BASIC-80

610P70641

basic-80
reference
manual

This manual is a reference for Microsoft's BASIC-80 language, release 5.0 and later.

There are significant differences between the 5.0 release of BASIC-80 and the previous releases (release 4.51 and earlier). If you have programs written under a previous release of BASIC-80, check Appendix A for new features in 5.0 that may affect execution.

Introduction

BASIC-80 is the most extensive implementation of BASIC available for the 8080 and Z80 microprocessors. In its fifth major release (Release 5.0), BASIC-80 meets the ANSI qualifications for BASIC, as set forth in document BSRX3.60-1978. Each release of BASIC-80 consists of three upward compatible versions: 8K, Extended and Disk . This manual is a reference for all three versions of BASIC-80, release 5.0 and later. This manual is also a reference for Microsoft BASIC-86 and the Microsoft BASIC Compiler. BASIC-86 is currently available in Extended and Disk Standalone versions, which are comparable to the BASIC-80 Extended and Disk Standalone versions.

There are significant differences between the 5.0 release of BASIC-80 and the previous releases (release 4.51 and earlier). If you have programs written under a previous release of BASIC-80, check Appendix A for new features in 5.0 that may affect execution.

The manual is divided into three large chapters plus a number of appendices. Chapter 1 covers a variety of topics, largely pertaining to information representation when using BASIC-80. Chapter 2 contains the syntax and semantics of every command and statement in BASIC-80, ordered alphabetically. Chapter 3 describes all of BASIC-80's intrinsic functions, also ordered alphabetically. The appendices contain information pertaining to individual operating systems; plus lists of error messages, ASCII codes, and math functions; and helpful information on assembly language subroutines and disk I/O.

Information in this document is subject to change without notice and does not represent a commitment on the part of Microsoft. The software described in this document is furnished under a license agreement or non-disclosure agreement. The software may be used or copied only in accordance with the terms of the agreement. It is against the law to copy Microsoft BASIC on cassette tape, disk, or any other medium for any purpose other than personal convenience.

To report software bugs or errors in the documentation, please complete and return the Problem Report at the back of this manual.

BASIC-80 Reference Manual

CONTENTS

INTRODUCTION

CHAPTER 1

GENERAL INFORMATION ABOUT BASIC-80

1.1 INITIALIZATION

The procedure for initialization will vary with different implementations of BASIC-80. Check the appropriate appendix at the back of this manual to determine how BASIC-80 is initialized with your operating system.

1.2 MODES OF OPERATION

When BASIC-80 is initialized, it types the prompt "Ok". "Ok" means BASIC-80 is at command level, that is, it is ready to accept commands. At this point, BASIC-80 may be used in either of two modes: the direct mode or the indirect mode.

In the direct mode, BASIC statements and commands are not preceded by line numbers.   They are executed as they are entered. Results of arithmetic and logical operations may be displayed immediately and stored for later use, but the instructions themselves are lost after execution. This mode is useful for debugging and for using BASIC as a "calculator" for quick computations that do not require a complete program.

The indirect mode is the mode used for entering programs. Program lines are preceded by line numbers and are stored in memory.   The program stored in memory is executed by entering the RUN command.

1.3 LINE FORMAT

Program lines in a BASIC program have the following format (square brackets indicate optional):

nnnnn BASIC statement[:BASIC statement...] <carriage return>

At the programmer's option, more than one BASIC statement may be placed on a line, but each statement on a line must be separated from the last by a colon.

A BASIC program line always begins with a line number, ends with a carriage return, and may contain a maximum of:

        72 characters in 8K BASIC-80
       255 characters in Extended and Disk BASIC-80.

In Extended and Disk versions, it is possible to extend a logical line over more than one physical line by use of the terminal's <line feed> key. <Line feed> lets you continue typing a logical line on the next physical line without entering a <carriage return>. (In the 8K version, <line feed> has no effect.)

1.3.1 Line Numbers

Every BASIC program line begins with a line number. Line numbers indicate the order in which the program lines are stored in memory and are also used as references when branching and editing. Line numbers must be in the range 0 to 65529. In the Extended and Disk versions, a period (.) may be used in EDIT, LIST, AUTO and DELETE commands to refer to the current line.

1.4 CHARACTER SET

The BASIC-80 character set is comprised of alphabetic characters, numeric characters and special characters.

The alphabetic characters in BASIC-80 are the upper case and lower case letters of the alphabet.

The numeric characters in BASIC-80 are the digits 0 through 9.

The following special characters and terminal keys are recognized by BASIC-80:

Character	Name
	Blank
=	Equal sign or assignment symbol
+	Plus sign
-	Minus sign
*	Asterisk or multiplication symbol
/	Slash or division symbol
^	Up arrow or exponentiation symbol
(	Left parenthesis
)	Right parenthesis
%	Percent
#	Number (or pound) sign
$	Dollar sign
!	Exclamation point
[	Left bracket
]	Right bracket
,	Comma
.	Period or decimal point
'	Single quotation mark (apostrophe)
;	Semicolon
:	Colon
&	Ampersand
?	Question mark
<	Less than
>	Greater than
\	Backslash or integer division symbol
@	At-sign
_	Underscore
<rubout>	Deletes last character typed.
<escape>	Escapes Edit Mode subcommands. See Section 2.16.
<tab>	Moves print position to next tab stop. Tab stops are every eight columns.
<line feed>	Moves to next physical line.
<carriage return>	Terminates input of a line.

1.4.1 Control Characters

The following control characters are in BASIC-80:

Control-A   Enters Edit Mode on the line being typed.

Control-C   Interrupts program execution and returns to BASIC-80 command level.

Control-G   Rings the bell at the terminal.

Control-H   Backspace. Deletes the last character typed.

Control-I   Tab. Tab stops are every eight columns.

Control-O   Halts program output while execution continues. A second Control-O restarts output.

Control-R   Retypes the line that is currently being typed.

Control-S   Suspends program execution.

Control-Q   Resumes program execution after a Control-S.

Control-U   Deletes the line that is currently being typed.

1.5 CONSTANTS

Constants are the actual values BASIC uses during execution. There are two types of constants: string and numeric.

A string constant is a sequence of up to 255 alphanumeric characters enclosed in double quotation marks. Examples of string constants:

    "HELLO"
    "$25,000.00"
    "Number of Employees"

Numeric constants are positive or negative numbers. Numeric constants in BASIC cannot contain commas. There are five types of numeric constants:

1. Integer constants   Whole numbers between -32768 and +32767. Integer constants do not have decimal points.

2. Fixed Point constants   Positive or negative real numbers, i.e., numbers that contain decimal points.

3. Floating Point   Positive or negative numbers repre-
    constants   sented in exponential form (similar
                              to   scientific   notation).   A
                              floating point constant consists of
                              an optionally signed integer or
                              fixed point number (the mantissa)
                              followed by the letter E and an
                              optionally signed integer (the
                              exponent). The allowable range for
                              floating point constants is 10-38
                              to 10+38.
                              Examples:

                              235.988E-7 = .0000235988
                              2359E6 = 2359000000

                              (Double precision floating point
                              constants use the letter D instead
                              of E. See Section 1.5.1.)

4. Hex constants   Hexadecimal numbers with the prefix
                              &H. Examples:

                                  &H76
                                  &H32F

5. Octal constants   Octal numbers with the prefix &O or
                              &. Examples:

                                  &O347
                                  &1234

1.5.1   Single And Double Precision Form For Numeric Constants

In the 8K version of BASIC-80, all numeric constants are
single precision numbers. They are stored with 7 digits of
precision, and printed with up to 6 digits.

In the Extended and Disk versions, however, numeric
constants may be either single precision or double precision
numbers. With double precision, the numbers are stored with
16 digits of precision, and printed with up to 16 digits.

A single precision constant is any numeric constant that has:

1.   seven or fewer digits, or

2.   exponential form using E, or

3.   a trailing exclamation point (!)

A double precision constant is any numeric constant that has:

1.   eight or more digits, or

2.   exponential form using D, or

3.   a trailing number sign (#)

Examples:

Single Precision Constants	Double Precision Constants
46.8	345692811
-1.09E-06	-1.09432D-06
3489.0	3489.0#
22.5!	7654321.1234

1.6   VARIABLES

Variables are names used to represent values that are used in a BASIC program. The value of a variable may be assigned explicitly by the programmer, or it may be assigned as the result of calculations in the program. Before a variable is assigned a value, its value is assumed to be zero.

1.6.1   Variable Names And Declaration Characters

BASIC-80 variable names may be any length, however, in the 8K version, only the first two characters are significant. In the Extended and Disk versions, up to 40 characters are significant. The characters allowed in a variable name are letters and numbers, and the decimal point is allowed in Extended and Disk variable names. The first character must be a letter. Special type declaration characters are also allowed -- see below.

A variable name may not be a reserved word. The Extended and Disk versions allow embedded reserved words; the 8K version does not. If a variable begins with FN, it is assumed to be a call to a user-defined function. Reserved words include all BASIC-80 commands, statements, function

names and operator names.

Variables may represent either a numeric value or a string. String variable names are written with a dollar sign ($) as the last character. For example: A$ = "SALES REPORT". The dollar sign is a variable type declaration character, that is, it "declares" that the variable will represent a string.

In the Extended and Disk versions, numeric variable names may declare integer, single or double precision values. (All numeric values in 8K are single precision.) The type declaration characters for these variable names are as follows:

    %   Integer variable

    !   Single precision variable

    #   Double precision variable

The default type for a numeric variable name is single precision.

Examples of BASIC-80 variable names follow.

In Extended and Disk versions:

```
PI#        declares a double precision value
MINIMUM!   declares a single precision value
LIMIT%     declares an integer value
```

In 8K, Extended and Disk versions:

```
N$         declares a string value
ABC        represents a single precision value
```

In the Extended and Disk versions of BASIC-80, there is a second method by which variable types may be declared. The BASIC-80 statements DEFINT, DEFSTR, DEFSNG and DEFDBL may be included in a program to declare the types for certain variable names. These statements are described in detail in Section 2.12.

1.6.2 Array Variables

An array is a group or table of values referenced by the same variable name. Each element in an array is referenced by an array variable that is subscripted with an integer or an integer expression. An array variable name has as many subscripts as there are dimensions in the array. For example V(10) would reference a value in a one-dimension array, T(1,4) would reference a value in a two-dimension array, and so on. The maximum number of dimensions for an

array is 255. The maximum number of elements per dimension
is 32767.

1.6.3 Space Requirements

VARIABLES: BYTES

        INTEGER   2
        SINGLE PRECISION   4
DOUBLE PRECISION   8

ARRAYS: BYTES

        INTEGER   2 per element
        SINGLE PRECISION   4 per element
DOUBLE PRECISION   8 per element

STRINGS:

3 bytes overhead plus the present contents of the string.

1.7 TYPE CONVERSION

When necessary, BASIC will convert a numeric constant from
one type to another.   The following rules and examples
should be kept in mind.

    1.   If a numeric constant of one type is set equal to a
        numeric variable of a different type, the number
        will be stored as the type declared in the variable
        name.   (If a string variable is set equal to a
        numeric value or vice versa, a "Type mismatch"
        error occurs.)
        Example:

        10 A% = 23.42
        20 PRINT A%
        RUN
         23

    2.   During expression evaluation, all of the operands
        in   an arithmetic or relational operation are
        converted to the same degree of precision, i.e.,
        that of the most precise operand. Also, the result
        of an arithmetic operation is returned to this
        degree of precision.
        Examples:

        10 D# = 6#/7   The arithmetic was performed

```
20 PRINT D#        in double precision and the
RUN                result was returned in D#
 .8571428571428571 as a double precision value.
```

```
10 D = 6#/7        The arithmetic was performed
20 PRINT D         in double precision and the
RUN                result was returned to D (single
 .857143           precision variable), rounded and
                   printed as a single precision
                   value.
```

3. Logical operators (see Section 1.8.3) convert their operands to integers and return an integer result. Operands must be in the range -32768 to 32767 or an "Overflow" error occurs.

