equivalent-Time Sampling Operation

Equivalent-time sampling operation of the Type 3S5 requires a sampling sweep unit in the right hand compartment of the indicator oscilloscope. In this First Time Operation procedure a Type 3T5 Programmable Sampling Sweep Unit, Type 568 Oscilloscope, Type 230 Digital Unit, and a Type

## Operating Instructions—Type 355

284 Pulse Generator are used. Any S-series sampling head can be used. If you are not already familiar with the operation of the oscilloscope and sampling sweep unit, read the manual for these instruments before proceeding. Two type S-2 Sampling Heads were used when making the waveform photographs for the following procedure.

### Control Settings

#### Type 355

Display Mode	CH A
NORMAL-SMOOTH	NORMAL
DC OFFSET (both Channels)	0.00 (Locked)
Units/Div (both Channels)	200
VARIABLE (both Channels)	CAL (detent)
INVERT (both Channels)	Push in

#### Type 3T5

Horiz Position	Midrange
Samples/Sweep	1000
Time/Div Decade	7 } (500 ns/Div)
Time/Div Multiplier	5 }
Delay	0000
Program Selector	Internal
Trigger Sensitivity	Fully clockwise (free run)
Recovery Time	Optional
Trigger Polarity	+
Trigger Source	External

#### Type 230

Measurement Averaging	8
CRT Intensification	Both Ref Zones and Time Measurement off
Measurement Mode	Time
CH A Reference Zones	Both at Average
Channel switches	Both at A
Time Measurement Start Point	10% Between Zones
Time Measurement Stop Point	90% Between Zones
Slope	Both at + 1 st
Display Time	Midrange
Triggered Measurement	Off
Limits	Optional

#### Type 284

Square Wave Amplitude	1.0 V
Period	1 $\mu$ s
Mode	Square Wave Output
Lead Time	175 ns

<sup>1</sup>Type 284 instruments having serial numbers prior to SN B030236 require installation of Field Modification Kit, Tektronix Part No. 040-0487-00 in order to obtain a 75 ns trigger Lead Time.

### NOTE

Operating the sampling head without the input connector terminated by a 50  $\Omega$  resistor or coaxial cable will cause a few millivolts vertical shift of the zero signal baseline. This occurs because the strobe kickout signal is reflected from the open input connector. The kickout signal arrives back at the sampling bridge during sampling time, while the bridge is still conducting. To avoid this, set the display zero reference point with the sampling head input circuit terminated. Also use at least 20 cm of airline between the Type S-2 input and a fast generator or circuit that is sensitive to the fast strobe kickout signal.

**Operating Adjustments.** Turn on power and allow the equipment to warm up for 5 minutes. Connect a 50  $\Omega$  coaxial cable with a 5 ns signal delay and GR 874 connectors to the input connectors of the sampling heads installed in the Channel A and B compartments. Do not connect the opposite ends of these cables at this time.

Operating adjustments should be checked periodically, and must be adjusted when the Type 355 is used in a different oscilloscope. The 355 POSITION, S-2 Bridge Balance, and the 355 GAIN controls are explained below.

With DC OFFSET controls for both channels locked at the 0 mV position (0.00), adjust the screwdriver-adjust POSITION control until the trace is at the graticule centerline. Position the trace start to the graticule left edge using the Type 3T5 horizontal position control. The sampling head Bridge Balance control (accessible through a hole in the left side of the case) is checked next.

Set the CH A UNITS/DIV Switch to 200. Remove the Type 568 top panel. Turn the UNITS/DIV Control clockwise. Adjust the sampling head control until the trace remains stationary near the graticule center as the UNITS/DIV Control is turned throughout its range. Set the DISPLAY Mode Switch to CH B and remove the sampling head from the CH A compartment. Adjust CH B sampling head Bridge Balance using the same procedure. Return the Display Mode Switch to CH A and reinstall the CH A sampling head. Replace the Type 568 top cover. Check the setting of the GAIN control next.

Connect the Square Wave Output signal from the Type 284 to the coaxial cable leading to the Channel A sampling head. Any applied signal (to sampling head) should be 1 volt or less. See the Specification section of the sampling head manual for further information. Connect the Trigger Output connector of the Type 284 to the External Trigger connector of the Type 3T5 through a 50  $\Omega$  coaxial cable with a 5 ns signal delay and BNC connectors.

Adjust the Type 3T5 Trigger Sensitivity control for a stable display. Center the display vertically using the DC OFFSET control. The displayed square wave will have a vertical amplitude of 5 major divisions if the GAIN control on the Type 355 panel is properly set. It may be necessary to adjust the GAIN control slightly with a small screwdriver.

Check Channel B gain by applying the square wave output of the Type 284 to the coaxial cable leading to the Channel B sampling head. Change the Display Mode switch to CH B. A square wave having a vertical amplitude of 5 major divisions should be displayed. If not, see the Performance Check and Calibration section of this manual.

Digital readout of the amplitude of the vertical input signal applied to either Channel of the Type 3S5 can be displayed on the Type 230 Digital Unit. Set the Type 230 Measurement Mode switch to A volts for Channel A, and B volts for Channel B. Return the Measurement Mode switch to Time to display digital readout of risetime during the following procedure.

**Measuring A Step Signal 10% to 90% Risettime.** Connect the coaxial cable from Channel A input to the Pulse Output connector of the Type 284. Set the Type 284 Mode switch for Pulse operation. Set the Type 3T5 CH A Units/Div switch to 50 and the Display Mode switch to CH A. Vertically position the display to midscreen using the CH A DC OFFSET control. Set the Type 3T5 Time/Div Decade to 9 and the Multiplier to 5 for a sweep rate of 5 ns/Div.

Adjust the Type 3T5 Trigger Sensitivity for a stable display. Position the display start to the graticule left edge using the Type 3T5 Horizontal Position control. Delay the time window start by adding delay in 1 ns increments, while noting the effect on the display. See Fig. 2-2A.

Add delay until the pulse start is less than 1 division from the graticule left edge. Note the delay reading and set the Time/Div Decade switch to 0 (fully cw). The sweep rate is now 500 ps/Div. It should be noted that with the Time/Div Decade turned to the fully cw position a decimal appears in the Decade readout area, indicating the Delay is now one-tenth of the previous value. Reset the Delay dials to equal the previous value. Change the Delay slightly to position the pulse start near the left edge of the graticule. Set the sweep rate to 100 ps by placing the Time/Div Multiplier at 1. Position the display to the position shown in Fig. 2-2B using the Type 3T5 Horizontal Position control and the Type 3S5 DC OFFSET control. Read the pulse 10% to 90% rise-time from CRT graticule markings by determining the horizontal distance in divisions between the 10% and 90% amplitude levels of the pulse. Multiply the number of divisions by the sweep rate to determine the pulse risetime. See Fig. 2-2B. Inaccurate measurement of risetime will result if a non-linear portion of the sweep is used. Refer to linearity specifications for your Sampling Sweep Unit to determine whether a portion of the sweep must be excluded.

To measure pulse risetime using a digital unit, set the Type 230 Time Measurement switch to On. Set the intensified reference zones to the positions shown in Fig. 2-2C by turning the 0% and 100% Position controls. Read the pulse risetime in the Type 230 readout window.

The function of the Type 3S5 front panel controls and connectors is explained below. See Fig. 2-3.

### FUNCTION OF FRONT PANEL CONTROLS AND CONNECTORS

Display Mode Switch	Selects one of the five following display modes.
CH A	The Channel A signal is displayed.
CH B	The Channel B signal is displayed.
DUAL-TRACE	Both channel signals are displayed, but each trace has one-half the normal numbers of dots per sweep. The display switches from CH A to CH B after each

Fig. 2-2. Fastrise pulse displays.

Fig. 2-3. Type 3S5 Front Panel.

	CH A dot, and vice versa. While operating in Dual-Trace, one sweep contains the same number of dots as if only one channel were displayed.		
A + B	The algebraic sum ( $\pm A \pm B$ as selected with the INVERT switches) of the two Channels is displayed.		For example, with a Type S-2 Sampling Head in Channel A and the Channel A Units/Div switch set at 100, each major division of deflection corresponds to 100 millivolts of applied signal at the Type S-2 input connector when the VARIABLE Control is in the CAL position.
EXT PROG	Selecting EXT PROG with the Display Mode Switch causes the Type 355 to operate in the Dual Trace Mode. Use either the EXTERNAL PROGRAM connector on the Type 355 front panel, or J214 on the Type 568 rear panel when remotely programming. Deflection factor, DC Offset amplitude, Offset polarity, and Normal/Smooth functions are externally programmable. The front panel Units/Div VARIABLE is inoperative and the Cal switch is shorted when using EXT PROG. Front panel screwdriver adjustments, output jacks, and invert switches operate in their normal manner when using EXT PROG.	VARIABLE Controls (Same control knob used for INVERT Switches)	Provide uncalibrated variation of the deflection factor between labeled values of the Units/Div switches. Display size increases at least 2.5 times as the control is rotated clockwise from the CAL (detent) position. The control is inoperative during external programming.
DOT RESPONSE (screwdriver adjustments)	Allows the loop gain of each Channel to be adjusted to unity when the NORMAL-SMOOTH switch is in the NORMAL position. The controls are inoperative in SMOOTH position.	INVERT Switches	In the Normal (pushed in) position, a positive input signal deflects the CRT beam upward. In the pulled position the displayed signal is inverted. When the Display Mode switch is set to A + B, algebraic addition of Channel A and B is obtained. The position of the INVERT switches determines the polarity of each channel before algebraic addition. Allows differential displays at the full frequency response of the sampling heads in use. Does not affect signal sent to a digital unit.
NORMAL-SMOOTH (Red knob concentric with the Display Mode switch)	Selects unity loop gain at NORMAL and reduces the loop gain to 0.3 or less at SMOOTH. SMOOTH reduces the effect of random noise on the display while requiring high sampling dot density for the correct displayed risetime.	B DELAY	Varies the time position of CH B display over a range of at least 10 ns. Time coincidence with Channel A depends upon the time difference of sampling heads and sampling head extender cable units.
DC OFFSET $\pm 1$ V Controls	These controls apply internal signal offset voltages of +1 to -1 V to the sampling head (unless otherwise stated on the sampling head front panel.) The input signal zero reference (related to the CRT) is the DC Offset voltage instead of ground. This permits all portions of a maximum +1 V input signal to be positioned through the CRT vertical window even at a deflection factor of 2 units/div (2 mV/Div with a Type S-1 or S-2).  The vertical window is a total of 16 mV when the deflection factor is 2 mV/Div, and 1.6 volts when the deflection factor is 200 mV/Div. The calibrated Offset dial is marked with 100 minor divisions (each of which represents 2 mV) and a total range of $\pm 500$ minor divisions for $\pm 1$ volt in 10 turns. Turning the control clockwise moves the display up and produces -200 mV of offset for each complete turn of the dial from the 0 mV position. Negative offset is indicated by the black numbers on the dial, and positive offset by the red numbers.	GAIN	Matches the vertical output amplifier gain to the oscilloscope CRT deflection factor. (Does not affect the internal Digital Gain accuracy.)
Units/Div Switches	Select calibrated deflection factor for each Channel. The units are selected and named on the adjacent S-series sampling head.	POSITION Control (Screwdriver adjust)	Adjusts the vertical position of the A and B displays.
		EXTERNAL PROGRAM Connector	Provides terminals through which logic can be applied when the Display Mode switch is in EXT PROG position. Deflection factor, DC Offset Voltage, Offset Polarity, and Normal-Smooth dot response can be programmed. Terminals for connecting an automatic calibrator are also provided. The Type 355 uses negative logic. Logical ONE is 0 to +2 V input and logical ZERO is produced by a +6 to +15 V input or an open circuit. Closure-type or saturating transistor-type programmers are to be used.
		Output Jacks A SIG OUT .2 V/Div 10 k $\Omega$	The Channel A facsimile signal (the same Memory output signal that drives the Vertical Amplifier) is available at this connector. The front panel labeled open-circuit deflection factor of 0.2 V per division of CRT deflection applies only when the Units/Div VARIABLE control is at its CAL detent position. (The VARIABLE control alters the CRT deflection factor but does not change the signal amplitude fed to the SIG OUT

## Operating Instructions—Type 3S5

jacks.) Maximum open-circuit signal amplitude is  $\pm 4$  V for all Units/Div switch-controlled deflection factors. A non-sampling type oscilloscope can monitor the facsimile signal the equivalent of 40 CRT divisions unless limited by the sampling head. Output resistance is 10 k $\Omega$ . Output amplitude is not affected by the Display Mode switch position.

B SIG OUT .2 V/Div 10 k $\Omega$	Performs the same function for Channel B as described above for Channel A.
A OFFSET $\times 10$ k $\Omega$	Unless otherwise specified on the sampling head front-panel, the open-circuit voltage at this jack is 10 times the internal DC offset voltage as set by the Channel A DC OFFSET Control. The output resistance is 10 k $\Omega$ .
B OFFSET $\times 10$ k $\Omega$	Unless otherwise specified on the sampling head front-panel, the open circuit voltage at this jack is 10 times the internal DC offset voltage as set by the Channel B DC OFFSET Control. The output resistance is 10 k $\Omega$ .

## BASIC OPERATING INFORMATION

### Gain Adjustment Using Oscilloscope Calibrator

#### NOTE

It is recommended that 60 Hz oscilloscope calibrators be used as a signal source for setting the Type 3S5 GAIN adjustment only when no other source is available, and only after verifying the signal amplitude with accurate measuring equipment. The following procedure uses the Type 567 or Type 568 20 kHz Calibrator (500 mV into 50  $\Omega$ ,  $\pm 2\%$ ), producing a Type 3S5 deflection factor accuracy of  $\pm 5\%$ .

1. Allow the equipment to warm up for at least 5 minutes.
2. Set the controls as follows:

#### Type 3S5

Display Mode	CH B
NORMAL-SMOOTH	NORMAL
DC Offset (both channels)	0 (zero)
Units/Div (both channels)	100
VARIABLE (both channels)	CAL
INVERT (both channels)	Push in

#### Type 3T5

Horiz Position	Midrange
Samples/Sweep	1000
Time/Div Decade	5
Time/Div Multiplier	1

} 100  $\mu$ s/Div

Delay	Optional
Program Selector	Internal
Trigger Sensitivity	For triggered display
Recovery Time	Clockwise
Trigger Polarity	+
Trigger Source	External

3. Apply the signal from the indicator oscilloscope calibrator (500 mV into 50  $\Omega$ ) connector to the Channel B 50  $\Omega$  input connector of the sampling head installed in the Type 3S5. Use a coaxial cable and a BNC to GR adapter at the calibrator.

Connect a coaxial cable with BNC connectors from the Type 568 Pre-trigger connector to the External Trigger connector of the Type 3T5.

4. With the DC OFFSET control, align the display with the graticule lines and check for exactly 5 divisions of vertical deflection. If the vertical deflection is not 5 divisions, adjust the GAIN control.

5. Check Channel A by connecting the signal into the sampling head 50  $\Omega$  input connector installed in the Channel A compartment of the Type 3S5. If the amplitude is not 5 vertical divisions refer to Section 7, Performance Check/Calibration.

### Triggering

Internal triggering of the sampling sweep unit from the signal applied to CH A can be used when the signal is a repetitive square or sine wave.

When observing a fast risetime pulse using the Type 3T5, an external pretrigger such as that supplied by the Type 284 is required. The amount of pretrigger time required is dependent upon the type of sampling head, extender cable (if used) delay in the Type 3S5, and the type of oscilloscope used. See the Type 3T5 Instruction Manual for detailed information on pretrigger requirements.

### Output Jacks

**A and B Signals.** Channel A and Channel B signals are available at the SIG OUT jacks. The signals at these jacks are taken after the sampling process, and are, therefore, proportional representations of the display signal rather than the input signals themselves. The open circuit voltage at either jack is 200 mV per division of display when the VARIABLE controls are in the CAL position. The maximum output is  $\pm 4$  volts. This permits a non-sampling type oscilloscope to monitor the facsimile signal the equivalent of 40 CRT divisions.

### Dual Trace

The dual-trace feature of the Type 3S5 provides for observing Channels A and B simultaneously. This is useful for determining the time relationship of two signals. The sweep may be triggered from an external source or by the signal applied to CH A input. Internal triggering is available only

Fig. 2-4. Initial Power divider connection.

from Channel A. No trigger output circuit is provided for Channel B. If the time relationship of two signals is to be displayed, use input cables with equal signal delays.

The B DELAY control adds a variable to the time coincidence of Channel B in relation to Channel A sampling time. The B DELAY range of 10 ns will accommodate small time differences in cables or sampling heads, so that both signals can be displayed in time coincidence.

For dual-trace operation, set the controls as follows:

**Type 355**

Display Mode	DUAL-TRACE
NORMAL-SMOOTH	NORMAL
DC OFFSET (both channels)	0 (zero)
Units/Div (both channels)	100
VARIABLE (both channels)	CAL
INVERT (both channels)	Push in

**3T5**

Horiz Position	Midrange
Samples/Sweep	1000
Time/Div Decade	7 } 100 ns/Div
Time/Div Multiplier	1 }

Program Selector	Internal
Delay	0000
Trig Sensitivity	For Triggered Display
Recovery Time	Counterclockwise
Trigger Polarity	+
Trigger Source	External

**Type 284**

Square Wave Amplitude	1.0 V
Period	1 $\mu$ s
Mode	Square Wave Output
Lead Time	Optional

Connect the Square Wave Output signal to Channel A and Channel B input connectors through a power divider and two 5 ns coaxial cables. See Fig. 2-4. Connect the Type 284 Trigger Output signal to the Type 3T5 50  $\Omega$  external trigger input connector through a 50  $\Omega$  coaxial cable.

Adjust the Type 3T5 Trig Sensitivity control for a stable display. Center both traces on the graticule with the DC OFFSET controls. One half of the Type 284 output signal is applied to each input. A properly triggered dual-trace display will be similar to Fig. 2-5A.

**Dot Response.** A convenient method of setting the DOT RESPONSE controls for unity loop gain is to cause double or multiple triggering of the sweep, so that some samples must respond to the full 0.5 volt signal amplitude.

## Operating Instructions—Type 355

### NOTE

The maximum allowable amplitude of the signal into the sampling head input for unity loop gain depends upon the sampling head used. (For example, 0.5 V with the Type S-1, and 0.2 V with the Type S-2.)

For adjusting the Dot Response of the Type S-2, the output of the Type 284 may be set at 100 mV (providing 50 mV at each output of the power divider) or a 50  $\Omega$  attenuator may be inserted between the power divider and the input of the Type S-2.

Turn the Type 3T5 Trigger Sensitivity control clockwise into the free-run region, and adjust the Recovery Time control until the display is similar to Fig. 2-5B. In the double triggered display of Fig. 2-5B, Channel A is operating at less than unity loop gain and Channel B is operating at unity loop gain. Clockwise rotation of the Channel A DOT RESPONSE control produced a unity loop gain display shown for Channel B. Adjust the DOT RESPONSE controls for the best flat upper or lower portions of the square-wave display.

Double or multiple triggering is useful in setting the DOT RESPONSE controls for unity loop gain. However, this type of display should be avoided in normal operation, since it is a false display.

**B DELAY.** To show the action of the B DELAY control, change the following controls:

	<b>Type 284</b>	
Mode Switch		Pulse Output
	<b>Type 355</b>	
Units/Div (both Channels)		50
	<b>Type 3T5</b>	
Time/Div Decade	9	} 1 ns/Div
Time/Div Multiplier	1	

Connect the Power divider to the Type 284 Pulse Output connector.

Adjust the Type 3T5 Trigger Sensitivity and Delay controls so the Channel A step signal is at the horizontal center of the graticule (see Fig. 2-5C).

Turn the B DELAY control to show the variable time-window relationship between operation of the A and B Channels. Fig. 2-5C is a double exposure showing the displays for the clockwise and counterclockwise positions of the B DELAY control.

Adjust the B DELAY control to move the Channel B step display to the same horizontal position as that of the Channel A step display. This coincidence of the two channel displays shows that the B DELAY circuit has compensated for the small delay differences in the two signal paths. The time coincidence of two signals fed into the two 50  $\Omega$  input cables can now be checked on the CRT display.

### A + B

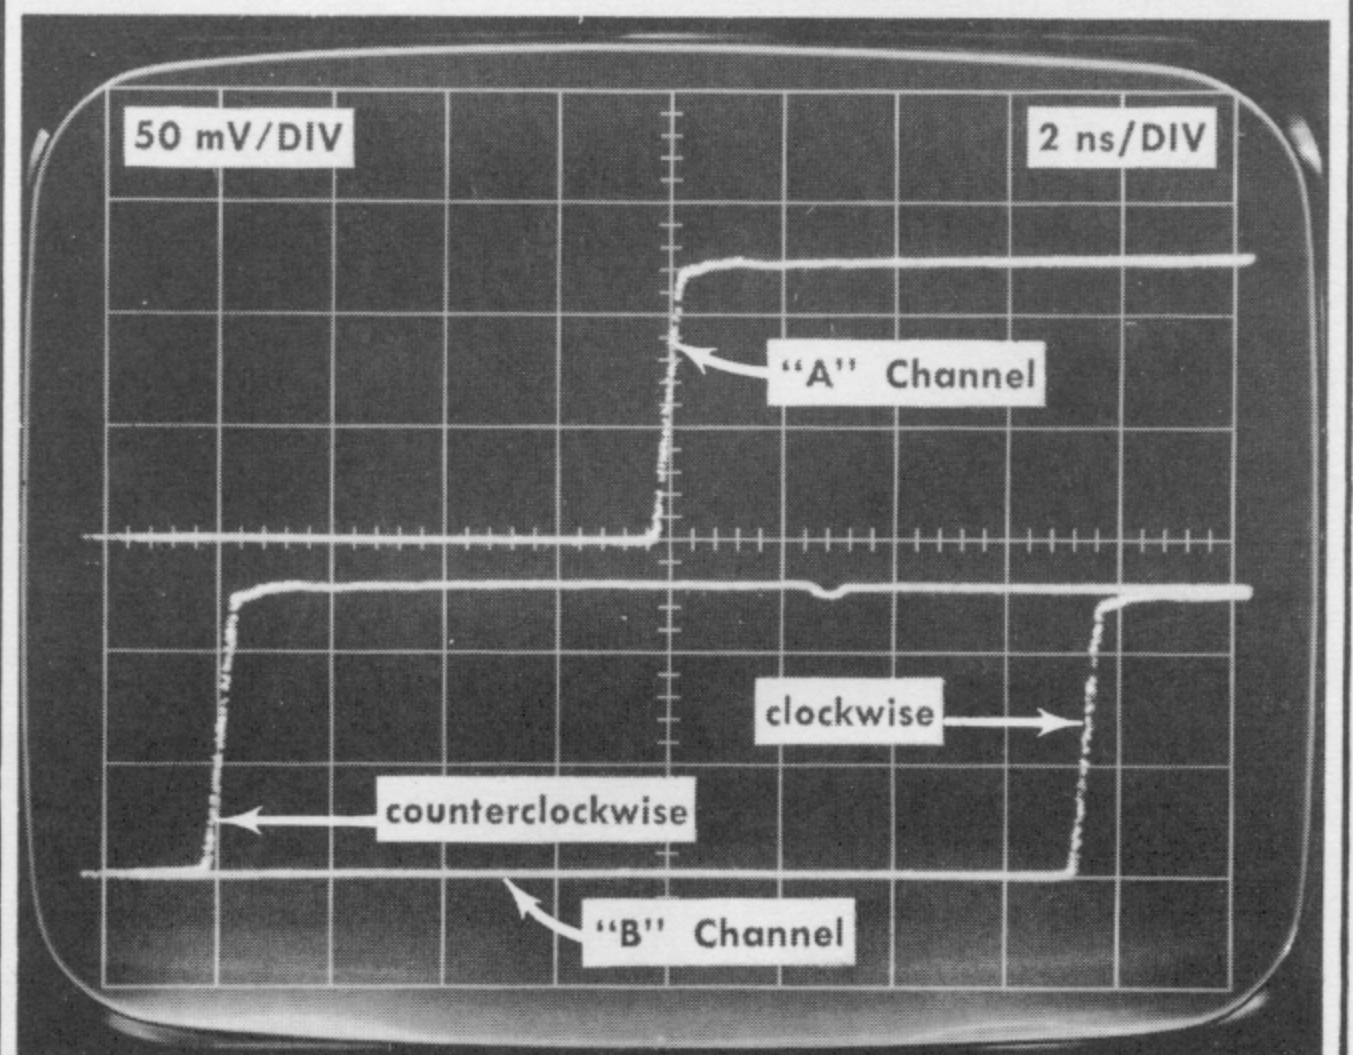

The algebraic addition of two signals can be obtained with the Display Mode switch set to the A + B position.

(A) Proper Dual-Trace Triggering

(B) Multiple triggering to check DOT RESPONSE operation

(C) Variable B DELAY operation (double exposure)

Fig. 2-5. Typical Displays to show dual trace operation.

The B DELAY control can be useful in compensating for small time delay differences in the setup before making accurate algebraic addition of two signals. For accurate algebraic addition, the sampling heads for Channel A and B should be the same.

The following example uses a single test signal to both Channels through identical length cables or probes.

For A + B operation, set the controls as follows:

**Type 355**

Display Mode	A + B
NORMAL-SMOOTH	NORMAL
DC OFFSET	0.00
(both channels)	
Units/Div	50
(both Channels)	
VARIABLE	CAL
(both Channels)	
INVERT	Push in
B DELAY	As in procedure below

**Type 3T5**

Horiz Position	Midrange
Samples/Sweep	1000
Time/Div Decade	9
Time/Div Multiplier	1 } 1 ns/Div
Delay	0000
Program Selector	Internal
Trig Sensitivity	Fully clockwise
Recovery Time	Optional
Trigger Polarity	+
Trigger Source	External

**Type 284**

Mode	Pulse Output
Lead Time	75 ns

Connect the Pulse Output signal from the Type 284 to the Channel A and B input connectors. Use a power divider and two 5 ns coaxial cables in the arrangement shown in Fig. 2-4.

Connect the Trigger Output signal from the Type 284 to the External Trigger input 50 Ω connector on the Type 3T5 through a 5 ns signal delay 50 Ω coaxial cable.

Initially set the Display Mode switch to Ch A or B and set the Type 3T5 for an externally-triggered 1 ns/Div stable sweep. Set the 3T5 Delay as necessary to obtain a display similar to Fig. 2-6A.

Set the Display Mode switch to DUAL-TRACE and adjust the Type 355 B DELAY control until the two displays are in time coincidence. Set the Display Mode switch to A + B. Addition of the two signals will be displayed. Again adjust the Type 355 B DELAY and notice its effect upon the composite display. Fig. 2-6B show the composite A + B display with the B DELAY adjusted about 1 ns away from time coincidence of the two signals.

Pull one of the INVERT switches, inverting one of the Channel displays. Now any time difference of the two signals

(A) A or B Channel display

(B) A + B both INVERT switches in the same position

(C) A + B one INVERT switch in the out position

Fig. 2-6. Displays used to show A + B operation.

## Operating Instructions—Type 3S5

will be displayed as a pulse, while those portions of the two signals that are equal and opposite will display a straight line. Adjust the B DELAY control and notice the change in polarity of the pulse as Channel B passes through time coincidence with Channel A. See Fig. 2-6C.

Adjust the B DELAY control for minimum time difference. The display will approach a single trace with no vertical deflection (if the two sampling heads are identical). When the composite A + B display is a straight line, the Channel B display is at time coincidence with the Channel A display.

When using the Type 3S5 with the Display Mode switch set to A + B and the INVERT switch of one channel pulled, the display is proportional to the difference in the applied signals. This differential operation can be useful for cancelling undesired in-phase (common-mode) signals. Input voltage limitation of the sampling head must be observed ( $\pm 1$  V for the Type S-2 sampling head).

### Calibrated DC OFFSET Controls

The DC Offset control can be rotated five complete turns clockwise or counterclockwise from the 0 mV position. Since five turns results in a 1 V change, each revolution of the dial gives a 200 mV change. Each of the 100 minor divisions on the inner dial represents 2 mV of offset. Numbers indicated above and below the index marker are multiplied by 10 and added together to determine the offset in millivolts.

If the no-signal free run trace position is known with the OFFSET control at 0.00, the DC OFFSET dials can be used to make a direct reading of the offset voltage. More accurate measurements of either the offset voltage or of a signal amplitude can be obtained using the slideback technique. Use the OFFSET control to position the display bottom to a graticule line. Read the control dial. Use the OFFSET control to position the display top to the SAME graticule line. Read the control dial. The difference between the two readings is the signal amplitude.

Unless otherwise stated on the sampling head front panel, the DC Offset voltage cancels the effects of an applied DC voltage of up to  $\pm 1$  V at the sampling head input.

**OFFSET Monitor Jacks.** The value of voltage at various points on a waveform with respect to ground or the difference in two levels (such as peak or peak-to-peak voltage of a signal) may also be determined by measuring the DC voltage at the OFFSET monitor jacks. A monitor jack is provided for measuring the offset of each Channel. The voltage measured at the OFFSET monitor jacks is 10 times the actual offset.

Source resistance for the voltage at the OFFSET monitor jacks is 10 k $\Omega$ ; therefore, meter loading may be a factor if other than an infinite-impedance meter is used. The accuracy of the DC offset voltage measurement depends upon the accuracy and the loading effect of the measuring device. The following measuring devices are recommended, in order of preference, for monitoring voltage at the OFFSET jacks.

(1) Differential, non-loading DC voltmeter with an accuracy of 0.2% or better. This type of device provides 2% accuracy of absolute voltage measurements. Measurements of small changes in offset voltage can be made more accurately than 2%.

(2) Vacuum-tube voltmeter with an input impedance of at least 10 megohms. Accuracy of the VTVM should be as high as practical.

(3) Zero-center  $\pm 1$  mA milliammeter with as high an accuracy as practical. The milliammeter should be connected directly between the appropriate OFFSET monitor jack and ground. When using a milliammeter, 100 microamperes is equivalent to 1 volt open-circuit at the OFFSET monitor jacks (0.1 volt of actual offset to the signal).

### EXTERNAL PROGRAMMING

Deflection factor, DC offset amplitude and polarity, and either Normal or Smooth dot response can be programmed. The display mode switch must be set to EXT PROG and an interconnecting cable run from the programming unit to the EXTERNAL PROGRAM connector at the front of the Type 3S5. Negative logic is used, together with a modified binary coded decimal system.

#### NOTE

The Type 3S5 may also be programmed from the Vertical Unit programming Connector J214, located on the rear panel of the Type 568 Oscilloscope. In order to program from the rear panel of the Type 568 oscilloscope an adapter (Connector, Circuit Board, Tektronix Part No. 012-0149-00) is required. The Connector is inserted in J14 at the rear of the Type 3S5 (See Fig. 2-7). This connector provides continuity from pins of J14 on the Type 3S5 to corresponding pins of J14 on the Type 568. Wiring within the Type 568 connects pins of J14 to J214 on the Type 568 rear panel.

The two logic levels required to program the Type 3S5 can be provided in a number of ways, depending upon the type

Fig. 2-7. Connecting Type 3S5 to digital readout unit.

Fig. 2-8. Potentials required at program lines for proper input logic to Type 355 Programmable functions.

of programmer used. Each logic line can be controlled using a switch, transistor, or other closure type programmer. With a negative logic system a logical ONE results when the voltage of a program line is at its less positive level. See Fig. 2-8. A voltage of 0 V to +2 V applied to a program line of the Type 355 will provide a logical ONE, while a potential of +6 to +15 volts results in a logical ZERO. Leaving a programming line open also provides a logical ZERO, while shorting the line to ground produces a logical ONE input.

Truth tables showing logic values required by the programmable functions are presented during the following discussion.

### Programming DC Offset

Use Table 2-1 in the following example of using a truth table while programming a DC Offset voltage.

1. Assume that a test display has been properly positioned on the CRT by use of the DC OFFSET control while operating the Type 355 from its front-panel.

2. The number appearing above the DC OFFSET control index marker is a black 40. The number directly below the index marker, of the same color, is 12.5. Adding the two numbers together and multiplying by 10 gives: 10 (40 + 12.5) or 525 mV of negative DC Offset voltage. The polarity is negative and black numbers are used since the DC OFFSET control has been rotated clockwise from the 0.00 mV position. This voltage can be checked using an accurate non-loading voltmeter at the proper OFFSET jack. The voltmeter reading will be -5.25 V or 10 times the actual offset voltage.

TABLE 2-1  
Offset Programming (Voltages in mV)

Offset	mV	Hundreds Lines				mV	Tens Lines				mV	Fives	Ground Return Lines
		800	400	200	100		80	40	20	10		5

<sup>2</sup>J15 is EXTERNAL PROGRAM Connector on front panel of Type 355.

<sup>3</sup>J14 is connector at rear of Type 355 and in Type 568 Vertical plug-in compartment.

<sup>4</sup>J214 is on rear panel of Type 568 Oscilloscope.

## Operating Instructions—Type 3S5

3. Table 2-1 shows that four logical ONE states are needed to program 525 mV of Offset voltage. In the HUNDREDS columns, a ONE is found in the 400 and 100 columns to the right of 500 mV; in the TENS columns, a ONE is found in the 20 column to the right of 20 mV; and in the FIVES column a ONE is found to the right of 5 mV.

4. The programming connector pin numbers are found at the bottom of Table 2-1, in vertical alignment with columns of the truth table. To program CH A for 525 mV of offset voltage requires a logical ONE at pins 6, 8, 11 and 13 of J15. If J214 is used for programming, use pins 6, 8, 11 and 13.

5. Table 2-2 shows logic required for selecting Offset Voltage Polarity. A negative polarity requires a logical ZERO (+6 V to +15 V or an open circuit). To program CH A for a positive polarity when J15 is used, requires a logical ONE (0 V to +2 V) at terminal 4.

**TABLE 2-2**  
Programming DC Offset Polarity<sup>1</sup>

	Channel A	Channel B
J15	Pin 4	Pin 23
J14	Pin 1	Pin D
J214	Pin 1	Pin 19

<sup>1</sup>A logical ONE is required for (+) polarity. A logical ZERO is required for (–) polarity.

Table 2-3 is a truth table for programming UNITS/DIV. The truth table and terminals for programming Smoothing are given in Table 2-4. These functions are programmed in the same manner as DC Offset. Do not ground any program lines to anything other than the Common Ground Return lines shown in Table 2-1.

**TABLE 2-3**

J214 Pin 15	0	1

**DC Offset Corrections.** A difference in offset voltage may be noted at high sensitivities when interchanging plug-ins (3S5's) used in a system in which DC Offset is programmed.

The setting of the 15 V power supply of the replacement 3S5 may be changed slightly to return the programmed DC Offset Voltage to its former value. Changing the +15 V supply will change other adjustments slightly, such as Bridge Balance and Smoothing Balance.

Using this method of correcting for a difference in programmed DC Offset Voltage between plug-ins, makes changes in the programming system unnecessary.

**Programmer Current Requirements.** In order that the Type 3S5 will see the proper input logic when externally programmed, certain current requirements must be met by the programmer supplying the logic.

A logical ONE is present on a Type 3S5 logic line if a potential of from 0 to +2 volts appears on the logic line. In order to meet this requirement the programmer must be capable of supplying a certain minimum current. The minimum current required depends upon the logic line considered.

A worst-case example (one requiring the most current) is shown in Fig. 2-10A. This circuit is used to provide 800 mV of DC Offset. To obtain 800 mV of offset, a logical ONE (0 to +2 V) is required on the programming line. A logical ONE on the programming line will reverse bias Q602 and keep it cut off. Fig. 2-10B illustrates that the resistance of the closed switch contacts cannot exceed 575  $\Omega$ , or more than 2 volts will appear on the programming line. The switch, or device used as a switch, must be able to pass at least 3.5 mA with not more than a 2 volt drop across it. This will ensure that Q602 remains cut off as required.

When programming the opposite logic level (logical ZERO), the worst-case condition occurs in the circuit having the highest internal resistance. This is the circuit used for programming 5 mV of DC Offset. See Fig. 2-10C.

Since the 5 mV of offset is not wanted, a logical ZERO (+6 to +15 V) is required on the programming line. Fig. 2-10C shows that leakage current through the open switch, or device used as a switch, must not exceed 16.5  $\mu$ A. Keeping leakage current below this value ensures that Q626 will be forward biased and will conduct sufficient current to perform its function.

## GENERAL APPLICATIONS

### Automatic Calibration

Another function provided is AUTO CAL. Terminals are present at both front and rear External Program connectors for connecting to circuits providing automatic deflection factor calibration. See Table 2-5. The AUTO CAL feature is intended primarily for use in systems employing digital readout and requiring close tolerance accuracy. An automatic calibrating system can be made that will check the reading of the digital unit against a known value of input signal (when programmed to do so). See Fig. 2-9. If the measured value is not within selected limits of the known

Fig. 2-9. Block diagram of a system for automatic calibration of digital readout.

value, the Type 355 gain will be automatically corrected. A reading above the upper limit selected results in a reduction in amplifier gain. A reading below the lower limit will cause amplifier gain to increase. Although only Channel A is shown in Fig. 2-9 the same provisions are available for Channel B.