4. When a floating point value is converted to an integer, the fractional portion is rounded.
    Example:

```
10 C% = 55.88
20 PRINT C%
RUN
 56
```

5. If a double precision variable is assigned a single precision value, only the first seven digits, rounded, of the converted number will be valid. This is because only seven digits of accuracy were supplied with the single precision value. The absolute value of the difference between the printed double precision number and the original single precision value will be less than $6.3E-8$ times the original single precision value.
    Example:

```
10 A = 2.04
20 B# = A
30 PRINT A;B#
RUN
 2.04  2.039999961853027
```

1.8 EXPRESSIONS AND OPERATORS

An expression may be simply a string or numeric constant, or a variable, or it may combine constants and variables with operators to produce a single value.

Operators perform mathematical or logical operations on values. The operators provided by BASIC-80 may be divided into four categories:

1. Arithmetic

2. Relational

3. Logical

4. Functional

1.8.1 Arithmetic Operators

The arithmetic operators, in order of precedence, are:

Operator	Operation	Sample Expression
^	Exponentiation	X^Y
-	Negation	-X
*,/	Multiplication, Floating Point Division	X*Y X/Y
+,-	Addition, Subtraction	X+Y

To change the order in which the operations are performed, use parentheses. Operations within parentheses are performed first. Inside parentheses, the usual order of operations is maintained.

Here are some sample algebraic expressions and their BASIC counterparts.

Algebraic Expression	BASIC Expression
$X+2Y$	X+Y*2
$X-\dfrac{Y}{Z}$	X-Y/Z
$\dfrac{XY}{Z}$	X*Y/Z
$\dfrac{X+Y}{Z}$	(X+Y)/Z
$(X^2)^Y$	(X^2)^Y
X^{Y^Z}	X^(Y^Z)
$X(-Y)$	X*(-Y) Two consecutive operators must be separated by parentheses.

1.8.1.1 Integer Division And Modulus Arithmetic -
Two additional operators are available in Extended and Disk
versions   of   BASIC-80:   Integer division and modulus
arithmetic.

Integer division is denoted by the baskslash (\).   The
operands are rounded to integers (must be in the range
-32768 to 32767) before the division is performed,   and the
quotient is truncated to an integer.
For example:

        10\4 = 2
        25.68\6.99 = 3

The precedence of   integer   division   is   just   after
multiplication and floating point division.

Modulus arithmetic is denoted by the operator MOD.   It gives
the integer value that is the remainder of an integer
division. For example:

        10.4 MOD 4 = 2 (10/4=2 with a remainder 2)
        25.68 MOD 6.99 = 5 (26/7=3 with a remainder 5)

The precedence of modulus arithmetic is just after integer
division.

1.8.1.2 Overflow And Division By Zero -
If, during the evaluation of an expression, a division by
zero is encountered, the "Division by zero" error message is
displayed, machine infinity with the sign of   the   numerator
is supplied as the result of the division, and execution
continues. If the evaluation of an exponentiation results
in zero being raised to a negative power, the "Division by
zero" error message is displayed, positive machine infinity
is supplied as the result of the exponentiation, and
execution continues.

If overflow occurs, the "Overflow" error   message   is
displayed, machine infinity with the algebraically correct
sign is supplied as the result, and execution continues.

1.8.2 Relational Operators

Relational operators are used to compare two values.   The
result of the comparison is either "true" (-1) or "false"
(0). This result may then used to make a decision regarding
program flow. (See IF, Section 2.26.)

Operator	Relation Tested	Expression
=	Equality	X=Y
<>	Inequality	X<>Y
<	Less than	X<Y
>	Greater than	X>Y
<=	Less than or equal to	X<=Y
>=	Greater than or equal to	X>=Y

(The equal sign is also used to assign a value to a variable. See LET, Section 2.30.)

When arithmetic and relational operators are combined in one expression, the arithmetic is always performed first. For example, the expression

    X+Y < (T-1)/Z

is true if the value of X plus Y is less than the value of T-1 divided by Z. More examples:

    IF SIN(X)<0 GOTO 1000
    IF I MOD J <> 0 THEN K=K+1

1.8.3 Logical Operators

Logical operators perform tests on multiple relations, bit manipulation, or Boolean operations. The logical operator returns a bitwise result which is either "true" (not zero) or "false" (zero). In an expression, logical operations are performed after arithmetic and relational operations. The outcome of a logical operation is determined as shown in the following table. The operators are listed in order of precedence.

NOT

X	NOT X
1	0
0	1

AND

X	Y	X AND Y
1	1	1
1	0	0
0	1	0
0	0	0

OR

X	Y	X OR Y
1	1	1
1	0	1
0	1	1
0	0	0

XOR

X	Y	X XOR Y
1	1	0
1	0	1
0	1	1
0	0	0

IMP

X	Y	X IMP Y
1	1	1
1	0	0
0	1	1
0	0	1

EQV

X	Y	X EQV Y
1	1	1
1	0	0
0	1	0
0	0	1

Just as the relational operators can be used to make
decisions regarding program flow, logical operators can
connect two or more relations and return a true or false
value to be used in a decision (see IF, Section 2.26). For
example:

    IF D<200 AND F<4 THEN 80
    IF I>10 OR K<0 THEN 50
    IF NOT P THEN 100

Logical operators work by converting their operands to
sixteen bit, signed, two's complement integers in the range
-32768 to +32767. (If the operands are not in this range,
an error results.) If both operands are supplied as 0 or -1,
logical operators return 0 or -1. The given operation is

performed on these integers in bitwise fashion, i.e., each bit of the result is determined by the corresponding bits in the two operands.

Thus, it is possible to use logical operators to test bytes for a particular bit pattern. For instance, the AND operator may be used to "mask" all but one of the bits of a status byte at a machine I/O port. The OR operator may be used to "merge" two bytes to create a particular binary value. The following examples will help demonstrate how the logical operators work.

63 AND 16=16   63 = binary 111111 and 16 = binary
                   10000, so 63 AND 16 = 16

15 AND 14=14   15 = binary 1111 and 14 = binary 1110,
                   so 15 AND 14 = 14 (binary 1110)

-1 AND 8=8   -1 = binary 1111111111111111 and
                   8 = binary 1000, so -1 AND 8 = 8

4 OR 2=6   4 = binary 100 and 2 = binary 10,
                   so 4 OR 2 = 6 (binary 110)

10 OR 10=10   10 = binary 1010, so 1010 OR 1010 =
                   1010 (10)

-1 OR -2=-1   -1 = binary 1111111111111111 and
                   -2 = binary 1111111111111110,
                   so -1 OR -2 = -1. The bit
                   complement of sixteen zeros is
                   sixteen ones, which is the
                   two's complement representation of -1.

NOT X=-(X+1)   The two's complement of any integer
                   is the bit complement plus one.

1.8.4 Functional Operators

A function is used in an expression to call a predetermined operation that is to be performed on an operand. BASIC-80 has "intrinsic" functions that reside in the system, such as SQR (square root) or SIN (sine). All of BASIC-80's intrinsic functions are described in Chapter 3.

BASIC-80 also allows "user defined" functions that are written by the programmer. See DEF FN, Section 2.11.

1.8.5 String Operations

Strings may be concatenated using +. For example:

```
10 A$="FILE" : B$="NAME"
20 PRINT A$ + B$
30 PRINT "NEW " + A$ + B$
RUN
FILENAME
NEW FILENAME
```

Strings may be compared using the same relational operators
that are used with numbers:

```
    =     <>     <     >     <=     >=
```

String comparisons are made by taking one character at a
time from each string and comparing the ASCII codes. If all
the ASCII codes are the same, the strings are equal. If the
ASCII codes differ, the lower code number precedes the
higher. If, during string comparison, the end of one string
is reached, the shorter string is said to be smaller.
Leading and trailing blanks are significant.   Examples:

```
"AA" < "AB"
"FILENAME" = "FILENAME"
"X&" > "X#"
"CL " > "CL"
"kg" > "KG"
"SMYTH" < "SMYTHE"
B$ < "9/12/78"     where B$ = "8/12/78"
```

Thus, string comparisons can be used to test string values
or to alphabetize strings.   All string constants used in
comparison expressions must be enclosed in quotation marks.

1.9 INPUT EDITING

If an incorrect character is entered as a line is being
typed, it can be deleted with the RUBOUT key or with
Control-H. Rubout surrounds the deleted character(s) with
backslashes, and Control-H has the effect of backspacing
over a character and erasing it. Once a character(s) has
been deleted, simply continue typing the line as desired.

To delete a line that is in the process of being typed, type
Control-U.   A carriage return is executed automatically
after the line is deleted.

To correct program lines for a program that is currently in
memory, simply retype the line using the same line number.
BASIC-80 will automatically replace the old line with the
new line.

More sophisticated editing capabilities are provided in the
Extended and Disk versions of BASIC-80. See EDIT, Section
2.16.

To delete the entire program that is currently residing in
memory, enter the NEW command. (See Section 2.41.) NEW is
usually used to clear memory prior to entering a new
program.

1.10   ERROR MESSAGES

If BASIC-80 detects an error that causes program execution
to terminate, an error message is printed.   In the 8K
version, only the error code is printed.   In   the Extended
and Disk versions, the entire error message is printed. For
a complete list of BASIC-80 error codes and error messages,
see Appendix J.

CHAPTER 2

BASIC-80 COMMANDS AND STATEMENTS

All of the BASIC-80 commands and statements are described in this chapter. Each description is formatted as follows:

Format: Shows the correct format for the instruction.
             See below for format notation.

Versions: Lists the versions of BASIC-80
             in which the instruction is available.

Purpose: Tells what the instruction is used for.

Remarks: Describes in detail how the instruction
             is used.

Example: Shows sample programs or program segments
             that demonstrate the use of the instruction.

Format Notation
Wherever the format for a statement or command is given, the following rules apply:

1.   Items in capital letters must be input as shown.

2.   Items in lower case letters enclosed in angle brackets (< >) are to be supplied by the user.

3.   Items in square brackets ([ ]) are optional.

4.   All punctuation except angle brackets and square brackets (i.e., commas, parentheses, semicolons, hyphens, equal signs) must be included where shown.

5.   Items followed by an ellipsis (...) may be repeated any number of times (up to the length of the line).

2.1 AUTO

Format: AUTO [<line number>[,<increment>]]

Versions: Extended, Disk

Purpose: To generate a line number automatically after every carriage return.

Remarks: AUTO begins numbering at <line number> and increments each subsequent line number by <increment>. The default for both values is 10. If <line number> is followed by a comma but <increment> is not specified, the last increment specified in an AUTO command is assumed.

              If AUTO generates a line number that is already being used, an asterisk is printed after the number to warn the user that any input will replace the existing line. However, typing a carriage return immediately after the asterisk will save the line and generate the next line number.

              AUTO is terminated by typing Control-C. The line in which Control-C is typed is not saved. After Control-C is typed, BASIC returns to command level.

Example: AUTO 100,50   Generates line numbers 100, 150, 200 ...

              AUTO   Generates line numbers 10, 20, 30, 40 ...

2.2 CALL

Format: CALL <variable name>[(<argument list>)]

Version: Extended, Disk

Purpose: To call an assembly language subroutine.

Remarks: The CALL statement is one way to transfer
                program flow to an external subroutine. (See
                also the USR function, Section 3.40)

                <variable name> contains an address that is the
                starting point in memory of the subroutine.
                <variable name> may not be an array variable
                name.   <argument list> contains the arguments
                that are passed to the external subroutine.
                <argument list> may contain only variables.

                The CALL statement generates the same calling
                sequence used by Microsoft's FORTRAN, COBOL and
                BASIC compilers.

Example: 110 MYROUT=&HD000
                120 CALL MYROUT(I,J,K)
                        .
                        .
                        .

NOTE: For a BASIC Compiler program, line 110 is not
                needed because the address of MYROUT will be
                assigned by the linking loader at load time.

2.3 <u>CHAIN</u>

Format: CHAIN [MERGE] <filename>[,[<line number exp>]
                [,ALL][,DELETE<range>]]

Version: Disk

Purpose: To call a program and pass variables to it from
             the current program.

Remarks: <filename> is the name of the program that is
             called. Example:

                 CHAIN"PROG1"

             <line number exp> is a line number or an
             expression that evaluates to a line number in
             the called program. It is the starting point
             for execution of the called program. If it is
             omitted, execution begins at the first line.
             Example:

                 CHAIN"PROG1",1000

             <line number exp> is not affected by a RENUM
             command.

             With the ALL option, every variable in the
             current program is passed to the called program.
             If the ALL option is omitted, the current
             program must contain a COMMON statement to list
             the variables that are passed. See Section 2.7.
             Example:

                 CHAIN"PROG1",1000,ALL

             If the MERGE option is included, it allows a
             subroutine to be brought into the BASIC program
             as an overlay. That is, a MERGE operation is
             performed with the current program and the
             called program. The called program must be an
             ASCII file if it is to be MERGEd. Example:

                 CHAIN MERGE"OVRLAY",1000

             After an overlay is brought in, it is usually
             desirable to delete it so that a new overlay may
             be brought in.   To do this, use the DELETE
             option. Example:

                 CHAIN MERGE"OVRLAY2",1000,DELETE 1000-5000

             The line numbers in <range> are affected by the
             RENUM command.

NOTE: The CHAIN statement with MERGE option leaves the
               files open and preserves the current OPTION BASE
               setting.

NOTE: If the MERGE option is omitted, CHAIN does not
               preserve variable types or user-defined
               functions for use by the chained program. That
               is, any DEFINT, DEFSNG, DEFDBL, DEFSTR, or DEFFN
               statements containing shared variables must be
               restated in the chained program.

NOTE: The Microsoft BASIC compiler does not support
               the ALL, MERGE, DELETE, and LINE number exp>
               options to CHAIN. Thus, the statement format is
               CHAIN   FILENAME>.   If you wish to maintain
               compatibility with the BASIC compiler, it is
               recommended   that   COMMON   be used to pass
               variables and that overlays not be used.   The
               CHAIN statement leaves the files open during
               CHAINing.

2.4 CLEAR

Format: CLEAR [,[<expression1>][,<expression2>]]

Versions: 8K, Extended, Disk

Purpose: To set all numeric variables to zero, all string
               variables to null, and to close all open files;
               and, optionally, to set the end of memory and
               the amount of stack space.

Remarks: <expression1> is a memory location which, if
               specified, sets the highest location available
               for use by BASIC-80.

               <expression2> sets aside stack space for BASIC.
               The default is 256 bytes or one-eighth of the
               available memory, whichever is smaller.

NOTE: In previous versions of BASIC-80, <expression1>
               set   the   amount   of   string   space,   and
               <expression2> set the end of memory.   BASIC-80,
               release 5.0 and later, allocates string space
               dynamically. An "Out of string space error"
               occurs only if there is no free memory left for
               BASIC to use.

NOTE: The BASIC Compiler supports the CLEAR statement
               with   the restriction that EXPRESSION1> and
               EXPRESSION2> must be integer expressions. If a
               value of 0 is given for either expression, the
               appropriate default is used. The default stack
               size is 256 bytes, and the default top of memory
               is the current top of memory.   The CLEAR
               statement performs the following actions:

                   Closes all files
                   Clears all COMMON and user variables
                   Resets the stack and string space
                   Releases all disk buffers

Examples: CLEAR

               CLEAR ,32768

               CLEAR ,,2000

               CLEAR ,32768,2000

2.5 CLOAD

Formats: CLOAD <filename>

               CLOAD?   <filename>

               CLOAD* <array name>

Versions: 8K (cassette), Extended (cassette)

Purpose: To load a program or an array from cassette tape
               into memory.

Remarks: CLOAD executes a NEW command before it loads the
               program from cassette tape. <filename> is the
               string expression or the first character of the
               string expression that was specified when the
               program was CSAVEd.

               CLOAD? verifies tapes by comparing the program
               currently in memory with the file on tape that
               has the same filename. If they are the same,
               BASIC-80 prints Ok. If not, BASIC-80 prints NO
               GOOD.

               CLOAD* loads a numeric array that has been saved
               on tape.   The data on tape is loaded into the
               array called <array name> specified when the
               array was CSAVE*ed.

               CLOAD and CLOAD? are always entered at command
               level as direct mode commands. CLOAD* may be
               entered at command level or used as a program
               statement.   Make   sure the array has been
               DIMensioned before it is loaded.   BASIC-80
               always returns to command level after a CLOAD,
               CLOAD? or CLOAD* is executed. Before a CLOAD
               is executed, make sure the cassette recorder is
               properly connected and in the Play mode, and the
               tape is possitioned correctly.

               See also CSAVE, Section 2.9.

NOTE: CLOAD and CSAVE are not included   in   all
               implementations of BASIC-80.

Example: CLOAD "MAX2"

               Loads file "M" into memory.

2.6 CLOSE

Format: CLOSE[[#]<file number>[,[#]<file number...>]]

Version: Disk

Purpose: To conclude I/O to a disk file.

Remarks: <file number> is the number under which the file
            was OPENed. A CLOSE with no arguments closes
            all open files.

            The association between a particular file and
            file number terminates upon execution of a
            CLOSE. The file may then be reOPENed using the
            same or a different file number; likewise, that
            file number may now be reused to OPEN any file.

            A CLOSE for a sequential output file writes the
            final buffer of output.

            The END statement and the NEW command always
            CLOSE all disk files automatically. (STOP does
            not close disk files.)

Example: See Appendix B.

2.7 COMMON

Format: COMMON <list of variables>

Version: Disk

Purpose: To pass variables to a CHAINed program.

Remarks: The COMMON statement is used in conjunction with
               the CHAIN statement. COMMON statements may
               appear anywhere in a program, though it is
               recommended that they appear at the beginning.
               The same variable cannot appear in more than one
               COMMON statement. Array variables are specified
               by appending "()" to the variable name. If all
               variables are to be passed, use CHAIN with the
               ALL option and omit the COMMON statement.

Example: 100 COMMON A,B,C,D(),G$
               110 CHAIN "PROG3",10
                 .
                 .
                 .

NOTE: The BASIC Compiler supports a modified version
               of the COMMON statement. The COMMON statement
               must appear in a program before any executable
               statements.   The   current   non-executable
               statements are:

                   COMMON
                   DEFDBL, DEFINT, DEFSNG, DEFSTR
                   DIM
                   OPTION BASE
                   REM
                   %INCLUDE

               Arrays in COMMON must be declared in preceding
               DIM statements,

               The standard form of the COMMON statement is
               referred to as blank COMMON.   FORTRAN style
               named COMMON areas are also supported; however,
               the variables are not preserved across CHAINs.
               The syntax for named COMMON is as follows:

                   COMMON /NAME>/ LIST of variables>

               where NAME> is 1 to 6 alphanumeric characters
               starting with a letter.   This is useful for
               communicating with FORTRAN and assembly language
               routines without having to explicityly pass
               parameters in the CALL statement.

The blank COMMON size and order of variables must be the same in the CHAINing and CHAINed-to programs. With the BASIC Compiler, the best way to insure this is to place all blank COMMON declarations in a single include file and use the %INCLUDE statement in each program. For example:

```
MENU.BAS
        10 %INCLUDE COMDEF
        .
        .
        . 1000 CHAIN "PROG1"

PROG1.BAS
        10 %INCLUDE COMDEF
        .
        .
        . 2000 CHAIN "MENU"

COMDEF.BAS
        100 DIM A(100),B$(200)
        110 COMMON I,J,K,A,()
        120 COMMON A$,B$,(),X,Y,Z
```

2.8 CONT

Format: CONT

Versions: 8K, Extended, Disk

Purpose: To continue program execution after a Control-C
               has been typed, or a STOP or END statement has
               been executed.

Remarks: Execution resumes at the point where the break
               occurred.   If the break occurred after a prompt
               from an INPUT statement, execution continues
               with the reprinting of the prompt (? or prompt
               string).

               CONT is usually used in conjunction with STOP
               for debugging.   When execution is stopped,
               intermediate values may be examined and changed
               using direct mode statements. Execution may be
               resumed with CONT or a direct mode GOTO, which
               resumes execution at a specified line number.
               With the Extended and Disk versions, CONT may be
               used to continue execution after an error.

               CONT is invalid if the program has been edited
               during the break.   In 8K BASIC-80, execution
               cannot be CONTinued if a direct mode error has
               occurred during the break.

Example: See example Section 2.61, STOP.

2.9 CSAVE

Formats: CSAVE <string expression>

               CSAVE* <array variable name>

Versions: 8K (cassette), Extended (cassette)

Purpose: To save the program or an array currently in
               memory on cassette tape.

Remarks: Each program or array saved on tape is
               identified by a filename. When the command
               CSAVE <string expression> is executed, BASIC-80
               saves the program currently in memory on tape
               and uses the first character in <string
               expression> as the filename. <string
               expression> may be more than one character, but
               only the first character is used for the
               filename.

               When the command CSAVE* <array variable name> is
               executed, BASIC-80 saves the specified array on
               tape. The array must be a numeric array. The
               elements of a multidimensional array are saved
               with the leftmost subscript changing fastest.

               CSAVE may be used as a program statement or as a
               direct mode command.

               Before a CSAVE or CSAVE* is executed, make sure
               the cassette recorder is properly connected and
               in the Record mode.

               See also CLOAD, Section 2.5.

NOTE: CSAVE and CLOAD are not included in all
               implementations of BASIC-80.

Example: CSAVE "TIMER"

               Saves the program currently in memory on
               cassette under filename "T".

2.10   DATA

Format: DATA <list of constants>

Versions: 8K, Extended, Disk

Purpose: To store the numeric and string constants that
                 are accessed by the program's READ statement(s).
                 (See READ, Section 2.54)

Remarks: DATA statements are nonexecutable and may be
                 placed anywhere in the program. A DATA
                 statement may contain as many constants as will
                 fit on a line (separated by commas), and any
                 number of DATA statements may be used in a
                 program. The READ statements access the DATA
                 statements in order (by line number) and the
                 data contained therein may be thought of as one
                 continuous list of items, regardless of how many
                 items are on a line or where the lines are
                 placed in the program.

                 <list of constants> may contain numeric
                 constants in any format, i.e., fixed point,
                 floating point or integer. (No numeric
                 expressions are allowed in the list.) String
                 constants in DATA statements must be surrounded
                 by double quotation marks only if they contain
                 commas, colons or significant leading or
                 trailing spaces. Otherwise, quotation marks are
                 not needed.

                 The variable type (numeric or string) given in
                 the READ statement must agree with the
                 corresponding constant in the DATA statement.

                 DATA statements may be reread from the beginning
                 by use of the RESTORE statement (Section 2.57).

Example: See examples in Section 2.54, READ.

2.11 DEF FN

Format: DEF FN<name>[(<parameter list>)]=<function definition>

Versions: 8K, Extended, Disk

Purpose: To define and name a function that is written by the user.