In systems using the automatic calibration feature, internal jumpers (at the input circuits of Q413 and Q433) must be removed. It is not necessary for the Type 355 Display Mode Switch to be in the EXT PROG position to utilize the Automatic Calibration feature. AUTO CAL can be used in the EXT PROG position, or any other mode.

The programmer must therefore be capable of delivering at least 3.6 mA for a logical ONE input and must not permit more than 16.5  $\mu$ A of current flow in the programming line for a logical ZERO input.

### Digital Readout

The Type 355 provides vertical information for use with Tektronix Digital Readout Systems, such as the Type 567, and 6R1A with Type 262 Programmer, or the Type 568-Type 230 system. With either digital system, a time base plug-in is needed along with the Type 355.

#### NOTE

The screwdriver POSITION control must be properly set when making amplitude measurements with a digital unit. Set the sampling unit DC

Offset control for zero volts. Without applied signal, free run the sampling sweep unit and position the no signal trace within the region of  $\pm \frac{1}{2}$  major division from the graticule centerline. Now all on-screen displays, regardless of DC Offset value will properly drive the digital unit for amplitude measurements.

TABLE 2-5

Automatic Calibration Connections

	Channel A	Channel B	Ground Return
J14	Pin 15	Pin 34	Pin 16
J15	Pin B	Pin C	Pin A
J214	Pin 17	Pin 18	Pin 16

#### NOTE

Moving the variable control from the CAL (detent) position affects the unit of measure lamp and decimal point of the readout unit. With the Type 6R1A the decimal neon and unit lamp goes out. With the Type 230 the unit lamp goes out, but the decimal point shifts instead of going out. This note applies with the Type 355 Display Mode switch in any position except EXT PROG. When the Display Mode switch is set to EXT PROG, turning the Type 355 Units/Div VARIABLE control has no effect on CRT deflection factor, or on the readout decimal or units lamp.

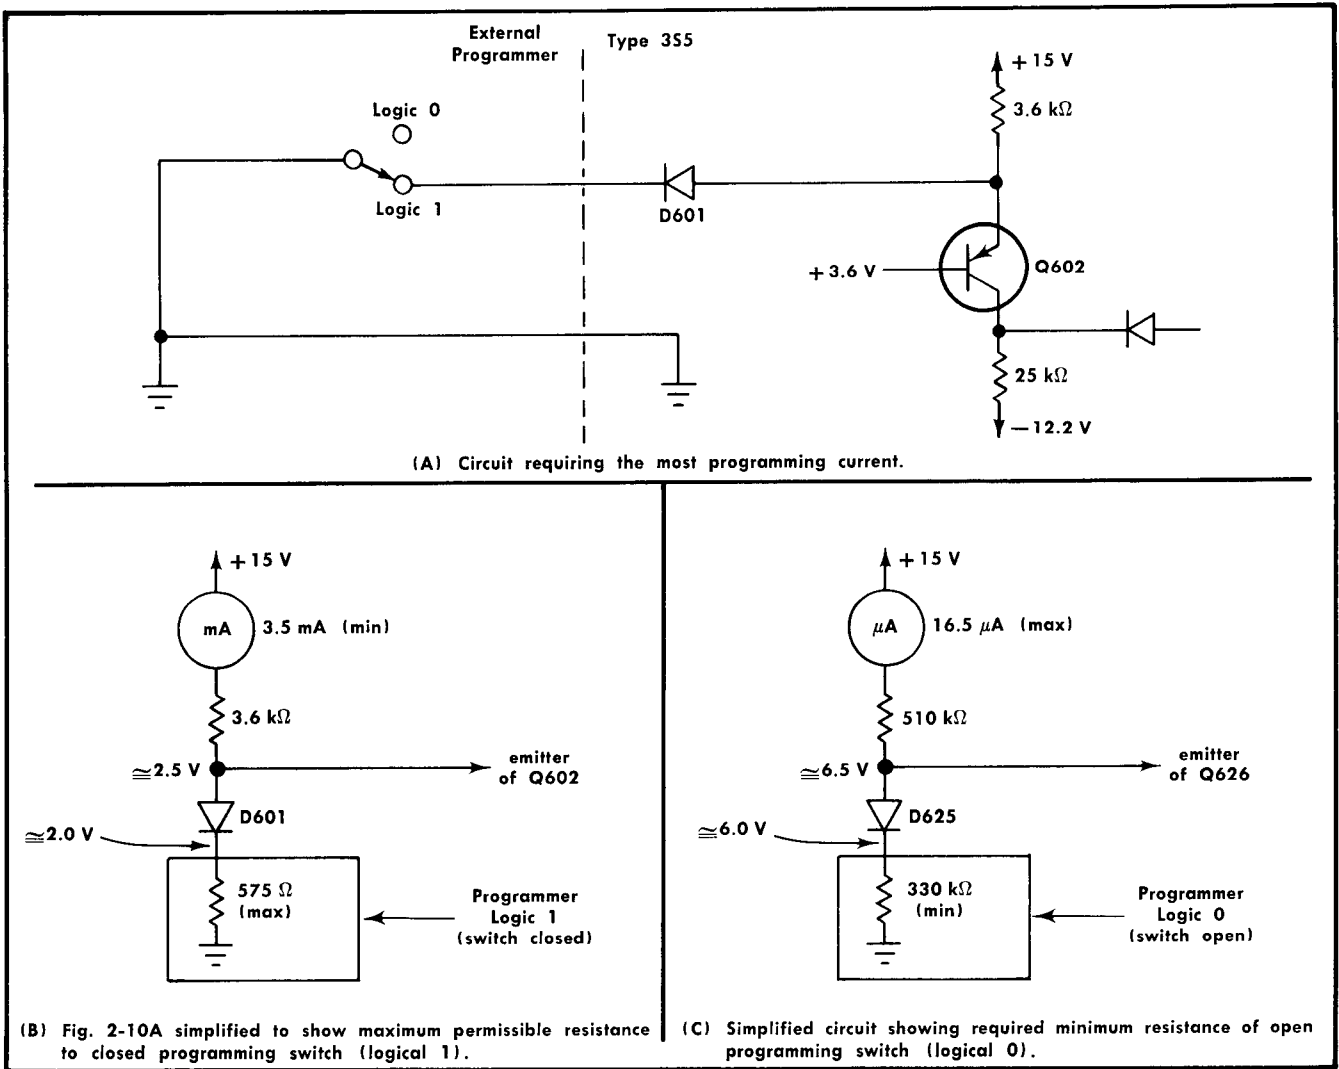

Fig. 2-10. External Programmer Current and Resistance requirements.

### Use of Smoothing

Time and amplitude noise may sometimes be objectionable when operating at minimum deflection factors or maximum sweep rates. For smoothing, turn the NORMAL-SMOOTH switch on the Type 355 to the SMOOTH position. This will reduce the random noise about one half by decreasing the gain of the sampling feedback loop. Fig. 2-11 shows the advantage of using smoothing when observing a low-amplitude signal.

**Dot Density.** Normally the SMOOTH position of the NORMAL-SMOOTH switch will not significantly affect the risetime of the display if the dot density is sufficient. If, however, the display wave shape is affected when the switch is changed from the NORMAL position to the SMOOTH position, a compromise must be made between smoothing and dot density. Fig. 2-12 illustrates the effect produced by using smoothing when the dot density is low. This effect can be compared to the high dot density of the same input signal as shown in Fig. 2-11B.

### Vertical Deflection Measurements

Vertical displacement of the trace on the CRT is directly proportional to the signal at the input connector of the sampling head installed in the Type 355. The amount of displacement for a given signal can be selected with the Units/Div switch. To provide sufficient deflection for best resolution, set the Units/Div switch so the display spans a large portion of the graticule. Also, when measuring between points on the display, be sure to measure consistently from either the bottom, middle, or top of the trace. This prevents the width of the trace from affecting the measurements.

To make a vertical deflection difference measurement between two points on the display, proceed as follows:

1. Note the vertical deflection in graticule divisions between the two points on the display. Make sure the VARIABLE control is in the CAL position.

**NOTE**

The vertical deflection factor is determined by the Units/Div switch and the value of the units as stated on the sampling head front panel. The

Fig. 2-11. Use of SMOOTH-NORMAL switch in normal process sampling for decreasing display noise when viewing a low-amplitude signal. (A) NORMAL-SMOOTH switch at NORMAL; (B) NORMAL-SMOOTH switch at SMOOTH.

ratio of the input signal to the resultant deflection is called the deflection factor. For example, with the sampling head unit values stated as mV/Div and the Units/Div switch set to 20, the vertical deflection factor will be 20 mV/division.

2. Multiply the divisions of vertical deflection by the deflection factor: Include any external attenuator or probe attenuation factor. The product is the voltage difference between the two points measured.

For example, suppose you measure 4.4 divisions of deflection between two points on the display and the Units/Div switch is set for 20 mV/Div. Multiply 20 millivolts/division by 4.4 divisions. The product is 88 millivolts. This is the voltage difference at the input connector between the two points on the display. Now assume there is a 10 $\times$  external attenuator (probe) between the input connector and the signal source. To determine the actual signal voltage at the source, multiply 10 (the attenuation factor of the probe) by 88 millivolts; this product (880 millivolts or 0.88 volts) is the actual voltage at the signal source.

Fig. 2-12. Degraded display of signal shown in Fig. 2-11B caused by use of smoothing with sampling sweep unit set for low dot density normal process sampling.

It is also possible to measure an instantaneous (or DC) voltage to ground from the display. This measurement is accomplished in the same manner, except that with no signal applied, you must first establish a ground-reference point on the CRT.

**NOTE**

To establish the ground reference point, be sure the input connector is terminated by either a 50  $\Omega$  resistor or a coaxial cable connected to the input.

To do this, trigger the sampling sweep unit with the signal source and display a trace. Then, position the trace so it is exactly aligned with one of the graticule lines. The actual graticule line you select will be largely determined by the polarity and amplitude of the applied signal. After establishing the ground reference, make no further adjustments with the DC OFFSET controls.

Apply the signal and measure the voltage in the manner previously described. Make all measurements from the established ground reference point. Accuracy of this measurement is within  $\pm 3\%$ .

If the applied signal has a relatively high DC level, the ground-reference point and the actual signal may be so far apart that neither will appear on the CRT. In this case, refer to the earlier discussion on using the DC Offset control.

**Time Domain Reflectometry (TDR)**

The Type 3S5 with the Type S-1 Sampling Head can be used for Time Domain Reflectometry displays. TDR using the Type 284 Pulse Generator is described in the Type 284 Instruction Manual. Very fast displays, and special TDR analysis of small reactances is possible with the Type S-2 and the Type 284. See the Type 1S2 Instruction Manual for information about such fast displays.

**Pen Recorder Operation**

The signals available at the A and B SIG OUT jacks provide a convenient source for driving the Y axis of a pen

## Operating Instructions—Type 3S5

recorder. It is common practice to manually scan the CRT (using the controls on a sampling sweep unit) while driving the time axis of the recorder with the sweep output voltage. Another method for pen recording is to couple the scanning voltage of the recorder to the external sweep input connector of the sampling sweep unit. Be sure the sweep voltage from the recorder agrees with the limits of the input to the sampling sweep plug-in. The source resistance of the A and B SIG OUT jacks is  $10\text{ k}\Omega$ . This resistance must be considered in the calibration of some types of pen recorder amplifiers.

### Use of a Sampling Head Extender Cable

Two different sampling head extender cables are available for operating one or both sampling heads outside the Type 3S5. One is three feet long (Tektronix Part No. 012-0124-00), and the other six feet long (Tektronix Part No. 012-0125-00). Contact your Tektronix Field Engineer or Representative for price and availability information.

Sampling heads can be operated on either length extender cable without compromising system step function response. However, the extender cable signal delay must be considered in allowing proper pretrigger leadtime for normal process sampling. As compared to operating the sampling head inside the Type 3S5, use of a three foot cable adds about 5 ns to the required pretrigger leadtime; use of the six foot extender cable adds about 10 ns. If sufficient trigger leadtime is not available, operate the sampling head and extender cable in Channel B and use the B delay control to provide up to 5 ns more leadtime.

The B DELAY control can also restore the time coincidence of two identical sampling heads when one is operating on a three foot extender cable; not, however, when one head is on a six foot cable and the other inside the Type 3S5.

The first time a sampling head is operated on an extender cable, its Bridge Bal control may need adjustment, particularly if DC Offset measurements are to be made accurately referenced to ground. The sampling head instruction manual describes Bridge Bal adjustments. Readjustment of the control may be required when the sampling head is again installed directly into the Type 3S5.

### Input Connectors

The Type of sampling heads installed in the Type 3S5 determines the input impedance. Type S-1 and S-2 sampling heads are both  $50\ \Omega$  input.  $50\ \Omega$  coaxial cables may be used for applying input signals with minimum signal loss or distortion.

#### NOTE

Operating the sampling head without the input connector terminated by the  $50\ \Omega$  resistor or coaxial cable will cause a vertical shift of the zero signal baseline by a few millivolts. This is because the strobe kickout signal is reflected from the open input connector. It arrives back at the sampling bridge during sampling time, while the bridge is still conducting. Set the display zero reference point with the input circuit connected, not before connecting it. Also use at least a 20 cm airline between the sampling head input and a fast generator that is sensitive to the fast strobe kickout signal.

When connecting a signal to the input, many factors must be taken into consideration, including loading of the source, losses in coaxial cables, time delay, AC or DC coupling, attenuation of large signals and matching impedances at high frequencies.

### Coaxial Cables

Signal cables that connect the vertical signal from the source to a  $50\ \Omega$  input connector should have a characteristic impedance of 50 ohms. Impedance other than 50 ohms will cause reflections that may make it difficult to interpret the display. High quality low-loss coaxial cables should be used to ensure that all the information obtained at the source will be delivered to the input. If it is necessary to use cables with a characteristic impedance other than 50 ohms, suitable impedance-matching devices will aid in obtaining meaningful displays.

The characteristic impedance, velocity of propagation and nature of signal losses in a coaxial cable are determined by the physical and electrical characteristics of the cable. Common coaxial cables, such as RG-213/U, have losses caused

Fig. 2-13. Coaxial cable in a fast-rise system (A) using a 5 ns-delay and (B) 15 ns-delay cable.

by energy dissipation in the dielectric proportional to the signal frequency. Some small diameter cables (1/8 inch) lose much of the high-frequency information of a fast rise pulse in a very few feet of cable.

Losses of high frequency information can be shown with a fast-rise pulse generator and sampling system. Using a 5 ns delay RG-58U coaxial cable as a connecting cable, a display similar to Fig. 2-13A can be shown. Adding an additional 10 ns delay RG-58/U coaxial cable in the signal path results in a display similar to that of Fig. 2-13B. By using larger diameter, higher quality cable such as RG213/U in the same system, less loss is shown with the same length of connecting cable. Tektronix Type 113 Delay Cable is a high quality, low loss cable with 60 ns signal delay.

### Attenuating the Input Signal

The maximum signal amplitude that should be applied to the input connector of the sampling head will depend upon the sampling head installed in the Type 355. To attenuate the signals of 50 Ω input sampling heads, use an attenuator probe and/or external coaxial attenuators. The attenuators must have good frequency response beyond the frequency response of the sampling head to avoid reducing system performance. High quality coaxial attenuators are available through your Tektronix Field Office or Representative with attenuation factors such as 10×, 5× and 2×. When the attenuators are stacked, their attenuation factors multiply; i.e., two 10× attenuators produce 100× attenuation. The 50 Ω attenuators must be matched to 50 Ω input and output impedances to provide their stated attenuation factor.

To divide a signal into two equal parts and maintain a good 50 Ω impedance match, use a power divider such as a GR 874 TPD, Tektronix Part No. 017-0082-00. The loss between any two of the power divider connectors is 6 dB (half voltage) when each connector has a 50 Ω circuit connected.

**Passive Probes.** The Tektronix P6034 10× Probe and P6035 100× Probe are moderate-resistance passive probes designed for use with 50-ohm systems. They are small in size permitting measurements to be made in miniaturized circuitry. Power rating is 0.5 watt up to a frequency of 500 MHz. Momentary voltage peaks up to 500 volts can be permitted at low frequencies, but voltage derating is required at higher frequencies. Characteristic data is given in the probe instruction manuals.

The P6034 10× Probe places 500 ohms resistance and less than 0.8 pF capacitance in parallel with the signal source at low frequencies. The probe bandwidth is DC to approximately 3.5 GHz, and risetime is 100 picoseconds or less (10% to 90%). At 1 GHz the input resistance is about 300 ohms and the capacitive reactance is about 400 ohms.

The P6035 100× Probe places 5 kΩ resistance and less than 0.7 pF capacitance in parallel with the signal source at low frequencies. Bandwidth of the probe is DC to approximately 1.5 GHz, and risetime is 200 picoseconds or less (10% to 90%). At 1 GHz the input resistance is about 2 kΩ and the capacitive reactance is about 450 ohms.

**Built-in Probes.** Another satisfactory method of coupling fractional nanosecond signals from within a circuit is to design the circuit with a built-in 50-ohm output terminal. With this built-in probe, the circuit can be monitored without being disturbed. When the circuit is not being tested, a 50-ohm

terminating resistor can be substituted for the test cable. If it is not convenient to build a permanent 50-ohm test point, an external coupling circuit, which may be considered a probe, can be attached to the circuit.

Several factors must be considered when constructing such a built-in signal probe. A probe is designed to transfer energy from a source to a load, with controlled fidelity and attenuation. Both internal and external characteristics affect its operation. It must be able to carry a given energy level, be mechanically adaptable to the measured circuit, and be equally responsive to all frequencies within the limits of the system. The probe must not load the circuit significantly or the display may not present a true representation of the circuit operation. Loading may even disrupt the operation of the circuit. When it is necessary to AC-couple the probe, the capacitor should be placed between the series attenuator resistance and the 50-ohm environment, stray capacitance to

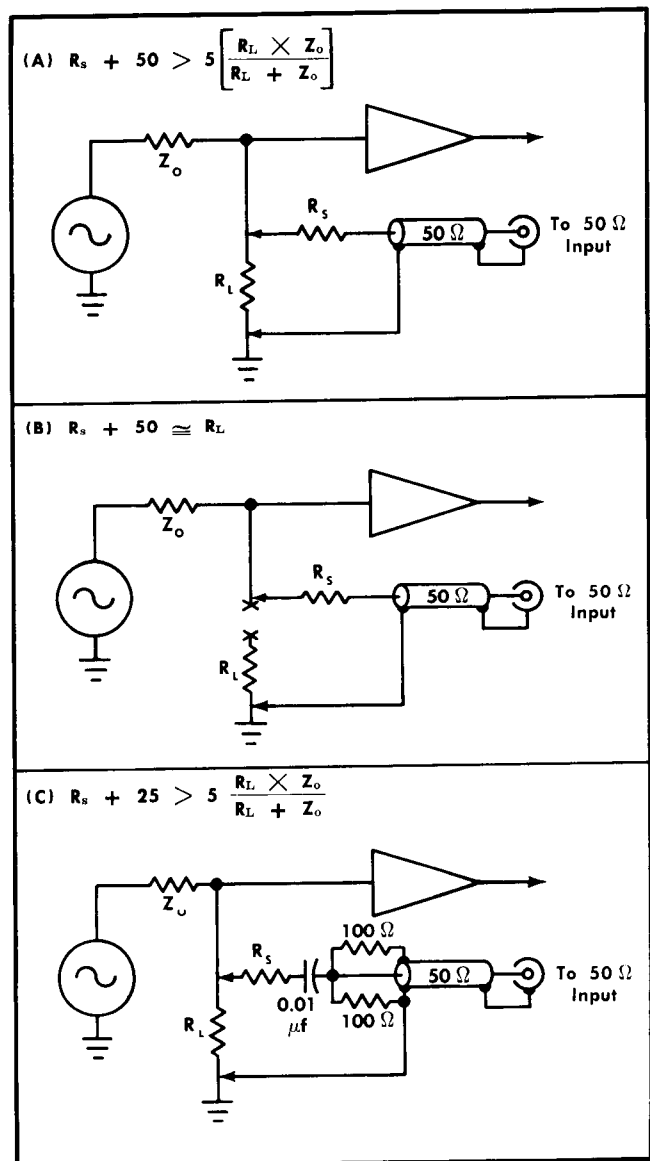

Fig. 2-14. Built-in probes for coupling to a test circuit. (A) Parallel method; (B) series method; (C) reverse-terminated parallel method.

## Operating Instructions—Type 355

ground has a shorter and more uniform time constant than if the capacitor were placed at the signal source where the impedance is usually higher and some times of unknown value.

Fig. 2-14A shows the parallel method of coupling to a circuit under test. Resistor  $R_s$  is connected in series with the 50-ohm input cable to the sampling unit, placing  $R_s + 50$  ohms across the impedance in the circuit. This method usually requires the use of an amplitude correction factor. In order to avoid overloading the circuit, the total resistance of  $R_s + 50$  ohms should not be less than 5 times the impedance of the device ( $R_L$  in parallel with  $Z_0$ ) requiring a 20% correction. The physical position of  $R_s$  will affect the fidelity of the coupling.

Fig. 2-14 shows the series method of coupling to a circuit. Resistor  $R_s$  plus the 50 ohm sampling head input resistance replaces the impedance of the circuit under test. If  $R_L$  is 50 ohms, simply substitute the 50-ohm test cable without  $R_s$ . It is best to locate  $R_s$  in the original position of  $R_L$  and to ground the coaxial cable where  $R_L$  was grounded.

A variation of the parallel method is the reverse-terminated network shown in Fig. 2-14C. This system may be used across any impedance up to about 200 ohms. At higher source impedances, circuit loading would require more than 20% correction. The two 100-ohm resistors across the cable input serve to reverse-terminate any small reflections due to connectors, attenuators, etc. The series capacitor, which is optional, blocks any DC component and protects the resistors.

# SECTION 3

## TEKTRONIX BASIC SAMPLING PRINCIPLES

Change information, if any, affecting this section will be found at the rear of the manual.

### Introduction

This section provides a basic functional description of the vertical channels of sampling oscilloscopes. A discussion of equivalent-time sampling process is included. Operating instructions, including first time operation, are given in Section 2.

### BASIC SAMPLING TECHNIQUES

The current state of the electronic art does not permit direct cathode-ray tube display of fractional-nanosecond risetime low-level signals. Risetimes in the order of 0.35 ns can be displayed on a CRT if the signal is at least several volts in amplitude.

An inherent limitation in linear amplifiers is the compromise necessary between bandpass and gain. A high gain amplifier is a low bandpass amplifier; and conversely, wide-band amplifiers are necessarily low gain amplifiers. For any particular configuration, gain times bandpass is nearly a constant, so anything done to increase the gain will proportionately reduce the bandpass and vice versa. The gain-bandpass product limitation of linear amplifiers restricts the display of millivolt signals on a CRT to the 50 to 200 MHz region.

The sampling technique permits the quantitative display (on a CRT) of a facsimile of fractional-nanosecond rise-time low-level signals. In sampling, many cycles of an input signal are translated into one cycle of low-frequency information. The change takes place at the input, or sampling bridge. Since only the sampling bridge is subjected to the input signal high frequencies, and all the amplification takes place at relatively low frequencies, the performance of a sampling

system is not dependent on the gain-bandpass limitations of conventional amplifiers.

However, the sampling technique introduces some limitations of its own. The sampling process being described is restricted to repetitive signals of low amplitude (typically 1 or 2 volts peak to peak), from low impedance sources. Fortunately, most fractional-nanosecond risetime signals exist in low impedance environments and are generally low amplitude. Piping the signal from the circuit under test to the input of the sampling oscilloscope vertical channel requires a more sophisticated technique than lower bandpass systems. In spite of its limitations, sampling can measure fast signals that otherwise defy observation.

A sampling system looks at the instantaneous amplitude of a signal during a specific small time period, remembers the amplitude, and displays a single dot on the CRT corresponding to the amplitude. After a dot is displayed for a fixed amount of time, the system again looks at the instantaneous amplitude of a different cycle of the input signal. Each successive look, or sample, is at a slightly later time in relation to a fixed point of each signal cycle. Each sample is displayed as a spot on the CRT. Generally the vertical position of the dot represents the equivalent time when the sample was taken. After many cycles of the input signal, the sampling system has reconstructed and displayed a single facsimile made up of many samples, each sample taken from a different cycle of the input signal.

Fig. 3-1 illustrates the equivalent time reconstruction of a repetitive square wave. The CRT display is a series of dots rather than the conventional oscilloscope continuous presentation. In the illustration, a series of samples is taken of the input signal. After each sample, when memory has been

Fig. 3-1. Equivalent time display of repetitive real time signal by means of the sampling technique.

established and stabilized, the CRT is unblanked and a dot appears. A large number of such dots form the display.

The number of dots per horizontal unit of display is called dot density. The dot density of a display is controlled by the operator to provide the best compromise between resolution and repetition rate of the display. Since only one sample is taken from any particular input cycle, the time required to reconstruct a display is a function of the dot density selected and the repetition rate of the signal. The higher the dot density selected (for higher resolution), the longer the time required to construct the equivalent time display. The higher the repetition rate of the signal, the less time required to reconstruct the waveform (limited by a maximum repetition rate of the system).

Sampling requires repetitive input signals, though not necessarily signals with constant repetition rate. The equivalent time between dots is determined by the time delay between the fixed point on the signal at which triggering occurs, and the point at which the sample is taken. Since both time reference (triggering-time and sample-time) are taken from the same cycle of the signal, the signal repetitions do not have to be identical in amplitude, time duration, and shape. Any differences in the individual cycles shows as noise or jitter in the reconstructed display.

Sampling systems have maximum signal repetition rates at which samples can be taken and accurately displayed. The primary limit is the time required for the preamp and the AC amplifier to stabilize after a sample has been taken.

Signals below 100 kHz may have considerable repetition rate jitter and still the sampling oscilloscope will present a sample of each cycle, without display jitter. For signals with a repetition rate higher than 100 kHz, the timing unit holds off retriggering for a maximum of about 10  $\mu$ s. This means that a sample will not be taken from every cycle of a high repetition rate signal. Only those cycles are sampled which occur after the end of the holdoff. If the signal is

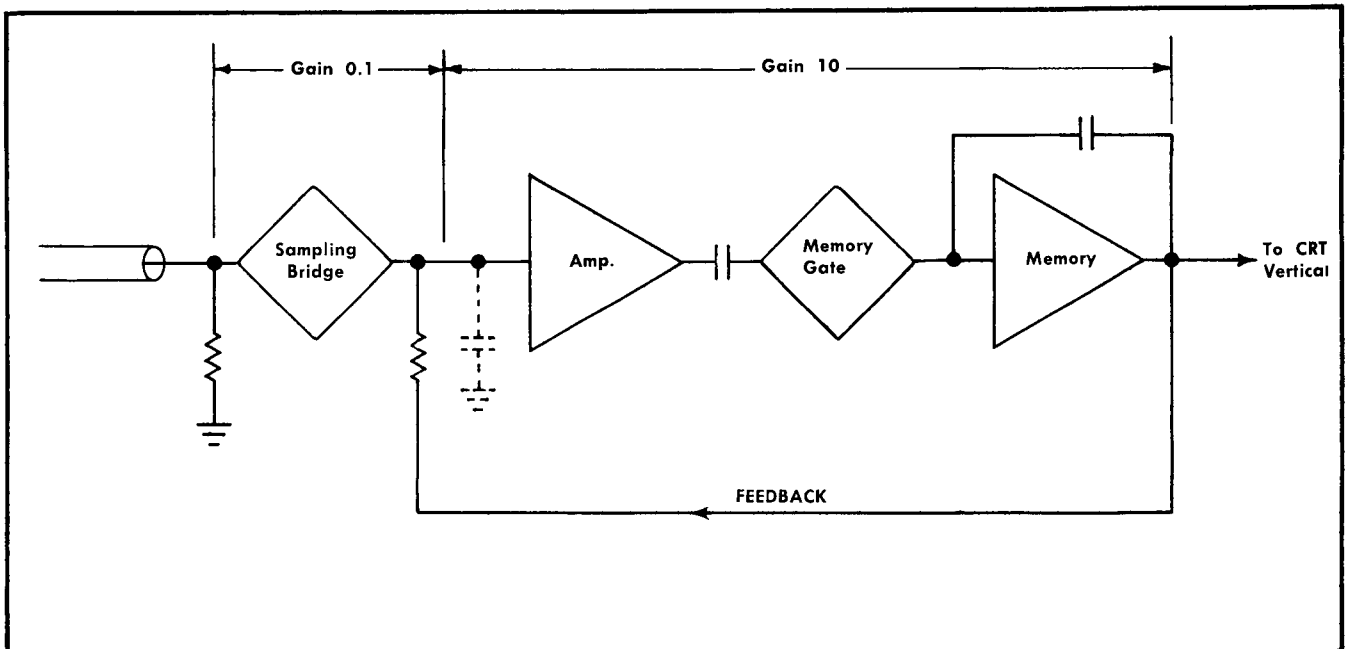

truly repetitive and each cycle is identical, these "missed" cycles are of little significance.

The circuits in the vertical channel of a Tektronix sampling oscilloscope comprise an error-sampled feedback system with ratchet memory. The memory output is not reset to zero after displaying a dot. The memory output remains at the displayed amplitude of each dot in succession until it is corrected by the next sample. The amplitude difference between the two samples is then the error between the memory output and the new sampled amplitude.

Fig. 3-2 shows a simplified block diagram of an error-sampled feedback system with ratchet memory. The output signal from the sampling bridge is the difference, or error, between the instantaneous amplitude of the signal at sample time and the previously memorized amplitude. A change is made to the memory output only when the instantaneous amplitude of the signal at sample time is different from the memory output. The memory output "ratchets" up or down at sample time as a result of the error signal sampled. The transition of memory from one output voltage to another occurs between displayed dots, and is therefore not seen on the CRT.

The error-sampled ratchet-memory technique has the advantage of allowing display noise to be "smoothed". Smoothing is discussed later in this section. The error-sampled approach also minimizes signal kickout into the input cable by the sampling bridge interrogate pulse (hereafter called "strobe" pulse). Since the sample is always the difference between the signal and the memory output, the error-signal and kickout are much smaller in amplitude than they would be if the memory output reverted to zero and the entire signal was sampled after each dot.

The output from the sampling bridge at sampling time is about 2% of the difference between the signal voltage and the memory output. The 2% signal is the input to the first amplifier. The output of the amplifier is AC-coupled to a

**Fig. 3-2. Simplified block diagram of an error-sampled feedback system with a ratchet memory.**

Fig. 3-3. Simplified representation of an error-sampled ratchet-memory waveform.

memory gate. The memory gate couples the signal to the memory amplifier during the time it is gated on. The memory amplifier changes the memory feedback voltage to equal the signal voltage at the instant of sampling. These changes in memory output occur while the CRT is blanked, and do not show up in the display. The memory output does not revert to zero, but remains at a fixed voltage until corrected by the next error signal. (The signal to the amplifier of a typical sampling system is only about 2% of the error signal sampled by the bridge. The percentage of response, or attenuation through the sampling bridge, is the sampling efficiency).

At each sample time, the difference between the memory feedback and the 2% signal value is amplified and applied to the memory circuit via the memory gate, to correct the memory output to follow a rising signal in a series of steps as shown in Fig. 3-3. This figure shows the input signal and memory feedback voltages for six samples along the rise of a step waveform.

At the time of sample 1, the input signal and the feedback voltage are equal. There is no error voltage, so the memory output is not changed. The CRT is blanked until the circuit stabilizes after the memory gate pulse ends.

At the time of sample 2, the input signal is (for example) 0.1 volt. The memory output is 0. Assuming a sampling efficiency of 10%, the input of the amplifier receives 10% of the error signal, or 0.01 volt. The 0.01 volt, times the gain of the amplifier ( $\times 10$ ), corrects the memory output and feedback to equal the 0.1 volt signal at sample time. Again, the CRT is blanked during this change until the circuit is stabilized.

At the time of sample 3, the difference between the input signal and the feedback is 0.35 volt. The amplifier input responds to 10% or 0.035 volt. The gain of the amplifier and memory changes the feedback 0.35 volt to the new value of 0.45 volt (equal to the signal at number three sampling time). The CRT is again blanked during this change until the circuit is stabilized.

This process continues until sample 7 (not shown). Here again, there is no difference between the input signal and the feedback. There is no error signal, and the memory output and feedback is not changed. The system will remain at this voltage until the input changes, or until system drift has caused an error in the memory output (if there is a long period of time between successive samples).

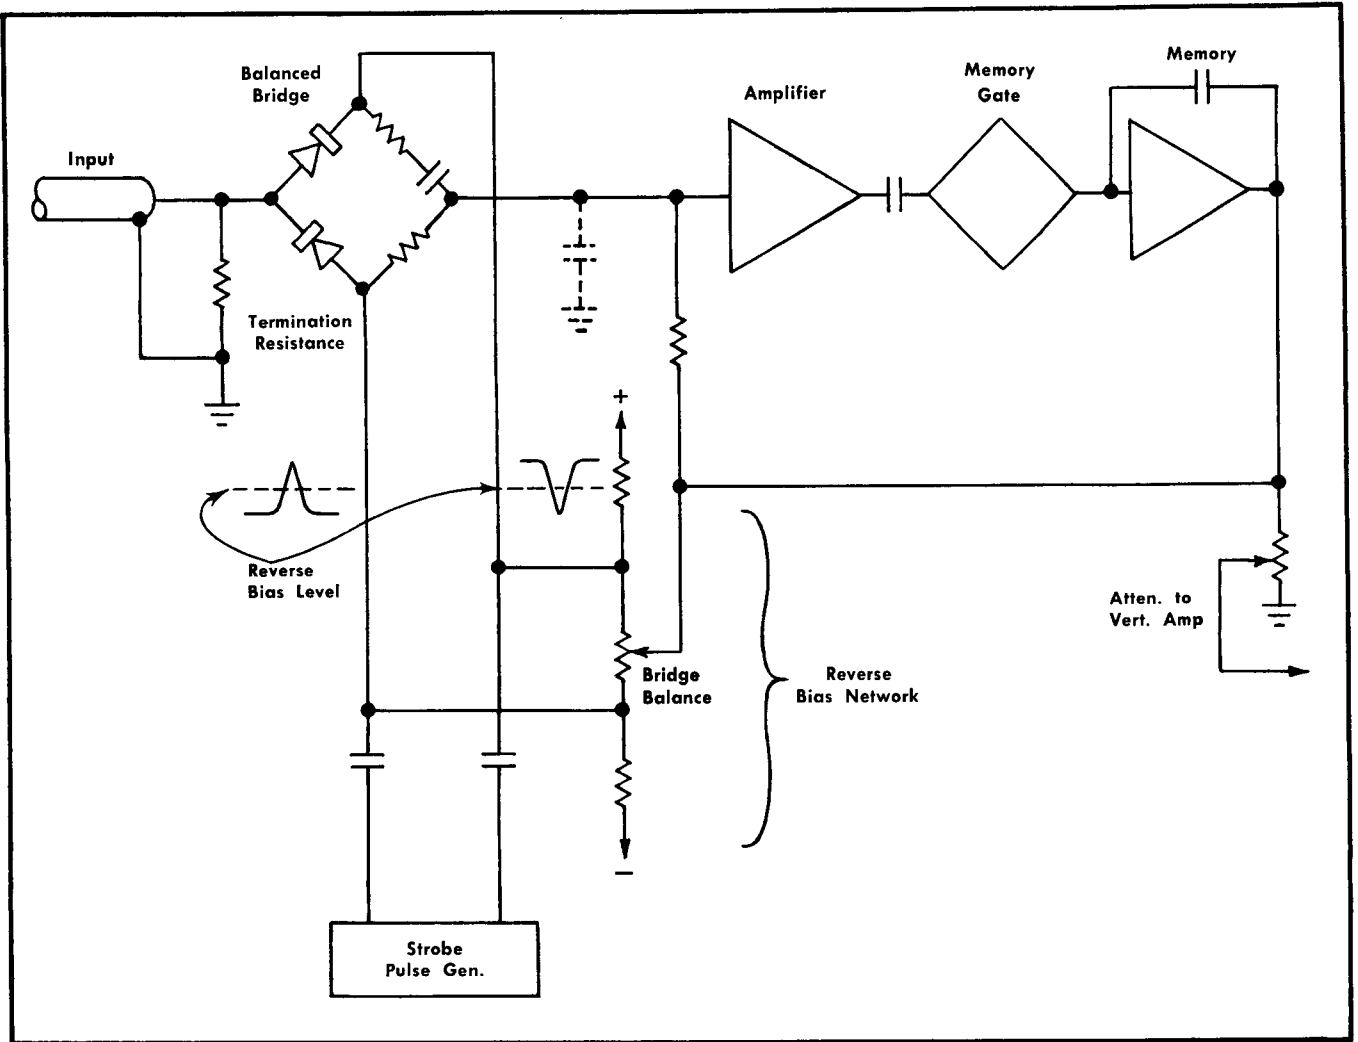

Fig. 3-4. Simplified diagram, showing how the strobe pulse causes the sampling bridge to conduct.

### Effective Sampling Time

The minimum risetime a sampling system can display is controlled by the time interval during which the strobe pulse applies forward bias to the sampling bridge diodes. The duration of the bridge forward bias is controlled by the time the strobe pulse exceeds a fixed reverse bias. Special circuitry is used to make the strobe duration as short as possible consistent with noise and diode recovery time. The strobe pulse is generated by a snap-off diode and a short section of shorted transmission line called a clipping line. The effective bridge conduction time is adjusted primarily by controlling the amplitude and duration of the strobe pulse, thus controlling the time during which the strobe pulse exceeds the reverse bias. Adjusting the reverse bias is a secondary means of controlling the sampling bridge conduction time. Fig. 3-4 shows how the strobe pulse breaks through the reverse bias on the sampling bridge. The reverse bias is shown by dashed lines through the strobe pulses.

### Dot Response (Loop Gain)

Dot response is the ability of the system to reduce the error voltage to zero after each sample. When the gain of

the memory feedback loop is equal to (and compensates for) the attenuation across the sampling bridge, the loop gain is unity or 1. In this case, the memory feedback voltage equals the value of sampling time signal voltage.

If the loop gain is less than unity, the memory output signal and feedback to the first amplifier is less than necessary to reduce the error voltage to zero. The memory output and the feedback will then approach the signal asymptotically after several samples have been taken. The error voltage thus approaches zero (for a steady state signal) after several samples, being reduced by the same factor after each sample. In the case of a loop gain of less than unity, the feedback voltage is effectively a moving average of several preceding samples.

If the loop gain is greater than unity, the feedback voltage will be greater than the error signal after each sample. The displayed dot sequence of a step signal will then alternately overshoot and undershoot for a few samples.

For least displayed waveform distortion, the loop gain must be unity, allowing the system to track the input signal as closely as possible.

### Smoothing

A loop gain of less than unity can be useful, if the resulting compromise is understood and the system is operated properly. Random noise in the display is reduced when loop gain is less than unity, since several consecutive samples are averaged. The averaging may also slow down the fastest display risetime capability, depending upon the number of dots contained in the step transition and or the loop gain. By increasing the number of dots in a step transition, the display will follow the actual step transition more closely.

Fig. 3-5 shows the usual effects on a step display when smoothing is used for two different sampling densities (sampling density or dot density is the number of samples or dots per horizontal division). In the Type 355 the operational choice of loop gain is either 1.0 (NORMAL) or 0.3 (SMOOTH).

In Fig. 3-5A the actual risetime (between the 10% and 90% points) for unity loop gain displays 4 dots. When operating at 0.3 loop gain 7 dots are shown. There is a significant difference between the 0.3 loop gain (SMOOTH) and the unity loop gain (NORMAL) displays.

In Fig. 3-5B the sampling density is increased, showing a difference of one sample in the SMOOTH and NORMAL positions between the 10% and 90% points of the step transition.

When the smoothed mode has a loop gain of 0.3, as in the Type 355, 15 or more samples between the 10% and 90% points of a risetime will result in the smoothed and unsmoothed displays having essentially the same risetime. When the smoothed display contains 12 samples between the 10% and 90% point, the smoothed risetime will be about 6% longer than for the unsmoothed display. As the number of samples contained in the risetime is reduced below 12,

Fig. 3-5. Equivalent-time display with and without smoothing for two different sampling densities.

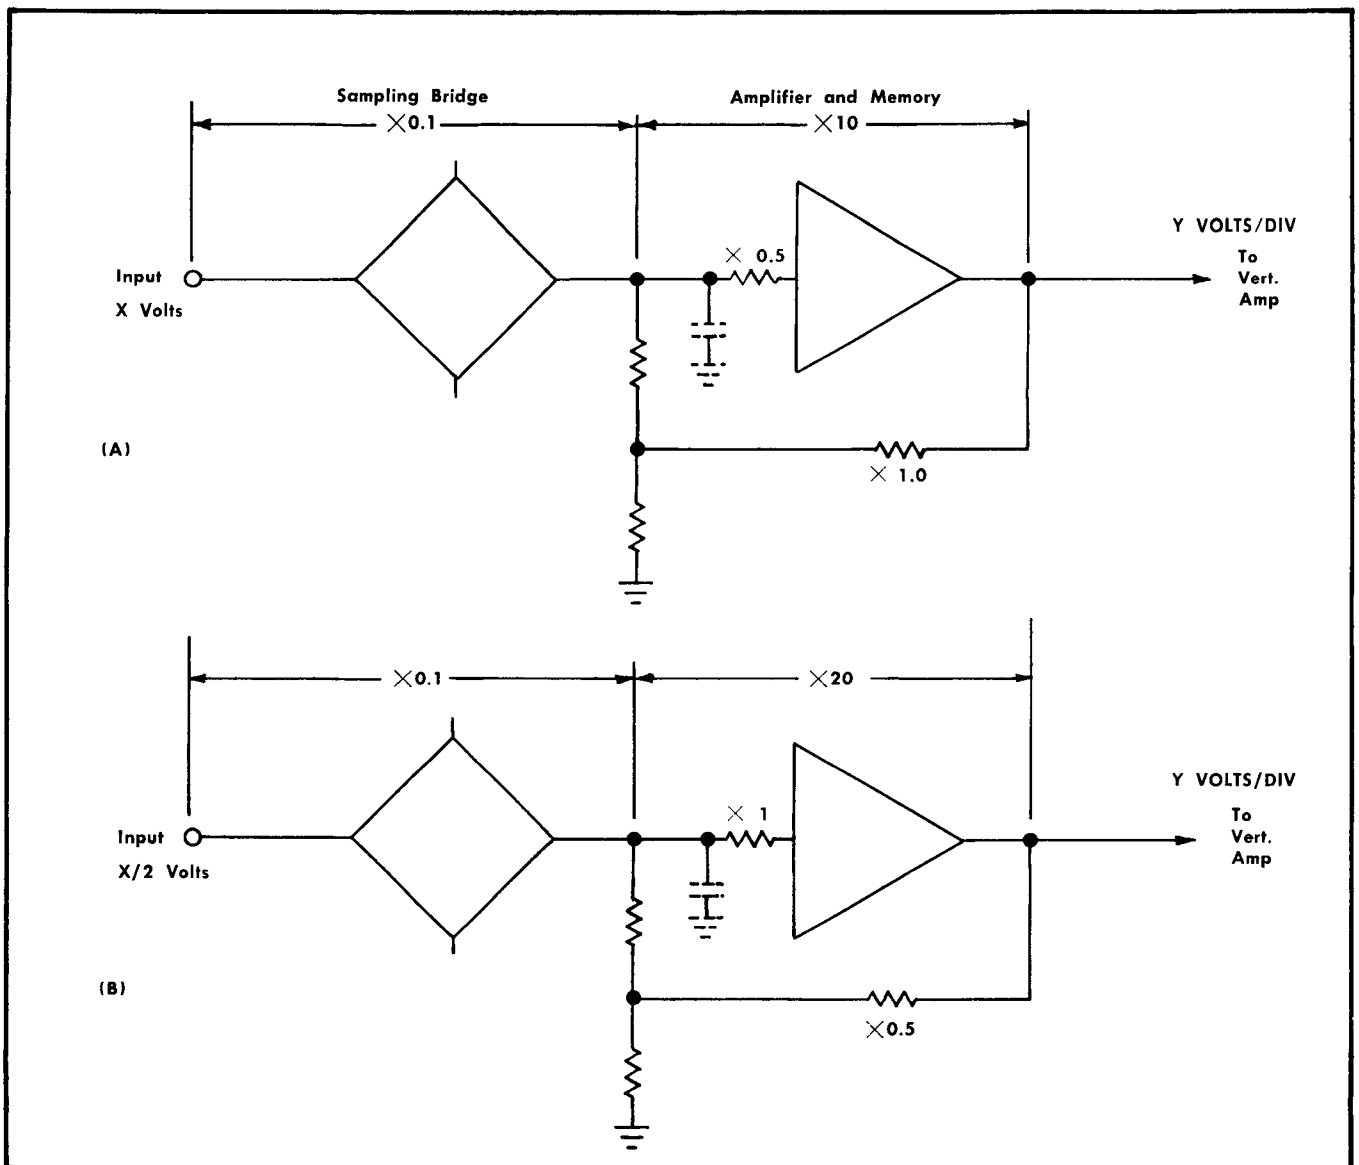

Fig. 3-6. Method of decreasing the vertical deflection factor while maintaining unity loop gain.

the difference between smoothed and unsmoothed display goes up rapidly.

### Smoothing of Random Noise

When the loop gain is reduced to 0.3, the displayed dots represent the average of several consecutive samples. Noise of a random nature will be materially reduced in the display at the possible expense of introducing an error in the displayed risetime. Therefore, if random noise is apparent, reducing the loop gain may improve the display. Note that this is only true for random noise. Systematic noise (noise with its repetition rate harmonically related to the signal) is treated as part of the signal.

The Type 355 has a loop gain control labeled NORMAL-SMOOTH. In the SMOOTH mode, loop gain is reduced to 0.3. Always check that there is sufficient sampling density

to warrant smoothing. This can be done by changing the dots/division, (or samples/division) control on the timing unit, and observing the effect of sampling density on the displayed risetime.

Smoothing cannot be applied where the full amplitude of each sample is required. When using the random sampling process of a sampling sweep unit like the Type 3T2, each sample requires unity loop gain. The display dots are not presented in time sequence, and therefore cannot be averaged.

### Tangential Noise

Traditionally the amplitude of random noise in an amplifier is qualified by stating the equivalent RMS value of the noise referred to the input of the amplifier. In the case of a CRT sampling display, qualifying the noise amplitude by stat-

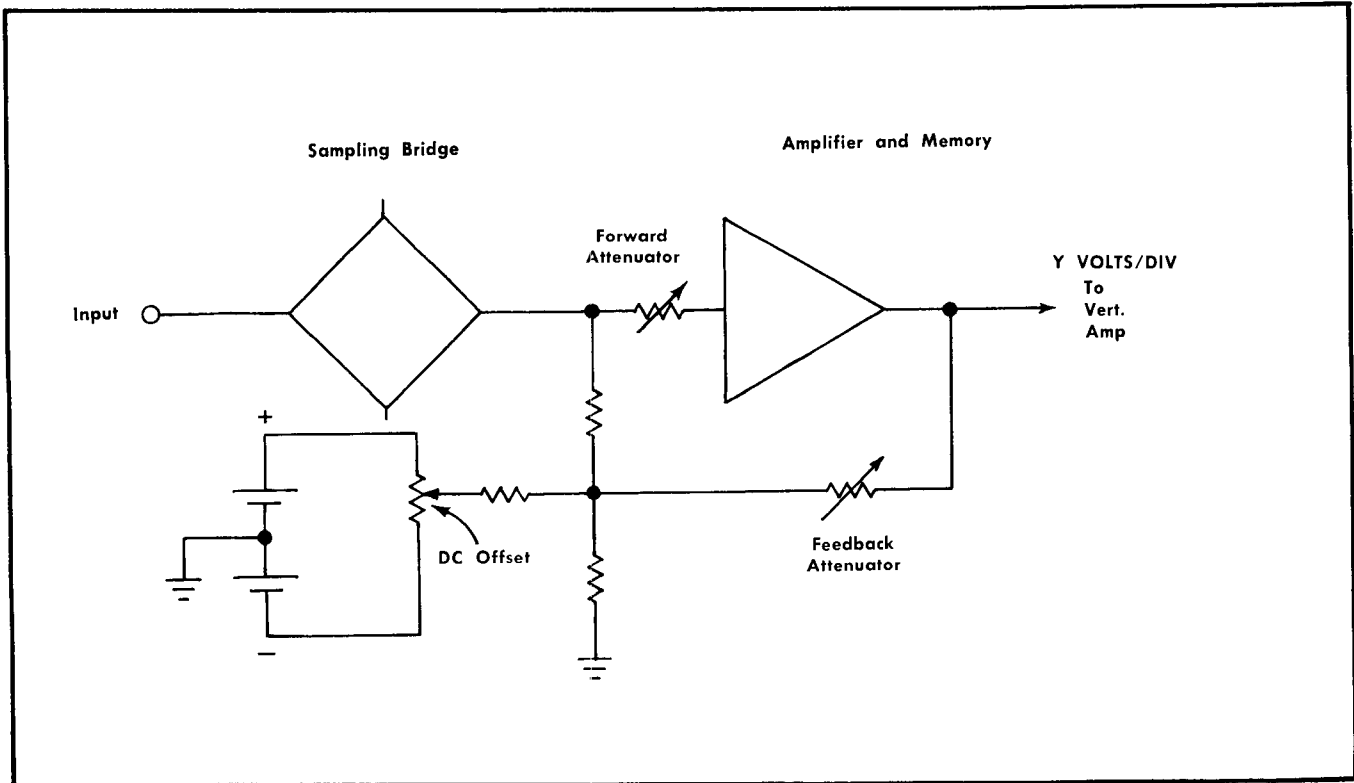

Fig. 3-7. Method of adding a DC Offset voltage to the memory feedback.

ing its RMS value is somewhat unsatisfactory. The visible effect of the random noise is more nearly 3 times the RMS value of the noise. Peak-to-peak limits of truly random noise would have to be stated as  $-\infty$  to  $+\infty$ . Obviously these broad limits would reveal nothing about the amount of significant noise to expect in a display. It has been determined empirically that 90% of the dispersion caused by random noise closely approximates the visible widening of the trace. The noise can be described as existing between two horizontal tangents representing the significant upper and lower limits of the trace width. Hence, the term **TANGENTIAL NOISE**. Tangential noise is defined as an equivalent peak-to-peak voltage at the input of a sampling system that will cause the same trace widening as 90% of the random noise. 5% of the dots can be expected to fall above the trace width and 5% below it. This method of stating the noise figure of a sampling system is considered to be more meaningful than the RMS value, in that it more closely approximates the actual observed trace widening. Measurement of Tangential Noise is described in Section 7.

### Display Sensitivity—Deflection Factor

The two terms display sensitivity and deflection factor are often mistakenly interchanged. Deflection factor is defined as the ratio of the input signal amplitude to the resultant displacement of the indicating spot. When the oscilloscope vertical gain control is calibrated in volts per division, it is indicating deflection factor. Deflection sensitivity is the reciprocal of deflection factor. Sensitivity is indicated by a vertical gain control calibrated in divisions per volt.

There is always some point within the oscilloscope vertical amplifier after which the signal remains at a fixed deflection factor. The signal out of the vertical memory amplifier of a sampling oscilloscope is usually the first point at which the standard vertical deflection signal exists. Thus, the memory and feedback voltages previously mentioned always deflect the CRT spot vertically with a fixed deflection factor.

Fig. 3-6A shows a simplified block diagram of a bridge and amplifier combination where the gain of the amplifier just compensates for the attenuation of the sampling bridge. In Fig. 3-6B the amplifier has twice as much gain as is necessary to compensate for the low sampling efficiency. By introducing a 2:1 attenuator in the feedback path between the memory output and the bridge output, the dot response is still maintained at unity. Now, only half as much input signal produces the same memory output as in Fig. 3-6A.

Fig. 3-6 shows two fixed attenuators in each example. The usual method of changing amplifier and memory gain in a sampling unit is to attenuate the signal through (or to) it. The attenuator in series with the amplifier and memory is called the forward attenuator, in contrast to the feedback attenuator.

The attenuators in Fig. 3-6 and Fig. 3-7 show that both the "forward gain" and the "feedback attenuator" are altered when changing a sampling system vertical deflection factor.

The system deflection factor can be altered two ways: 1) by changing both the forward and the feedback attenuation and thereby maintaining the same loop gain, and 2) by changing only the feedback attenuation, at the expense of varying the loop gain. If loop gain is not greater

## Tektronix Basic Sampling Principles—Type 355

than unity, and many samples are included in a signal transition, the memory feedback to the sampling bridge always approaches the signal amplitude regardless of the forward attenuator attenuation ratio.

Since loop gain is determined by the combined forward and feedback attenuation ratios, the dot response can be altered without altering the deflection factor by changing the forward attenuation only. Increasing the forward attenuation ratio (decreasing the amplifier and memory gain) "smooths" the display by making the loop gain less than unity.

### DC Offset

Since the sampling bridge can be operated over a range of +2 to -2 volts of input signal, and the system has resolution

capability of 2 mV/div, it is advantageous to be able to display a small vertical "window" of the input signal. Fig. 3-7 shows the method of adding a DC offset voltage to the memory feedback. The error signal produced at sampling time is no longer referenced to ground. Instead, it is referenced to the DC offset voltage.

A DC Offset voltage is recognized as a signal by the sampling bridge, algebraically adding it to the error signal. Therefore, the memory feedback signal in a system with DC Offset includes a DC value to cancel the DC Offset voltage at the output side of the sampling bridge. The deflection factor of a system with DC Offset is centered around the DC Offset voltage instead of ground. This permits portions of the signal (other than ground) to be positioned to the CRT center, without altering the deflection factor.

# SECTION 4

## CIRCUIT DESCRIPTION

Change information, if any, affecting this section will be found at the rear of the manual.

### Introduction

This section of the manual contains a block diagram description and circuit description of the Type 355 Sampling Unit. The block diagram description is an expansion of Section 3, Basic Sampling Principles. The circuit description follows the sequence of diagrams at the back of this manual.

The Digital Unit Control circuits are described in Section 5, Digital Unit Control Description.

### BLOCK DIAGRAM

Refer to Fig. 4-1 and the complete block diagram at the back of this manual during the following description. Since most of Channel A and Channel B are identical, no reference is made to either channel except where they differ. Channel A occupies the top half of the block diagram.

Fig 4-1 includes a simplified block diagram of a typical sampling head. The Type 355 Sampling Unit serves no useful purpose by itself, but functions as part of a sampling system only when a sampling head is installed. Thus, the sampling head simplified blocks are included.

### Feedback Loop and Pulse Amplifier Chain

Fig. 4-1 relates to Fig. 3-4 and Fig. 3-7. The reconstructed signal out of the Memory block (Fig. 4-1) is the first point in the Type 355 at which the amplitude is always a standard value of 0.5 volt per CRT vertical division. The signal between the sampling head output and the Memory input bears no similarity to the signal at the Memory output. Under ideal conditions, there is no signal between those two points whenever the sampling head input signal is at a steady value. The Post Amplifier, AC Amplifier and Memory Gate all are part of a pulse amplifier chain that amplifies the sampling head output signal just after each sample is taken. The pulse chain signals are greatest in amplitude when the sampled signal is at its full amplitude difference from the last sample (as in using the random sampling process in the Type 3T2 Random Sampling Sweep unit).

The Smoothing, DC Offset, and the Units/Div circuits can be externally programmed when the Vertical Mode Switch is in the EXT PROG position. Programming is accomplished by connecting the program lines to ground through saturated transistors or relay closures to pin 16 (front panel) or pin A (rear panel), described in the Operating Instructions, Section 2.

The Type 355 provides connections from the sampling head to the Digital Unit Control circuits to select the Units/Div multiplier and the units of measure (Volts or Amps). These connections provide information to an external digital unit as described in Section 5, Digital Unit Control Description.

To complete the association of Fig. 4-1 with Section 3, the following describes the operating cycle:

a. The sampling head bridge applies an error signal to the head preamp whenever there is a voltage difference at the bridge input and output terminals at sampling time. The error-signal voltage amplitude is just a few per cent of the difference (sampling efficiency), and the pulse duration out of the bridge is equal to the bridge conduction time. A small storage capacitance at the head Preamp input time-stretches the pulse so the pulse chain can amplify the error signal pulses at moderate rates of rise.

b. The time-stretched signal is amplified by the Type 355 Post Amplifier. Its gain is affected by the Smoothing circuit which operates in either the Smooth or Normal modes. The Smooth or Normal operation can be programmed externally in the EXT PROG position of the vertical Mode switch, or controlled from the front panel by the SMOOTH-NORMAL switch. In the Normal mode, the DOT RESPONSE control allows a small adjustment of the Post Amplifier gain to obtain unity loop gain. In the Smooth mode, the DOT RESPONSE control is disconnected. This reduces the Post Amplifier gain so that the sampling loop operates at about 0.3 of the gain in the Normal mode. The output of the Post Amplifier is capacitively coupled to the AC Amplifier and Forward Attenuator.

c. The AC Amplifier and Forward Attenuator block is an AC amplifier with its gain determined by the ratio of the feedback resistance to the selected input resistance. The Units/Div switch or external program, (through the Attenuator Decoder block) selects the input resistance and feedback circuit of the AC Amplifier. The output pulse is applied to the Memory circuit during conduction time of the Memory Gate.

d. The Memory circuit applies its output voltage to both the Vertical Amplifier and the Feedback Attenuator block. 40% of the signal is also available through 10 k $\Omega$  at the front panel SIG OUT connector.

e. The Feedback Attenuator block attenuates the standard 0.5 Volt/Div signal from the Memory circuit and feeds it to the sampling head. Here the feedback voltage is combined with the DC Offset voltage and applied to the output side of the sampling bridge through the bridge balance circuit. The Units/Div switch or external program (through the Attenuator Decoder block) selects the attenuation of the Feedback Attenuator. The forward Attenuator operates concurrently with the Feedback Attenuator to maintain constant loop gain.

### Vertical Channel Following Memory

Blocks between the Memory and the CRT (See Fig. 4-2) include the Inverter and the INVERT switch, the Units/Div VARIABLE control and internal Digital Gain control, the Channel

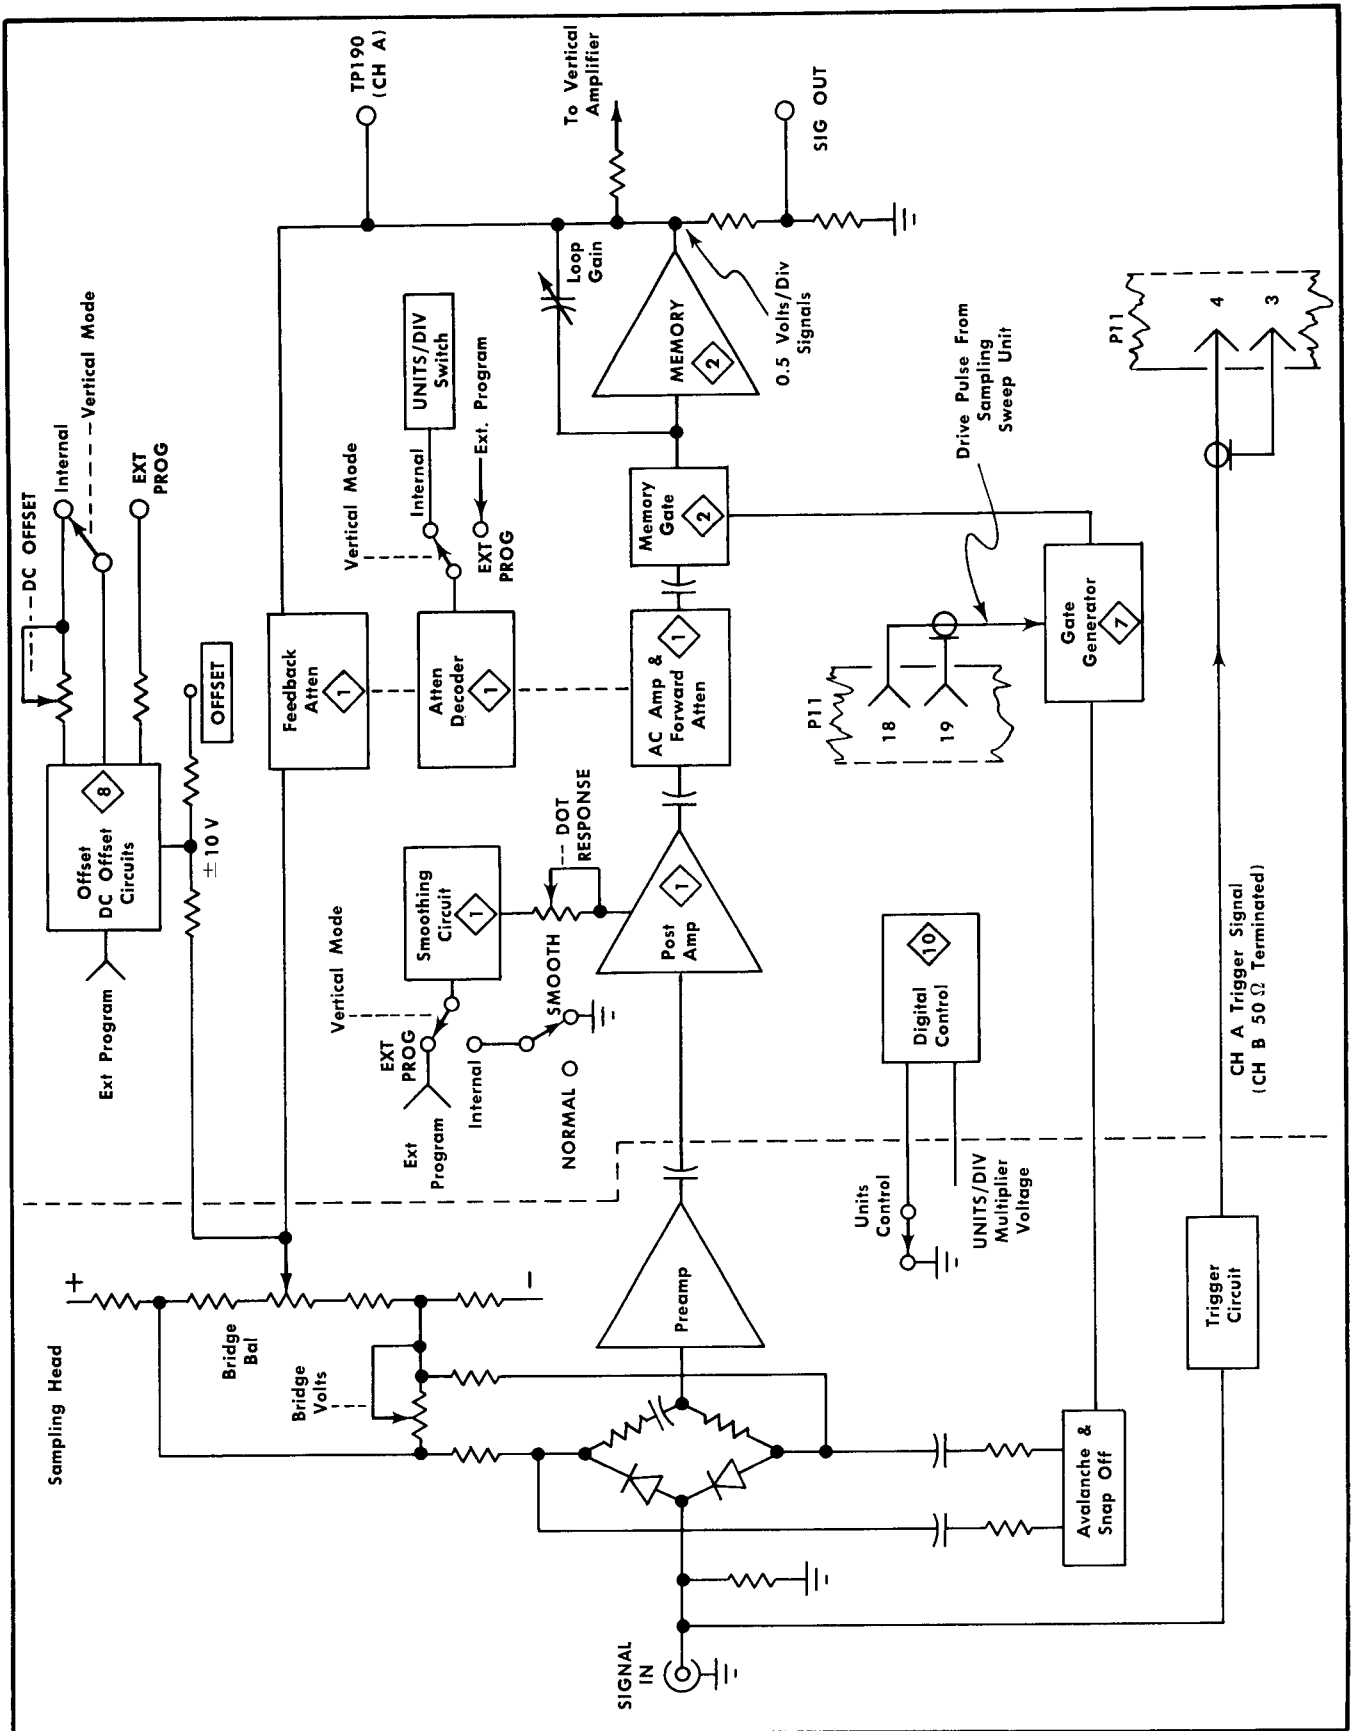

Fig. 4-1. Type 355 and sampling head feedback loop diagram.

Fig. 4-2. A and B Vertical Channel block diagram following the Memory showing A+B mode signal connections.

Amplifier and the Output Amplifier with its input controlled by the Dual-Trace multi. The Output Amplifier drives the indicator oscilloscope CRT vertical deflection plates directly.

The Inverter is a  $\times 1$  gain inverting amplifier that is normally in the circuit. The Inverter is by-passed when the INVERT switch is pulled out to invert the display.

The Channel Amplifier is a  $\times 2$  gain inverting amplifier with both the Units/Div VARIABLE and Digital Gain controls in series with the signal input.

During external program operation, the Units/Div VARIABLE control center arm is disconnected and does not operate. With external automatic calibration equipment connected to the proper pins of one of the external program connectors, the Channel Amplifier gain can be changed over a small range for calibration to a standard input signal. Except in A+B operation, the A and B Digital Gain controls allow the gain to be adjusted for a digital readout unit. (Channel A signal is disconnected from the A Channel Amplifier in A+B operation).

In the A+B position of the Vertical Mode switch, the B Channel Amplifier is driven by both Channel A and Channel B signals, providing algebraic addition displays. A-B control allows the Channel A signal to be balanced with the B signal in the A+B position.

The Output Amplifier is a high gain inverting amplifier that drives the CRT vertical deflection plates directly. The input is from either Channel A or Channel B, selected by the Dual-Trace multi. The multi control circuit selects one channel continuously (CH A or CH B), alternates between channels after each sample (Dual-Trace), and EXT PROG selects Channel B for algebraic addition (A+B).

The Position Lamp Driver circuit (not shown on the block diagram) monitors the DC voltage of the Output Amplifier lines and turns on the appropriate neon lamp to indicate whether the deflection voltage has placed the trace above or below the graticule center.

## Gate Generators

The Type 355 Gate Generator block consists of a Blocking Oscillator, Dual-Trace Driver, and two Strobe and Memory Gate Drivers. The sampling drive pulse from the sweep unit drives the Blocking Oscillator, which then drives the Dual-Trace Driver and both Strobe & Memory Gate Driver blocks.

Since the Type 355 will operate with several different sampling sweep units, the Gate Generator is designed to operate from slightly different sampling drive pulses. The Blocking

## Circuit Description—Type 355

Oscillator converts the normal variations in amplitude, rise-time and duration of the sampling drive pulses to a standardized drive pulse with always the same amplitude, risetime and duration.

The Blocking Oscillator output pulse is converted to an RC ramp signal at both Delay circuits, and the (internal) A Delay and (front-panel) B Delay controls select a point along each ramp at which the Strobe Drive is generated. As the individual channel Strobe Drive is generated, the Memory Gate Driver causes the same channel Memory Gate to conduct. The duration of Memory Gate conduction is controlled by the Memory Gate Width control. Thus, a few nanoseconds after the arrival of the sampling drive pulse, a Strobe Drive pulse is sent to the sampling head, and the Memory Gate is driven into conduction. The instrument is calibrated so the B DELAY control alters the time of the Channel B Strobe Drive pulse approximately  $\pm 5$  ns with respect to the Channel A Strobe Drive pulse (when both sampling heads are the same type).

The Dual-Trace Driver circuit drives both the CRT blanking circuit (to extinguish the CRT beam while the dot is being moved between samples) and the Dual-Trace Multi. If the Vertical Mode switch is at DUAL-TRACE or at EXT PROG, the Dual-Trace Driver causes the Dual-Trace Multi to change state at the time each sample is taken.

### Internal Trigger

The Type 355 has a coaxial connector in the Channel A sampling head compartment that couples the internally derived trigger pickoff signal through the oscilloscope to the sampling sweep unit. The Channel B trigger output is terminated in  $50\ \Omega$  at the Channel B head coaxial connector.

## CIRCUIT DESCRIPTION

The following circuit description sequence follows the order of the diagrams in Section 10.

### Programmed Amplifiers and Attenuators

The Programmed Amplifiers and Attenuator diagram for each channel includes the Post Amplifier, Smoothing, AC Amplifier, Forward and Feedback Attenuators, and Attenuator Decoder circuits. The Forward Attenuator is described as part of the AC Amplifier. The Feedback Attenuator circuits includes a  $\times 2$  gain operational amplifier. Where the two channels are identical, the operation of only one is described. Differences between the channels are discussed in detail.

**The Post Amplifier** is a two-stage non-inverting operational amplifier with complementary emitter followers at the output. Low output impedance drives the Forward Attenuator resistors of the AC Amplifier. The resistance of R13 (CH A) terminates the coaxial cable feed from the sampling head preamplifier. The coaxial cable shield is DC isolated from ground to provide a Units/Div Multiplier control connection from the sampling head to the Digital Unit Control circuits. The gain of the Post Amplifier is changed by varying the resistance of R9 to change the feedback. The Smoothing circuit has two modes of operation, Normal and Smooth. In the Normal mode Q8 is saturated, allowing the DOT RESPONSE control to adjust

the gain of the Post Amplifier. In the Smooth mode, Q8 is not conducting thus disconnecting the DOT RESPONSE control. This increases the feedback and decreases the gain of the Post Amplifier. Total Post Amplifier AC gain (in Normal mode) with unity loop gain is approximately 11, producing a 2.2 volt output signal at TP25 for a 0.2 volt input signal at Q15 base. DC gain is about two, and DC feedback keeps the Amplifier within its proper dynamic range.

Q15 and Q16 provide voltage gain while Q19 and Q22 are the output emitter followers. Q19 assures low output impedance for positive output signals, and Q22 provides low output impedance for negative output signals. Each emitter follower has a resistor in the collector for parasitic oscillation suppression. C20 permits the output emitters to be at different DC voltages.

The Smoothing function is either internally or externally controlled, depending upon the position of the Vertical Mode switch. For front-panel operation of the NORMAL/SMOOTH switch, the switch is an open circuit at NORMAL and grounds the Smoothing circuit input at SMOOTH.

At NORMAL, R3, R4 and R5 bias Q6 to cutoff and R7 biases Q8 on to saturation. The low saturation resistance of Q8 connects one end of the DOT RESPONSE control (R9) to ground. This connects R9 in parallel with R10 in the Post Amplifier AC feedback circuit. C11 is allowed to bypass more signal, thereby reducing the AC feedback. Thus, the Post Amplifier gain can be adjusted over a small range by the DOT RESPONSE control.

When the NORMAL/SMOOTH switch is at SMOOTH, D3 conducts and R4 biases Q6 to saturation. Q6 collector voltage turns Q8 off, disconnecting the DOT RESPONSE control from ground. With R9 disconnected, R10 resistance in series with C11 increases the Post Amplifier AC feedback voltage and thus decreases the gain. This reduces the sampling loop gain of the Type 355 to 0.3 or less compared to the loop gain at NORMAL.

External programming of the SMOOTHING circuit merely duplicates the NORMAL/SMOOTH switch functions when the Vertical Mode switch is at EXT PROG. A logical ONE or a ground closure programs the Smooth mode and a logical ZERO or an open circuit programs the Normal mode.

**The AC Amplifier and Forward Attenuators** consist of an inverting operational amplifier with complementary emitter follower output circuit. The Amplifier gain is changed whenever the Units/Div switch (or external program) is changed. Control is by FET-switched input resistors together with a transistor-switched feedback circuit.