Remarks: <name> must be a legal variable name. This name, preceded by FN, becomes the name of the function. <parameter list> is comprised of those variable names in the function definition that are to be replaced when the function is called. The items in the list are separated by commas. <function definition> is an expression that performs the operation of the function. It is limited to one line. Variable names that appear in this expression serve only to define the function; they do not affect program variables that have the same name. A variable name used in a function definition may or may not appear in the parameter list. If it does, the value of the parameter is supplied when the function is called. Otherwise, the current value of the variable is used.

The variables in the parameter list represent, on a one-to-one basis, the argument variables or values that will be given in the function call. (Remember, in the 8K version only one argument is allowed in a function call, therefore the DEF FN statement will contain only one variable.)

In Extended and Disk BASIC-80, user-defined functions may be numeric or string; in 8K, user-defined string functions are not allowed. If a type is specified in the function name, the value of the expression is forced to that type before it is returned to the calling statement. If a type is specified in the function name and the argument type does not match, a "Type mismatch" error occurs.

A DEF FN statement must be executed before the function it defines may be called. If a function is called before it has been defined, an "Undefined user function" error occurs. DEF FN is illegal in the direct mode.

Example:
.
.
.
```
410 DEF FNAB(X,Y)=X^3/Y^2
420 T=FNAB(I,J)
```
.
.
.

Line 410 defines the function FNAB. The function is called in line 420.

2.12 DEFINT/SNG/DBL/STR

Format: DEF<type> <range(s) of letters>
             where <type> is INT, SNG, DBL, or STR

Versions: Extended, Disk

Purpose: To declare variable types as integer, single
             precision, double precision, or string.

Remarks: A DEFtype statement declares that the variable
             names beginning with the letter(s) specified
             will be that type variable. However, a type
             declaration character always takes precedence
             over a DEFtype statement in the typing of a
             variable.

             If no type declaration statements are
             encountered, BASIC-80 assumes all variables
             without declaration characters are single
             precision variables.

Examples: 10 DEFDBL L-P   All variables beginning with
                             the letters L, M, N, O, and P
                             will be double precision
                             variables.

             10 DEFSTR A   All variables beginning with
                             the letter A will be string
                             variables.

             10 DEFINT I-N,W-Z
                             All variable beginning with
                             the letters I, J, K, L, M,
                             N, W, X, Y, Z will be integer
                             variables.

2.13 DEF USR

Format: DEF USR[<digit>]=<integer expression>

Versions: Extended, Disk

Purpose: To specify the starting address of an assembly
               language subroutine.

Remarks: <digit> may be any digit from 0 to 9. The digit
               corresponds to the number of the USR routine
               whose address is being specified. If <digit> is
               omitted, DEF USR0 is assumed.   The value of
               <integer expression> is the starting address of
               the USR routine.   See Appendix C, Assembly
               Language Subroutines.

               Any number of DEF USR statements may appear in a
               program   to   redefine subroutine starting
               addresses, thus allowing access to as many
               subroutines as necessary.

Example: .
                  .
                  .
               200 DEF USR0=24000
               210 X=USR0(Y^2/2.89)
                  .
                  .
                  .

2.14 DELETE

Format: DELETE[<line number>][-<line number>]

Versions: Extended, Disk

Purpose: To delete program lines.

Remarks: BASIC-80 always returns to command level after a
               DELETE is executed. If <line number> does not
               exist, an "Illegal function call" error occurs.

Examples: DELETE 40   Deletes line 40

               DELETE 40-100   Deletes lines 40 through
                                  100, inclusive

               DELETE-40   Deletes all lines up to
                                  and including line 40

2.15 DIM

Format: DIM <list of subscripted variables>

Versions: 8K, Extended, Disk

Purpose: To specify the maximum values for array variable
            subscripts and allocate storage accordingly.

Remarks: If an array variable name is used without a DIM
            statement, the maximum value of its subscript(s)
            is assumed to be 10. If a subscript is used
            that is greater than the maximum specified, a
            "Subscript out of range" error occurs. The
            minimum value for a subscript is always 0,
            unless otherwise specified with the OPTION BASE
            statement (see Section 2.46).

            The DIM statement sets all the elements of the
            specified arrays to an initial value of zero.

Example: 10 DIM A(20)
            20 FOR I=0 TO 20
            30 READ A(I)
            40 NEXT I
               .
               .
               .

2.16 EDIT

Format: EDIT <line number>

Versions: Extended, Disk

Purpose: To enter Edit Mode at the specified line.

Remarks: In Edit Mode, it is possible to edit portions of
              a line without retyping the entire line. Upon
              entering Edit Mode, BASIC-80 types the line
              number of the line to be edited, then it types a
              space and waits for an Edit Mode subcommand.

Edit Mode Subcommands

Edit Mode subcommands are used to move the
cursor or to insert, delete, replace, or search
for text within a line. The subcommands are not
echoed. Most of the Edit Mode subcommands may
be preceded by an integer which causes the
command to be executed that number of times.
When a preceding integer is not specified, it is
assumed to be 1.

Edit Mode subcommands may be categorized
according to the following functions:

1. Moving the cursor

2. Inserting text

3. Deleting text

4. Finding text

5. Replacing text

6. Ending and restarting Edit Mode

NOTE

In the descriptions that follow, <ch>
represents any character, <text>
represents a string of characters of
arbitrary length, [i] represents an
optional integer (the default is 1), and
$ represents the Escape (or Altmode)
key.

1. Moving the Cursor

    Space   Use the space bar to move the cursor to the
            right. [i]Space moves the cursor i spaces to
            the right. Characters are printed as you space
            over them.

    Rubout In Edit Mode, [i]Rubout moves the cursor i
            spaces to the left (backspaces). Characters are
            printed as you backspace over them.

2. Inserting Text

    I   I<text>$ inserts <text> at the current cursor
            position. The inserted characters are printed
            on the terminal. To terminate insertion, type
            Escape. If Carriage Return is typed during an
            Insert command, the effect is the same as typing
            Escape and then Carriage Return. During an
            Insert command, the Rubout, Delete, or
            Underscore key on the terminal may be used to
            delete characters to the left of the cursor.
            Rubout will print out the characters as you
            backspace over them. Delete and Underscore will
            print an Underscore for each character that you
            backspace over. If an attempt is made to insert
            a character that will make the line longer than
            255 characters, a bell (Control-G) is typed and
            the character is not printed.

    X   The X subcommand is used to extend the line. X
            moves the cursor to the end of the line, goes
            into insert mode, and allows insertion of text
            as if an Insert command had been given. When
            you are finished extending the line, type Escape
            or Carriage Return.

3. Deleting Text

    D   [i]D deletes i characters to the right of the
            cursor. The deleted characters are echoed
            between backslashes, and the cursor is
            positioned to the right of the last character
            deleted. If there are fewer than i characters
            to the right of the cursor, iD deletes the
            remainder of the line.

    H   H deletes all characters to the right of the
            cursor and then automatically enters insert
            mode. H is useful for replacing statements at
            the end of a line.

4. Finding Text

    S   The subcommand [i]S<ch> searches for the ith

occurrence of <ch> and positions the cursor before it. The character at the current cursor position is not included in the search. If <ch> is not found, the cursor will stop at the end of the line. All characters passed over during the search are printed.

K   The subcommand [i]K<ch> is similar to [i]S<ch>, except all the characters passed over in the search are deleted. The cursor is positioned before <ch>, and the deleted characters are enclosed in backslashes.

5. Replacing Text

C   The subcommand C<ch> changes the next character to <ch>. If you wish to change the next i characters, use the subcommand iC, followed by i characters. After the ith new character is typed, change mode is exited and you will return to Edit Mode.

6. Ending and Restarting Edit Mode

<cr>   Typing Carriage Return prints the remainder of the line, saves the changes you made and exits Edit Mode.

E   The E subcommand has the same effect as Carriage Return, except the remainder of the line is not printed.

Q   The Q subcommand returns to BASIC-80 command level, without saving any of the changes that were made to the line during Edit Mode.

L   The L subcommand lists the remainder of the line (saving any changes made so far) and repositions the cursor at the beginning of the line, still in Edit Mode. L is usually used to list the line when you first enter Edit Mode.

A   The A subcommand lets you begin editing a line over again. It restores the original line and repositions the cursor at the beginning.

NOTE

If BASIC-80 receives an unrecognizable command or illegal character while in Edit Mode, it prints a bell (Control-G) and the command or character is ignored.

Syntax Errors

When a Syntax Error is encountered during
execution of a program, BASIC-80 automatically
enters Edit Mode at the line that caused the
error. For example:

    10 K = 2(4)
    RUN
    ?Syntax error in 10
    10

When you finish editing the line and type
Carriage Return (or the E subcommand), BASIC-80
reinserts the line, which causes all variable
values to be lost. To preserve the variable
values for examination , first exit Edit Mode
with the Q subcommand. BASIC-80 will return to
command level, and all variable values will be
preserved.

Control-A

To enter Edit Mode on the line you are currently
typing, type Control-A. BASIC-80 responds with
a carriage return, an exclamation point (!) and
a space.   The cursor will be positioned at the
first character in the line. Proceed by typing
an Edit Mode subcommand.

                            NOTE

        Remember, if you have just entered a
        line and wish to go back and edit it,
        the command "EDIT." will enter Edit Mode
        at the current line. (The line number
        symbol "." always refers to the current
        line.)

2.17 __END__

Format: END

Versions: 8K, Extended, Disk

Purpose: To terminate program execution, close all files
               and return to command level.

Remarks: END statements may be placed anywhere in the
               program to terminate execution. Unlike the STOP
               statement, END does not cause a BREAK message to
               be printed.   An END statement at the end of a
               program is optional. BASIC-80 always returns to
               command level after an END is executed.

Example: 520 IF K>1000 THEN END ELSE GOTO 20

2.18 ERASE

Format: ERASE <list of array variables>

Versions: Extended, Disk

Purpose: To eliminate arrays from a program.

Remarks: Arrays may be redimensioned after they are
              ERASEd, or the previously allocated array space
              in memory may be used for other purposes. If an
              attempt is made to redimension an array without
              first ERASEing it, a "Redimensioned array" error
              occurs.

NOTE: The Microsoft BASIC compiler does not support
              ERASE.

Example: .
                 .
                 .
              450 ERASE A,B
              460 DIM B(99)
                 .
                 .
                 .

2.19 ERR AND ERL VARIABLES

When an error handling subroutine is entered,
the variable ERR contains the error code for the
error, and the variable ERL contains the line
number of the line in which the error was
detected. The ERR and ERL variables are usually
used in IF...THEN statements to direct program
flow in the error trap routine.

If the statement that caused the error was a
direct mode statement, ERL will contain 65535.
To test if an error occurred in a direct
statement, use IF 65535 = ERL THEN ...
Otherwise, use

    IF ERR = error code THEN ...

    IF ERL = line number THEN ...

If the line number is not on the right side of
the relational operator, it cannot be renumbered
by RENUM. Because ERL and ERR are reserved
variables, neither may appear to the left of the
equal sign in a LET (assignment) statement.
BASIC-80's error codes are listed in Appendix J.
(For Standalone Disk BASIC error codes, see
Appendix H.)

2.20   ERROR

Format: ERROR <integer expression>

Versions: Extended, Disk

Purpose: 1) To simulate the occurrence of a BASIC-80
                error; or 2) to allow error codes to be
                defined by the user.

Remarks: The value of <integer expression> must   be
                greater than 0 and less than 255. If the value
                of <integer expression> equals an error code
                already in use by BASIC-80 (see Appendix J), the
                ERROR statement will simulate the occurrence of
                that error, and the corresponding error message
                will be printed. (See Example 1.)