The gain change function of the amplifier is called the Forward Attenuator because it affects the signal amplitude through the circuitry from the Post Amplifier to the Memory input. Fig. 4-3 shows the AC Amplifier input resistors R26 through R29. R27, R28 and R29 are connected into the circuit by Q27, Q28 and Q29 (shown as switches) to change the input resistance and thereby the gain. These Fet's are held at low resistance conduction (less than  $30\ \Omega$ ) or at cutoff by the Attenuator Decoder circuit (from logic lines A1 and A2). The line A4 (through the Attenuator Decoder) controls the AC Amplifier feedback network by turning Q53 on or off. Q53 saturation increases the gain of the amplifier ten times by reducing the feedback to 0.1 its normal value. The feedback circuit consists of R59-C55, R58-C54 and R55-R56. The Decoder

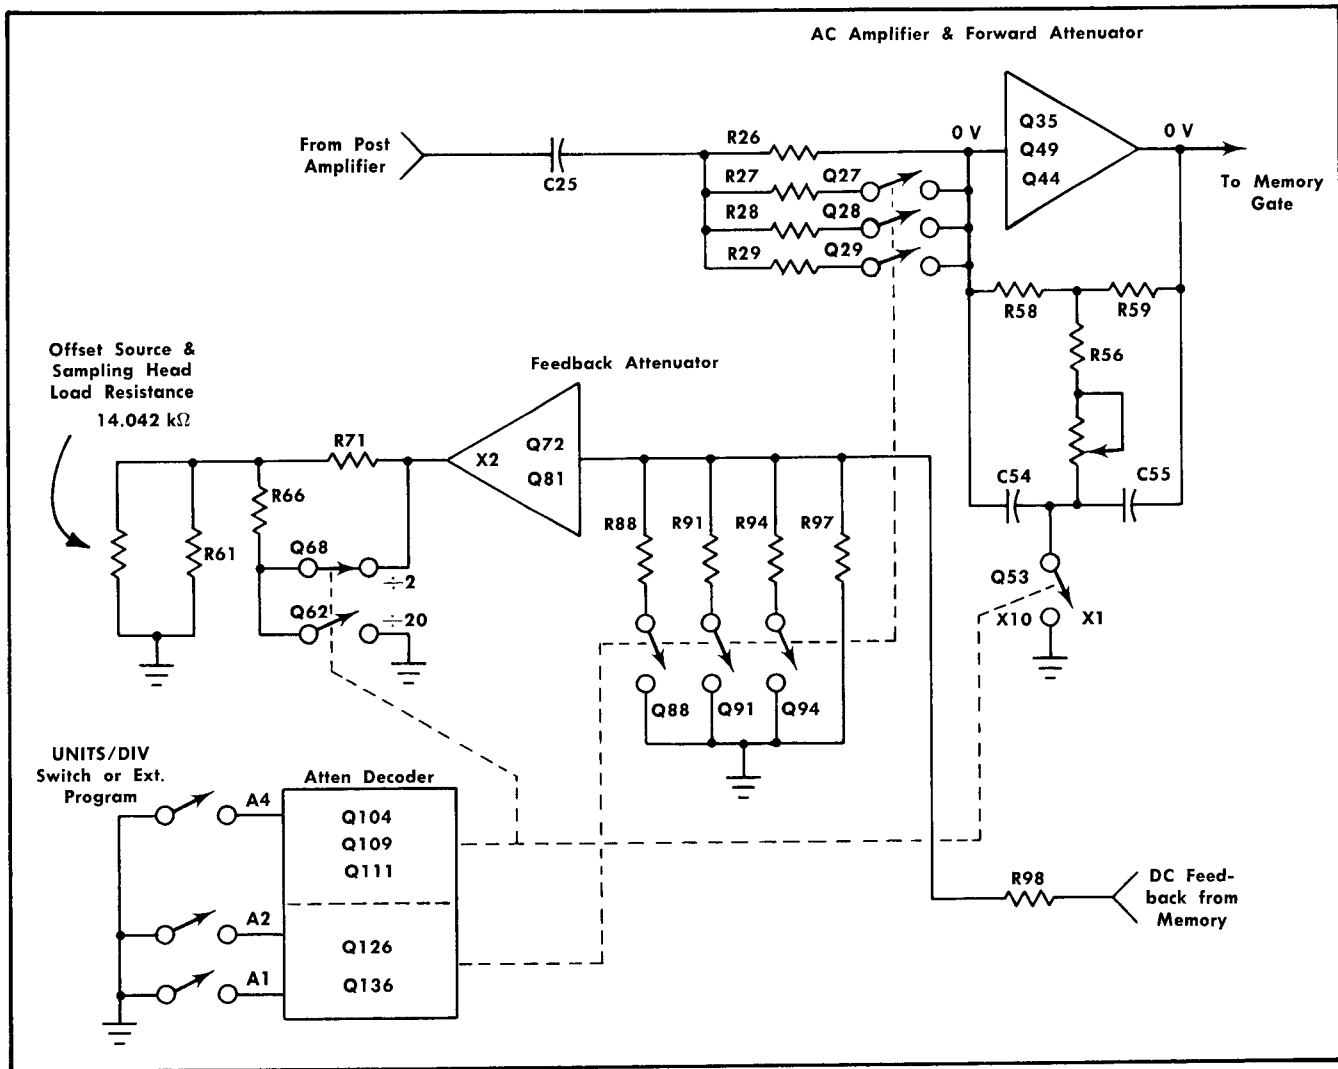

Fig. 4-3. Simplified Programmed Amplifiers and Attenuators diagram.

circuits operate the Feedback Attenuator circuits simultaneously so that the sampling loop gain is maintained constant. (See Section 3 for loop gain relationship between forward and feedback attenuators).

Schematic diagram 1 has truth tables in the AC Amplifier section showing the relation between the lines A1, A2 and A4, and the transistors' on-off states.

At quiescence, the base of Q35 in the AC Amplifier is at 0 volts. Temperature compensation for Q35 is provided by D37. Q35 collector voltage is about +10 volts, and Q49 emitter follower output is slightly negative (between -0.25 V and ground). 0 volts input (at Q35 base) allows Q27, Q28 and Q29 to be biased off or on by the Attenuator Decoder circuits. When Q53 is turned on to change the gain of the AC Amplifier, Q53 connects the center of the feedback circuit to ground with about 125 Ω (R55 and R56). This causes only about 0.2 volt shift in the output quiescent voltage. R55 is adjusted for a gain increase of exactly  $\times 10$  when Q53 is saturated.

Two possible Q111 collector voltages of -24 or +7 V con-

trol Q52 and turn Q53 on or off. Operation is as follows: when the collector of Q111 is at +7 volts, R51 and D51 back bias Q52 by about 0.5 volt. With Q52 off, R53 turns Q53 on. The -24 volts from Q111 collector saturates Q52. This sets Q53 base positive and turns off Q53.

The summing input of the AC Amplifier (at Q35 base) receives both the input signal from the Post Amplifier (through C25 and the FET-selected input resistors) and the feedback signal from the feedback network. Q35 amplifies the signal and drives the bases of emitter followers Q49 and Q44. Q49 provides a low output impedance for positive signals and Q44 provides a low output impedance for negative signals. Q44 is AC-coupled to the output by C47. R48-C48 and R45-C45 are power supply decoupling networks in the collector circuits of Q44 and Q49. D42 protects Q44 base-emitter junction if Q35 is removed from its socket. The low output impedance of the AC Amplifier is required to drive the Memory Gate circuit for full screen transitions.

**The Feedback Attenuator** circuit consists of a selectable attenuator network at the input of a non-inverting  $\times 2$  gain operational amplifier (Q81-Q72) and a divide-by-two or

## Circuit Description—Type 355

divide-by-twenty divider network between Q72 and the sampling head. See Fig. 4-3. Attenuator resistors are changed by special low resistance FET transistors, drawn as switches in Fig. 4-3. The  $\times 2$  amplifier low output impedance drives the divider network R71, R66, R61 and 14.042 k $\Omega$ . The 14.042 k $\Omega$  consists of the Offset circuit output resistance in parallel with the sampling head bridge volts circuit resistance.

The CH A (CH B) Programmed Amplifier and Attenuators diagram shows truth tables listing the feedback attenuation as a percentage of the Memory DC output voltage. The input to the Feedback Attenuator at point (A) is the Memory signal at the standard deflection factor of 0.5 volt per displayed division. The truth table shows the percentage of memory output signal that reaches Q81 base at point (B). Q88-Q91 and Q94 turn on and ground appropriate attenuator resistors as a function of the program applied to the A1 and A2 lines, altering the signal at point (B). The output signal at point (C) is also included in the truth table as a percentage of the voltage at (A). Q62 or Q68 turn on and ground appropriate attenuator resistors as a function of the program applied to the A4 line. Point (C) voltage provides current through R71 and/or R66 to the DC Offset and sampling head circuits so that the voltage across R61 is held at about zero with no sampling head input signal.

Q72 and Q81 operate as a  $\times 2$  gain, non-inverting operational amplifier between the two attenuator networks. R75 and R79 (both 0.1% tolerance resistors) set the gain at  $\times 2$ . The amplifier has high input resistance at Q81B base, and very low output resistance at Q72 collector. This low output resistance drives the  $2\times/20\times$  divider network.

The collector signal of Q81B drives Q72 base. Q72 collector drives the output and provides a feedback signal to Q81A base through R75 and R79. The common emitters of Q81 complete the feedback path and provide temperature compensation. All quiescent base current of Q81B passes through R85, and all quiescent base current of Q81A passes through R78. Both halves base current pass through the Attenuator Zero control, R86. R86 is adjusted during calibration so that Q81 base currents do not offset the Memory output signal as it passes through the Feedback Attenuator networks. The Attenuator Zero control requires adjustment only if Q81 or Q72 is replaced. The adjustment assures that when the Memory output voltage is zero, the output voltage at Q72 collector is nearly zero. R73 and C73 comprise a power supply decoupling network. C72 slows the amplifier risetime, preventing self oscillations.

**The Attenuator Decoder** circuit has two sections; 1) Q104, Q109 and Q111 controlled by conditions at the A4 line and 2) Q126, Q136, D129 and D136 controlled by the condition at the A1 and A2 lines. The circuits work together to turn on or cutoff field effect transistors in the Feedback Attenuator and the Forward Attenuator circuit according to the Units/Div (deflection factor) programmed. The Units/Div can be controlled from the front panel, or externally programmed depending on the setting of the Vertical Mode switch. Conditions required at the A1, A2 and A4 lines are identical for either internal or external control. A "true" logic state ONE must place A1, A2 or A4 between 0V and +2V or at ground. A "false" logic state ZERO must place A1, A2 or A4 between +6V and +15V or open circuit. The Programmed Amplifier and Attenuator diagrams show truth tables listing the correct circuit voltages for both logic states of the input lines.

The A4 decoder circuit controls Q62 and Q68 in the Feedback Attenuator and Q53 in the AC Amplifier circuit. When

the A4 line is grounded the decoder and the attenuator respond as follows:

When A4 = ONE: D101 conducts by current in R101 permitting R102 and R103 to forward bias Q104. Q104 positive collector voltage forward biases Q109, setting Q109 collector voltage at approximately  $-25$  volts. This voltage forward biases D110 and D69. D69 conduction couples the  $-25$  volts to Q68 gate, causing Q68 to cutoff. At the same time D110 conduction couples the  $-25$  volts to Q111 base, reverse biasing Q111. With Q111 off, its collector voltage is set at +7 volts (caused by conduction through R111, R51 and D51) reverse biasing D64. D62 gate is zero biased by R63. Zero bias to Q62 sets its channel resistance to less than 30  $\Omega$ , in effect grounding one end of R66. Conduction of D51 in the AC Amplifier reverse biases Q52 and protects Q52 from excessive reverse bias. With Q52 off, R53 turns on Q53. Therefore, with a logical ONE at A4, Q62 and Q53 are on and Q68 is off. If A4 condition is a logical ZERO, Q62 and Q53 will be off and Q68 will be on.

The A1, A2 decoder circuit controls six attenuator FET's. Q136 is controlled by the A1 line and Q126 is controlled by the A2 line. Both transistors drive attenuator FET's and the OR gate, D129-D136. Q136 controls both Q94 in the Feedback Attenuator and Q27 in the Forward Attenuator. Q126 controls Q88 in the Feedback Attenuator and Q29 in the Forward Attenuator. The OR gate circuit controls Q91 in the Feedback Attenuator and Q28 in the Forward Attenuator.

When either or both of the Units/Div logic lines A1 and A2 are grounded (for a logical ONE), the decoder and attenuator networks respond as follows:

1. When A1 = ONE: D131 conducts, causing R132 and R133 to forward bias Q136. With Q136 saturated, its collector voltage of +3.4 to +3.5 volts back biases D139. This causes R139 to zero bias both Q94 and Q27.
2. When A2 = ONE: D121 conducts, causing R122 and R123 to forward bias Q126. With Q126 saturated, its collector voltage of +3.4 to +3.5 volts back biases D128, which causes R128 to zero bias both Q88 and Q29.
3. When A1 and A2 both = ONE: the +3.4 volts at the OR gate inputs (D129 and D136 cathodes) reverse biases both gate diodes so their common anode voltage is held at zero by R137. R137 applies zero bias to both Q91 and Q28.

If only A1 or only A2 is grounded, the OR gate holds both Q91 and Q28 in heavy reverse bias (by conduction of D137), and they are both open circuits. Only two positions of the Units/Div switch (or two externally programmed deflection factors) 20 and 2, cause all three feedback attenuator input sections and all three AC Amplifier input sections to be active.

D137 conduction limits the negative voltage to  $-26$  volts and thus protects both D129-D136 and the FET's from the  $-100$  volts supply when Q126 and/or Q136 are at cutoff.

## Memory Diagram

The Memory diagram of each channel includes the Memory Gate the Memory Amplifier and the Inverter. The AC Amplifier signal pulse is applied to the Memory circuit during the conduction time of the Memory Gate. The resulting DC signal from the Memory circuit output drives the Feedback Attenuator, the SIG OUT jack, the Inverter and the INVERT switch. The Inverter is normally in the circuit to drive the Channel Amplifier circuits through the INVERT switch. The Inverter is by-passed when the INVERT switch is pulled out to invert the display.

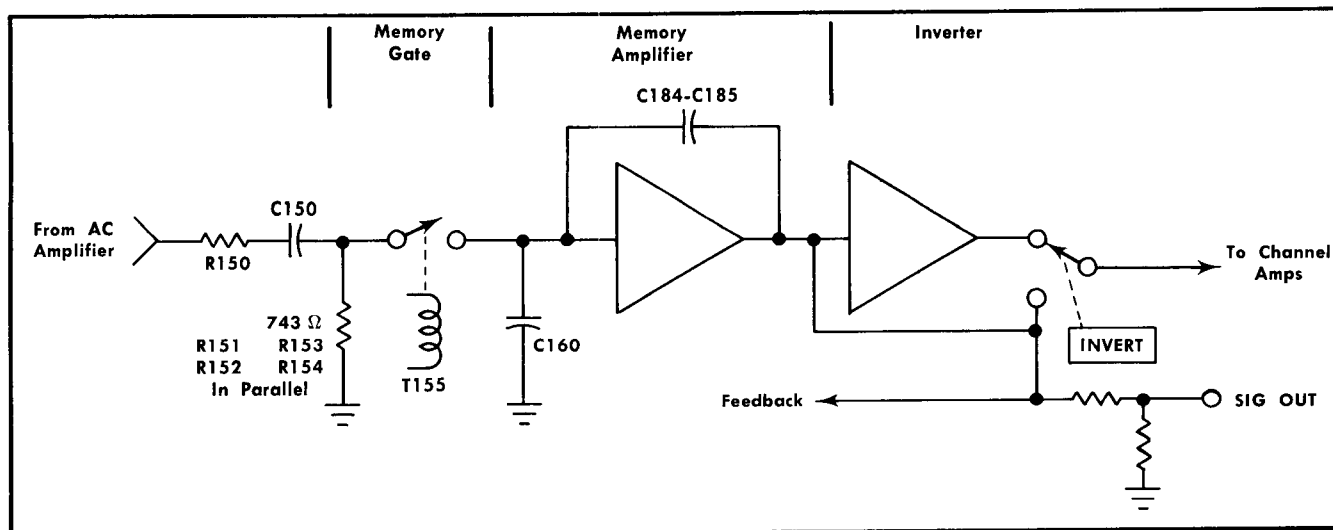

Fig. 4-4. Detailed block of Memory diagram showing basic Memory Gate circuit.

The **Memory Gate** is a pulse-driven diode gate that assures a very high input resistance to the Memory Amplifier except for about 0.15 to 0.2  $\mu\text{s}$  at the time of each sample. During conduction time, the Memory Gate is a low resistance path that allows the AC Amplifier to introduce charge to the Memory input through R150, C150 and the gate diodes conduction resistance.

Fig. 4-4 is a detailed block diagram of the circuits on the Memory diagram. The Memory Gate is represented by a resistor, a coil and a relay switch. The resistor is the parallel value of the four biasing resistors which assure that the four gating diodes are normally not conducting. This equivalent circuit shows that the Memory Amplifier input is zero volts when there is no error signal at sample time.

Looking from the Memory Gate output toward its input, the four gating diodes are normally reverse biased by the voltage of Zener diode D151. (Two of the four diodes provide very high reverse biased leakage resistance, although they don't turn off very fast. The other two turn off fast at the end of the gating pulse, although they don't provide high resistance when reverse biased). D151 voltage is balanced to ground by R153 and R154 so D156 cathode rests at +2.5 volts and D158 anode rests at -2.5 volts. C151 assures that the AC Amplifier output signal drives both sides of the Memory Gate diodes.

The gate diodes are forward biased into conduction by T155 at the time of each sample due to the drive pulse from the Memory Gate Driver. T155 is a toroidal transformer specially wound to balance capacitive and inductive coupling to the two secondary windings. The winding with only one connected provides the capacitive balance. The magnetic toroid core provides the inductive balance. Thus, the drive pulse is converted to identical drive signals to assure that the output junction of the four diodes accurately divides the 5 volts of D151-C151. This places the junction of D157-D159 at ground when no error signal is applied from the AC Amplifier. The Functions of the two limiting diodes D153-D154, and the Memory Gate, are discussed in the Memory Amplifier description next. R156, R158 and D155 are shunt damping loads to T155 which minimize self-induction ringing when the memory gate drive pulse ends.

The **Memory Amplifier** is an integrating operational amplifier with special low leakage (high DC resistance) input circuit. The input and feedback components are capacitors, making the AC input impedance very low. The internal high gain assures a very low output resistance; so that as long as there is no change at the input, the output DC voltage remains stable. The input low leakage circuit has no DC connection to ground except during the time the Memory Gate conducts.

The Memory Amplifier is specially decoupled from the power supplies because the output stage (Q181-Q182) can require a current pulse as great as 30 mA for a 20 volt output change at sample time. The decoupling networks are: R161-C161, R180-C180 and R183-C183. L197 in the output lead to the INVERT switch, presents a high impedance to the Memory output for high frequency (fast change) signals. The inductor assures that the output amplifier does not have to provide high current to the output load. L197 slows the output signal response, but at a time when the CRT is blanked.

A dual junction FET (Q162) is the input stage. It is biased for essentially no leakage at the input gate, and the stage has high voltage gain at the in-phase output drain lead. Any voltage change at Q162A gate lead is amplified and applied to the inverting amplifier Q174. Q174 collector circuit applies proper bias to both bases of the output complementary emitter follower pair Q181-Q182, and restores the DC level so a zero input signal (at Q162A) causes a zero output signal. Q174 collector and Q181-Q182 outputs operate linearity through the range of +10 to -10 volts.

Positive feedback is supplied through R178 to Q162B gate to increase the open-loop gain and thereby reduce the input resistance of the Memory Amplifier. The Memory Amplifier has a slower risetime than the Post and AC Amplifiers. C160 at Q162A input gate lead accepts some of the charge from the AC Amplifier, temporarily storing it until the Memory Amplifier can respond.

A cycle of operation at sample time takes the following sequence:

- a. The Memory Gate drive pulse arrives at essentially the same time the Sampling Bridge is strobed into conduction.

## Circuit Description—Type 3S5

Propagation delay through the three AC coupled amplifiers is quite short. The CRT is blanked at the same time. (The fact that the Memory Amplifier input is always at zero volts, and the Memory Gate is balanced around zero volts, prevents any false changes in C184-C185 charge. Therefore, there is no change in the Memory Amplifier output voltage during the time the Memory Gate conducts ahead of the arrival of the AC Amplifier output signal.)

b. The AC Amplifier applies a pulse signal through R150-C150 and the Memory Gate to the Memory Amplifier input. C160 accepts some of the charge until the amplifier begins to respond, driving an equal and opposite current back to the input through the feedback capacitors.

c. Since the AC Amplifier output signal is applied to the Memory Amplifier "virtual signal ground" input, C150 receives about 10% of the total error signal charge before the Memory Gate stops conducting. Thus, as the AC Amplifier output returns to its quiescent voltage, the output side of C150 overshoots. The  $743\ \Omega$  (resistance of R151, 152, 153, 154 in parallel) of the Memory Gate discharges C150 well in advance of the next error signal.

If the Type 3S5 is displaying a single transition step over the full graticule with the display starting at the lower left and ending at the upper right, the error signal is very large during retrace. Such large error signals (even during random process sampling) apply a significant charge to C150. Then the overshoot at the end of the error signal pulse is large enough to cause one side of the Memory Gate to conduct, and remove some of the intended charge in the feedback capacitors. Two normally non-conducting clamp diodes prevent such undesired removal of memory charge. D153 and D154 help to discharge C150 if it receives too great a charge during the Memory Gate conduction time, thus preventing false amplitude displays. These two diodes do not conduct at any other time.

d. As the Memory Gate drive pulse ends, C160 charge is removed by the Memory Amplifier feedback. This causes the Memory output voltage to continue changing toward proper amplitude for a short period of time after the Memory Gate stops conducting. As soon as C160 charge is returned to normal, the output voltage remains fixed until the next sample.

The actual resting voltage at Q162 gate may not be precisely zero, but it is within a few millivolts of zero. Any deviation from zero can be due to several things: slight differences in conduction of the Memory Gating diodes; slight differences in resistance of the four Memory Gate biasing resistors; some small error signal being generated at each sample time even when the sampling head input signal is zero. Q162B gate voltage is adjusted over a small range to allow the above normal variations. Adjustment of Q162B gate voltage is called the Smoothing Balance adjustment, because it is set so there is no change in Memory Amplifier output when the forward attenuation or gain is changed. The Post Amplifier gain is changed (through the smoothing circuit) by changing the NORMAL/SMOOTH switch from one position to the other, or the equivalent by external programming. Whatever small zero-input error signal may exist in the system it always has an average value that will not alter the memory stored charge. Changing the forward attenuation or gain changes the peak amplitude of the residual error signal, but not its average voltage zero value. Therefore, Q162B gate voltage is adjusted to equal the

average voltage zero value of the residual error signal, and the trace does not move when changing the NORMAL-SMOOTH switch position.

Memory output voltage limits of about +10 and -10 are set by two diodes in parallel with the feedback capacitors. The diodes, D187 and D188 are reverse biased by 9 volts each. If the output tries to go more positive than about +10 volts, D188 conducts ( $9 + 0.6 = 9.6$  volts) reducing the amplifier gain to much less than 1. If the output tries to go more negative than about -10 volts D187 conducts, reducing the amplifier gain to much less than 1. The clamping diodes prevent the amplifier output transistors from saturating at the time of an overdrive signal, and thus assure fast response away from the clamped voltage at the next sample.

The amplifier contains two protective diodes that conduct only when a transistor is removed from its socket. D163 prevents Q162 source leads from having to withstand -100 volts when it is plugged into its socket while the power is on. D173 protects Q174 base-emitter junction in the event Q162 is removed from its socket while the power is on.

Temperature compensation of the amplifier is accomplished effectively by the source-coupled FET input amplifier and D176 and D177. The two identical halves of Q162 compensate each other so their total current does not change with temperature change. D176 and D177 have junction-drop temperature coefficients similar to Q181 and Q182 base-emitter junctions, and thus stabilize the output circuit.

The Memory Amplifier drives the front panel vertical output jack through a resistive attenuator that deliver 40% of the memory signal through  $10\ \text{k}\Omega$ . The jack is labeled A (or B) SIG OUT, 0.2 V/DIV,  $10\ \text{k}\Omega$ . The memory output signal drives the feedback attenuator circuit. The signal is the standard deflection signal mentioned in Section 3, 0.5 volt/CRT division. The memory also drives a  $1\times$  gain inverting amplifier (the Inverter) because the rest of the vertical amplifier stages (Channel Amplifier and Output Amplifier) invert the signal to the CRT.

### NOTE

The Memory output limits of  $\pm 10$  volts at 0.5 V/div equals 40 CRT divisions of display area, required to keep amplitude limiting off screen. The whole pulse amplifier chain is designed for full response and fast recovery so that on-screen displays have accurate deflection factors and DC Offset reference. Such operation provides accurate signals at the front panel Vert Output jacks, even through much of the signal is not displayed on the 8 division CRT.

**The Inverter Amplifier** is a temperature compensated DC coupled operational amplifier with a gain of 1. R194 and R190 (0.1% tolerance resistors) set the gain. Q190 and Q192 emitter-coupled stage provides both the temperature compensation and high internal gain. Q195 provides the inversion and positive offset so the input and output can both be at zero volts at the same time. Q195 collector has the same  $\pm 10$  volt operating range as the Memory output. L195 raises the load resistance during fast changes at sample time to limit the pulse current amplitude required of the -12.2-volt supply at Q195 emitter.

Protective components are D190 which conducts when Q195 is removed from its socket and protects Q190 base-emitter

junction from excessive reverse bias; D195 which conducts when Q192 is removed from its socket and protects Q195 base-emitter junction from excessive reverse bias; and C195 which stabilizes the amplifier against self-oscillation.

The Inverter drives the Channel Amplifier through the INVERT switch and the VARIABLE and Digital Gain controls.

## A and B Channel Amps

The two Channel Amplifiers are  $\times 2$  gain inverting operational amplifiers. The input circuit switching by the Vertical Mode switch disconnects the Units/Div VARIABLE controls, so that they are at maximum resistance at EXT PROG. The switch also connects the A signal into the B Channel Amplifier in the A+B position. The gain is adjusted by the Digital Gain control (with the Units/Div VARIABLE control at maximum resistance, and the Vertical Mode switch not in the A+B position) so that the output to the Digital Unit is the required 1 V/Div. A center-screen zero signal input produces an output of about +10 volts. The output voltage can swing through approximately a 20-volt range, corresponding to  $\pm 10$  CRT divisions.

The input summing point of both amplifiers is referenced at zero volts at the base of Q413 (Q433), Q413 biasing is set by D414. D414 also provides temperature compensation. The input signal divider network R401 (Units/Div VARIABLE control), R404 (Digital Gain control) and R405 in series with R407 to ground, divide the signal before it feeds through R408 (499  $\Omega$  input resistor) to the summing input point at Q413 base.

The Digital Gain control varies the series resistance of the divider network as does the Units/Div VARIABLE control. To use Auto Cal, disconnect R407 by removing the strap diagrammed directly above R407, and provide a remote resistor substituting for R407. Varying the external resistance above and below the value of R407 (from 7.9 k $\Omega$  to open circuit) changes the amplifier input current division and the amplifier gain is changed accordingly. A similar arrangement using R427 is provided in Channel B. See the Operating Instructions for additional information on Auto Cal.

Placing the Vertical Mode switch at A+B disconnects the A signal from the A channel Amplifier input and feeds it to the B Channel Amplifier through the A-B Bal control R430 and R431. Thus the A and B signal currents are combined at the B Channel Amplifier input current summing point, Q433 base. The B Channel Amplifier then provides the algebraic sum of the two signals at its output to the Output Amplifier and the Digital Unit.

Q413 is the inverting amplifier and Q418 is the current gain emitter follower output. When a positive signal overdrives the amplifier, both Q413 and Q418 turn on hard, and both transistors may saturate. With a negative drive signal overdrives the amplifier, Zener diode D417 and D416 limit Q418 emitter voltage to about +20.7 volts, stopping any increase in feedback current. Once the feedback current stops following the input current, the summing input point becomes a higher impedance and starts negative. Q413 is completely cut off. D418 catches its collector at 21.3 volts, and D405 catches its base at less than 1 volt. The amplifier remains in this condition until the negative overdrive ceases.

D405 and D406 limit the input signal drive to the amplifier. C413 slows the amplifier risetime, preventing high frequency

oscillations. D416 disconnects zener diode D417 until the diode is required to clamp a positive excursion at approximately +20 V.

## Output Amplifier

The Output Amplifier diagram contains circuits for three blocks of the complete block diagram: The Dual-Trace Multi, the Output Amplifier and the Position Lamp Driver.

**The Dual-Trace Multi** selects which Channel Amplifier drives the Output Amplifier. Dual Trace Multi operation is programmed by the Vertical Mode switch on the front panel. The Dual Trace Multi is actually a multivibrator when the Vertical Mode switch is placed in the DUAL-TRACE or EXT PROG position. At the other modes of operation, the Dual Trace signal is diode-disconnected, and only one of the two transistors may conduct. A conducting transistor takes the signal current of the channel not displayed, and a non-conducting transistor permits its associated channel to be displayed. Multi transistor Q450 controls Channel B, and Q455 controls Channel A.

The signals of the Channel Amplifiers are coupled to the digital output connector (P12) by L465 and L460. L465 and L460 prevent oscillation in the A and B Channel Amplifiers by isolating the capacitance load of the Digital Unit. The Channel Amplifier signals are also coupled into two grounded base amplifiers. These amplifiers share the collector load resistance of R463, R467 and R470 in parallel. Only one of the common base amplifiers (either Q461 or Q466) is connected to the collector load resistance at a time. The Output Amplifier diagram lists DC voltages for displaying Channel A.

Q450 conduction (controlled by the Vertical Mode switch set to CH A) forward-biases D461 so the Q461 collector voltage reverse-biases D462. This disconnects the Channel B signal from the Output Amplifier. Q455 non-conduction permits R459 to reverse bias D466. Thus Q466 collector current path is through D467 and the Channel A signal reaches the Output Amplifier input.

Dual-Trace operation forward biases D441 so the  $-50$  V to 0 V Dual-Trace Driver signal can reach the Dual-Trace Multi and switch it at each sample time. Each time a sample is taken, the Dual-Trace Multi changes states on the positive portion of the drive pulse. Each time the multi changes states, the Output Amplifier is driven by the other channel. The multi divides the sampling rate by two and delivers a Digital Intensified Zone Enable signal (up = logical ZERO at about +1 volt = CH A; down = logical ONE at about  $-1$  volt = CH B) to the digital unit from Q450 collector.

**The Output Amplifier** consists of the high gain stage Q477 and Q478, and a  $\times 1$  inverting amplifier Q487 and Q488. The high gain stage drives the inverter. Both circuits are DC coupled operational amplifiers with a common negative point at Zener diode D480.

Signals arrive from the common-base stages Q461 and/or Q466 and pass through the front panel GAIN control to the summing input at the base of Q477. The POSITION control also applies a DC signal to the same summing point, permitting positioning of the trace.

Signals are amplified by Q477 and given current gain by emitter follower Q478. (All four Output Amplifier transistors have  $BV_{CEO}$  ratings of 300 volts.) D479 connects Q477 collec-

## Circuit Description—Type 3S5

tor to the output if Q478 base falls faster than its emitter for fast full screen positive-going changes. Q478 emitter also drives the  $\times 1$  inverter input.

The inverter amplifier is identical to that just described, except that the gain is 1. D489 connects Q487 collector to the output if Q488 base falls faster than its emitter for fast full screen negative-going changes. Both sides of the Output Amplifier drive the Position Lamp Driver stage.

**The Position Lamp Driver** is a floating current switch that operates the two position-indicating neons on the front panel.

The average voltage at the CRT deflection plates is about +180 volts, which sets the total emitter current of Q495 and Q496 at 0.3 mA. When the two deflection plate voltages are equal, the two transistors share the 0.3 mA and both neons are lighted. If either deflection plate goes more positive than the other, the transistor on that side takes all the 0.3 mA and the other transistor cuts off. Each transistor has a  $BV_{CBO}$  rating of 85 volts, so R497 prevents the turned-off transistor collector from going all the way to +300 volts. The dark neon has some voltage across it, but not enough to cause it to glow. D492 and D493 assure that the two transistor base voltages are never more than 0.6 volt apart.

## Gate Generators

The Gate Generators diagram contains circuits for the Blocking Oscillator, Dual-Trace Driver, both Delay and Strobe Drivers and both Memory Gate Drivers. The Blocking oscillator starts the sampling process when driven by the sampling sweep unit.

Its output drives the two Delay and Strobe Driver circuits, and the Dual-Trace Driver circuit. The Dual-Trace Driver circuit drives the Dual-Trace Multivibrator and CRT cathode for interdot blanking of the display.

**The Blocking Oscillator** can be thought of as a risetime improving circuit. Q502 always delivers an output pulse of the same amplitude and risetime, regardless of variations that may occur in the drive pulse from the sampling sweep unit. The stage is a simple amplifier until T503 builds up enough positive feedback for regeneration. After regeneration, the circuit ignores the drive pulse shape, amplitude and energy content. Q503 is normally biased to cutoff, causing the output signal to go from +15 volts to ground each time it is driven. D502 disconnects T503 backswing pulse from Q503 and also makes certain T503 does not load the drive pulse.

**The Dual-Trace Driver** is a monostable multivibrator. Neither transistor conducts until driven. -12 volts is applied through L516 to R515 and R518, placing Q515 at zero bias. Q522 is reverse biased by the junction drop of D520 and current in R520.

A negative drive pulse from the Blocking Oscillator is coupled through R505, C505, and C513 to Q522 base. (D506 is reverse-biased 15 volts while Q515 is off, so it doesn't stop the drive pulse from reaching Q522). Q522 turns on hard and D519-C519 couples the drive to Q515 base. Q515 turns on and applies more drive to Q522. D506 turns on and keeps Q515 from saturating. Thus a heavy regeneration cause a 50 volt output pulse to drive both the Dual-Trace Multi and the CRT blanking circuit. C513 charges very rapidly, but C511 does not. C511 holds base drive current applied to Q522 for

a longer period. When C511 is charged, Q522 cuts off and its falling collector signal is AC coupled by C519 alone to Q515 base, turning it off. The turn-off is also regenerative with D520 limiting the reverse bias on Q522 and helping to recharge C513 for the next cycle.

**The Delay and Strobe Driver and Memory Gate Driver** circuits are unusual multivibrators. The A and B Channel circuits are identical except for R530, a power supply isolation resistor located between +15 volts and the B DELAY control. The Channel B circuit is explained below.

The complete circuit, from Blocking Oscillator output to the two pulse outputs, consists of: A two-diode comparator that compares a negative-going ramp with a fixed DC voltage variable by the Delay control; a very low-current amplifier that follows the Delay control voltage without affecting its output to the next stage; and a monostable multivibrator with two output terminals.

Quiescent circuit conditions are: Q538 base voltage rests between +15 and +11 volts, as set by the B DELAY control. Q538 current is limited to about 1 mA by R537 which leaves the collector clamped by D539 at -12.8 volts, assuring that there is no change in output voltage when the Delay control position is changed. Q541 is reverse biased 0.6 volt by D539 and Q555 is reverse biased 0.6 volt by current in D555, D552, R551 and the Memory Gate Width control. Q555 collector voltage is -12.2 volts.

As the Blocking Oscillator fires, R536-C536 form a negative-going ramp that soon causes D536 to conduct. When D536 conducts, the ramp turns on Q538. C537 contains enough charge for Q538 collector to clear D539 of carriers, and to forward bias Q541. As Q541 conducts, the negative signal is coupled through C541 and C543 back to Q538 base in a regenerative turn-on. The feedback signal also reverse biases D534 and D536 so as not to disturb the other channel Delay circuit.

The -27 volt signal from Q541 collector drives Q555 through C547 and C548. C548 couples a fast turn-on pulse to Q555 while C547 signal current reverse biases D552, allowing R553 to keep Q555 turned on. Q555 collector signal is coupled through R549 back to Q541 base and holds Q541 in steady conduction. R557 applies a steady 40 mA current to the Memory Gate transformer primary (T355) for the pulse duration of about 180 ns.

C543 regenerative turn-on to Q538 does not last as long as Q555 turn-on to Q541, but since Q541 is saturated, Q538 collector is not disturbed. The duration of Q555 conduction is therefore controlled only by the position of the Memory Gate Width control which adjusts C547 charge rate. The smaller the resistance, the shorter the gate duration. As C547 charges toward +15 volts, D552 again conducts and turns Q555 off, stopping the Memory Gate pulse and the drive to Q541 base. However, Q541 was in saturation, so it does not stop conducting immediately. Q541 collector signal rises positive about 350 ns after it is driven negative. This RC rise is slow and does not couple much energy through either C541 or C543. Q541 total negative step is coupled by C541 as a Strobe Drive pulse to the sampling head.