                To define your own error code, use a value that
                is greater than any used by BASIC-80's error
                codes. (It is preferable to use the highest
                available   values,   so compatibility may be
                maintained when more error codes are added to
                BASIC-80.) This user-defined error code may then
                be conveniently handled in an error   trap
                routine. (See Example 2.)

                If an ERROR statement specifies a code for which
                no error message has been defined, BASIC-80
                responds with the message UNPRINTABLE ERROR.
                Execution of an ERROR statement for which there
                is no error trap routine causes an error message
                to be printed and execution to halt.

Example 1:   LIST
                10 S = 10
                20 T = 5
                30 ERROR S + T
                40 END
                Ok
                RUN
                String too long in line 30

                Or, in direct mode:

                Ok
                ERROR 15   (you type this line)
                String too long   (BASIC-80 types this line)
                Ok

Example 2:   .
                .
                .
        110 ON ERROR GOTO 400
        120 INPUT "WHAT IS YOUR BET";B
        130 IF B > 5000 THEN ERROR 210
                .
                .
                .
        400 IF ERR = 210 THEN PRINT "HOUSE LIMIT IS $5000"
        410 IF ERL = 130 THEN RESUME 120
                .
                .
                .

2.21 FIELD

Format: FIELD[#]<file number>,<field width> AS <string variable>...

Version: Disk

Purpose: To allocate space for variables in a random file
               buffer.

Remarks: To get data out of a random buffer after a GET
               or to enter data before a PUT, a FIELD statement
               must have been executed.

               <file number> is the number under which the file
               was OPENed.   <field width> is the number of
               characters to be allocated to <string variable>.
               For example,

               FIELD 1, 20 AS N$, 10 AS ID$, 40 AS ADD$

               allocates the first 20 positions (bytes) in the
               random file buffer to the string variable N$,
               the next 10 positions to ID$, and the next 40
               positions to ADD$.   FIELD does NOT place any
               data in the random file buffer. (See LSET/RSET
               and GET.)

               The total number of bytes allocated in a FIELD
               statement must not exceed the record length that
               was specified when the file was   OPENed.
               Otherwise, a "Field overflow" error occurs.
               (The default record length is 128.)

               Any number of FIELD statements may be executed
               for the same file, and all FIELD statements that
               have been executed are in effect at the same
               time.

Example: See Appendix B.

NOTE: Do not use a FIELDed variable name in an INPUT
               or LET statement.   Once a variable name is
               FIELDed, it points to the correct place in the
               random file buffer.   If a subsequent INPUT or
               LET statement with that variable name is
               executed, the variable's pointer is moved to
               string space.

2.22 FOR...NEXT

Format: FOR <variable>=x TO y [STEP z]
                .
                .
                .
                NEXT [<variable>][,<variable>...]

                where x, y and z are numeric expressions.

Versions: 8K, Extended, Disk

Purpose: To allow a series of instructions to be
                performed in a loop a given number of times.

Remarks: <variable> is used as a counter. The first
                numeric expression (x) is the initial value of
                the counter. The second numeric expression (y)
                is the final value of the counter. The program
                lines following the FOR statement are executed
                until the NEXT statement is encountered. Then
                the counter is incremented by the amount
                specified by STEP. A check is performed to see
                if the value of the counter is now greater than
                the final value (y). If it is not greater,
                BASIC-80 branches back to the statement after
                the FOR statement and the process is repeated.
                If it is greater, execution continues with the
                statement following the NEXT statement. This is
                a FOR...NEXT loop. If STEP is not specified,
                the increment is assumed to be one. If STEP is
                negative, the final value of the counter is set
                to be less than the initial value. The counter
                is decremented each time through the loop, and
                the loop is executed until the counter is less
                than the final value.

                The body of the loop is skipped if the initial
                value of the loop times the sign of the step
                exceeds the final value times the sign of the
                step.

                Nested Loops
                FOR...NEXT loops may be nested, that is, a
                FOR...NEXT loop may be placed within the context
                of another FOR...NEXT loop. When loops are
                nested, each loop must have a unique variable
                name as its counter. The NEXT statement for the
                inside loop must appear before that for the
                outside loop. If nested loops have the same end
                point, a single NEXT statement may be used for
                all of them.

                The variable(s) in the NEXT statement may be

omitted, in which case the NEXT statement will
match the most recent FOR statement. If a NEXT
statement is encountered before its
corresponding FOR statement, a "NEXT without
FOR" error message is issued and execution is
terminated.

Example 1:   10 K=10
              20 FOR I=1 TO K STEP 2
              30 PRINT I;
              40 K=K+10
              50 PRINT K
              60 NEXT
              RUN
               1   20
               3   30
               5   40
               7   50
               9   60
              Ok

Example 2:   10 J=0
              20 FOR I=1 TO J
              30 PRINT I
              40 NEXT I

              In this example, the loop does not execute
              because the initial value of the loop exceeds
              the final value.

Example 3:   10 I=5
              20 FOR I=1 TO I+5
              30 PRINT I;
              40 NEXT
              RUN
               1   2   3   4   5   6   7   8   9   10
              Ok

              In this example, the loop executes ten times.
              The final value for the loop variable is always
              set before the initial value is set. (Note:
              Previous versions of BASIC-80 set the initial
              value of the loop variable before setting the
              final value; i.e., the above loop would have
              executed six times.)

2.23 GET

Format: GET [#]<file number>[,<record number>]

Version: Disk

Purpose: To read a record from a random disk file into a
               random buffer.

Remarks: <file number> is the number under which the file
               was OPENed. If <record number> is omitted, the
               next record (after the last GET) is read into
               the buffer. The largest possible record number
               is 32767.

Example: See Appendix B.

NOTE: After a GET statement, INPUT# and LINE INPUT#
               may be done to read characters from the random
               file buffer.

2.24 GOSUB...RETURN

Format: GOSUB <line number>
             .
             .
             .
             RETURN

Versions: 8K, Extended, Disk

Purpose: To branch to and return from a subroutine.

Remarks: <line number> is the first line of the subroutine.

             A subroutine may be called any number of times in a program, and a subroutine may be called from within another subroutine. Such nesting of subroutines is limited only by available memory.

             The RETURN statement(s) in a subroutine cause BASIC-80 to branch back to the statement following the most recent GOSUB statement. A subroutine may contain more than one RETURN statement, should logic dictate a return at different points in the subroutine. Subroutines may appear anywhere in the program, but it is recommended that the subroutine be readily distinguishable from the main program. To prevent inadvertant entry into the subroutine, it may be preceded by a STOP, END, or GOTO statement that directs program control around the subroutine.

Example: 10 GOSUB 40
             20 PRINT "BACK FROM SUBROUTINE"
             30 END
             40 PRINT "SUBROUTINE";
             50 PRINT " IN";
             60 PRINT " PROGRESS"
             70 RETURN
             RUN
             SUBROUTINE IN PROGRESS
             BACK FROM SUBROUTINE
             Ok

2.25 <u>GOTO</u>

Format: GOTO <line number>

Versions: 8K, Extended, Disk

Purpose: To branch unconditionally out of the normal
             program sequence to a specified line number.

Remarks: If <line number> is an executable statement,
             that statement and those following are executed.
             If it is a nonexecutable statement, execution
             proceeds at the first executable statement
             encountered after <line number>.

Example: LIST
             10 READ R
             20 PRINT "R =";R,
             30 A = 3.14*R^2
             40 PRINT "AREA =";A
             50 GOTO 10
             60 DATA 5,7,12
             Ok
             RUN
             R = 5   AREA = 78.5
             R = 7   AREA = 153.86
             R = 12   AREA = 452.16
             ?Out of data in 10
             Ok

2.26 IF...THEN[...ELSE] AND IF...GOTO

Format: IF <expression> THEN <statement(s)> | <line number>

               [ELSE <statement(s)> | <line number>]

Format: IF <expression> GOTO <line number>

               [ELSE <statement(s)> | <line number>]

Versions: 8K, Extended, Disk

NOTE: The ELSE clause is allowed only in Extended and
               Disk versions.

Purpose: To make a decision regarding program flow based
               on the result returned by an expression.

Remarks: If the result of <expression> is not zero, the
               THEN or GOTO clause is executed. THEN may be
               followed by either a line number for branching
               or one or more statements to be executed. GOTO
               is always followed by a line number.   If the
               result of <expression> is zero, the THEN or GOTO
               clause is ignored and the ELSE clause, if
               present, is executed. Execution continues with
               the next executable statement. (ELSE is allowed
               only in Extended and Disk versions.) Extended
               and Disk versions allow a comma before THEN.

                    Nesting of IF Statements

               In   the   Extended   and   Disk   versions,
               IF...THEN...ELSE statements may be nested.
               Nesting is limited only by. the length of the
               line. For example

               IF X>Y THEN PRINT "GREATER" ELSE IF Y>X
                   THEN PRINT "LESS THAN" ELSE PRINT "EQUAL"

               is a legal statement. If the statement does not
               contain the same number of ELSE and THEN
               clauses, each ELSE is matched with the closest
               unmatched THEN. For example

               IF A=B THEN IF B=C THEN PRINT "A=C"
                   ELSE PRINT "A<>C"

               will not print "A<>C" when A<>B.

               If an IF...THEN statement is followed by a line
               number in the direct mode, an "Undefined line"
               error results unless a statement with   the
               specified line number had previously been
               entered in the indirect mode.

NOTE: When using IF to test equality for a value that
                 is the result of a floating point computation,
                 remember that the internal representation of the
                 value may not be exact. Therefore, the test
                 should be against the range over which the
                 accuracy of the value may vary. For example, to
                 test a computed variable A against the value
                 1.0, use:

                     IF ABS (A-1.0)<1.0E-6 THEN ...

                 This test returns true if the value of A is 1.0
                 with a relative error of less than 1.0E-6.

Example 1:   200 IF I THEN GET#1,I

                 This statement GETs record number I if I is not
                 zero.

Example 2:   100 IF(I<20)*(I>10) THEN DB=1979-1:GOTO 300
                 110 PRINT "OUT OF RANGE"
                        .
                        .
                        .

                 In this example, a test determines if I is
                 greater than 10 and less than 20. If I is in
                 this range, DB is calculated and execution
                 branches to line 300.   If I is not in this
                 range, execution continues with line 110.

Example 3:   210 IF IOFLAG THEN PRINT A$ ELSE LPRINT A$

                 This statement causes printed output to go
                 either to the terminal or the line printer,
                 depending on the value of a variable (IOFLAG).
                 If IOFLAG is zero, output goes to the line
                 printer, otherwise output goes to the terminal.

2.27 INPUT

Format: INPUT[;] [<"prompt string">;]<list of variables>

Versions: 8K, Extended, Disk

Purpose: To allow input from the terminal during program
               execution.

Remarks: When an INPUT statement is encountered, program
               execution pauses and a question mark is printed
               to indicate the program is waiting for data. If
               <"prompt string"> is included, the string is
               printed before the question mark. The required
               data is then entered at the terminal.

               A comma may be used instead of a semicolon after
               the prompt string to suppress the question mark.
               For   example,   the   statement INPUT   "ENTER
               BIRTHDATE",B$ will print the prompt with no
               question mark.

               If INPUT is immediately followed by a semicolon,
               then the carriage return typed by the user to
               input data does not echo a carriage return/line
               feed sequence.

               The data that is entered is assigned to the
               variable(s)   given in <variable list>.   The
               number of data items supplied must be the same
               as the number of variables in the list. Data
               items are separated by commas.

               The variable names in the list may be numeric or
               string variable names (including subscripted
               variables). The type of each data item that is
               input must agree with the type specified by the
               variable name.   (Strings input to an INPUT
               statement need not be surrounded by quotation
               marks.)

               Responding to INPUT with too many or too few
               items, or with the wrong type of value (numeric
               instead of string, etc.) causes the messsage
               "?Redo from start" to be printed. No assignment
               of input values is made until an acceptable
               response is given.

               In the 8K version, INPUT is illegal in the
               direct mode.

```
Examples:   10  INPUT X
            20  PRINT X "SQUARED IS" X^2
            30  END
            RUN
            ?  5        (The 5 was typed in by the user
                         in response to the question mark.)
             5 SQUARED IS 25
            Ok

            LIST
            10  PI=3.14
            20  INPUT "WHAT IS THE RADIUS";R
            30  A=PI*R^2
            40  PRINT "THE AREA OF THE CIRCLE IS";A
            50  PRINT
            60  GOTO 20
            Ok
            RUN
            WHAT IS THE RADIUS?  7.4   (User types 7.4)
            THE AREA OF THE CIRCLE IS 171.946

            WHAT IS THE RADIUS?
            etc.
```

2.28 INPUT#

Format: INPUT#<file number>,<variable list>

Version: Disk

Purpose: To read data items from a sequential disk file
            and assign them to program variables.

Remarks: <file number> is the number used when the file
            was OPENed for input. <variable list> contains
            the variable names that will be assigned to the
            items in the file. (The variable type must
            match the type specified by the variable name.)
            With INPUT#, no question mark is printed, as
            with INPUT.

            The data items in the file should appear just as
            they would if data were being typed in response
            to an INPUT statement. With numeric values,
            leading spaces, carriage returns and line feeds
            are ignored. The first character encountered
            that is not a space, carriage return or line
            feed is assumed to be the start of a number.
            The number terminates on a space, carriage
            return, line feed or comma.

            If BASIC-80 is scanning the sequential data file
            for a string item, leading spaces, carriage
            returns and line feeds are also ignored. The
            first character encountered that is not a space,
            carriage return, or line feed is assumed to be
            the start of a string item. If this first
            character is a quotation mark ("), the string
            item will consist of all characters read between
            the first quotation mark and the second. Thus,
            a quoted string may not contain a quotation mark
            as a character. If the first character of the
            string is not a quotation mark, the string is an
            unquoted string, and will terminate on a comma,
            carriage or line feed (or after 255 characters
            have been read). If end of file is reached when
            a numeric or string item is being INPUT, the
            item is terminated.

Example: See Appendix B.

2.29 KILL

Format: KILL <filename>

Version: Disk

Purpose: To delete a file from disk.

Remarks: If a KILL statement is given for a file that is
             currently OPEN, a "File already open" error
             occurs.

             KILL is used for all types of disk files:
             program files, random data files and sequential
             data files.

Example: 200 KILL "DATA1"

             See also Appendix B.

2.30 <u>LET</u>

Format: [LET] <variable>=<expression>

Versions: 8K, Extended, Disk

Purpose: To assign the value of an expression to a
               variable.

Remarks: Notice the word LET is optional, i.e., the equal
               sign is sufficient when assigning an expression
               to a variable name.

Example: 110 LET D=12
               120 LET E=12^2
               130 LET F=12^4
               140 LET SUM=D+E+F
                      .
                      .
                      .

                 or

               110 D=12
               120 E=12^2
               130 F=12^4
               140 SUM=D+E+F
                      .
                      .
                      .

2.31 LINE INPUT

Format: LINE INPUT[;] [<"prompt string">;]<string variable>

Versions: Extended, Disk

Purpose: To input an entire line (up to 254 characters)
                to a string variable, without the use of
                delimiters.

Remarks: The prompt string is a string literal that is
                printed   at   the   terminal before input is
                accepted. A question mark is not printed unless
                it is part of the prompt string. All input from
                the end of the prompt to the carriage return is
                assigned to <string variable>. However, if a
                line feed/carriage return sequence (this order
                only)   is   encountered, both characters are
                echoed; but the carriage return is ignored, the
                line feed is put into STRING variable>, and data
                input continues.

                If LINE INPUT is immediately followed by a
                semicolon, then the carriage return typed by the
                user to end the input line does not echo a
                carriage   return/line   feed sequence at the
                terminal.

                A LINE INPUT may be escaped by typing Control-C.
                BASIC-80 will   return to command level and type
                Ok. Typing CONT resumes execution at the LINE
                INPUT.

Example: See Example, Section 2.32, LINE INPUT#.

2.32 LINE INPUT#

Format: LINE INPUT#<file number>,<string variable>

Version: Disk

Purpose: To read an entire line (up to 254 characters),
               without delimiters, from a sequential disk data
               file to a string variable.

Remarks: <file number> is the number under which the file
               was OPENed.   <string variable> is the variable
               name to which the line will be assigned.   LINE
               INPUT# reads all characters in the sequential
               file up to a carriage return.   It then skips
               over the carriage return/line feed sequence, and
               the next LINE INPUT# reads all characters up to
               the   next   carriage   return.   (If   a line
               feed/carriage return sequence is encountered, it
               is preserved.)

               LINE INPUT# is especially useful if each line of
               a data file has been broken into fields, or if a
               BASIC-80 program saved in ASCII mode is being
               read as data by another program.

Example: 10 OPEN "O",1,"LIST"
               20 LINE INPUT "CUSTOMER INFORMATION? ";C$
               30 PRINT #1, C$
               40 CLOSE 1
               50 OPEN "I",1,"LIST"
               60 LINE INPUT #1, C$
               70 PRINT C$
               80 CLOSE 1
               RUN
               CUSTOMER INFORMATION? LINDA JONES   234,4   MEMPHIS
               LINDA JONES   234,4   MEMPHIS
               Ok

2.33 LIST

Format 1:   LIST [<line number>]

Versions: 8K, Extended, Disk

Format 2:   LIST [<line number>[-[<line number>]]]

Versions: Extended, Disk

Purpose: To list all or part of the program currently in memory at the terminal.

Remarks: BASIC-80 always returns to command level after a LIST is executed.

Format 1: If <line number> is omitted, the program is listed beginning at the lowest line number. (Listing is terminated either by the end of the program or by typing Control-C.) If <line number> is included, the 8K version will list the program beginning at that line; and the Extended and Disk versions will list only the specified line.

Format 2: This format allows the following options:

1.   If only the first number is specified, that line and all higher-numbered lines are listed.

2.   If only the second number is specified, all lines from the beginning of the program through that line are listed.

3.   If both numbers are specified, the entire range is listed.

Examples: Format 1:

        LIST   Lists the program currently
                          in memory.

        LIST 500   In the 8K version, lists
                          all programs lines from
                          500 to the end.
                          In Extended and Disk,
                          lists line 500.

        Format 2:

        LIST 150-   Lists all lines from 150
                          to the end.

        LIST -1000   Lists all lines from the
                          lowest number through 1000.

        LIST 150-1000   Lists lines 150 through
                          1000, inclusive.

2.34 LLIST

Format: LLIST [<line number>[-[<line number>]]]

Versions: Extended, Disk

Purpose: To list all or part of the program currently in
             memory at the line printer.

Remarks: LLIST assumes a 132-character wide printer.

             BASIC-80 always returns to command level after
             an LLIST is executed. The options for LLIST are
             the same as for LIST, Format 2.

NOTE: LLIST and LPRINT are not included in   all
             implementations of BASIC-80.

Example: See the examples for LIST, Format 2.

2.35 LOAD

Format: LOAD <filename>[,R]

Version: Disk

Purpose: To load a file from disk into memory.

Remarks: <filename> is the name that was used when the
            file was SAVEd. (With CP/M, the default
            extension .BAS is supplied.)

            LOAD closes all open files and deletes all
            variables and program lines currently residing
            in memory before it loads the designated
            program. However, if the "R" option is used
            with LOAD, the program is RUN after it is
            LOADed, and all open data files are kept open.
            Thus, LOAD with the "R" option may be used to
            chain several programs (or segments of the same
            program). Information may be passed between the
            programs using their disk data files.

Example: LOAD "STRTRK",R

2.36 LPRINT AND LPRINT USING

Format: LPRINT [<list of expressions>]

                LPRINT USING <string exp>;<list of expressions>

Versions: Extended, Disk

Purpose: To print data at the line printer.

Remarks: Same as PRINT and PRINT USING, except output
                goes to the line printer. See Section 2.49 and
                Section 2.50.

                LPRINT assumes a 132-character-wide printer.

NOTE: LPRINT and LLIST are not included in   all
                implementations of BASIC-80.

2.37 LSET AND RSET

Format: LSET <string variable> = <string expression>
               RSET <string variable> = <string expression>

Version: Disk

Purpose: To move data from memory to a random file buffer
               (in preparation for a PUT statement).

Remarks: If <string expression> requires fewer bytes than
               were FIELDed to <string variable>, LSET
               left-justifies the string in the field, and RSET
               right-justifies the string. (Spaces are used to
               pad the extra positions.) If the string is too
               long for the field, characters are dropped from
               the right. Numeric values must be converted to
               strings before they are LSET or RSET. See the
               MKI$, MKS$, MKD$ functions, Section 3.25.

Examples: 150 LSET A$=MKS$(AMT)
               160 LSET D$=DESC($)

               See also Appendix B.

NOTE: LSET or RSET may also be used with a non-fielded
               string variable to left-justify or right-justify
               a string in a given field.   For example, the
               program lines

                   110 A$=SPACE$(20)
                   120 RSET A$=N$

               right-justify the string N$ in a 20-character
               field.   This can be very handy for formatting
               printed output.

2.38   MERGE

Format: MERGE <filename>

Version: Disk

Purpose: To merge a specified disk file into the program
             currently in memory.

Remarks: <filename> is the name used when the file was
             SAVEd. (With CP/M, the default extension .BAS
             is supplied.) The file must have been SAVEd in
             ASCII format. (If not, a "Bad file mode" error
             occurs.)

             If any lines in the disk file have the same line
             numbers as lines in the program in memory, the
             lines from the file on disk will replace the
             corresponding lines in memory. (MERGEing may be
             thought of as "inserting" the program lines on
             disk into the program in memory.)

             BASIC-80 always returns to command level after
             executing a MERGE command.

Example: MERGE "NUMBRS"

2.39 MID$

Format: MID$(<string expl>,n[,m])=<string exp2>

             where n and m are integer expressions and
             <string expl> and <string exp2> are string
             expressions.

Versions: Extended, Disk

Purpose: To replace a portion of one string with another
             string.

Remarks: The characters in <string expl>, beginning at
             position n, are replaced by the characters in
             <string exp2>. The optional m refers to the
             number of characters from <string exp2> that
             will be used in the replacement.   If m is
             omitted, all of <string exp2> is used. However,
             regardless of whether m is omitted or included,
             the replacement of characters never goes beyond
             the original length of <string expl>.

Example: 10 A$="KANSAS CITY, MO"
             20 MID$(A$,14)="KS"
             30 PRINT A$
             RUN
             KANSAS CITY, KS

             MID$ is also a function that returns a substring
             of a given string. See Section 3.24.

2.40 NAME

Format: NAME <old filename> AS <new filename>

Version: Disk

Purpose: To change the name of a disk file.

Remarks: <old filename> must exist and <new filename>
              must not exist; otherwise an error will result.
              After a NAME command, the file exists on the
              same disk, in the same area of disk space, with
              the new name.

Example: Ok
              NAME "ACCTS" AS "LEDGER"
              Ok

              In this example, the file that was
              formerly named ACCTS will now be named LEDGER.

2.41 NEW

Format: NEW

Versions: 8K, Extended, Disk

Purpose: To delete the program currently in memory and
            clear all variables.