The sampling drive pulse from the sampling sweep unit is slewed in time from the initial trigger event for each sample. An additional time positioning is accomplished in the two Delay (ramp comparator) circuits. The additional time slewing of the strobe drives pulses requires an identical time slew-

ing of the Memory Gate drive pulses in order to maintain proper processing of the error signals into the Memory Amplifier. This is accomplished since the Memory Gate Driver is driven by the Delay and Strobe Driver.

## Programmed Offset

The Programmed Offset diagrams for each channel include the Offset Current Selector, Offset Amplifier, Offset Inverter, Electronic Switch and Polarity Decoder circuits. The offset circuits provide a DC voltage which is combined with the signal feedback voltage in the sampling head and applied to the sampling bridge. The circuit operates in two modes; external, with the Vertical Mode switch in the EXT PROG position; and internal, with the Vertical Mode switch in any other position other than the EXT PROG position.

In the external mode, the DC Offset voltage is externally programmed by external voltages or connections made to the proper pins of the front or rear program connectors. The program operates the Offset Current Selector block and the Polarity Decoder block. The Offset Current Selector circuit provides a programmed current to the Offset Amplifier. This current causes the Offset Amplifier to produce an output voltage from 0 to +9.95 volts in 0.05 volt increments. The voltage is fed to the Offset Inverter (a  $\times 1$  inverting amplifier) and the Electronic Switch circuits.

The Electronic Switch circuit, operated by the Polarity Decoder circuit, selects the positive (or the inverted negative) voltage which is coupled to the OFFSET out jack and to the sampling head.

In the internal mode, the Offset Amplifier block provides an analog voltage output with a range of  $-10$  to  $+10$  volts as set by the DC OFFSET control. The Polarity Decoder circuit operates the Electronic Switch circuit (Q677) to couple this output voltage to the OFFSET out jack and to the sampling head. The Offset Inverter circuit is not used in the internal mode. Also the Offset Current Selector circuit is not programmable in this mode, but does supply input current to the Offset Amplifier.

**The Offset Current Selector** circuit supplies a programmed current in the external mode to the Offset Amplifier. Each of the nine current selector transistor circuits supplies a different amount of current. The output currents are added through diodes to the Offset Amplifier summing input at Q633A base. In the external mode, each transistor can be turned on or off by the external program.

The mV of Offset voltage controlled by each input line is labeled at the left edge of diagram 8. For further programming information see the Operation Instructions, Section 3.

In external program, the Offset Current Selector circuit operates as follows (since both Channels are the same, only Channel A is described):

1. +15 volts is connected by the Vertical Mode switch to the emitter return resistors of Q602, Q610, Q616, Q620 and Q622. +3.6 volts is connected to the bases of Q604, Q608, Q614 and Q626 through decoupling resistor R638. Each transistor collector is connected to the Offset Amplifier summing input through a diode. Each transistor circuit can provide current for the Offset Amplifier circuit, but only when externally programmed to do so.

2. (Using the Q626 circuit as an example.) With a logical ONE at connector A of the logic card, D625 is forward biased by current in R625. This sets Q626 emitter at about +0.6 volt, cutting off Q626 (because its base voltage is at +3.6 volts). With Q626 off, R626 current forward biases D626. This applies the current into the Offset Amplifier summing input at Q633A base.

3. When terminal A of the logic card is left an open circuit (logical ZERO), D625 cannot conduct R625 current. Instead, Q626 is forward biased and its collector takes all of the R626 current away from D625 and the Offset Amplifier input.

4. The other transistors in the Offset Current Selector circuit operate as just described for Q626, except that the output current path is from the  $-50$  volt supply, and the current values are different due to different resistance values for the collector resistors. It is the sum of all currents out of the Offset Current Selector circuits that sets the final programmed DC OFFSET voltage. The accuracy of the current for the Offset Amplifier is affected by the collector resistors and the  $-50$ -volt supply voltage.

When the DC Offset is a front-panel controlled, the Vertical Mode switch connects emitter return resistors of Q602, Q610, Q616, Q620 and Q622 to ground. This reverse biases these transistors, since their bases are connected to decoupled +3.6 volts. With these transistors off, a current path is provided from the  $-50$  V supply through each collector resistor and coupling diode to Q633A base. This supplies a total of 2 mA to the Offset Amplifier summing point at Q633A base.

**Offset Amplifier.** The Offset amplifier is a DC coupled inverting (operational) amplifier consisting of Q633, Q642 and Q645. Both the input and feedback components differ in internal operation as compared to external programming of the DC Offset voltage. The input summing terminal is at the base of dual transistor Q633A. The output terminal is at the emitter of emitter follower Q645. Internal gain is very high due to large collector load resistors for both Q633B and Q642. The high gain assures that the variable current input is converted to a variable voltage output with very low output resistance.

Internal operation connects R648 and the Offset Zero control as one of the input elements to the amplifier, and the DC OFFSET control (R647) is a variable resistance feedback element.

Externally programmed control of the Offset output voltage connects various resistors of the Offset Current Selector circuits as the input elements, and R646 as the fixed resistance feedback element.

Output voltage swing is from  $-10$  to  $+10$  volts when internally controlled, and from 0 V to +9.95 V when externally programmed. The two different voltage ranges require that the high gain input comparator amplifier, Q633, operate at different reference voltages for the two modes of operation. The reference voltage is applied to the base of Q633B, and is  $-10$  V for internal operation, and ground for externally programmed operation. The base voltage is only 10% of the total emitter return supply voltage ( $-100$  V) which limits the stage current change between the two conditions to only 10%.

Internal operation uses a fixed input current to Q633A base circuit summing input through R648. The output voltage is a function of Ohm's law and the same value of current through the variable DC OFFSET control, R647. Assume

## Circuit Description—Type 3S5

R647 is zero ohms (fully clockwise at Black scale =  $-10$  V Offset). Whatever the current value through R647, zero ohms causes zero volts difference between the amplifier summing input and the output at Q645 emitter. Since Q633A base is at  $-10$  V, the output is also at  $-10$  V. Turning the DC OFFSET control so it introduces resistance in the feedback path causes the output voltage to change in a positive direction. By the time the control is fully counterclockwise, the feedback current and the resistance cause the output at Q645 emitter to be at  $+10$  V.

Externally programmed operation uses a fixed feedback resistor and different amounts of input current as selected by the Offset Current Selector circuits and the external program. R646 is the fixed feedback resistor, and even through the front panel DC OFFSET control is not completely disconnected, its current load on the output does not alter the output voltage as controlled by the feedback amplifier. The reference voltage for external control at Q633B base is ground. With all the input resistors connected to a negative voltage, it is not possible to program an output voltage that passes through zero and changes polarity. Thus, the Offset Inverter  $\times 1$  gain amplifier is used when a negative Offset output voltage is required. Protection diodes are D634, D641, D643 and D645.

C647 connected across the DC OFFSET control minimizes the effect of wiper contact noise on the output voltage when the control setting is changed. C634 prevents AC pickup in the Vertical Mode switch lead by providing a low impedance to ground for any AC signals at Q633B base.

**The Offset Inverter Amplifier** is a temperature-compensated DC coupled amplifier with a gain of 1. Feedback resistor R660 and input resistor R650, both 0.1% tolerance resistors, set the gain. Q653 dual-transistor is an emitter-coupled stage providing both temperature compensation and high internal gain. Q658 operates as an inverting amplifier feeding Q660 emitter follower output circuit.

Any input voltage other than zero causes a current in the input resistor R650. Any change in Q653A base voltage changes Q653B collector voltage to Q658 base in the same direction. Q658 amplifies and inverts the signal, applying it to Q660 emitter follower. Q660 voltage output produces an equal and opposite current to Q653A base, making the output voltage equal and opposite to the amplifier input voltage.

Two diodes provide protection when transistors are removed from their sockets. D658 conducts when Q658 is removed. D657 conducts when Q653 is removed. R657 and C657 comprise a decoupling network in Q658 emitter circuit.

**The Electronic Switch** circuit operates during external programming as a single pole double throw switch consisting of field effect transistors Q663 and Q677. One transistor is on while the other is off as set by the Polarity Decoder circuit. The transistor drain leads are connected together (TP663) to provide whichever polarity output voltage is desired by the external program. When Q677 is on, it connects the Offset Amplifier output voltage (0 to  $+10$  V) to the output circuits. When Q663 is on, it connects the Inverter Amplifier output voltage (0 to  $-10$  V) to the output circuits. Conduction of either transistor is set by the Polarity Decoder circuit.

**The Polarity Decoder** circuit operates the two transistors Q663 and Q677 in the Electronic Switch circuit, turning one transistor on while holding the other off.

The circuit holds Q677 on (exclusively) during internal operation. Q670, Q673 and Q675 are the decoder transistors. An external program that places a logical ONE at the front panel connector J15 pin 4 will cause the Decoder circuit to turn Q663 off and Q677 on. See the Operating Instructions for programming this circuit through the rear panel connector.

An external program of a logical ONE to the Decoder input causes D667 to conduct R657 current. Then R668 and R669 forward bias Q670 into saturation. R670 turns Q673 on to saturation, placing Q663 gate lead at about  $-25$  V and assuring that it remains cutoff. Q673 collector voltage also reverse biases Q675, causing R675 to reverse bias D676 and set Q677 gate lead at zero bias, turning Q677 on.

An external program of a logical ZERO to the Decoder input reverses the conditions, causing Q663 to conduct and Q677 to be at cutoff. At that time, D674 reverse biases, and prevents Q673 high collector voltage from overdriving Q675 base circuit. D675 in Q675 emitter circuit provides an equal junction drop to that of D674, assuring that Q675 can be placed at cutoff when the external program is a logical ONE.

## Power Supplies

The Power Supply diagram contains the internal power supplies, power connections from the indicator oscilloscope and power connections to the sampling heads. Power from the indicator oscilloscope enters through P11 at the left edge of the diagram. P11 also shows pin connections to other circuits within the Type 3S5.

Internal power supplies obtain power from the indicator oscilloscope at 6.3 VAC, and from the  $-12.2$ -volt,  $+125$ -volt, and  $-100$ -volt, supplies. The 6.3 VAC is fed to T950 primary. T950 secondary windings feed the  $+15$ - and  $+3.6$ -volt supplies.

**The  $+15$ -Volt Supply** is fed from T950 secondary winding at terminals 5, 6 and 7. The secondary voltage of approximately 52 VAC is rectified by D951-D953, filtered by C950, and regulated by D955, Q957, Q959, Q966 and Q969. The regulator circuit is of the series type, with Q969 the series pass (variable resistance) transistor. Q957 and Q959 form a temperature compensated comparator circuit, and Q966 inverts and amplifies the comparator output which controls Q969. The output voltage is compared with the reference Zener diode D955. Current reduction in Q966 causes Q969 base and emitter to go more negative. Or more properly stated, Q969 increases its series resistance so the load current increases the voltage across it, restoring the output to its proper value.

If the  $+15$ -volt supply is accidentally shorted to ground excessive current through R951 and R953 will cause these resistors to overheat and open up, protecting Q969, the rectifiers and the transformer.

**The  $-50$ -Volt Supply** consists of the comparator, Q901-Q907, and shunt regulator Q903. (The  $-50$ -volt supply is one of two voltage references for the  $+50$ -volt supply).

The supply changes the resistance of Q903 to take more current when the load current reduces, and to take less current when the load current increases. D905 protects Q903 from damage in the event the output is shorted to a voltage more positive than  $-12.2$  volts.

Comparator transistors Q901-Q907 compare a voltage near ground at the junction of R908-R909 with zero volts at ground. If the output load current increases (output voltage goes positive), Q907 base and emitter follow the change. Q907 emitter drives Q901 emitter positively, which is an increase in forward bias and turns Q901 on harder. Q901 collector voltage change decreases Q903 turn-on bias. Increasing Q903 resistance and permitting a negative return in voltage at the supply output.

**The +50-Volt Supply** uses one transistor as an emitter follower and the other transistor as both a comparator and as the shunt regulating element. R917-R918 presents a voltage near +15 volts to the base of emitter follower Q911. Q911 provides current gain to the signal and applies it to the base of comparator-regulator transistor Q915.

If the output load current increases (voltage goes negative), Q911 emitter takes Q915 base negative, reducing Q915 current. As Q915 current reduces, the output voltage rises back to its proper value.

A short circuit that places the +50-Volt line less positive than +15 volts will reverse-bias D915 and protect Q915 from damage. The large resistance value of R917 and R918 protects Q911 from damage. A short circuit on the -50-Volt line will cause the +50-Volt output to be a few volts low. Again, no transistors will be damaged.

**The +3.6-Volt Supply** is fed from TP950 secondary connections 3 and 4. The secondary voltage of approximately 6.7 VAC is rectified by the bridge rectifier D930A-B-C-D, filtered by C931 and fed to the output through Q938. Q936 emitter follower controls Q938. R933 and R934 set Q936 base at +3.6 volts. Through equal and opposite base-emitter junction drops of Q936 and Q938, the output voltage is +3.6 volts. The circuit transforms the input impedance at Q936 base to less than one ohm at Q938 emitter, so load changes do not significantly affect the output voltage.

**The -25-Volt Supply** is fed from the -100-Volt Supply of the indicator oscilloscope through R946 and Q944 emitter follower. R941 and R942 set Q944 base at about 25.6 V, which provides a low impedance -25 volts output at Q944 emitter. R946 limits the current from the -100-volt supply and limits power dissipation in Q944.

### Card Connectors and Decoupling Networks

The Card Connectors and Decoupling Networks diagram contains the Offset and Logic Card connectors, and the power supply decoupling networks on the Output and Vertical boards.

The Offset card connector J600 and the Logic Card connector J800 show the signal contained at the pin, and the number of the schematic where it can be found.

Decoupling networks are drawn within outlined areas that represent particular diagrams already described.

### Vertical Mode Switch and Program Connectors

The Vertical Mode Switch and Program Connectors diagram contains information on the Vertical Mode Switch, the front and rear external program connectors and the digital readout connector.

All of the Vertical Mode Switch connections are shown with references to the other schematic diagrams where sections of the switch are shown. Each section or wafer of the switches is coded to indicate its position in the switch assembly. The numbered portion of the code refers to the wafer number counting from the front (the mounting end of the switch) toward the rear. The letters F and R indicate whether the front or rear of the wafer performs the particular switching function.

# SECTION 5

## DIGITAL UNIT CONTROL DESCRIPTION

Change information, if any, affecting this section will be found at the rear of the manual.

### General Information

This section of the manual describes the circuits and logic of the Type 3S5 Digital Unit Control diagram. A logic diagram titled Digital Unit Control Logic is included at the back of the manual following the Digital Unit Control diagram.

The Digital Unit Control circuits operate exclusively to program the readout logic circuits of a Tektronix digital unit, either a Type 230 or a Type 6R1A. The Type 3S5 controls the digital unit only when it is programmed by the digital unit. The type of units (either volts or amperes) programmed into the digital unit is in agreement with the type of sampling head installed in the Type 3S5.

Description of the Digital Unit Control circuit is separate from the description of other Type 3S5 circuits. This is because the Digital Unit Control circuits do not contribute to the Type 3S5 operation. Only the Type 230 or Type 6R1A Digital Units use the Digital Unit Control outputs. All outputs pass out the rear of the Type 3S5, through P12, through the oscilloscope (either a Type 568 or Type 567), and into the associated digital unit.

Three types of signal sources control the circuit functions: (1) the deflection factor selected by either the front panel Units/Div switch or an external program, (2) the sampling head units (Volts or Amps) and its units decade (multiplier:  $\times 0.1$ ,  $\times 1$  or  $\times 10$ ) and (3) the digital unit amplitude measurement program. If the digital unit is programmed to make a time measurement, all of the Digital Unit Control outputs are inhibited. If the digital unit is programmed to make an amplitude measurement, the Digital Unit Control circuits function as instructed by the other two sources.

#### NOTE

Both the Digital Unit Control circuit diagram and its Digital Unit Control Logic diagram include logic symbols. Logic symbols used are based on ASA Y32.14-1962 Standards, and are drawn using negative logic symbols only.

Three types of outputs control the digital unit: 1) the type of units, Volts or Amps, 2) the readout number decimal point, including an "M" for mV or mA and 3) the digital unit counter circuit divide command (see the digital unit instruction manual for use of the counter divide outputs).

All input and output lines are considered to be a logical ONE when grounded, and a logical ZERO when left open circuit. (Grounding is accomplished in both cases by saturating transistors in the digital unit, saturating transistors at the Digital Unit Control output leads, and by solid ground connections by the Units/Div switches.)

### Block Diagram

The main Block diagram includes the Digital Unit Control blocks at the lower left corner. Each block name agrees with

areas outlined on both the Digital Unit Control diagram and the Digital Unit Control Logic diagram. The general layout of all blocks on all three diagrams is the same, with input lines at the left and output lines at the right.

Comparing the block diagram to the Digital Unit Control Logic diagram during the following block description may prove useful in understanding the Digital Unit Control circuits. The eight blocks of the Digital Unit Control circuits show that the input lines from both CH A and CH B are always connected, but that only one set of output lines drives the digital unit circuits. Two pairs of channel selection lines from the digital unit tell the Digital Unit Control circuits which channel is being used. One pair carries the channel selection instructions for the decimal and units output, and the other pair carries the channel selection instructions for the digital unit counter divide output. When the digital unit is programmed to make an amplitude measurement, one of each pair of channel select lines is grounded. If the measurement is being made on Channel A, the three input sources from Channel B are inhibited by the digital unit grounding the "A, D, U, GND" and "A  $\div$  GND" lines. When the digital unit is programmed to make a time measurement, none of the channel select lines is grounded, and all outputs are inhibited.

#### NOTE

This description does not indicate the point from which digital unit programming originates. The circuits in the Type 3S5 operate the same whether the digital unit is externally programmed or controlled from its own front panel. However, externally programming the Type 3S5 does make the plug-in's circuits operate in a slightly different manner than controlling it from the Type 3S5 front panel. Front panel control of the Type 3S5 permits the VARIABLE control CAL switches to inhibit the decimal and units section of the Digital Unit Control circuits; externally programming the Type 3S5 causes both the VARIABLE control and its CAL switch to be removed from operation, so that turning the control will neither affect the CRT deflection factor, nor inhibit the decimal and units outputs.

Input lines from the Units/Div switches are labeled A1, A2 and A4, and B1, B2 and B4. The Units/Div lines are grounded according to Truth Table 5-1. The 1's digit and the 2's digit lines go to both the 200 UNITS/DIV DECODER block and the COUNTER DIVIDE CONTROL block. Output from the 200 UNITS/DIV DECODER block is a logical ONE only when 200 Units/Div is programmed. Output from the 10, 5, 2 UNITS/DIV DECODER block is a logical ONE only when the 10, 5 and 2 Units/Div deflection factor is programmed. Outputs from the COUNTER DIVIDE CONTROL block are logical

## Digital Unit Control Description—Type 3S5

ONE according to Table 5-1; only one output line is a logical ONE at any particular time and the other two lines are then a logical ZERO.

**TABLE 5-1**

Units/Div Truth Table

Units/ Div	A4 B4	A2 B2	A1 B1	÷ *
200	0	0	0	5
100	0	0	1	1
50	0	1	0	2
20	0	1	1	5
10	1	0	1	1
5	1	1	0	2
2	1	1	1	5

\*÷ = Output line at Logical 1.

### NOTE

Logical 1 means the line is grounded. Logical 0 means an open circuit; not grounded.

Two other input line pairs (to the Digital Unit Control circuits) come from the sampling heads. One pair, to the UNITS CONTROL block gives instruction to the digital unit to indicate that the readout units are either Volts or Amperes. The other pair, to the UNITS/DIV MULTIPLIER DECODER block gives instructions regarding the sampling head deflection factor in relation to the Type 3S5 Units/Div control. The sampling head may require the the numbers around the Units/Div switch be multiplied by  $\times 0.1$ ,  $\times 1$  or  $\times 10$ , indicating the need for a decimal shift in the digital unit readout. The Units/Div multiplier instructions are ternary (three levels) rather than binary (two levels) as are all the other instructions given.

Both the UNITS CONTROL and the UNITS/DIV MULTIPLIER DECODER blocks receive information from both Channel A and Channel B. These blocks use the Channel Select lines from the digital unit to inhibit information from the channel not in use.

Included in the UNITS/DIV MULTIPLIER DECODER block is a Ternary to Binary decoder that converts one-line ternary information to three-line binary information at the lines labeled  $\times 0.1$ ,  $\times 1$  and  $\times 10$ .

Outputs from all four of the Units/Div Decoder blocks feed the DECIMAL CONTROL block. The DECIMAL CONTROL block decodes both the Units/Div number programmed and the sampling head Units/Div multiplier to operate the digital unit decimal neon and the "milli" M readout lamp. The M control line is part of the Decimal Control block because lighting the M (for "milli") affects the location of the readout decimal.

## Logic Voltages

Negative logic is used throughout this manual to describe the operation of Type 3S5 circuits. By the standards of negative logic, a TRUE state, or logical ONE (1) exists at a lead which is at or very near ground. A FALSE state or logical ZERO (0) is present at an open-circuit lead or one more positive with respect to ground. External control line voltage limits are stated in Section 1, Specification, to be logical

ONE (TRUE) 0V to +2V; logical ZERO (FALSE) +6V to +15V or open circuit. Externally controlled logic lines can be operated either by saturating transistors that do not completely ground the line, or by using cut off transistors that exhibit some  $I_{CBO}$  leakage and do not really leave the line open.

Voltage levels of logic states produced within the Type 3S5 are different than the voltage levels of logical ONES or ZEROS in externally controlled logic. This results because the principal voltage supply for integrated circuits in the Type 3S5 is +3.6 volts rather than +15 volts.

Output voltage limits for a logical ONE or ZERO may also vary because those limits are set by the digital unit in use. However, it can be noted that a logical ONE is always accomplished by a saturated transistor.

Internal logic voltages that relate to the intergrated circuits are stated at the bottom of Fig. 5-1. Other voltage values such as the ternary voltages out of the Units/Div Multiplier Decoder are given later on in this section.

Logic states throughout the Digital Unit Control Logic diagram (without giving the voltage values) are included in the four truth Tables 5-2, 5-3, 5-4 and 5-5. The first three truth tables give the output logic states of all significant gates for three conditions of a sampling head Units/Div multiplier,  $\times 0.1$ ,  $\times 1$  and  $\times 10$ . The truth tables are of primary value when searching for a failure.

Control settings for using the first three truth tables are: the digital unit operating to make a Channel A amplitude measurement; the sampling head multiplier as stated at the top of the Table; the Units/Div as stated at the left of the Table; and if not externally programming the Type 3S5 the Units/Div VARIABLE control at CAL. The tables also apply to Channel B if all controls are properly set for an amplitude measurement on Channel B.

Table 5-5 applies to the circuits of the Counter Divide Control block, and is altered only by the Units/Div switch(es). If not externally programming the Type 3S5, the Units/Div VARIABLE control must be at CAL.

## Digital Unit Control Logic Diagram

Fig. 5-1 is a key to the logic symbols used in the Digital Unit Control Logic Diagram. If you are not experienced with logic symbols, it is recommended that this area of the Logic Diagram be read after reading the circuit description later in this section.

Symbols in the lower portions of Tables 5-2, 5-3, 5-4 and 5-5 differ slightly from the symbols on the Logic Diagram. Specifically, the column headed "M Q806" has a 3 input NAND gate symbol with a logic negation at one input. This symbol is equivalent to a group of symbols on the Logic Diagram: U805B inverter; R804, R805 and R806 3 input AND gate; and the (non-inhibited) 2 input NOR gate Q806, D806. The logical ONE in this column indicates that Q806 is saturated and the digital unit M lamp will be lighted. A second symbol difference includes the logic symbols leading to and including the DEC 3 column. Q839 is shown in a manner that ignores D839. This is justified by the fact that there will be output only when the last gate is not inhibited. The truth tables, and the symbols used, do not apply when the digital unit inhibits the outputs.

TABLE 5-4  
Decimal & M Output Logic States When Units/Div Multiplier = X10

All symbols used in this manual are negative logic symbols, regardless of the "active" state of the input or output lines. This applies even to the logic symbols on the circuit diagram. Thus, the function of any gate can be defined independently of the circuits intended function, and all symbols on the circuit diagram or Logic diagram have truth tables found in Fig. 5-1.

Abbreviations on the diagram include D for Decimal; U signifying Unit; GND, ground;  $\bar{A}$ , Not A; and CH, channel.

**Logic Symbols**

The logic symbols used in the Type 355 are presented in diagram form below. The sequence relates to Fig. 5-1 in a right-to-left and top-to-bottom sequence.

**1 Input, 1 Output Non-Inverter**

(High Z to Low Z, or voltage changing)

**1 Input, 1 Output Inverter**

**2 Input AND Gate**

Both input leads must be grounded for the output to be at a logical 1.

**2 Input NAND Gate**

If either input is pulled up to a logical ZERO, the output will be at a logical ONE. Both inputs must be at ONE for the output to be at ZERO.

1/2  $\mu$ L914

**2 Diode OR Gate**

Either input at ONE makes the output at ONE.

**2 Transistor NOR Gate (Inverting)**

Neither input at ONE; output is at ONE.

10	0	1	1	1	1	0	1	0	0	1	1
5	1	0	0	0	0	1	1	1	0	0	2
2	1	1	0	1	1	1	0	0	1	0	5

standing the relationship between formal block diagram, circuit diagram and logic diagram. The block shown in Fig. 5-2 is the 10, 5, 2 UNITS/DIV DECODER.

To program the 10, 5, 2 UNITS/DIV Decoder circuit for a channel A measurement,  $\bar{B}$  is grounded. ( $\bar{B}$  is the line labeled on the schematic diagram as A: D, U, GND.) At the same time, the  $\bar{A}$  (not A = B: D, U, GND) line must be at a logical

ZERO. This leaves only one line into the decoder circuit, the A4 line, which can affect the output at Q814 collector.

If A4 is a logical ZERO, R807 reverse-biases Q812. Q812 at cutoff lets R813 apply forward bias to Q814, saturating Q814. The circuit output is then a logical ZERO in agreement with the logical ZERO at the A4 input. This operation then agrees with the statement earlier in the block diagram

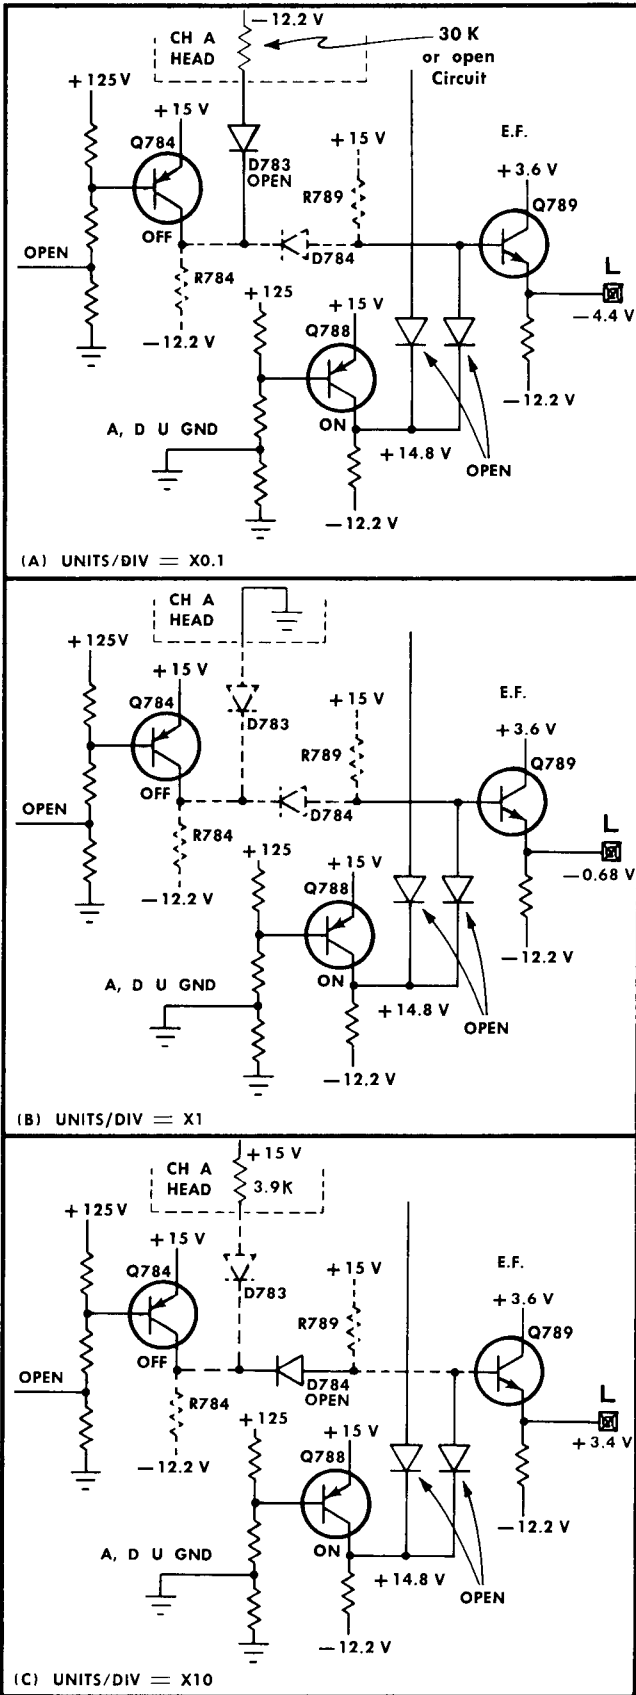

Fig. 5-3. Units/Div Multiplier Decoder circuit showing the ternary voltages for  $\times 0.1$ ,  $\times 1$  and  $\times 10$  Units/Div multipliers of the sampling head.

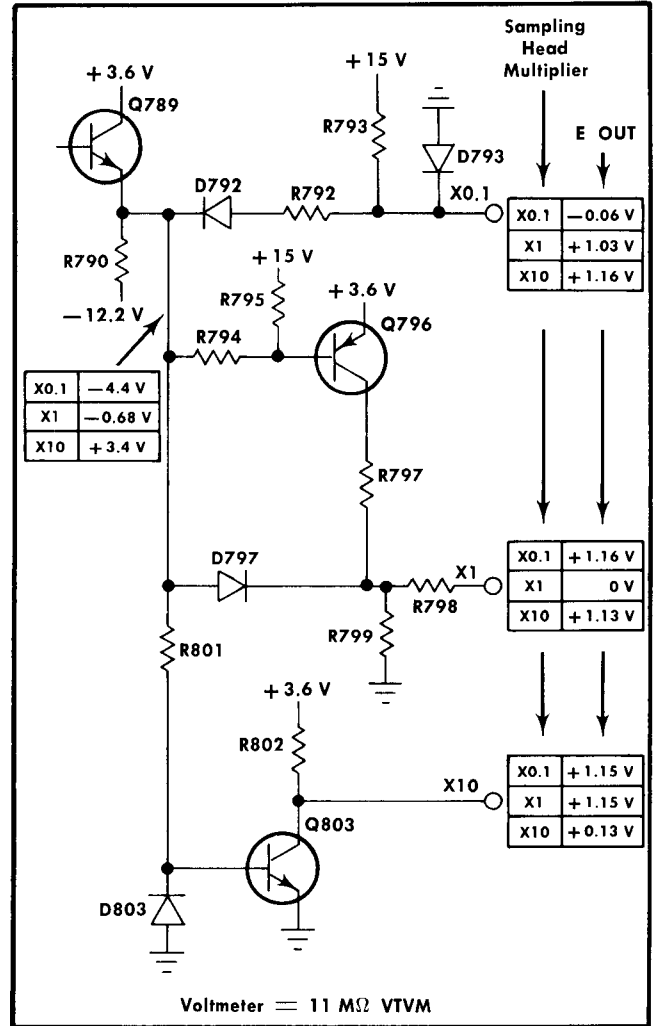

Fig. 5-4. Ternary to Binary Decoder circuit voltages.

description, that the 10, 5, 2 UNITS/DIV DECODER output is a logical ONE only when 10, 5 or 2 UNITS/DIV is programmed. Table 5-1 shows that the A4 (or B4) line is a logical ONE at only 10, 5 and 2 Units/Div.

No other logic circuit will be detailed, but the simple principles stated for Fig. 5-2 apply through the rest of the Decimal Unit Control circuits that can be diagrammed into logic symbols.

Analog circuits of the Type 355 Digital Unit Control circuit are in the UNITS/DIV MULTIPLIER DECODER block. These are described in detail.

### Units/Div Multiplier Decoder

The Units/Div Multiplier Decoder circuits (outlined on both the schematic and logic diagrams) consists of a Channel Select circuit and a Ternary to Binary Decoder. A secondary function of the Channel Select circuit is to limit the amplitude of the  $\times 0.1$  and  $\times 10$  Units/Div multiplier signals from the sampling head to voltage values usable at the Ternary to Binary Decoder. The multiplier signal for  $\times 1$  Units/Div is not limited, but is instead a ground connection in the sampling head.

Fig. 5-3 shows the circuit changes to the input circuits of the Units/Div Multiplier Decoder for the three sampling head multiplier settings. The Channel Select portion is shown, including the current paths and output voltages for  $\times 0.1$ ,  $\times 1$  and  $\times 10$  multiplier conditions. Output voltage is controlled within the Channel Select circuit for both the  $\times 0.1$  and  $\times 10$  condition. For the  $\times 1$  condition, output voltage is determined by the ground connection in the sampling head. Thus, the circuit does not depend upon a stable current source from the sampling head except at the  $\times 1$  condition.

**Ternary to Binary Decoder**

Fig. 5-4 shows the Ternary To Binary Decoder circuit with input and output voltages. This part of the circuit is similar to the channel select section, in that they both translate certain input voltage values to other output voltage values. Component conduction conditions that generate (translate) the output voltages are listed in Table 5-6.

**TABLE 5-6**

**Ternary to Binary Conduction Paths**

Units/Div MULT	Electron Path
$\times 0.1$	Logical 1 —4.4 V at Q789 emitter, through D792, R792 and D793 to give —0.06 V at $\times 0.1$ out.
	Logical 0 —4.4 V at Q789 emitter saturates Q796. R797-R798 current into load drops Q796 collector voltage to +1.16 V to $\times 1$ out.
	Logical 0 Q803 is at cutoff. Current in R802 and load gives +1.15 V at $\times 10$ out.
$\times 1$	Logical 0 —0.68 V at Q789 emitter causes electron current in D792-R792-R793 to set +1.03 V at $\times 0.1$ out.
	Logical 1 R794-R795 reverse-bias Q796. No current in R797-R798 gives 0 V at $\times 1$ out.
	Logical 0 Q803 still at cutoff. Current in R802 and load gives +1.15 V at $\times 10$ out.
$\times 10$	Logical 0 +3.4 V at Q789 emitter reverse-biases D792. R793 current into load gives +1.15 V at $\times 0.1$ out.
	Logical 0 D797 conducts. Current in R798 and load gives +1.13 V at $\times 1$ out.
	Logical 1 Q803 saturates to give +0.13 V at $\times 10$ out.

**OUTPUTS TO DIGITAL UNIT**

**Decimal Control**

All Units/Div Decoder and Units Multiplier Decoder signals are processed by the Decimal Control circuits as two-

level binary logic. The 10, 5, 2 Units/Div Decoder, the 100, 50, 20 Units/Div Decoder, and the 200 Units/Div Decoder each feed two dual-input NAND gates of the Decimal Decoder. The  $\times 0.1$ ,  $\times 1$  and  $\times 10$  input lines inhibit one gate of each pair of gates, allowing each Units/Div decoder to control only one decimal. Actually, only Decimal 4 and Decimal 5 are controlled by the decoders because the 200 Units/Div Decoder is combined with the 100, 50, 20 Units/Div Decoder output. Thus there are only two Units/Div categories controlling Decimal 4 or Decimal 5 (200, 100-50-20 and 10-5-2). Decimal 3 is programmed only when Decimal 4 or Decimal 5 are not asked for (by the combination of Units/Div decoders and Units multiplier). Table 5-7 identifies the category control in the columns marked 6R1A; the Type 230 modifies the Decimal Control outputs when it receives a  $\div 5$  command from the Counter Divide Control circuits.

Use Tables 5-2, 5-3 and 5-4 if the circuits require maintenance. Set the digital unit controls for an amplitude measurement and use an 11 M $\Omega$  VTVM to check for proper gate voltages. Voltage values for the truth tables are given at the bottom of Fig. 5-1.

**Units Control**

The Units Control block contains logic-type circuits that cause Q855 to conduct (for Volts) when the sampling head input logic line is at a logical ONE. Q857 conducts (for Amps) when the sampling head input line is at a logical ZERO (+15 volts through 30 k $\Omega$ ). This simple mode of operation is possible whenever one of the digital unit D, U GND lines is at a logical ONE. If both D, U GND lines are at a logical ZERO, the output tries to program Volts, but the D, U INHIBIT signal from Q859 makes both outputs a logical ZERO. Both D, U GND lines will be at logical ZERO when the digital unit is programmed to make a Time measurement.