Remarks: NEW is entered at command level to clear memory
            before entering a new program. BASIC-80 always
            returns to command level after a   NEW   is
            executed.

2.42 NULL

Format: NULL <integer expression>

Versions: 8K, Extended, Disk

Purpose: To set the number of nulls to be printed at the
                end of each line.

Remarks: For   10-character-per-second   tape   punches,
                <integer expression> should be >=3. When tapes
                are not being punched, <integer expression>
                should   be   0   or   1   for   Teletypes   and
                Teletype-compatible CRTs. <integer expression>
                should be 2 or 3 for 30 cps hard copy printers.
                The default value is 0.

Example: Ok
                NULL 2
                Ok
                100 INPUT X
                200 IF X<50 GOTO 800
                        .
                        .
                        .

                Two null characters will be printed after each
                line.

2.43 ON ERROR GOTO

Format: ON ERROR GOTO <line number>

Versions: Extended, Disk

Purpose: To enable error trapping and specify the first line of the error handling subroutine.

Remarks: Once error trapping has been enabled all errors detected, including direct mode errors (e.g., Syntax errors), will cause a jump to the specified error handling subroutine. If <line number> does not exist, an "Undefined line" error results. To disable error trapping, execute an ON ERROR GOTO 0. Subsequent errors will print an error message and halt execution. An ON ERROR GOTO 0 statement that appears in an error trapping subroutine causes BASIC-80 to stop and print the error message for the error that caused the trap. It is recommended that all error trapping subroutines execute an ON ERROR GOTO 0 if an error is encountered for which there is no recovery action.

NOTE: If an error occurs during execution of an error handling subroutine, the BASIC error message is printed and execution terminates. Error trapping does not occur within the error handling subroutine.

Example: 10 ON ERROR GOTO 1000

2.44 ON...GOSUB AND ON...GOTO

Format: ON <expression> GOTO <list of line numbers>

             ON <expression> GOSUB <list of line numbers>

Versions: 8K, Extended, Disk

Purpose: To branch to one of several specified line
             numbers, depending on the value returned when an
             expression is evaluated.

Remarks: The value of <expression> determines which line
             number in the list will be used for branching.
             For example, if the value is three, the third
             line number in the list will be the destination
             of the branch. (If the value is a non-integer,
             the fractional portion is rounded.)

             In the ON...GOSUB statement, each line number in
             the list must be the first line number of a
             subroutine.

             If the value of <expression> is zero or greater
             than the number of items in the list (but less
             than or equal to 255), BASIC continues with the
             next executable statement.   If the value of
             <expression> is negative or greater than 255, an
             "Illegal function call" error occurs.

Example: 100 ON L-1 GOTO 150,300,320,390

2.45 OPEN

Format: OPEN <mode>,[#]<file number>,<filename>,[<reclen>]

Version: Disk

Purpose: To allow I/O to a disk file.

Remarks: A disk file must be OPENed before any disk I/O
               operation can be performed on that file. OPEN
               allocates a buffer for I/O to the file and
               determines the mode of access that will be used
               with the buffer.

               <mode> is a string expression whose   first
               character is one of the following:

                 O   specifies sequential output mode

                 I   specifies sequential input mode

                 R   specifies random input/output mode

               <file number> is an integer expression whose
               value is between one and fifteen. The number is
               then associated with the file for as long as it
               is OPEN and is used to refer other disk I/O
               statements to the file.

               <filename> is a string expression containing a
               name that conforms to your operating system's
               rules for disk filenames.

               <reclen> is an integer expression which, if
               included, sets the record length for random
               files. The default record length is 128 bytes.
               See also page A-3.

NOTE: A file can be OPENed for sequential input or
               random access on more than one file number at a
               time. A file may be OPENed for output, however,
               on only one file number at a time.

Example: 10 OPEN "I",2,"INVEN"

               See also Appendix B.

2.46 OPTION BASE

Format: OPTION BASE n
               where n is 1 or 0

Versions: 8K, Extended, Disk

Purpose: To declare the minimum value for array
               subscripts.

Remarks: The default base is 0. If the statement

                   OPTION BASE 1

               is executed, the lowest value an array subscript
               may have is one.

2.47 OUT

Format: OUT I,J
              where I and J are integer expressions in the
              range 0 to 255.

Versions: 8K, Extended, Disk

Purpose: To send a byte to a machine output port.

Remarks: The integer expression I is the port number, and
              the integer expression J is the data to be
              transmitted.

Example: 100 OUT 32,100

2.48 POKE

Format: POKE I,J
             where I and J are integer expressions

Versions: 8K, Extended, Disk

Purpose: To write a byte into a memory location.

Remarks: The integer expression I is the address of the
             memory location to be POKEd. The integer
             expression J is the data to be POKEd. J must be
             in the range 0 to 255. In the 8K version, I
             must be less than 32768. In the Extended and
             Disk versions, I must be in the range 0 to
             65536.

             With the 8K version, data may be POKEd into
             memory locations above 32768 by supplying a
             negative number for I. The value of I is
             computed by subtracting 65536 from the desired
             address. For example, to POKE data into
             location 45000, I = 45000-65536, or -20536.

             The complementary function to POKE is PEEK. The
             argument to PEEK is an address from which a byte
             is to be read. See Section 3.27.

             POKE and PEEK are useful for efficient data
             storage, loading assembly language subroutines,
             and passing arguments and results to and from
             assembly language subroutines.

Example: 10 POKE &H5A00,&HFF

2.49 <u>PRINT</u>

Format: PRINT [<list of expressions>]

Versions: 8K, Extended, Disk

Purpose: To output data at the terminal.

Remarks: If <list of expressions> is omitted, a blank
             line is printed. If <list of expressions> is
             included, the values of the expressions are
             printed at the terminal. The expressions in the
             list may be numeric and/or string expressions.
             (Strings must be enclosed in quotation marks.)

                        <u>Print</u> <u>Positions</u>

             The position of each printed item is determined
             by the punctuation used to separate the items in
             the list. BASIC-80 divides the line into print
             zones of 14 spaces each. In the list of
             expressions, a comma causes the next value to be
             printed at the beginning of the next zone. A
             semicolon causes the next value to be printed
             immediately after the last value. Typing one or
             more spaces between expressions has the same
             effect as typing a semicolon.

             If a comma or a semicolon terminates the list of
             expressions, the next PRINT statement begins
             printing on the same line, spacing accordingly.
             If the list of expressions terminates without a
             comma or a semicolon, a carriage return is
             printed at the end of the line. If the printed
             line is longer than the terminal width, BASIC-80
             goes to the next physical line and continues
             printing.

             Printed numbers are always followed by a space.
             Positive numbers are preceded by a space.
             Negative numbers are preceded by a minus sign.
             Single precision numbers that can be represented
             with 6 or fewer digits in the unscaled format no
             less accurately than they can be represented in
             the scaled format, are output using the unscaled
             format. For example, 1E-7 is output as .0000001
             and 1E-8(-7) is output as 1E-08. Double
             precision numbers that can be represented with
             16 or fewer digits in the unscaled format no
             less accurately than they can be represented in
             the scaled format, are output using the unscaled
             format. For example, 1D-15 is output as
             .0000000000000001 and 1D-16 is output as 1D-16.

A question mark may be used in place of the word
PRINT in a PRINT statement.

Example 1:   10 X=5
              20 PRINT X+5, X-5, X*(-5), X^5
              30 END
              RUN
               10   0   -25   3125
              Ok

In this example, the commas in the PRINT
statement cause each value to be printed at the
beginning of the next print zone.

Example 2:   LIST
              10 INPUT X
              20 PRINT X "SQUARED IS" X^2 "AND";
              30 PRINT X "CUBED IS" X^3
              40 PRINT
              50 GOTO 10
              Ok
              RUN
              ? 9
               9 SQUARED IS 81 AND 9 CUBED IS 729

              ? 21
               21 SQUARED IS 441 AND 21 CUBED IS 9261

              ?

In this example, the semicolon at the end of
line 20 causes both PRINT statements to be
printed on the same line, and line 40 causes a
blank line to be printed before the next prompt.

Example 3:   10 FOR X = 1 TO 5
              20 J=J+5
              30 K=K+10
              40 ?J;K;
              50 NEXT X
              Ok
              RUN
               5 10 10 20 15 30 20 40 25 50
              Ok

In this example, the semicolons in the PRINT
statement cause each value to be printed
immediately after the preceding value.   (Don't
forget, a number is always followed by a space
and positive numbers are preceded by a space.)
In line 40, a question mark is used instead of
the word PRINT.

2.50 PRINT USING

Format: PRINT USING <string exp>;<list of expressions>

Versions: Extended, Disk

Purpose: To print strings or numbers using a specified
                format.

Remarks   <list of expressions> is comprised of the string
and   expressions or numeric expressions that are to
Examples: be printed, separated by semicolons.   <string
                exp> is a string literal (or variable) comprised
                of special formatting characters.   These
                formatting characters (see below) determine the
                field and the format of the printed strings or
                numbers.

String Fields

When PRINT USING is used to print strings, one
of three formatting characters may be used to
format the string field:

"!"   Specifies that only the first character in the
          given string is to be printed.

"\n spaces\" Specifies that 2+n characters from the string
          are to be printed. If the backslashes are typed
          with no spaces, two characters will be printed;
          with one space, three characters will be
          printed, and so on. If the string is longer
          than the field, the extra characters are
          ignored. If the field is lonnger than the
          string, the string will be left-justified in the
          field and padded with spaces on the right.
          Example:

          10 A$="LOOK":B$="OUT"
          30 PRINT USING "!";A$;B$
          40 PRINT USING "\ \";A$;B$
          50 PRINT USING "\   \";A$;B$;"!!"
          RUN
          LO
          LOOKOUT
          LOOK OUT !!

"&"   Specifies a variable length string field. When
             the field is specified with "&", the string is
             output exactly as input. Example:

             10 A$="LOOK":B$="OUT"
             20 PRINT USING "!";A$;
             30 PRINT USING "&";B$
             RUN
             LOUT

Numeric Fields

When PRINT USING is used to print numbers, the
following special characters may be used to
format the numeric field:

\#   A number sign is used to represent each digit
             position. Digit positions are always filled.
             If the number to be printed has fewer digits
             than positions specified, the number will be
             right-justified (preceded by spaces) in the
             field.

.   A decimal point may be inserted at any position
             in the field. If the format string specifies
             that a digit is to precede the decimal point,
             the digit will always be printed (as 0 if
             necessary). Numbers are rounded as necessary.

             PRINT USING "##.##";.78
              0.78

             PRINT USING "###.##";987.654
             987.65

             PRINT USING "##.##   ";10.2,5.3,66.789,.234
             10.20   5.30   66.79   0.23

             In the last example, three spaces were inserted
             at the end of the format string to separate the
             printed values on the line.

+   A plus sign at the beginning or end of the
             format string will cause the sign of the number
             (plus or minus) to be printed before or after
             the number.

-           A minus sign at the end of the format field will
            cause negative numbers to be printed with a
            trailing minus sign.

            PRINT USING "+##.##   ";-68.95,2.4,55.6,-.9
            -68.95   +2.40   +55.60   -0.90

            PRINT USING "##.##-   ";-68.95,22.449,-7.01
            68.95-   22.45   7.01-

**   A double asterisk at the beginning of the format
            string causes leading spaces in the numeric
            field to be filled with asterisks. The ** also
            specifies positions for two more digits.

            PRINT USING "**#.#   ";12.39,-0.9,765.1
            *12.4   *-0.9   765.1

$$ A double dollar sign causes a dollar sign to be
            printed to the immediate left of the formatted
            number. The $$ specifies two more digit
            positions, one of which is the dollar sign. The
            exponential format cannot be used with $$.
            Negative numbers cannot be used unless the minus
            sign trails to the right.