**Counter Divide Control**

All states of the Counter Divide Control block are shown in Table 5-5. The circuits are not described. Use the truth table of Table 5-5, and the voltages at the bottom of Fig. 5-1 when servicing the circuits.

**Outputs Summary**

Table 5-7 lists all the Digital Unit Control circuit inputs and outputs (except the V or A units) in summary form related to the digital unit readout display. Both the Type 6R1A and Type 230 Digital Unit are listed because the Type 6R1A takes the outputs and uses them directly while the Type 230 interprets them internally. On a decimal output line that is a logical ZERO, a Type 6R1A will place the output voltage at about +105 V and a Type 230 will place the output voltage at about +6 or +8 volts. The Units Mult column of Table 5-7 indicates whether the digital unit "M" lamp is lighted.

Both digital units contain 5 decimal neons; however, the Type 6R1A contains 5 number readout lamps, while the Type 230 contains 5 number readout lamps and one polarity readout lamp. Table 5-8 identifies the lighted decimal neon in each of the two digital units.

**Digital Unit Control Description—Type 3S5**

Another difference between the two digital units is the way the decimal and units lamps respond to an uncalibrated VARIABLE control when the Type 3S5 is front-panel controlled. All decimal and units lamps extinguish in a Type 6R1A when the VARIABLE control is turned from its CAL detent position. In a Type 230, the units lamps go out, but the decimal neons shift around in a random manner, depending upon the position of the Units/Div switches. This is normal.

**TABLE 5-7**

# SECTION 6

## MAINTENANCE

Change information, if any, affecting this section will be found at the rear of the manual.

### Introduction

This section of the manual contains maintenance information for use in preventive maintenance, corrective maintenance or troubleshooting of the Type 3S5.

### PREVENTATIVE MAINTENANCE

#### General

Preventative maintenance consists of cleaning, visual inspection, lubrication, etc. Preventive maintenance performed on a regular basis will help prevent instrument failure and will improve reliability of this instrument. The severity of the environment to which the Type 3S5 is subjected will determine the frequency of maintenance.

#### Cleaning

The Type 3S5 should be cleaned as often as operating conditions require. Accumulation of dirt in the instrument can cause overheating and component breakdown. Dirt on components acts as an insulating blanket and prevents efficient heat dissipation. It also provides an electrical conduction path.

The top and bottom covers of the 560-series instruments into which the Type 3S5 fits, provide protection against dust in the interior of the instrument. Operating without the covers in place will require more frequent cleaning.

#### CAUTION

Avoid the use of chemical cleanings agents which might damage the plastic used in this instrument. Some chemicals to avoid are benzene, toluene, xylene, acetone or similar solvents.

**External.** Loose dust accumulated on the outside of the Type 3S5 can be removed with a soft cloth or small paint brush. The paint brush is particularly useful for dislodging dirt on and around the front-panel controls. Dirt which remains can be removed with a soft cloth dampened in a mild solution of water and detergent. Abrasive cleaners should not be used.

**Interior.** Dust in the interior of the instrument should be removed occasionally due to its electrical conductivity under high-humidity conditions. The best way to clean the interior is to blow off the accumulated dust with dry, low-velocity air. Remove any dirt which remains with a soft paint brush or a cloth dampened with a mild detergent and water solution. A cotton-tipped applicator is useful for cleaning in narrow spaces on circuit boards.

#### Lubrication

The reliability of potentiometers, rotary switches and other moving parts can be increased if they are kept properly lubricated. Use a cleaning-type lubricant (such as Tektronix Part No. 006-0218-00) on switch contacts. Lubricate switch detents with a heavier grease (such as Tektronix Part No. 006-0219-00). Potentiometers should be lubricated with a lubricant which will not affect electrical characteristics (such as Tektronix Part No. 006-0220-00). Do not over-lubricate. A lubrication kit containing the necessary lubricants and instructions is available from Tektronix. Order Tektronix Part No. 003-0342-00.

#### Visual Inspection

The Type 3S5 should be inspected occasionally for such defects as broken connections, improperly seated transistors, damaged circuit boards and heat-damaged parts.

The remedy for most visible defects is obvious; however, care must be taken if heat-damaged parts are located. Overheating is usually only a symptom of trouble. For this reason, it is essential to determine the actual cause of overheating before the heat-damaged parts are replaced; otherwise the damage may be repeated.

#### Recalibration

To assure accurate measurement, check the calibration of this instrument after each 500 hours of operation or once every six months.

#### Parts Identification

**Identification of Switch Wafers.** Wafers of switches shown on the circuit diagram are numbered from the first wafer located behind the detent section of the switch to the last wafer. The letters F and R indicate whether the front or the rear of the wafer is used to perform the particular switching function. For example, the designation 2R printed by a switch section on a schematic identifies the switch section as being on the rear side of the second wafer when counting back from the front panel.

**Wiring Color Code.** The wiring in the Type 3S5 is color coded to facilitate circuit tracing. In the case of power-supply leads, the color code indicates the voltage carried, with the widest stripe denoting the first significant figure. Table 6-1 lists the color combinations and the voltages indicated by the colors.

**Resistor Coding.** The Type 3S5 uses a number of vary stable metal film resistors identified by their gray background color and color coding.

Fig. 6-1. Resistor and ceramic capacitor color code.

If the resistor has three significant figures with a multiplier, the resistor will be EIA color coded. If it has four significant figures with a multiplier, the value will be printed on the resistor. For example, a 333 kΩ resistor will be color coded, but a 333.5 kΩ resistor will have its value printed on the resistor body.

The color-coding sequence is shown in Fig. 6-1.

TABLE 6-1

Power Supplies Wire Color Coding

Supply	Color Code
-100 V	Brown-Black-Brown on Tan
-50 V	Green-Black-Black on Tan
-25 V	Blue-Black-Black on Tan
-12.2 V	Brown-Red-Black on Tan
+3.6 V	Orange-Violet-Black on White
+15 V	Brown-Green-Black on White
+50 V	Green-Black-Black on White
+125 V	Brown-Red-Brown on White
+300 V	Orange-Black-Brown on White

**Capacitor Marking.** The capacitance values of common disc capacitors and small electrolytics are marked in microfarads on the side of the component body. The white ceramic

capacitors used in the Type 355 are color coded in picofarads using a modified EIA code (see Fig. 6-1).

**Diode Color Code.** The cathode end of each glass-enclosed diode is indicated by a stripe, a dot or a series of stripes. For normal silicon or germanium diodes the stripes also indicate the type of diode, using the resistor color-code system (e.g., 6165 indicates the type of diode with Tektronix Part No. 152-0165-00). The cathode and anode ends of metal-encased diodes can be distinguished by the diode symbol marked on the body or by the flared end of the anode.

**Parts Replacement**

All parts used in the Type 355 can be purchased directly through your Tektronix Field Office or Representative. However, replacements for standard electronic items can generally be obtained locally in less time than is required to obtain them from Tektronix. Replacements for the special parts used in the assembly of the Type 355 should be ordered from Tektronix since these parts are either manufactured or selected by Tektronix to satisfy a particular requirement. Before purchasing or ordering, consult the Electrical Parts List to determine the value, tolerance and rating required.

**NOTE**

When selecting the replacement parts, it is important to remember that the physical size and shape

of a component may affect its performance at high frequencies. Parts orientation and lead dress should duplicate those of the original part since many of the components are mounted in a particular way to reduce or control stray capacitance and inductance. After repair, portions of the instrument may require recalibration.

**Rotary Switches.** Individual wafers or mechanical parts of rotary switches are normally not replaced. If a switch is defective, replace the entire assembly. The availability of replacement switches, either wired or unwired, is detailed in the Electrical Part List.

**Circuit Boards.** Use ordinary 60/40 solder and a 35- to 40-watt pencil type soldering iron on the circuit boards. The tip of the iron should be clean and properly tinned for best heat transfer to the solder joint. A higher wattage soldering iron may separate the etched wiring from the base material.

Most of the components mounted on the Vertical and Output circuit boards can be replaced without removing the boards from the instrument. Observe soldering precautions given under Soldering Techniques in this section. However, if the underside of the board must be reached, refer to the directions for Circuit Board Replacement.

#### NOTE

Cleaning of the circuit board hole is not recommended while the board is mounted in the instrument. Solder pushed through the hole toward the back side cannot always be cleaned away unless the back side is accessible. Thus, clear the mounting hole only when the board is out of the instrument.

**Power Supply Capacitors, C931 and C950.** Unsolder the leads and pull the capacitor from the clamp towards the top of the unit. Unsolder the bottom lead of C931. Install the replacement capacitor, solder the leads and resistor.

**Power Transistor, Q969.** Remove the Output Circuit Board following directions for replacement of circuit boards. Lift the insulation for the circuit board, unsolder the leads, then remove the nuts holding the transistor with a  $\frac{5}{16}$ " wrench and remove the transistor. Install the replacement transistor, resolder the leads, then replace the insulation sheet and circuit board.

**Power Transformer, T950.** Remove the Output Circuit Board or the Vertical Circuit Board following directions for replacement of circuit boards. Lift the circuit board insulation. Unsolder the leads and remove the screws on each side of the transformer and remove it through the opening. Install the replacement transformer, resolder the leads, then replace the insulation sheet and circuit board.

**Replacement of soldered-in diodes.** Grasp the diode lead between the body of the diode and the circuit board with a small pair of tweezers.

Touch the tip of the soldering iron to the lead where it enters the circuit board. Do not lay the iron tip directly on the circuit board. Gently but firmly pull the diode lead from the hole in the circuit board. If removal of the lead does not leave a clean hole, apply a sharp object such as a toothpick or pointed tool while reheating the solder. Avoid

using too much heat. Access to rear of the circuit board is desirable.

To mount the new diode, bend the leads and trim to fit just through the board. Tin each lead while using the tweezers as a heat sink. Place the diode leads in the holes. Apply a small amount of solder, if necessary, to assure a good bond. Use the tweezers as a heat sink and use only enough heat for a good connection.

**Replacement of other soldered-in components.** Grip the component lead with long-nose pliers. Touch the soldering iron to the lead at the solder connection. Do not lay the iron directly on the board, as it may damage the board. Refer to Fig. 6-2.

Fig. 6-2. Apply the soldering iron to the heat-shunted lead when removing a component from a circuit card.

When the solder begins to melt, pull the lead out gently. The hole can be cleaned by reheating the solder and placing a sharp object such as a toothpick or pointed tool into the hole to clean it out.

Bend the leads of the new component to fit the holes in the board. If the component is replaced while the board is mounted in the instrument, cut the leads so they will just protrude through the board.

Pre-fin the leads of the component by applying the soldering iron and a small amount of solder to each (heat-shunted) lead. Insert the leads into the board until the component is firmly seated against the board. If it does not seat properly, heat the solder and gently press the component into place.

Apply the iron and a small amount of solder to the connection to make a firm solder joint. To protect heat-sensitive components, hold the lead between the component body and the solder joint with a pair of long-nose pliers or other heat sink.

Clip the excess lead that protrudes through the board.

Clean the area around the soldered connection with a flux-remover solvent to maintain good environmental characteristics. Be careful not to remove information printed on the board.

**Metal Terminals.** When soldering metal terminals (e.g., switch terminals, potentiometers, etc.), ordinary 60/40 solder

## Maintenance—Type 355

can be used. The soldering iron should have a 40- to 75-watt rating with a 1/8 inch wide chisel-shaped tip.

Observe the following precautions when soldering metal terminals.

1. Apply only enough heat to make the solder flow freely.
2. Apply only enough solder to form a solid connection. Excess solder may impair the function of the part.
3. If a wire extends beyond the solder point, clip off the excess.
4. Clean the flux from the solder joint with a flux-remover solvent to maintain good environmental characteristics.

## Subassembly Removal

**Circuit Board Replacement.** If a circuit board is damaged and cannot be repaired, the entire assembly including all soldered-on component should be replaced. The part number given in the Mechanical Parts List is for the completely wired board.

Procedure for replacing circuit boards follows:

The center circuit boards, Offset and Logic, are removed by a steady pulling at the white plastic handle, either with thumb and forefinger, pliers or by a wire looped around the handle so the entire hand can be used. To replace the circuit boards, keep the bottom parallel to the chassis as the circuit board is placed in the side holders and push down on the handle until it is firmly in place.

The vertical and Output circuit board assemblies are held to the Type 355 chassis by screws connecting to spring mountings. Be certain that the screws are gradually loosened so the circuit board assembly does not spring up at one end and cause damage. Loosen the screws one turn at a time to equalize stress caused by the springs. Check that the pins are straight before replacement. Replace the circuit board with careful alignment of the holes over the pins and with pressure on the area around the screws to overcome spring resistance for the initial screw tightening, then tighten all the screws gradually, (as in the removal,) one turn at a time. If difficulty is encountered because of bent pins, remove the plastic insulating sheet, then re-install it at a position near the tops of the pins for better alignment of the pins. Install the board as above. As the board is tightened down, it will push the plastic sheet into proper position. Tighten all screws until they stop turning.

## TROUBLESHOOTING

### Introduction

The following information is provided to facilitate troubleshooting of the Type 355 if trouble develops. Information contained in other sections should be used along with the following information to aid in locating the defective component.

### Troubleshooting Aids

**Diagrams.** Circuit diagrams are given on foldout pages in Section 10. The circuit number and electrical value of each component in this instrument are shown on the diagram.

Important voltages and waveforms are also shown on the diagrams.

**Component Numbering.** The circuit number of each electrical part is shown on the circuit diagram. Each main circuit is assigned a series of circuit numbers. Table 6-2 lists the main circuits in the Type 355 and the series of circuit numbers assigned to each. For example, using Table 6-2, a resistor numbered R615 is identified as being located in the CH A Programmed Offset circuit, diagram No. 8.

TABLE 6-2

Circuit Numbers On Schematics	Circuit
1-149	CH A Programmed Amp & Attenuators
150-199	CH A Memory
200-349	CH B Programmed Amp & Attenuators
350-399	CH B Memory
400-439	A & B Channel Amps
440-499	Output Amplifier
500-599	Gate Generators
600-699	CH A Programmed Offset
700-779	CH B Programmed Offset
780-899	Digital Logic
900-969	Power Supply
970-999	Card Connectors & Decoupling Networks

### Troubleshooting Techniques

This troubleshooting procedure is arranged in an order which checks the simple trouble possibilities before proceeding with extensive troubleshooting. The first few checks assure proper connection, operation and calibration. If the trouble is not located by these checks, the remaining steps aid in locating the defective component. When the defective component is located, it should be replaced following the replacement procedures given in this section.

**1. Check Associated Equipment.** Before proceeding with troubleshooting of the Type 355 check that the equipment used with the Type 355 is operating correctly. Check that the signal is properly connected and that the interconnecting cables are not defective. Also, check the power source.

**2. Check Control Settings.** Incorrect control settings can indicate a trouble that does not exist. For example, incorrect setting of the VARIABLE control appears as incorrect gain, etc. If there is any question about the correct function or operation of any control, see the Operating Instructions section of this manual.

**3. Check Instrument Calibration.** Check the calibration of the instrument, or the affected circuit if the trouble exists in one circuit. The indicated trouble may only be a result of misadjustment or may be corrected by calibration. Complete instructions are given in the Calibration section of this manual.

**4. Isolate the Trouble to a Circuit.** If the trouble has not been corrected or isolated to a particular circuit with the preceding steps, make the following checks if possible.

a. Check for the correct resistance readings at the interconnecting plug terminals, as indicated in Table 6-3.

If the resistance values at the interconnecting plug are equal or higher than stated in Table 6-3, proceed with the next step.

**TABLE 6-3**

Interconnecting Plug Resistance Checks  
Sampling Heads removed and the Type 355 disconnected from Oscilloscope (pin numbers omitted are unconnected)

Pin Number	Resistance to Ground	With Ohmmeter Leads Reversed
1	infinite	infinite
2	infinite	infinite
3	0	0
4	infinite	infinite
9	0	0
10	37 k $\Omega$	12 k $\Omega$
11	0	0
12	45 k $\Omega$	47 k $\Omega$
15	4.5 k $\Omega$	4.4 k $\Omega$
16	600 $\Omega$	330 $\Omega$
17	37 k $\Omega$	12 k $\Omega$
18	300 $\Omega$	300 $\Omega$
19	0	0
20	5.6 k $\Omega$	5.5 k $\Omega$
21	37 k $\Omega$	13.5 k $\Omega$
22	0	0
23	3 k $\Omega$	3 k $\Omega$
24	5 k $\Omega$	9.5 k $\Omega$

b. Install any sampling head and connect the Type 355 to the oscilloscope in which it will normally operate. Use the flexible cable extension, Tektronix Part No. 012-0066-00. Turn on the instrument and allow at least 5 minutes warm-up time.

Check the power supply voltages. Convenient test points are listed in Table 6-4.

Incorrect operation of all circuits often indicates trouble in the power supplies. Check first for correct voltage of the individual supplies. However, a defective component elsewhere in the instrument can appear as a power-supply trouble and may also affect the operation of other circuits.

Table 6-4 shows the tolerance of the internal power supply voltages, and the normal voltages supplied by the oscilloscope. If a power supply voltage is within the listed tolerances, the supply can be assumed to be working correctly. If outside the tolerances, the +15-volt supply may be incorrectly set, or a component may be defective.

Power Supply voltage checks may be made at the points indicated in Table 6-4.

### Servicing the Feedback Loop

Problems that are caused by the sampling feedback loop can usually be isolated using a calibrated signal amplitude at various deflection factors.

**TABLE 6-4**

Power Supply	Tolerance	Test Point Number and Location
-100 V		Pin AD, Output circuit board Pin AH, Vertical circuit board
-50 V	$\pm 0.5$ V	Pin AI, Output circuit board
-25 V	$\pm 1.25$ V	Pin AS, Output circuit board
-12.2 V		Pin AM, Vertical circuit board
+3.6 V	$\pm 0.18$ V	Pin AR, Output circuit board Pin X, Vertical circuit board
+15 V <sup>1</sup>	$\pm 0.15$ V	Pin AE, AF, Output circuit board Pin AJ, Vertical circuit board
+50 V (DCPL)	$\pm 1$ V	Pin AK, AL, Output circuit board
+125 V		Pin AG, Output circuit board Pin AG, Vertical circuit board
+300 V		Pin V, Output circuit board

<sup>1</sup>Adjusted by R962.

Errors in deflection factor, when the display does not require unity dot response, are caused only by an attenuation error in the feedback attenuator circuits. For displays that require unity dot response, if both the deflection factor and dot response are significantly in error at one setting of the Units/Div switch, the feedback attenuator circuit is probably at fault. For displays that have a significant dot response error, without a deflection factor error, the fault is in the AC Amplifier gain changing circuits.

Truth tables located on both Programmed Amp and Attenuators diagrams list the attenuator (FET) transistors which conduct for each deflection factor. These tables are valuable when troubleshooting the AC Amplifier and Feedback Attenuator circuits.

The faulty display may occur at only two positions of the Units/Div switch that are a decade apart. When this occurs, the fault is either one of the three FETs at the AC Amplifier input, or one of the three FETS at the Feedback Attenuator input. If the fault occurs over the Units/Div ranges of 200, 100, 50 and 20, the fault is either Q68/R66 or a shorted Q53, or an open Q52. If the fault occurs over the Units/Div ranges of 10, 5 and 2, the fault is either Q62/R66, misadjustment of the AC Amplifier X10 gain control, shorted Q52 or an open Q53.

Two of the truth tables list the feedback attenuation in percentage of the Memory DC output voltage. The AC Amplifier truth table does not list gain changes because neither the DC nor the instantaneous AC gain figures apply to proper circuit operation. The DC gain figures are higher than the AC gain figures, and neither apply to actual circuit operation. Correct operation of the AC amplifier at each position of the Units/Div switch can be determined only by using a calibrated amplitude signal and the CRT display. (Proper gain changes are charge quantity changes, not AC peak or DC gain changes that can be monitored on a test oscilloscope.)

What may appear as feedback loop problems can actually be attenuator control transistors Q104 through Q136. These transistors function the same for both internal control and

external programming control of the deflection factor. One AND gate, D129/D136 must also be considered when the problem includes several ranges of the Units/Div switch.

Once the problem has been isolated to an area of the loop, start solving the problem by transistor substitution. If that does not lead to correction, then it may be necessary to check attenuator resistor values with an accurate DC resistance bridge.

**Transistor Checks**

Transistors should not be replaced unless they are actually defective. Transistor defects usually take the form of the transistor opening, shorting or developing excessive leakage. To check a transistor for these and other defects, use a transistor curve display instrument such as a Tektronix Type 575. However, a defective transistor can be found by signal-tracing, by making in-circuit voltage checks, by measuring the transistor forward-to-back resistance using proper ohmmeter resistance ranges, or by using the substitution method. The location of all transistors is shown in the parts location figures later in this section.

To check transistors using a voltmeter, measure the emitter-to-base and emitter-to-collector voltages and determine if the voltages are consistent with the normal resistances and currents in the circuit (see Fig. 6-3). Note the lead configuration in Fig. 6-4.

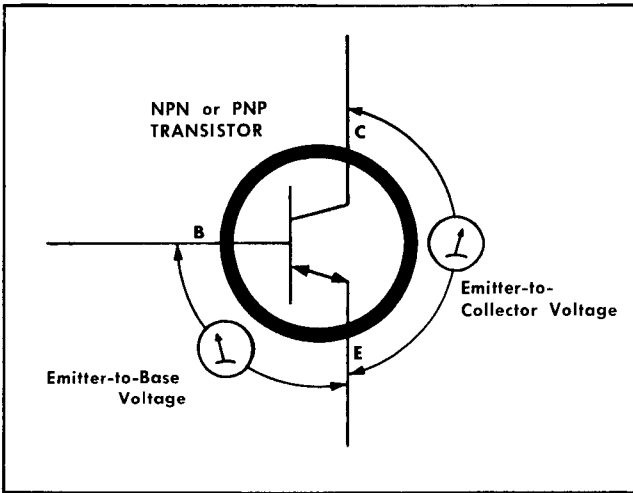

Fig. 6-3. In-circuit voltage checks NPN or PNP transistors.

To check a transistor using an ohmmeter, know your ohmmeter ranges, the currents they deliver and the internal battery voltage(s). If your ohmmeter does not have sufficient resistance in series with its internal voltage source, excessive current will flow through the transistor under test. Excessive current and/or high internal source voltage may permanently damage the transistor.

**NOTE**

As a general rule, use the R X 1 K range where the current is usually limited to less than 2 mA and the internal voltage is usually 1½ volts.

You can quickly check the current and voltage by inserting a multimeter between the ohmmeter leads and measuring the current and voltage for the range you intend to use.

When you know which ohmmeter ranges will not harm the transistor, use those ranges to measure the resistance with the ohmmeter connected both ways as given in Table 6-6.

When checking transistors by substitution, be sure that the voltages on the transistor are normal before making the substitution. If a transistor is substituted without first checking out the circuit, the new transistor may immediately be damaged by some defect in the circuit.

**TABLE 6-5**

**Transistor Resistance Checks**

Ohmmeter Connections <sup>1</sup>	Resistance Readings That Can Be Expected Using the R X 1 K Range
Emitter-Colecor	High readings both ways (about 60 kΩ to around 500 kΩ).
Emitter-Base	High reading one way (about 200 kΩ or more). Low reading the other way (about 400 Ω to 2.5 kΩ).
Base-Collector	High reading one way (about 500 kΩ or more). Low reading the other way (about 400 to 2.5 kΩ).

<sup>1</sup>Test prods from the ohmmeter are first connected one way to the transistor leads and then the test prods are reversed (connected the other way). Thus, the effect of the polarity reversal of the voltage applied from the ohmmeter to the transistor can be observed.

**CAUTION**

Be careful when making measurements on live circuits. The small size and high density of components used in this instrument result in close spacing. An inadvertent movement of the test probes, or the use of oversized probes may short between circuits.

**Diode Checks**

A diode can be checked for an open or shorted condition by measuring the resistance between terminals. With an ohmmeter scale having an internal source of about 1.5 volts, the resistance should be very high in one direction and very low when the leads are reversed.

**CAUTION**

Do not use on ohmmeter scale that has a high internal current. High currents may damage the diode. Do not measure tunnel diodes with an ohmmeter; use a dynamic tester (such as Tektronix Type 575 Transistor-Curve Tracer).

**Field Effect Transistors (FET)**

Memory Amplifier field effect transistors in the Type 355 should not be tested with an ohmmeter. Rather, if you suspect a dual FET, pull the unit out of the socket, rotate it 180° and re-insert it. The leads are arranged in a manner to per-

TRANSISTORS  
Metal Cased

TRANSISTORS  
Epoxy Cased

FIELD EFFECT TRANSISTORS

INTEGRATED CIRCUIT

Fig. 6-4. Lead configuration for socket-mounted transistors and Integrated Circuits, top view.

## Maintenance—Type 3S5

mit the unit to be installed with the guide pin pointing either forward or backward. If there is no change in circuit operation, both sections of the dual FET are probably good.

Actual condition of either half of a dual FET can be checked using a Tektronix Type 575 Transistor Curve Tracer. The Gate corresponds to the Base, Drain to the Collector, and Source to the Emitter of an ordinary transistor at the curve tracer sockets.

Set the curve tracer controls:

### Collector Sweep Controls

Peak Volts Range	20.0
Polarity	+ (NPN)
Peak Volts Control	Fully counterclockwise
Dissipation Limiting Resistor	2 K

### Vertical Controls

CURRENT OR VOLTAGE	1 Collector mA
Position	Spot at lower left corner of graticule

### Horizontal Controls

Volts/Div	10 Collector Volts
Position	Spot at lower left corner of graticule

### Base Step Generator Controls

Repetitive/Off/Single Family	Repetitive
Steps/Family	Fully counterclockwise
Polarity	—

Steps/Sec	120 (up)
Series Resistor	Optional
Step Selector	.2 mA Per Step
Slope Panel Controls	
Center rotary switch	Emitter Grounded

Connect a 1000  $\Omega$  (1% or 5%) 1/2 watt resistor between the B and E binding posts on whichever side of the sloping panel you plan to test the FET. This resistor develops a voltage bias for the Gate lead at 1 volt per mA base step current.

Since the leads of the FET are short, you can avoid bending them (with a chance of breakage) by building an adapter out of a spare transistor socket and wire leads to the sloping panel binding posts.

**Switching FET Checks.** Each attenuator switching FET channel resistance must be  $\leq 30 \Omega$  at 1 mA and zero volts bias. Limit the drain-to-source voltage to 35 volts at cutoff.

**Integrated Circuit Checks.** Integrated circuits are best checked by direct substitution. Where a replacement is not available, use any of the test methods listed for transistors that can be safely used for integrated circuits.

## Major Circuit and Parts Location

The remainder of this section includes photographs of sections of the Type 3S5. Major circuits areas are identified. All components mounted on circuit boards are identified by circuit numbers. All circuit board connections are identified by pin letters.

# SECTION 7

## PERFORMANCE CHECK / CALIBRATION

Change information, if any, affecting this section will be found at the rear of the manual.

### General Information

The Performance Check is a method of checking the instrument's performance without internal adjustments. Failure to meet the requirements given in any check indicates the need for calibration. Performance Check steps are those identified in the type style used in the sub-heading for this paragraph. Calibration Steps are headlined in the style of the next sub-heading.

Any needed maintenance should be performed before proceeding with calibration. The calibration steps restore the instrument to original performance standards stated in Section 1.

Completing the calibration steps of this procedure matches the performance of one channel to the other, and enables both channels to operate with any S-series sampling head. It assures that the DOT RESPONSE controls and B DELAY control have sufficient electrical range for all heads. Either a Type S-1 or Type S-2 is used, with the Type S-1 recommended.

### Equipment Required

The equipment list following, or its equivalent, is required for calibrating or checking the performance of the Type 3S5. To assure accuracy, all test equipment must be calibrated. If other equipment is substituted, it must meet or exceed the limits stated in the description. The first group of items includes those used in both the Performance Check and Calibration procedures. Following are additional items used only for one or the other of the two procedures.

1. Indicator oscilloscope and Digital Unit (optional) in which to operate the Type 3S5; for example, the Type 568 Oscilloscope and the Type 230 Digital Unit.

2. Type S-1 or S-2 Sampling head; **two** Type S-1 sampling heads are recommended.

3. 3T-series sampling sweep unit; Type 3T5 Programmable Sampling Sweep recommended.

4. Test oscilloscope with vertical risetime of 20 ns or less, minimum deflection factor of 5 mV/div or less, and a comparator. For example, Tektronix Type 545B with Type W plug-in unit.

5. 1× Probe, P6011. Tektronix Part No. 010-0193-00.

6. Square wave and pulse generator that produces 1 μs and 10 μs period square waves with 1.0 volt peak amplitude into 50 Ω, 0.5 volt peak amplitude into S-1 or 0.2 volt peak amplitude into S-2. Also required is a pulse of approximately 0.25 volt with ≤70 ps risetime. The Tektronix Type 284 will meet the above requirements, with attenuators, items 7 and 8.

(If your Type 284 leadtime switch is labeled 5 ns-50 ns, order modification Kit, Tektronix Part No. 040-0487-00).

7. 50 Ω 2× attenuator with GR 874 connectors, such as GR874-G6. Tektronix Part No. 017-0080-00.

8. 50 Ω 5× attenuator with GR 874 connectors, such as GR874-G14. Tektronix Part No. 017-0079-00.

9. 50 Ω coaxial cable with GR 874 connectors, such as 5 ns signal delay RG58C/U cable, Tektronix Part No. 017-0512-00.

10. 50 Ω cable, approximately 4 feet long with BNC connectors, for example, RG58C/U, Tektronix Part No. 012-0057-01. (This cable is supplied with the Type 284).

11. Small-bit screwdriver for making adjustments.

### Calibration Aids

Items in the list below are required for complete calibration, but not for Performance Check.

12. Flexible plug-in extension cable to operate the Type 3S5 outside the indicator oscilloscope. Tektronix Part No. 012-0066-00.

13. 10× Probe, P6010. Tektronix Part No. 010-0188-00.

14. If a Type W Plug-In is not available, a precision voltmeter is needed that can measure up to +50 or -50 volts with an accuracy of ±0.25%. John Fluke Model 801B meets the requirements.

15. Bench multimeter such as Triplet Model 630-NA.

16. Normalizer Head, optional for Loop Gain adjustment, and to check Digital Logic, Tektronix Calibration Fixture 067-0572-00.

17. Patch cord with insulated alligator clips (not shown).

18. Circuit board connector (extender). Tektronix Part No. 012-0149-00.

19. DC Resistance Bridge for measuring 10 kΩ. Accuracy, ±0.05% (not shown).

### Performance Check Equipment

The items listed below are needed to complete the Performance Check, but are not required for calibration.

20. 50 Ω Amplitude Calibrator. Output impedance 50 Ω; voltage range 0.012 to 1.2 volts square wave; accuracy within ±0.25%. Tektronix Calibration Fixture 067-0508-00.

21. Patch cord, BNC to banana plug. Tektronix Part No. 012-0090-00. A 10 kΩ resistor (not shown) is required with a Type 3T5 Sampling Sweep unit.

Fig. 7-1. Equipment required for calibration or performance check.

## PERFORMANCE CHECK AND CALIBRATION RECORD INDEX

The following abridged procedure may be used as a performance check or calibration procedure guide by the experienced calibrator, or it may be used as a record. (Tektronix, Inc. authorizes reproduction of the abridged procedure by any user of the equipment.) The step numbers and titles are identical to those used in the complete procedure. When the instrument meets the requirements in the Performance Check steps, the Type 3S5 will meet all Characteristics listed in Section 1.

Type 3S5 Serial No. . . . .

Performance/Calibration Date . . . . .

Performed by . . . . .

- 1. Check and Adjust Power Supplies page 7-6
  - +3.6 Volt value . . . . .
  - +15 Volt value . . . . .
  - +50 Volt value . . . . .
  - 25 Volt value . . . . .
  - 50 Volt value . . . . .
- 2. Check Gate Generator and Sampling Head Avalanche Operation page 7-6
  - Blanking pulse width at 50% amplitude points . . . . . (2  $\mu$ s to 4  $\mu$ s)
- 3. Check Dot Response and Smoothing page 7-6
  - DOT RESPONSE control can be set for a unity loop gain display. Change of NORMAL-SMOOTH switch from NORMAL to SMOOTH changes loop gain from unity to  $\leq 0.3$ .
- 4. Adjust Memory Gate Width Controls page 7-7
  - Maximum loop gain
- 5. Adjust Sampling Head Snap Off and Avalanche Volts Controls page 7-8
  - Near Maximum loop gain
- 6. Adjust Sampling Head Bridge Balance page 7-9
  - No trace movement with Units/Div switch change
- 7. Adjust Smoothing Balance Controls page 7-9
  - No trace shift as NORMAL-SMOOTH switch is changed.
- 8. Check Vertical Digital Accuracy (with Readout System) page 7-10
  - Accuracy within 2%.
- 9. Check Digital Intensified Zone page 7-10
  - Enable Square Wave  $\pm 0.7$  V or more at TP445
- 10. Adjust Digital Gain Controls page 7-11
  - Correct Digital Unit reading
- 11. Check Deflection Factor Accuracies Over Range of Units/Div Switch and Variable Control at CAL; accuracy within 3% at NORMAL and 4% at SMOOTH settings of NORMAL-SMOOTH switch; Variable control increases deflection 2.5 times or more when control is turned clockwise from CAL position. page 7-12

- 12. Adjust GAIN and A-B Bal Controls page 7-12
  - Correct operation
- 13. Check DC Offset (EXT PROG and Front Panel Controls) page 7-12
  - EXT PROG, Accuracy within 2% of programmed value, or 5 mV whichever is greater; Front Panel control, range of +1 V to -1 V, accuracy within 10 mV of same offset voltage in EXT PROG mode.
- 14. Check Offset Output page 7-13
  - Range of +10 to -10 V; actual offset voltage = (0.1) (Offset output) within 1%.
- 15. Check position Indicators and Position Control Range page 7-14
  - Position control will move trace +4 div and -4 div from graticule center; indicator neon will light showing the direction trace is off graticule.
- 16. Adjust Loop Gain Using Normalizer Head Calibration Fixture page 7-14
  - 2.5 volt peak amplitude of signal at TP190 (Channel A) or (Channel B) TP390 with mid-range (electrical center) setting of DOT RESPONSE control.
- 17. Adjust Loop Gain page 7-14
  - Correct balance between sampling head Gain control and Type 3S5 Loop Gain controls.
- 18. Check Interchannel Delay Range page 7-15
  - B DELAY control range is 10 ns and can match the B display to the A display.
- 19. Adjust A Delay Control page 7-15
  - B DELAY control range is within +5 ns and -5 ns of A display.
- 20. Check Memory Slash page 7-16
  - Vertical dot drift is  $\leq 0.1$  div when sampling sweep unit is triggered at 20 Hz.
- 21. Adjust Offset Cal and Zero page 7-16
  - Correct Offset voltage.
- 22. Adjust Attenuator Zero page 7-16
  - Correct operation, see procedure.
- 23. Check A SIG OUT and B SIG OUT page 7-17
  - Output is  $200 \times \frac{\text{Signal Input}}{\text{Units/Div}}$  in volts,  $\pm 2\%$
- 24. Check Digital Control Logic with Normalizer Head page 7-17
  - Units and Decimal lamps to be lit with setting of Units/Div Multiplier and Units/Div switches; see Table 7-5.

### PRELIMINARY PROCEDURE

Before installing the Type 3S5 in the oscilloscope, check the source resistance of the Offset and Sig Out outputs.

a. Place the center mounted Offset circuit card on an extender (item 18 of equipment req'd). Ground test points TP663 and TP763. Use a DC resistance bridge and measure

**Performance Check/Calibration—Type 3S5**

the DC source resistance at the A OFFSET and B OFFSET jacks.

Offset jack resistance must be  $10\text{ k}\Omega \pm 1\%$ , (9.9 k $\Omega$  to 10.1 k $\Omega$ ).

Remove the ground clips and place the Offset circuit card back into its proper mounting position.

b. Ground TP190 and TP390, located on the Vertical circuit board. Use a DC Resistance Bridge and measure the DC source resistance at the A SIG OUT jack and the B SIG OUT jack.

Sig Out jack resistance must be  $10\text{ k}\Omega \pm 0.5\%$  (9.95 k $\Omega$  to 10.05 k $\Omega$ ).

**Performance Check**

Install the Type 3S5 (with a calibrated sampling head installed in Channel A) in the left side compartment of the indicator oscilloscope.

**Calibration Procedure**

a. Remove the indicator oscilloscope left side panel and connect the flexible interconnecting cable between the oscil-

loscope horizontally mounted connector, J11, and the Type 3S5.

b. Install the Type 3T5 (or other sampling sweep unit) into the indicator oscilloscope right side compartment.

c. Remove the case from the sampling head to be used in this procedure. Install the head (without case) into the Type 3S5 left side (Channel A) compartment. Make certain that both the coaxial (trigger) connector and the Sampler board multi-terminal contacts are properly mated. Leave the Type 3S5 right side compartment vacant.

**CAUTION**

When the sampling head cover is off, always turn off the oscilloscope power before installing the head or changing channel installations. Component damage (blow-by compensating transistor) can be caused by irregular contact sequence when the head is installed with no cover.

**MAIN PROCEDURE**

**Both Procedures**

Make all power connections. Turn on the power to all equipment. Allow five minutes warm up time before proceeding. Set the controls as listed following Fig. 7-2.

Sweep Rate	5 ms/div
Vertical With 1 $\times$	
Probe	10 mV/div, AC coupled
Triggering	+Line

**NOTE**

If the Sampling Head being used is known to operate correctly, do not adjust any control at this time. If the sampling head is being calibrated at the same time the Type 3S5 is being calibrated, preset the Bridge Volts control fully clockwise; see Fig. 7-8. (The control will probably remain full clockwise in a Type S-1, and may be adjusted in a Type S-2).

Fig. 7-3. Location of power supply test points and +15 Volt adjustment, instrument right side.

### 1. Check and Adjust Power Supplies

a. Refer to Fig. 7-3 to locate the power supply test points and the +15 Volt adjustment. Location is on the Output circuit board, instrument right side.

b. Use the Type W Unit with a 1X probe or a precision voltmeter. Connect the probes to the test points in succession. Set the Type W mV/cm switch to 5 mV to check the ripple on the test oscilloscope.

c. CHECK—Power supplies within tolerance listed as follows:

Voltage	Tolerance	Ripple
+3.6 V	5%, ±0.18 V	20 mV
+15 V	1%, ±0.15 V	2 mV
+50 V	2%, ±1.0 V	7 mV
-25 V	5%, ±1.25 V	10 mV
-50 V	1%, ±0.5 V	7 mV

#### NOTE

Power supply voltage and ripple tolerances are guides to correct instrument operation, not instrument performance requirements. Actual values may exceed listed tolerances with no loss in measurement accuracy, if the instrument meets the performance requirements in Section 1 as tested in this procedure.

d. ADJUST—+15 Volts control, R962, for +15 volts if part C showed the +15 volt supply to be out of tolerance.

### 2. Check Gate Generator and Sampling Head Avalanche Operation

a. Change the test oscilloscope probe from 1X to 10X, and reset the test oscilloscope controls for:

Sweep rate	20 μs/div
Vertical With 10X Probe	20 V/div, AC Coupled
Triggering	+Internal

b. Connect the test oscilloscope 10X Probe ground clip to a ground test point so the tip can reach (Test Point) TP522, on the instrument right side; see Fig. 7-4A. The signal at TP522 should be similar to that shown in Fig. 7-4C.

c. Center the test oscilloscope display vertically and increase the sweep rate to 1 μs/div.

d. Check that the blanking pulse duration at the 50% amplitude points is between 2 μs and 4 μs (2 to 4 divisions).

e. Reset the test oscilloscope sweep rate to 20 μs/cm.

f. Connect the probe ground clip so the tip can be connected to Q69 emitter (sampling head); see Fig. 7-4B. The signal should be similar to that shown in Fig. 7-4D.

#### NOTE

The test points checked in step 2 are of particular value if you cannot obtain a free-run trace. If there is no signal at TP522, check that the sampling sweep unit is actually free running.

### 3. Check Dot Response and Smoothing

Requirement—NORMAL: DOT RESPONSE control can be set for unity loop gain display when the NORMAL-SMOOTH switch is at NORMAL.

SMOOTH: Loop gain is  $\leq 0.3$  when the sampling sweep unit operates in a normal sequential dot sampling process (Type 3T2 Start Point Switch at With Trigger).

a. Set the Units/Div switch to 100 with a Type S-1; to 50 with a Type S-2. Set the Type 284 to deliver 1 μs square waves at 1.0 volt. Install the appropriate 50 Ω attenuator listed in Table 7-1 between the signal cable and the Type 284 output connector.

b. Set the sampling sweep unit for 500 ns/div (0.5 μs/div). Obtain a double-triggered display on the indicator oscilloscope by free running the time based and adjusting the Recovery Time control. The display should be similar to any one in Fig. 7-5.

c. Set the DOT RESPONSE control for a unity loop gain display as in Fig. 7-5A.

d. Change the NORMAL-SMOOTH switch from NORMAL to SMOOTH.

Fig. 7-4. Gate Generator and Sampling Head Avalanche operation.

e. Check that the display is less than 1.7 divisions at the points indicated in Fig. 7-6A with the Type S-1 or less than 1.3 divisions at the same points with the Type S-2.

f. Reset the switch to NORMAL.

g. Move the sampling head to Channel B, (turn power off if Sampling head cover was removed) and repeat Part C for B DOT RESPONSE.

TABLE 7-1

Attenuator To Be Used With Type 284

Sampling Head	Attenuator	P-P Signal Desired at Input	Type 284 Square Wave Amplitude
S-1	2X	0.5 V	1.0 V
S-2	5X	0.2 V	1.0 V

h. Return the sampling head to Channel A (turn power off if cover was removed).

#### 4. Adjust Memory Gate Width Controls

a. Leave the 10X Probe on the test oscilloscope vertical input. Connect the 1X Probe to the test oscilloscope External Trigger input connector. Reset the test oscilloscope controls for:

Sweep Rate	0.1 $\mu$ s/div
Vertical With 10X Probe	0.1 V/div
Triggering	+ External

b. Install a 50  $\Omega$  attenuator onto the Type 284 Square Wave and Sine Wave Output connector (see Table 7-1). Place a coaxial cable (with GR 874 connectors) between the attenuator and the sampling head input connector.

c. Place a coaxial cable (with BNC connectors) between the Type 284 Trigger Out connector and the sampling sweep unit External Trigger input connector (on the Type 3T2, this refers to the 50  $\Omega$  input).

d. Refer to Fig. 7-7 for the Type 355 test points located on the instrument left side. Controls are shown in Fig. 7-4A. Connect the test oscilloscope external trigger 1X probe tip to TP155. Connect the vertical 10X probe tip to Q15 base at R13.

Fig. 7-5. Type 3S5/S-1 waveforms, 1  $\mu$ s period square wave, sampling sweep double triggered at 500 ns/div.

e. Adjust the sampling sweep unit Trigger Sensitivity and Recovery Time controls for a double-triggered indicator oscilloscope display similar to any in Fig. 7-5. The test oscilloscope display should be similar to the waveform shown in Fig. 7-8A when the sampling head is a Type S-1 and similar to Fig. 7-8B or C if the sampling head is a Type S-2. (It is recommended that a Type S-1 be used if available).

f. Locate R580, the A MEMORY GATE WIDTH control (see Fig. 7-4) and adjust it for an indicator oscilloscope display of maximum loop gain. The test oscilloscope display is at maximum amplitude for maximum loop gain.

g. Move the sampling head into the Type 3S5 Channel B compartment. (It is not necessary to turn the power off unless sampling head cover has been removed). Move the test oscilloscope 10 $\times$  probe tip to Q215 base at R213. Change the Type 3S5 Mode switch to CH B and obtain a

display. Locate R550, the B MEMORY GATE WIDTH control (see Fig. 7-4) and adjust it for maximum loop gain.

### 5. Adjust Sampling Head Snap Off and Avalanche Volts Controls

#### NOTE

If the sampling head used in this procedure is operating properly, and there is no intent to calibrate the head, disregard this step. This step is to be used only when the sampling head also need colibration.

a. Continue with the double-triggered display obtained in Step 4, and leave the test oscilloscope on Q215 base at R213.

(A) Display with Type S-1 Sampling Head.

(B) False display requiring adjustment of Recovery Time and Trigger Sensitivity controls.

Fig. 7-6. Smoothed displays of 1  $\mu$ s square wave, double triggered.

b. Refer to Fig. 7-4B for control locations. Adjust the Snap Off Current control, R57. The test oscilloscope display amplitude will change. Adjust R57 for a test oscilloscope display near the maximum amplitude obtainable (near maximum loop gain). The final position of R57 is decided thus: Note that the Type 3S5 display moves up and down when turning R57; if a maximum vertical up or down excursion occurs near a point where the test oscilloscope display amplitude is maximum, leave R57 at the Type 3S5 maximum excursion point.

**NOTE**

Part b applies when the sampling head is a Type S-1. If it is any other type head, refer also to the calibration procedure for setting risetime in the sampling head instruction manual. It may be to your advantage to combine this procedure with the sampling head calibration procedure.

Fig. 7-7. Type 3S5 test points for adjustment of Memory Gate Width controls.

c. Move the test oscilloscope probe to the emitter of the sampling head avalanche transistor, Q69 (shown in Fig. 7-4B). Adjust the Avalanche Volts control, R66, slightly clockwise and note that the avalanche circuit operation becomes unstable. Return R66 about  $\frac{1}{8}$  turn counterclockwise from the point of instability.

d. Interaction between the two controls may require that the above two adjustments be repeated.

**NOTE**

Step 5 adjustments do not assure proper sampling noise and risetime calibration. Those adjustments are described in the sampling head instruction manual calibration procedure.

**6. Adjust Sampling Head Bridge Balance Controls**

a. Disconnect the signal cable from the Type 284. Leave the cable connected to the sampling head. Leave the sampling sweep unit triggered from the Type 284 for a displayed no-signal trace.

b. Adjust both DC OFFSET controls so they deliver zero volts to the front panel OFFSET OUT jacks.

c. Change the Units/Div switch from 200 to 2 and adjust Bridge Bal R22, (shown in Fig. 7-9) for no more than one division of trace movement as the switch is changed from 200 to 2.

**7. Adjust Smoothing Balance Controls**

a. Disconnect the cable from the Type 284. Leave the cable connected to the sampling head. Leave the sampling sweep unit triggered from the Type 284 for a displayed no-signal trace.

b. Adjust both Type 3S5 DC OFFSET controls so they deliver zero volts to the front panel OFFSET OUT jacks.

Fig. 7-8. Test oscilloscope displays of sampling head output signals at Q15 (Q215) base at R13 (R213), step 4, unity loop gain.

c. Turn the NORMAL-SMOOTH control to SMOOTH and note the trace shift. If the trace moves vertically, readjust the Channel B SMOOTHING BALANCE control R367, (shown in Fig. 7-10) until there is no trace movement as the NORMAL-SMOOTH control is switched between its two positions.

d. Move the sampling head back to Channel A. (Turn oscilloscope power off if sampling head cover was removed).

Fig. 7-9. Sampling Head left side control locations.

Change the Type 3S5 Mode switch to CH A. Readjust the Channel A SMOOTHING BALANCE control R167, shown in Fig. 7-10, until there is no trace shift as the NORMAL-SMOOTH control is switched between its two positions.

### 8. Check Vertical Digital Accuracy (with Readout System)

Requirement—The Type 3S5 will permit a Tektronix digital readout system to make voltage measurements with an accuracy of  $\pm 2\%$ .

a. Connect the Type 284 Square Wave Output to the sampling head input through a 50  $\Omega$  coaxial cable. Set the Type 3S5 Units/Div switches to 200 and check that the VARIABLE controls are at CAL. The square wave amplitude is now 1.0 volt,  $\pm 0.5\%$  when the sampling head input resistance is 50  $\Omega$ .

b. Set the Type 284 Period switch for 10  $\mu$ s square waves. Set the sampling sweep unit for a sweep rate of 2  $\mu$ s/div.

c. Set the digital unit controls to measure voltage from Channel A, along a rising slope waveform.

d. Check—Digital readout is between 0.975 and 1.025 V.

e. Change the sampling head to Channel B and the Mode switch to CH B. Set the digital unit to read voltage from Channel B.

f. CHECK—Digital readout is between 0.975 V and 1.025 V. Refer to step 10 if not within tolerance.

### 9. Check Digital Intensified Zone Enable

#### NOTE

Disconnect the lower flexible interconnecting cable that goes from the Type 3S5 to P12 of either a Type 567 or Type 568. Separate the cable from the Type 3S5 rear so the leads going to the digital unit are disconnected. If the Type 3S5 is being calibrated using a Type 561A or Type 564, the digital leads are not used, and no change is to be made to the flexible interconnections.

Fig. 7-10. Vertical circuit board control locations, left side.

(Turn the power off before removing or replacing the flexible interconnecting cable.)

- Set the sampling sweep unit Time/div to 100 ns (Decade to 7 and Multiplier to 1) and the Trigger Sensitivity control fully clockwise.
- Set the Type 3S5 Mode switch to DUAL-TRACE.
- Connect the  $1\times$  probe from the Type W Input A connector to TP445; see Fig. 7-12. Set the test oscilloscope sweep rate to  $20\ \mu\text{s}/\text{div}$ , and deflection factor to 1 V/div.
- Check that the square wave levels above and below the zero volt reference line are  $\pm 0.7\ \text{V}$  or more (at least 0.7 division above and below the zero reference line).
- Disconnect the probe.
- Turn the power off and replace the flexible interconnecting cable between the oscilloscope P12 and the digital information connector at the rear of the Type 3S5. Turn the power back on.

## 10. Adjust Digital Gain Controls

### NOTE

This step applies only if the Type 3S5 is used with a Type 567/6R1A or Type 568/230 Digital System and if R404 or R424 have been replaced or otherwise misadjusted. If this step does not apply, then DO NOT adjust R404 or R424 from the factory adjustment positions.

- Turn Off indicator oscilloscope power, remove the flexible extension cable, and install the Type 3S5 in the compartment, (or use flexible extensions). Turn the instrument power on.

Fig. 7-11. Typical display for checking Vertical accuracy.  $10\ \mu\text{s}$  square wave at  $2\ \mu\text{s}/\text{div}$ .

- Remove any attenuator that is in the signal cable between the Type 284 and the sampling head input. The square wave amplitude is now 1.0 volt,  $\pm 0.5\%$  when the sampling head input resistance is  $50\ \Omega$ . Set the Type 284 Period switch to deliver  $10\ \mu\text{s}$  square waves. Set both Type

Fig. 7-12. Location of controls on Output circuit board, right side of instrument.

## Performance Check/Calibration—Type 355

355 Units/Div switches to 200 and obtain a display similar to Fig. 7-11. Check that both VARIABLE controls are at CAL. Set the digital unit controls to measure voltage from Channel A, along a rising slope waveform. Set the sampling sweep unit for 2  $\mu\text{s}/\text{div}$ .

c. Refer to Fig. 7-12 and locate the A DIGITAL GAIN control, R404. Adjust R404 until the digital unit reads 1.00 volt.

d. Move the sampling head to Channel B. (Turn oscilloscope power off if sampling head cover was removed). Set the Type 355 Mode switch to CH B.

e. Locate the B DIGITAL GAIN control, R424. Change the digital unit to read voltage from Channel B. Adjust R424 until the digital unit reads 1.00 volt.

### NOTE

Changing either Digital Gain control requires that the front panel GAIN control and the A - B Bal control be adjusted as described in step 12.

f. Turn the power off, re-install the Type 355 on the extension and turn the power on.

## 11. Check Deflection Factor Accuracies Over Range of Units/Div Switch and Variable Control Range

Requirement—All calibrated deflection factors will produce displays with amplitude accuracy of  $\pm 3\%$  at NORMAL and  $\pm 4\%$  at SMOOTH (when the VARIABLE control is at CAL). VARIABLE control increases display amplitude to 25% or more of calibrated amplitude.

a. Set the Type 355 Units/Div switch to 200 and apply 1.2 volts from the 50  $\Omega$  Amplitude Calibrator (item 20, equipment required) to the Channel B input through 50  $\Omega$  coaxial cable. Connect a coaxial cable from the Amplitude Calibrator Trigger Output connector to the sampling sweep unit External Trigger Input 50  $\Omega$  connector.

b. Set the sampling sweep unit for a sweep rate of 10  $\mu\text{s}/\text{div}$  and obtain a stable triggered display.

c. Adjust the front panel GAIN control for a display amplitude of 6 divisions.

d. Check all positions of the Units/Div switch as listed in Table 7-2 for a 6 division display amplitude within a tolerance of  $\pm 0.18$  div. Also check with the NORMAL-SMOOTH switch at SMOOTH within a tolerance of  $\pm 0.24$  div.

TABLE 7-2

Units/Div	50 $\Omega$ Amplitude Calibrator
200	1.2 V
100	.6 V
50	.3 V
20	.12 V
10	.06 V
5	.03 V
2	.012 V

### NOTE

Record deflection in each case. If one range is above tolerance, GAIN can be reduced to bring all ranges within tolerance without need for checking the attenuator circuits.

e. Set the Units/Div switch to 200 and the 50  $\Omega$  Amplitude Calibrator to 0.6 volts. Display amplitude is 3 divisions.

f. Turn the VARIABLE control fully clockwise from the detent setting and check the display amplitude for 7.5 divisions or more.

g. Return the VARIABLE control to the detent (CAL) position.

h. Change the sampling head to the Channel A compartment and the Mode switch to CH A. Repeat the check for Channel A.

## 12. Adjust GAIN and A-B BAL Controls ①

a. Move the sampling head to Channel B.

b. Connect the cable between the Type 284 and the sampling head input. Set the sampling sweep unit for a sweep rate of 0.5  $\mu\text{s}/\text{div}$  (500 ns; Decade at 7, Multiplier at 5). Set the Type 284 to deliver 10  $\mu\text{s}$  square wave at 1.0 volt. Obtain a display similar to Fig. 7-11, normally triggered (not double triggered).

c. Adjust the front panel GAIN control for a 5 division display.

d. Disconnect the signal cable. Connect the bench multi-meter between chassis and the B SIG OUT jack. Set the B DC OFFSET control for zero volts on the meter.

e. Install a second, calibrated head in Channel A and connected the signal cable to the Channel A sampling head input. Allow a 5 minute warm up.

f. Set the Type 355 Mode switch to A + B and check for a 5 division display.

g. If the display amplitude is not 5 divisions, refer to Fig. 7-12 for location of the A-B BAL control, R430, and adjust R430 for a 5 division display.

### NOTE

This step assures that the Type 355 will operate in any 560 series indicator oscilloscope.

## 13. Check DC Offset (Ext PROG and Front Panel Control)

Requirement—EXT PROG, range of  $-995$  mV to  $+995$  mV in 5 mV steps; accuracy within 2% of the programmed value, or 5 mV, whichever is greater.

Front Panel control, range of  $+1$  V to  $-1$  V ( $+10$  V to  $-10$  V at OFFSET jack); accuracy within 10 mV of same offset voltage in EXT PROG mode (100 mV at OFFSET jack).

a. Connect the 1 $\times$  probe from the Type W Input A to the Type 355 A OFFSET jack. Set the Type W Input Atten to R = infinity.

b. Set the sampling sweep unit Trigger Sensitivity control fully counterclockwise.

**TABLE 7-3**  
External Program DC Offset

DC Offset	Channel A		Channel B		Logic State
	Front or Rear Pin Number	Logic State	Pin Number		
			Front	Rear	
+Polarity	4	1	23	H	1
—Polarity	4	0	23	H	0
800 mV	5		24	J	
400 mV	6		25	K	
200 mV	7		26	L	
100 mV	8		27	M	
80 mV	9		28	N	
40 mV	10		29	P	
20 mV	11		30	R	
10 mV	12		31	S	
5 mV	13		32	14	

The logic state 1 is 0 to +2 V (True) and Logic state 0 is +6 to +15 V (False) or an open circuit.

c. Set the Mode switch to EXT PROG and externally program —995 mV of A Offset. Refer to Table 7-3 for Channel A DC Offset.

d. With the Type W Comparison Voltage, check that the OFFSET jack voltage is  $-9.95\text{ V} \pm 2\%$  ( $\pm 199\text{ mV}$ ).

e. Set the Mode switch to CH A and the DC OFFSET control to —995 mV (black numbers).

f. Check that the OFFSET jack voltage is within 100 mV of the voltage measured in step d.

g. Repeat the comparisons for settings at 0 mV, +660 mV, and +995 mV. Tolerance at 0 mV is 50 mV. Set the Mode switch to EXT PROG and externally program B Offset —995 mV. Refer to Table 7-3 for Channel B DC Offset.

h. Connect the  $1\times$  probe from the Type W Input A to the Type 355 B OFFSET jack.

i. Use the Type W Comparison Voltage and check that the OFFSET jack voltage is  $-9.95\text{ V} \pm 2\%$  ( $\pm 199\text{ mV}$ ).

j. Set the Mode switch to CH B and the DC OFFSET control to —995 mV (black numbers).

k. Check that the OFFSET jack voltage is within 100 mV of the voltage measured in step j.

l. Repeat the comparisons for settings at 0 mV, +660 mV and +995 mV. Tolerance at 0 mV is 50 mV. See Calibration step 21 if not within tolerance.

m. Connect the 50  $\Omega$  Amplitude Calibrator to the sampling head input connector, set the Volts switch to .6, and set the Type 355 Mode switch to EXT PROG.

n. Externally program 10 Units/Div and 0 mV offset. Refer to Tables 7-3 and 7-4. Set the sampling sweep unit sweep rate for 2  $\mu\text{s}/\text{div}$ , obtain a display and note the position of the trace on the indicator oscilloscope.

o. Externally program 600 mV, Table 7-3, and note the new position of the trace.

p. Check that new position is within 1.2 div, 12 mV (2% of 600 mV) of the first position.

q. Repeat the check for the other channel.

**TABLE 7-4**  
External Program Units/Div

Units/Div	Channel A Pin Number Logic State			Channel B Pin Number Logic State					
	Front or Rear			Front			Rear		
	1	2	3	20	21	22	D	E	F
200	0	0	0	0	0	0	0	0	0
100	0	0	1	0	0	1	0	0	1
50	0	1	0	0	1	0	0	1	0
20	0	1	1	0	1	1	0	1	1
10	1	0	1	1	0	1	1	0	1
5	1	1	0	1	1	0	1	1	0
2	1	1	1	1	1	1	1	1	1

Negative Logic; True (Logical 1): 0 to +2 V; False (Logical 0): +6 to +15 V or open circuit.

## 14. Check Offset Output

Requirement—Range of +10 V to —10 V, with the actual offset voltage = (0.1) (OFFSET output) within 1%.

a. Connect the  $1\times$  probe from the Type W Input A connector to the OFFSET jack.

b. Apply 0.6 volts from the 50  $\Omega$  Amplitude Calibrator to the sampling head in Channel A. Set the Type 355 Mode switch to CH A.

c. Set the A DC OFFSET control for 0 volts at the OFFSET jack, and at 5 Units/Div note the position of the square wave bottom.

d. Set the A DC OFFSET control to obtain —6 volts at the A OFFSET jack and note the new position of the square wave top.

e. Check that the new position is within 1.2 div, 6 mV (1% of 600 mV).

f. Repeat the check for the other channel.

## 15. Check Position Indicators and Position Control Range

Requirement—Up position indicator neon lights, and down position indicator neon is dark, when CRT beam is above the graticule. Down position indicator lights and up position indicator is dark when CRT beam is below the graticule.

POSITION control will position a free run trace at least 8 divisions vertically.

a. Set the sampling sweep unit triggering controls for a free-running trace and the Type 3S5 A DC OFFSET control to place the trace above the top graticule line.

b. Check that the up indicator is on and the down indicator is off.

c. Position the trace below the bottom graticule line.

d. Check that the down indicator is on and the up indicator is off.

e. Set the POSITION control fully counterclockwise and the DC OFFSET control so the trace is at the bottom graticule line.

f. Turn the POSITION control fully clockwise and check that the trace moves up 4 divisions or more.

g. Reset the POSITION control to midrange. If the instrument does not operate as stated above in steps b and d, check the Position Indicator neon control circuit. If the POSITION control range is less than 4 divisions, check the Output circuits for transistors with low  $\beta$  or feedback resistors that have changed value.

## 16. Adjust Loop Gain Using Normalizer Head ① Calibration Fixture

### NOTE

Steps 16 and 17 (parts a through d) accomplish the proper Loop Gain (200, 100, 50, 20) capacitor adjustment. Step 16 uses a special Tektronix calibration fixture (item 16 of equipment required), and Step 17 uses a Type S-1 or S-2 Sampling Head. Both steps are included in this procedure to allow the Type 3S5 to be adjusted when a Normalizer is used, and Step 17, parts a through d, can be disregarded.

a. Install the Normalizer Head in the Channel B opening and set the Units/Div switch to 100.

b. Free run the sampling sweep unit. Use a sweep rate that produces a continuous double trace display.

c. Set the NORMAL-SMOOTH switch to NORMAL. Use the DC OFFSET control so the sampling display is two traces, several divisions apart.

d. Connect the test oscilloscope  $10\times$  probe to TP390 (or TP190 for Channel A), see Fig. 7-10. Free run the test oscilloscope, sweep rate at 1 ms/div and vertical deflection factor of 1.0 V/div (including the probe  $10\times$  attenuation).

e. Set the DOT RESPONSE control fully clockwise, and note either the indicator or test oscilloscope display. Record the number of divisions of trace separation. Set the DOT RESPONSE control fully counterclockwise. Record the number of divisions of trace separation. Calculate the number of divisions by which the two traces should be separated when the DOT RESPONSE control is at its electrical midrange setting. Set the DOT RESPONSE control to its electrical midpoint as calculated.

f. Adjust the LOOP GAIN (200, 100, 50, 20) capacitor C384 (184 for Channel A) until the two indicator oscilloscope traces are exactly 5 major divisions apart. See Fig. 7-10 for capacitor location. The test oscilloscope display should indicate exactly 2.5 volts difference between the two traces (or square wave signal peak to peak value.) The  $\pm 3\%$  tolerance of both the test oscilloscope and indicator oscilloscope displays may show that they differ. This is of no consequence to the Type 3S5 calibration, because of the range of the DOT RESPONSE control. The real value of this adjustment is that if more than one Type 3S5 is calibrated in the same lab, they will permit unity loop gain operation of any calibrated sampling head in any Type 3S5. This step or Step 17 (a through d) should be performed before attempting a sampling head recalibration, particularly when adjusting the sampling head Preamplifier Gain control.

g. Repeat the above procedure for the other Type 3S5 channel.

## 17. Adjust Loop Gain ①

### NOTE

This step established the correct balance between the sampling head Preamplifier Gain control (R46 in Fig. 7-9) and the Type 3S5 Loop Gain (200, 100, 50, 20) controls C184 and C384. The procedure includes both the indicator oscilloscope and test oscilloscope displays.

a. Input signal amplitude to the sampling head must be the value stated earlier in Table 7-1. The test oscilloscope displays of the sampling head output signals (Fig. 7-8) are to be adjusted for  $\pm 0.2$  volt when using a Type S-1, and for  $\pm 0.08$  volt when using a Type S-2.

Set the Type 284 to deliver 1  $\mu$ s square waves at 1.0 volt. Install the correct 50  $\Omega$  attenuator in the signal cable at the Type 284 output connector. Set the sampling sweep rate to 500 ns/div (0.5  $\mu$ s/div). Set both Type 3S5 Units/Div switches to 100.

b. Obtain a double-triggered display on the indicator oscilloscope by free running the sampling sweep unit and adjusting the Recovery Time control. The display should be similar to any one in Fig. 7-5.

Turn the Type 3S5 DOT RESPONSE control through its range. The double-triggered display amplitude should change over the control range in a manner similar to the triple exposure of Fig. 7-13. Set the DOT RESPONSE control to its electrical midpoint, not necessarily to unity loop gain.

Fig. 7-13. Finding electrical center of Type 355 DOT RESPONSE control. Triple exposure; double triggered; 1  $\mu$ s square wave; 200 ns/div; 100 mV/div.

c. Connect the test oscilloscope 10 $\times$  probe to Q15 base (or Q215 base for Channel B) shown in Fig. 7-7. Externally trigger the test oscilloscope from TP155, using a sweep rate of 0.1  $\mu$ s/div and vertical deflection factor of 0.1 V/div (including the probe 10 $\times$  attenuation).

d. Decide whether the sampling display loop gain is greater or less than unity. Also note carefully the test oscilloscope display amplitude.

If the sampling head output signal on the test oscilloscope stated in part a at the beginning of this step, and at the same time the sampling display shows greater than unity loop gain, adjust the Type 355 LOOP GAIN control, C184 (C384 for Channel B), for unity loop gain. See Fig. 7-10 for locations.

If the sampling head output signal on the test oscilloscope is still greater than required, reduce the sampling head Pre-amplifier Gain (R46 shown in Fig. 7-9) a small amount, but not all the way to unity loop gain. Return the loop to unity loop gain with the LOOP GAIN capacitor.

If the sampling head output signal is less than required when the indicator oscilloscope displays unity loop gain, increase the sampling head Pre-amplifier Gain a small amount. Return the loop to unity loop gain with the Loop Gain capacitor.

Through such interacting adjustments, set the system loop gain to unity while the test oscilloscope reveals that the sampling head output signal is the correct amplitude listed in part a of this step.

e. Set the Type 284 Square Wave Amplitude switch to 100 mV. (Do not remove the attenuator). Set the Type 355 Units/Div switch to 10.

f. If the indicator oscilloscope display does not show unity loop gain, adjust  $\times 10$  (LOOP GAIN in 10, 5, 2) control, R55 (R255 for Channel B), for unity loop gain.

g. Repeat the above procedure for the other channel.

## 18. Check Interchannel Delay Range

Requirement—B DELAY control range is at least 10 ns.

a. Only one sampling head should be used, changing it from one channel to the other as necessary.

b. Connect the Type 284 fast pulse output to the Channel A sampling head input connector. Externally trigger the sampling sweep unit from the Type 284 Trigger Output connector. Set the sampling sweep rate to 2 ns/div. Set the Type 355 Mode switch to CH A.

c. Obtain a step display of the signal fed to Channel A. Adjust the sampling sweep unit Delay and Horiz Pos controls so the center of the rise passes through the center of the graticule.

d. Change the Mode switch to CH B, move the sampling head to Channel B and apply the Type 284 fast pulse to the Channel B input connector.

e. Set the Type 355 B DELAY control fully counterclockwise and note the position of the step 50% amplitude point. It should be 2.5 divisions or more to the left of the graticule center (at least 5 ns to the left of center).

f. Turn the B DELAY control fully clockwise and check that the Channel B 50% amplitude point is to the right of the center graticule line, for a total range of at least 10 ns.

## 19. Adjust Type 355 A Delay Control

a. Connect the Type 284 fast pulse output to the Channel B Sampling Head input connector. Set the sampling sweep unit to 2 ns/div. Set the Type 355 Mode switch to DUAL-TRACE.

b. Obtain a step display of the signal fed to Channel B. Set the B DELAY control fully counterclockwise and use the sampling sweep unit Time Position controls to move the step so the center of its rise passes to the left of the graticule 2.5 div point; see point no. 1, Fig. 7-14.

Fig. 7-14. Waveforms for steps 18 and 19, B DELAY control range.

Fig. 7-15. Control locations, Type 355 top view.

c. Turn the B DELAY control fully clockwise. The step display should now be to the right of the graticule 7.5 div point; see point no. 2, Fig. 7-14. Adjust the sampling sweep unit Time Position controls so the two points (no. 1 and no. 2 of Fig. 7-14) fall equal distances on the left and right of the graticule centerline.

d. Move the sampling head to Channel A with the signal cable still attached. The step display should now be at the graticule centerline: see Fig. 7-14, point no. 3. If not, adjust the A DELAY control, R561 shown in Fig. 7-7, so that the step display half-amplitude point does cross at the graticule centerline.

## 20. Check Memory Slash

Requirement—Vertical dot drift is  $\leq 0.1$  division when sampling sweep unit is triggered at 20 Hz.

a. Set the test oscilloscope Time/Div switch to 5 ms/div, Triggering Mode to Auto and Level control fully clockwise.

b. Connect a BNC to banana plug patch cord from the + GATE jack to the sampling sweep unit External Trigger input connector thru a 10 k $\Omega$  resistor.

c. Set the sampling sweep unit Trigger Sensitivity control fully clockwise, Time/Div to 500 ns (Decade to 7, Multiplier to 5) and adjust the indicator oscilloscope Focus and Astigmatism controls for the sharpest dot.

d. Turn the sampling sweep unit Trigger Mode switch to Ext Auto and observe the dot as it crosses the CRT.

e. Check that the vertical elongation of a displayed dot is 0.1 div or less.

f. Set the sampling sweep unit Trigger Mode to Ext.

## 21. Adjust Offset Cal and Offset Zero

a. Turn indicator oscilloscope power off, remove the Offset circuit board assembly, re-install on an extender card, and turn the power on.

b. Connect the 1 $\times$  probe from the Type W Input to TP663 (Channel A). Set the Type W Input Selector to Ground and the Vc Range to 0. Position the test oscilloscope trace at the centerline and set the Comparison Voltage to 995.

c. Set the Type 355 A DC OFFSET control to  $-995$  mV (black numbers). Set the Type W Input Selector to DC and the Vc Range switch to  $-1.1$ .

d. Check that the test oscilloscope trace is at the centerline,  $-995$  mV at TP663. If trace is not at the centerline, adjust the A OFFSET CAL control, R638 shown in Fig. 7-15, for  $-995$  mV, trace at test oscilloscope centerline.

e. Change the A DC OFFSET control to 0, set the Type W Vc Range switch to 0, and Comparison Voltage to 000.

f. Set the Type W Vc Range switch to  $-1.1$ . Check that the test oscilloscope trace is at the graticule centerline, 0 mV at TP663. If not 0 mV, adjust the B OFFSET ZERO control, R649, for 0 mV, trace at test oscilloscope centerline.

g. Repeat the check and/or adjustment for the B CHANNEL, using TP763. Control locations are shown in Fig. 7-15.

h. Disconnect the probe.

## 22. Adjust Attenuator Zero

a. With the Offset circuit board on the extender, set both Units/Div switches to 200 and the Mode switch to CH B.

b. Adjust the B DC OFFSET control for zero volts at the B SIG OUT jack as measured with the bench multimeter.

- c. Connect Pin 21, Offset circuit board interconnector, to ground using a patch cord with insulated alligator clips.
- d. Connect the 1× probe from the Type W Input A to the base of Q281B.
- e. Change the B Units/Div switch to 2 and check that the test oscilloscope display shows not more than 4 mV of change.
- f. If the voltage change is more than 4 mV, adjust R286, the ATTENUATOR ZERO control, for not more than 4 mV of change as the Units/Div switch is changed from 200 to 2.

**NOTE**

Do not ground Pin 21 (or Pin 18) longer than necessary to make the adjustment.

- g. Disconnect the patch cord Probe and meter lead, and move the sampling head to Channel A. Set the Mode Switch to CH A.
- h. Adjust the A DC OFFSET control for zero volts at the A SIG OUT jack as measured with the bench multimeter.
- i. Connect Pin 8, Offset circuit board interconnector, to ground with the patch cord.
- j. Connect the 1× probe to the base of Q81B.
- k. Change the A Units/Div switch to 2 and check for not more than 4 mV change.
- l. If the voltage change is more than 4 mV, adjust R86, A ATTENUATOR ZERO control, for not more than 4 mV of change as the Units/Div switch is changed from 200 to 2.
- m. Disconnect the ground patch cord, probe and meter leads.
- n. Turn the power off, remove the Offset circuit board assembly from the extender, replace the Offset circuit board without the extender, and turn on the power.

**23. Check A SIG OUT and B SIG OUT**

Requirement—Output voltage of each channel, A or B, is  $200 \times \frac{\text{Signal Input}}{\text{Units/Div}}$  in volts, +2%.

- a. Set both Units/Div switches to 100 and set the 50 Ω Amplitude Calibrator Volts switch to .6.
- b. Set the Type W Comparison Voltage to 0.00 and the Vc Range switch to -11.
- c. Connect the 1× probe from the Type W Input A to the B SIG OUT jack.
- d. Adjust the Position control of the Type W so the positive portion of the square wave (top of the display) is at the center of the graticule. Some adjustment of the B DC OFF-SET control of the Type 355 may be necessary.
- e. Set the Comparison Voltage of Type W so the negative portion of the square wave (bottom of the display) is at the center of the graticule.
- f. Check that the Comparison Voltage is 1.2 volts ±2% (1.176 to 1.224 volts).
- g. Move the signal and sampling head to the Channel A compartment and set the Mode switch to CH A.
- h. Move the 1× probe to the A SIG OUT jack and repeat the measurement procedure for the A SIG OUT.
- i. Disconnect the test oscilloscope probe.

**24. Check Digital Control Logic with Normalizer Head**

In all vertical mode positions with the exception of EXT PROG, the units lamps go out when the VARIABLE control is moved from the CAL position. The V units lamp lights with a voltage-measuring sampling head and the A units lamp lights<sup>1</sup> with a current-measuring sampling head.

Table 7-5 lists the Units and Decimal lamps to be lit with the Type 355 Units/Div and Normalizer Units/Div Multiplier switch settings. X indicates which decimal is lighted.

<sup>1</sup>Some Type 230 Units are connected for operation of the V lamp only. See your Field Engineer for modification instructions to permit A lamp to operate.

## ABBREVIATIONS AND SYMBOLS

A or amp	amperes	L	inductance
AC or ac	alternating current	$\lambda$	lambda—wavelength
AF	audio frequency	$\gg$	large compared with
$\alpha$	alpha—common-base current amplification factor	$\ll$	less than
AM	amplitude modulation	$\angle$	low frequency
$\approx$	approximately equal to	lg	length or long
$\beta$	beta—common-emitter current amplification factor	LV	low voltage
BHB	binding head brass	M	mega or $10^6$
BHS	binding head steel	m	milli or $10^{-3}$
BNC	baby series "N" connector	$M\Omega$ or meg	megohm
X	by or times	$\mu$	micro or $10^{-6}$
C	carbon	mc	megacycle
C	capacitance	met.	metal
cap.	capacitor	MHz	megahertz
cer	ceramic	mm	millimeter
cm	centimeter	ms	millisecond
comp	composition	—	minus
conn	connector	mtg hdw	mounting hardware
~	cycle	n	nano or $10^{-9}$
c/s or cps	cycles per second	no. or #	number
CRT	cathode-ray tube	ns	nanosecond
csk	countersunk	OD	outside diameter
$\Delta$	increment	OHB	oval head brass
dB	decibel	OHS	oval head steel
dBm	decibel referred to one milliwatt	$\Omega$	ohm—ohms
DC or dc	direct current	$\omega$	omega—angular frequency
DE	double end	p	pico or $10^{-12}$
$^{\circ}$	degrees	/	per
$^{\circ}$ C	degrees Celsius (degrees centigrade)	%	percent
$^{\circ}$ F	degrees Fahrenheit	PHB	pan head brass
$^{\circ}$ K	degrees Kelvin	$\phi$	phi—phase angle
dia	diameter	$\pi$	pi—3.1416
$\div$	divide by	PHS	pan head steel
div	division	$\pm$	plus
EHF	extremely high frequency	$\pm$	plus or minus
elect.	electrolytic	PIV	peak inverse voltage
EMC	electrolytic, metal cased	plstc	plastic
EMI	electromagnetic interference (see RFI)	PMC	paper, metal cased
EMT	electrolytic, metal tubular	poly	polystyrene
$\epsilon$	epsilon—2.71828 or % of error	prec	precision
$\geq$	equal to or greater than	PT	paper, tubular
$\leq$	equal to or less than	PTM	paper or plastic, tubular, molded
ext	external	pwr	power
F or f	farad	Q	figure of merit
F & I	focus and intensity	RC	resistance capacitance
FHB	flat head brass	RF	radio frequency
FHS	flat head steel	RFI	radio frequency interference (see EMI)
Fil HB	fillister head brass	RHB	round head brass
Fil HS	fillister head steel	$\rho$	rho—resistivity
FM	frequency modulation	RHS	round head steel
ft	feet or foot	r/min or rpm	revolutions per minute
G	giga or $10^9$	RMS	root mean square
g	acceleration due to gravity	s or sec.	second
Ge	germanium	SE	single end
GHz	gigahertz	Si	silicon
GMV	guaranteed minimum value	SN or S/N	serial number
GR	General Radio	$\ll$	small compared with
$>$	greater than	T	tera or $10^{12}$
H or h	henry	TC	temperature compensated
h	height or high	TD	tunnel diode
hex.	hexagonal	THB	truss head brass
HF	high frequency	$\theta$	theta—angular phase displacement
HHB	hex head brass	thk	thick
HHS	hex head steel	THS	truss head steel
HSB	hex socket brass	tub.	tubular
HSS	hex socket steel	UHF	ultra high frequency
HV	high voltage	V	volt
Hz	hertz (cycles per second)	VAC	volts, alternating current
ID	inside diameter	var	variable
IF	intermediate frequency	VDC	volts, direct current
in.	inch or inches	VHF	very high frequency
incd	incandescent	VSWR	voltage standing wave ratio
$\infty$	infinity	W	watt
int	internal	w	wide or width
$\int$	integral	w/	with
k	kilohms or kilo ( $10^3$ )	w/o	without
$k\Omega$	kilohm	WW	wire-wound
kc	kilocycle	xmfr	transformer
kHz	kilohertz		

### PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial or model number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

### SPECIAL NOTES AND SYMBOLS

- ×000 Part first added at this serial number
- 00× Part removed after this serial number
- \*000-0000-00 Asterisk preceding Tektronix Part Number indicates manufactured by or for Tektronix, Inc., or reworked or checked components.
- Use 000-0000-00 Part number indicated is direct replacement.
-  Screwdriver adjustment.
-  Control, adjustment or connector.

# SECTION 8

## FIGURE AND INDEX NUMBERS

Items in this section are referenced by figure and index numbers to the illustrations which appear on the pullout pages immediately following the Diagrams section of this instruction manual.

## INDENTATION SYSTEM

This mechanical parts list is indented to indicate item relationships. Following is an example of the indentation system used in the Description column.

*Assembly and/or Component*  
*Detail Part of Assembly and/or Component*  
*mounting hardware for Detail Part*  
*Parts of Detail Part*  
*mounting hardware for Parts of Detail Part*  
*mounting hardware for Assembly and/or Component*

Mounting hardware always appears in the same indentation as the item it mounts, while the detail parts are indented to the right. Indented items are part of, and included with, the next higher indentation.

**Mounting hardware must be purchased separately, unless otherwise specified.**

## PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial or model number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

## ABBREVIATIONS AND SYMBOLS

For an explanation of the abbreviations and symbols used in this section, please refer to the page immediately preceding the Electrical Parts List in this instruction manual.

## TEST CONDITIONS FOR VOLTAGES AND WAVEFORMS

Typical voltage measurements and waveform photographs (shown in blue) were obtained under the following conditions unless noted otherwise on the individual diagrams:

### Test Oscilloscope

Bandwidth	DC to at least 50 MHz
Probe Input Impedance	10 Megohms, 7 picofarads
Probe Ground Lead	Clipped to Type 3S5 chassis
Triggering	Internal unless indicated otherwise

### DC Voltmeter

Type	Volt-Ohmmeter
Sensitivity	20,000 $\Omega$ /volt

### Type 3S5 Conditions

A calibrated Sampling Head installed or connected to Channel A (or B) being tested. Connected to Oscilloscope through 30-inch flexible extension (Tektronix Part No. 012-0060-00)

### Vertical Input Signal

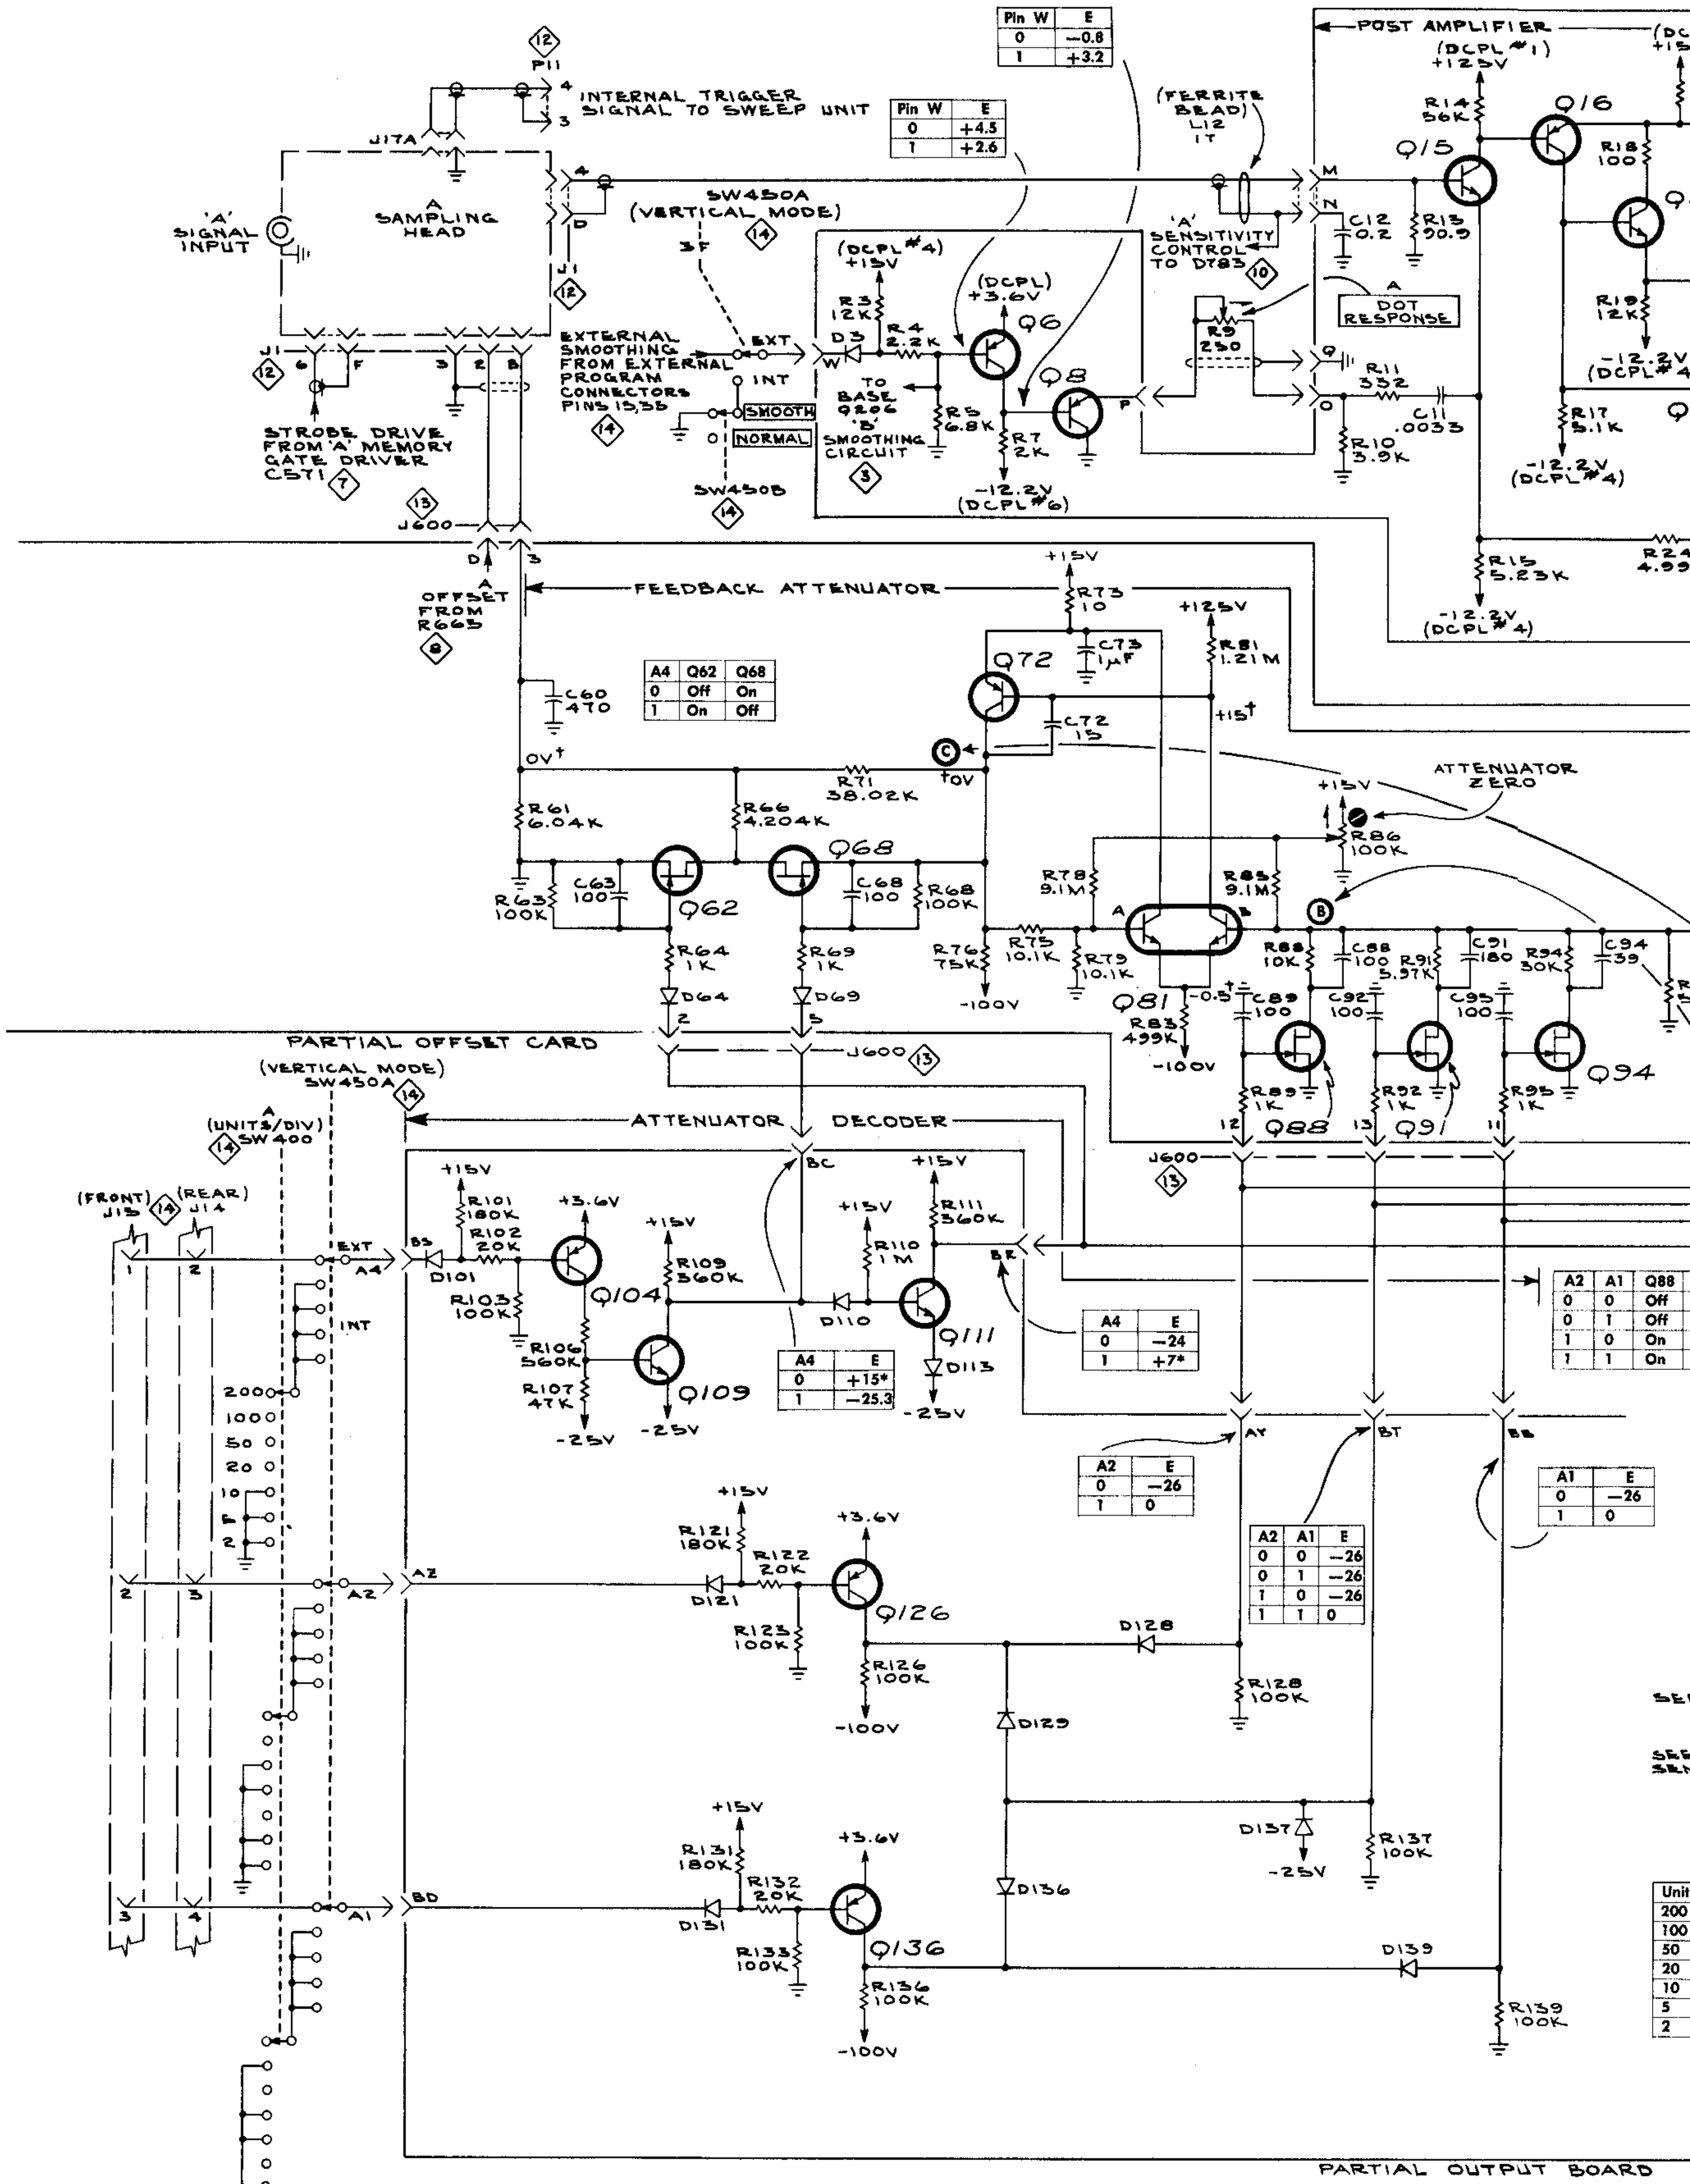

Termination or Coaxial cable connected. (Refer to Sampling Head Instruction Manual) No input Signal.

### Type 3S5 Control Settings (both Channels)

Mode Switch	CH A (CH B)
Units/Div	200
VARIABLE	CAL
INVERT	Pushed in
DC OFFSET	Midrange, 0 volts at OFFSET out jack.

### Sampling Sweep Unit 100 ns/Div or faster Triger Sensitivity

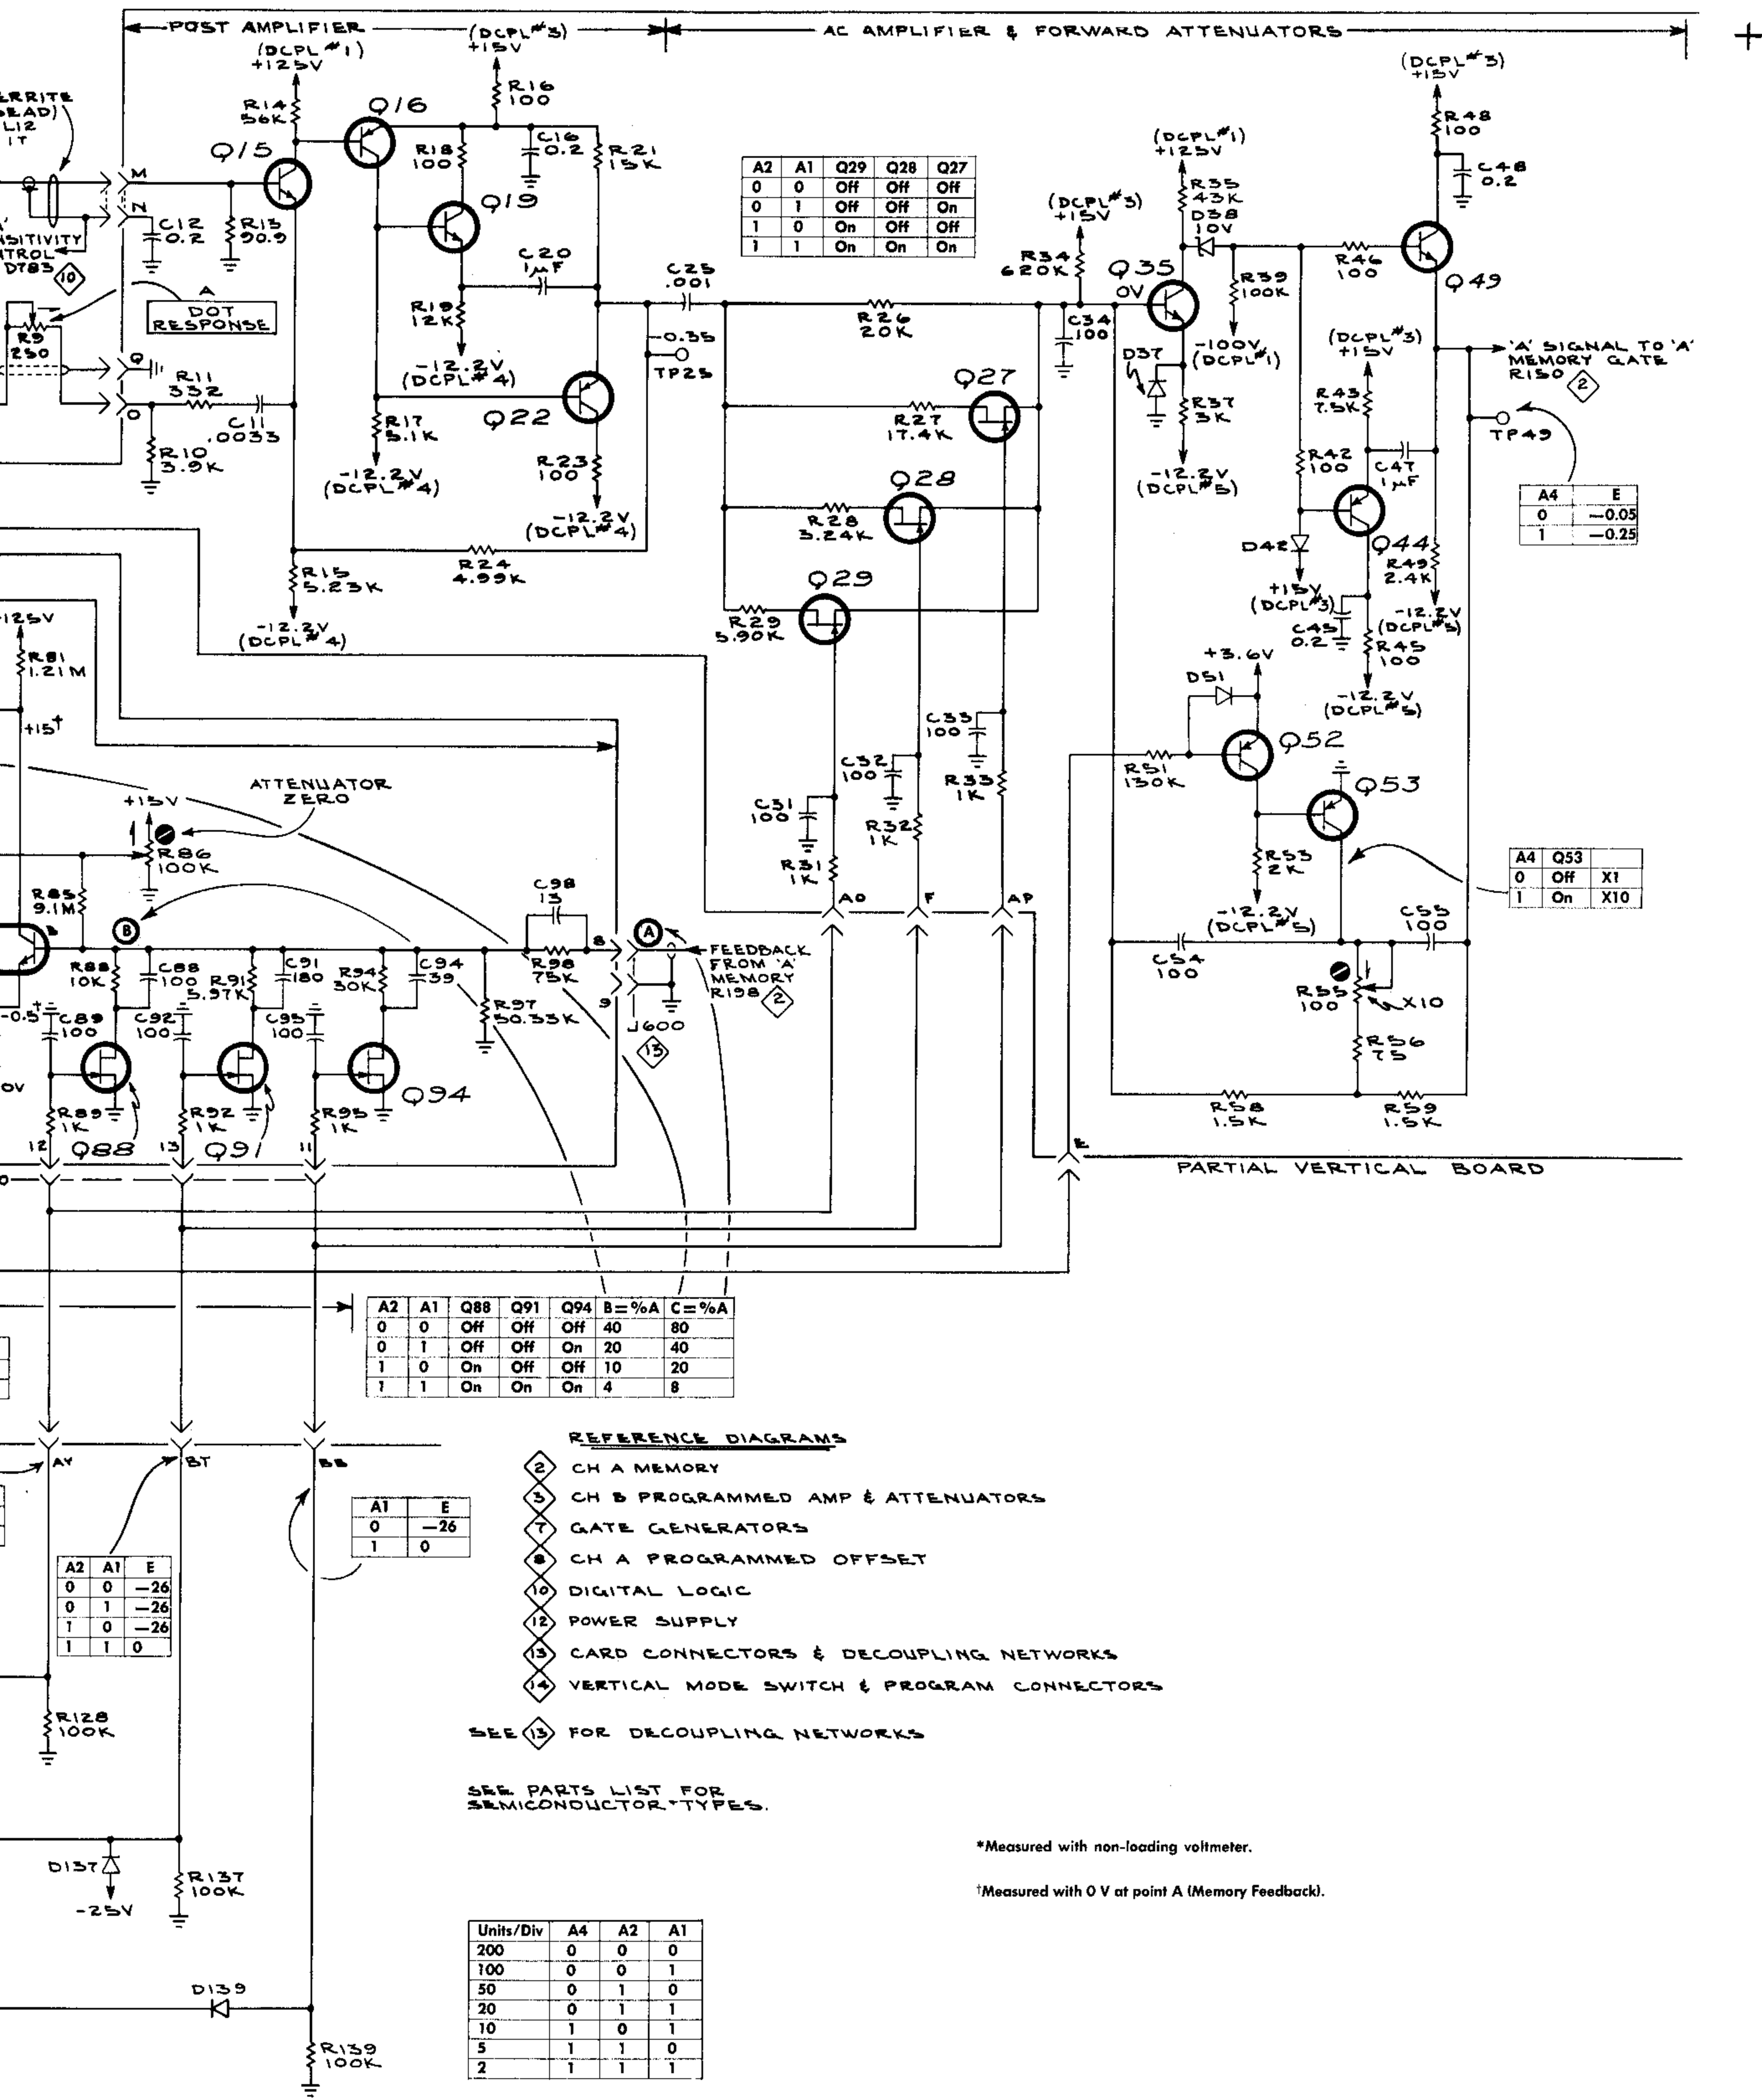

Fully clockwise (free run)

+ **A**

FIG. & INDEX NO.	TEKTRONIX PART NO.	SERIAL/MODEL NO.		Q T Y	DESCRIPTION
		EFF.	DISC.		
2-1	131-0422-00			1	CONNECTOR, 37 pin, male
-2	200-0660-00			1	COVER, connector
-3	388-0805-00			1	BOARD, circuit, connector
	070-0788-00			2	MANUAL, instruction (not shown)

## **MANUAL CHANGE INFORMATION**

At Tektronix, we continually strive to keep up with latest electronic developments by adding circuit and component improvements to our instruments as soon as they are developed and tested.

Sometimes, due to printing and shipping requirements, we can't get these changes immediately into printed manuals. Hence, your manual may contain new change information on following pages. If it does not, your manual is correct as printed.

## TEXT CORRECTION

Section 1            Specification

Page 1-2            ELECTRICAL CHARACTERISTICS

DELETE: the portion of the table that describes Loop Gain.

CHANGE: Position Control Range to read "CENTERING Control Range", and change all other references that appear in the manual from POSITION to CENTERING.

Section 2            Operating Instructions

Page 2-2            Operating Adjustments

CHANGE: the second paragraph under Operating Adjustments to read as follows:

Operating adjustments should be checked periodically, and must be adjusted when the Type 3S5 is used in a different oscilloscope. The 3S5 CENTERING, sampling head Bridge Balance, and the 3S5 GAIN controls are explained below.

Page 2-5            POSITION Control

CHANGE: to read as follows:

CENTERING            Adjusts a no-signal zero-offset free  
Control                run trace to the graticule centerline.  
(Screwdriver  
adjust)

Section 7            Performance Check/Calibration

Page 7-3            PERFORMANCE CHECK AND CALIBRATION RECORD INDEX

CHANGE: Step 15 to read as follows:

15. Check position Indicators and Adjust CENTERING Control. page 7-14  
Indicator neon will light showing the direction trace is off graticule.

Page 7-14      Step 15

REPLACE: the existing Step 15 with the following:

15. Check Position Indicators and Adjust CENTERING Control

Requirement-Up position indicator neon lights, and down position indicator neon is dark, when CRT beam is above the graticule. Down position indicator lights and up position indicator is dark when CRT beam is below the graticule.

- a. Set the sampling sweep unit triggering controls for a free-running trace and the Type 3S5 A DC OFFSET control to place the trace above the top graticule line.
- b. Check that the up indicator is on and the down indicator is off.
- c. Offset the trace below the bottom graticule line.
- d. Check that the down indicator is on and the up indicator is off.
- e. Set the DC OFFSET control for zero volts offset. Terminate the sampling head input (Types S-1 or S-2) with 50  $\Omega$  or a 50  $\Omega$  coaxial cable (no signal input). (Types S-3, leave probe tip unconnected.)
- f. Adjust the front panel CENTERING control to place the free run trace at the graticule centerline.

NOTE

The Type 230 may not give valid amplitude readout if the no-signal zero-offset trace position is more than 1/2 major division away from the graticule centerline.

Page 7-18 Table 7-5

ADD: the following after the last lines in XO.1 and X1, as indicated:

	Type 3S5	Decimal					Units	÷
	Units/Div	1	2	3	4	5	Multiplier	Outputs
XO.1	2	0	X <sup>3</sup>	X <sup>2</sup>	0	0	m	5
X 1	2	0	0	X <sup>3</sup>	X <sup>2</sup>	0	m	5

ELECTRICAL PARTS LIST CORRECTION

CHANGE TO:

R11	321-0147-00	332 Ω	1/8 W	1%
R24	321-0260-00	4.99 kΩ	1/8 W	1%
R211	321-0147-00	332 Ω	1/8 W	1%
R224	321-0260-00	4.99 kΩ	1/8 W	1%

TYPE 3S5

TEXT CORRECTION

Section 2            Operating Instructions

Page 2-5            INVERT Switches

CHANGE: the last sentence to read as follows:

"Inverts the signal sent to a digital unit."

c2/868

## TEXT CORRECTION

## Section 7 PERFORMANCE CHECK/CALIBRATION

## Page 7-1 Calibration Aids

ADD: the following to item 12:

A rigid extender, Tektronix Part No. 067-0590-00, may be used with a rack mounted Type 568.

## Page 7-12 Step 12, part e

DELETE: ed on the word connected in line 2 of part e.

## Step 13, part a

ADD: the following to the last sentence in part a:

, the Display to A-Vc and the Millivolts/cm to 50.

## Page 7-15 Step 19, part b

CHANGE: line 5 to read:

div point; see point no. 2, Fig. 7-14.

## Page 7-16 Step 19, part c

CHANGE: lines 3 and 4 to read as follows:

point; see point no. 3, Fig. 7-14. Adjust the sampling sweep unit Time Position controls so the two points (no. 2 and no. 3)

## Step 19, part d

CHANGE: lines 3 and 4 to read as follows:

graticule centerline: see Fig. 7-14, point no. 1. If not, adjust the A DELAY control, R561 shown in Fig. 7-4, so that the step

Page 7-16            Step 21

CHANGE: line 3 of part c to read:

the Vc Range switch to 1.11 with the Input Atten at R=infinity.

CHANGE: line 2 thru 4 of part d to read:

line, -9.95 V at TP663. If trace is not at the centerline,  
adjust the A OFFSET CAL control, R638 shown in Fig. 7-15,  
for -9.95 V, trace at test oscilloscope centerline.

Page 7-17            Step 22

CHANGE: the NOTE following part f to read:

NOTE

Do not ground Pin 21 (or Pin 8) longer than  
necessary to make the adjustment.

TYPE 3S5

SUBJECT: Power supply circuit changes to all instruments.

The +300-Volt Supply is decoupled by the addition of two capacitors and a small change in value of two resistors.

DIAGRAM 12

Add C970 from P11 pin 10 to ground. (.01  $\mu$ F)

DIAGRAM 13

Add C971 (diagram upper left corner) at junction of R970 and pin S to ground. (.001  $\mu$ F)

ELECTRICAL PARTS LIST CORRECTIONS

Page 8-4, Add:

C970	283-0002-00	0.01 $\mu$ F	Cer	500 V
C971	283-0000-00	0.001 $\mu$ F	Cer	500 V

Page 8-31, Change value and part number for:

R665	321-0316-03	19.1 k $\Omega$	1/8 W	<del>1/4 W</del>
------	-------------	-----------------	-------	------------------

Page 8-32, Change value and part number for:

R765	321-0316-03	19.1 k $\Omega$	1/8 W	<del>1/4 W</del>
------	-------------	-----------------	-------	------------------

NOTE: Some early instruments will contain an 18.99 k $\Omega$  and a 100  $\Omega$  resistor in series for both R665 and R765. In case of failure, replace with parts listed above.