            PRINT USING "$$###.##";456.78
             $456.78

**$ The **$ at the beginning of a format string
            combines the effects of the above two symbols.
            Leading spaces will be asterisk-filled and a
            dollar sign will be printed before the number.
            **$ specifies three more digit positions, one of
            which is the dollar sign.

            PRINT USING "**$##.##";2.34
            ***$2.34

            A comma that is to the left of the decimal point
            in a formatting string causes a comma to be
            printed to the left of every third digit to the
            left of the decimal point. A comma that is at
            the end of the format string is printed as part
            of the string. A comma specifies another digit
            position. The comma has no effect if used with
            the exponential (^^^^) format.

            PRINT USING "####,.##";1234.5
            1,234.50

            PRINT USING "####.##,";1234.5
            1234.50,

^^^^   Four carats (or up-arrows) may be placed after
                the digit position characters to specify
                exponential format. The four carats allow space
                for E+xx to be printed. Any decimal point
                position may be specified. The significant
                digits are left-justified, and the exponent is
                adjusted. Unless a leading + or trailing + or -
                is specified, one digit position will be used to
                the left of the decimal point to print a space
                or a minus sign.

                PRINT USING "##.##^^^^";234.56
                 2.35E+02

                PRINT USING ".####^^^^-";888888
                 .8889E+06

                PRINT USING "+.##^^^^";123
                +.12E+03

_   An underscore in the format string causes the
                next character to be output as a literal
                character.

                PRINT USING "_!##.##_!";12.34
                !12.34!

                The literal character itself may be an
                underscore by placing "__" in the format string.

%   If the number to be printed is larger than the
                specified numeric field, a percent sign is
                printed in front of the number. If rounding
                causes the number to exceed the field, a percent
                sign will be printed in front of the rounded
                number.

                PRINT USING "##.##";111.22
                %111.22

                PRINT USING ".##";.999
                %1.00

                If the number of digits specified exceeds 24, an
                "Illegal function call" error will result.

2.51 PRINT# AND PRINT# USING

Format: PRINT#<filenumber>,[USING<string exp>;]<list of exps>

Version: Disk

Purpose: To write data to a sequential disk file.

Remarks: <file number> is the number used when the file
              was OPENed for output. <string exp> is
              comprised of formatting characters as described
              in Section 2.50, PRINT USING. The expressions
              in <list of expressions> are the numeric and/or
              string expressions that will be written to the
              file.

              PRINT# does not compress data on the disk. An
              image of the data is written to the disk, just
              as it would be displayed on the terminal with a
              PRINT statement. For this reason, care should
              be taken to delimit the data on the disk, so
              that it will be input correctly from the disk.

              In the list of expressions, numeric expressions
              should be delimited by semicolons. For example,

              PRINT#1,A;B;C;X;Y;Z

              (If commas are used as delimiters, the extra
              blanks that are inserted between print fields
              will also be written to disk.)

              String expressions must be separated by
              semicolons in the list. To format the string
              expressions correctly on the disk, use explicit
              delimiters in the list of expressions.

              For example, let A$="CAMERA" and B$="93604-1".
              The statement

              PRINT#1,A$;B$

              would write CAMERA93604-1 to the disk. Because
              there are no delimiters, this could not be input
              as two separate strings. To correct the
              problem, insert explicit delimiters into the
              PRINT# statement as follows:

              PRINT#1,A$;",";B$

              The image written to disk is

              CAMERA,93604-1

which can be read back into two string
variables.

If the strings themselves contain commas,
semicolons, significant leading blanks, carriage
returns, or line feeds, write them to disk
surrounded by explicit quotation marks,
CHR$(34).

For example, let A$="CAMERA, AUTOMATIC" and
B$=" 93604-1". The statement

PRINT#1,A$;B$

would write the following image to disk:

CAMERA, AUTOMATIC   93604-1

and the statement

INPUT#1,A$,B$

would input "CAMERA" to A$ and
"AUTOMATIC 93604-1" to B$. To separate these
strings properly on the disk, write double
quotes to the disk image using CHR$(34). The
statement

PRINT#1,CHR$(34);A$;CHR$(34);CHR$(34);B$;CHR$(34)

writes the following image to disk:

"CAMERA, AUTOMATIC""   93604-1"

and the statement

INPUT#1,A$,B$

would input "CAMERA, AUTOMATIC" to A$ and
"   93604-1" to B$.

The PRINT# statement may also be used with the
USING option to control the format of the disk
file. For example:

PRINT#1,USING"$$###.##,";J;K;L

For more examples using PRINT#, see Appendix B.

See also WRITE#, Section 2.68.

2.52 PUT

Format: PUT [#]<file number>[,<record number>]

Version: Disk

Purpose: To write a record from a random buffer to a random disk file.

Remarks: <file number> is the number under which the file was OPENed. If <record number> is omitted, the record will have the next available record number (after the last PUT). The largest possible record number is 32767. The smallest record number is 1.

Example: See Appendix B.

NOTE: PRINT#, PRINT# USING, and WRITE# may be used to put characters in the random file buffer before a PUT statement.

            In the case of WRITE#, BASIC-80 pads the buffer with spaces up to the carriage return. Any attempt to read or write past the end of the buffer causes a "Field overflow" error.

2.53 RANDOMIZE

Format: RANDOMIZE [<expression>]

Versions: Extended, Disk

Purpose: To reseed the random number generator.

Remarks: If <expression> is omitted, BASIC-80 suspends
             program execution and asks for a value by
             printing

                  Random Number Seed (-32768 to 32767)?

             before executing RANDOMIZE.

             If the random number generator is not reseeded,
             the RND function returns the same sequence of
             random numbers each time the program is RUN. To
             change the sequence of random numbers every time
             the program is RUN, place a RANDOMIZE statement
             at the beginning of the program and change the
             argument with each RUN.

Example: 10 RANDOMIZE
             20 FOR I=1 TO 5
             30 PRINT RND;
             40 NEXT I
             RUN
             Random Number Seed (-32768 to 32767)? 3   (user
             types 3)
              .88598 .484668 .586328 .119426 .709225
             Ok
             RUN
             Random Number Seed (-32768 to 32767)? 4 (user
             types 4 for new sequence)
              .803506 .162462 .929364 .292443 .322921
             Ok
             RUN
             Random Number Seed (-32768 to 32767)? 3 (same
             sequence as first RUN)
              .88598 .484668 .586328 .119426 .709225
             Ok

2.54 <u>READ</u>

Format: READ <list of variables>

Versions: 8K, Extended, Disk

Purpose: To read values from a DATA statement and assign
               them to variables. (See DATA, Section 2.10.)

Remarks: A READ statement must always be used   in
               conjunction   with   a   DATA   statement.   READ
               statements assign variables to DATA statement
               values on a one-to-one basis. READ statement
               variables may be numeric or string, and the
               values read must agree with the variable types
               specified. If they do not agree, a "Syntax
               error" will result.

               A single READ statement may access one or more
               DATA   statements (they will be accessed in
               order), or several READ statements may access
               the same DATA statment.   If the number of
               variables in <list of variables> exceeds the
               number of elements in the DATA statement(s), an
               OUT OF DATA message is printed. If the number
               of variables specified is fewer than the number
               of elements in the DATA statement(s), subsequent
               READ statements will begin reading data at the
               first unread element.   If there are   no
               subsequent READ statements, the extra data is
               ignored.

               To reread DATA statements from the start, use
               the RESTORE statement ·(see RESTORE, Section
               2.57)

Example 1:   .
               .
               .
               80 FOR I=1 TO 10
               90 READ A(I)
               100 NEXT I
               110 DATA 3.08,5.19,3.12,3.98,4.24
               120 DATA 5.08,5.55,4.00,3.16,3.37
               .
               .
               .

               This program segment READs the values from the
               DATA statements into the array A.   After
               execution, the value of A(1) will be 3.08, and
               so on.

Example 2: LIST
            10 PRINT "CITY", "STATE", " ZIP"
            20 READ C$,S$,Z
            30 DATA "DENVER,", COLORADO, 80211
            40 PRINT C$,S$,Z
            Ok
            RUN
            CITY   STATE   ZIP
            DENVER,   COLORADO   80211
            Ok

            This program READs string and numeric data from
            the DATA statement in line 30.

2.55 <u>REM</u>

Format: REM <remark>

Versions: 8K, Extended, Disk

Purpose: To allow explanatory remarks to be inserted in a
             program.

Remarks: REM statements are not executed but are output
             exactly as entered when the program is listed.

             REM statements may be branched into (from a GOTO
             or GOSUB statement), and execution will continue
             with the first executable statement after the
             REM statement.

             In the Extended and Disk versions, remarks may
             be added to the end of a line by preceding the
             remark with a single quotation mark instead of
             :REM.

             WARNING: Do not use this in a data statement as
             it would be considered legal data.

Example: .
                 .
                 .
             120 REM CALCULATE AVERAGE VELOCITY
             130 FOR I=1 TO 20
             140 SUM=SUM + V(I)
                 .
                 .
                 .

             or, with Extended and Disk versions:

                 .
                 .
                 .
             120 FOR I=1 TO 20   'CALCULATE AVERAGE VELOCITY
             130 SUM=SUM+V(I)
             140 NEXT I
                 .
                 .
                 .

2.56 RENUM

Format: RENUM [[<new number>][,[<old number>][,<increment>]]]

Versions: Extended, Disk

Purpose: To renumber program lines.

Remarks: <new number> is the first line number to be used
               in the new sequence. The default is 10. <old
               number> is the line in the current program where
               renumbering is to begin.   The default is the
               first line of the program. <increment> is the
               increment to be used in the new sequence. The
               default is 10.

               RENUM also changes all line number references
               following   GOTO,   GOSUB,   THEN,   ON...GOTO,
               ON...GOSUB and ERL statements to reflect the new
               line numbers. If a nonexistent line number
               appears after one of these statements, the error
               message "Undefined line xxxxx in yyyyy" is
               printed. The incorrect line number reference
               (xxxxx) is not changed by RENUM, but line number
               yyyyy may be changed.

NOTE: RENUM cannot be used to change the order of
               program lines (for example, RENUM 15,30 when the
               program has three lines numbered 10, 20 and 30)
               or to create line numbers greater than 65529.
               An "Illegal function call" error will result.

Examples: RENUM   Renumbers the entire program.
                                     The first new line number
                                     will be 10. Lines will
                                     increment by 10.

               RENUM 300,,50   Renumbers the entire pro-
                                     gram. The first new line
                                     number will be 300. Lines
                                     will increment by 50.

               RENUM 1000,900,20   Renumbers the lines from
                                     900 up so they start with
                                     line number 1000 and
                                     increment by 20.

2.57 RESTORE

Format: RESTORE [<line number>]

Versions: 8K, Extended, Disk

Purpose: To allow DATA statements to be reread from a specified line.

Remarks: After a RESTORE statement is executed, the next READ statement accesses the first item in the first DATA statement in the program. If <line number> is specified, the next READ statement accesses the first item in the specified DATA statement.

Example: 10 READ A,B,C
               20 RESTORE
               30 READ D,E,F
               40 DATA 57, 68, 79
                       .
                       .
                       .

2.58 RESUME

Formats: RESUME

              RESUME 0

              RESUME NEXT

              RESUME <line number>

Versions: Extended, Disk

Purpose: To continue program execution after an error
recovery procedure has been performed.

Remarks: Any one of the four formats shown above may be
used, depending upon where execution is to
resume:

RESUME   Execution resumes at the
  or   statement which caused the
RESUME 0   error.

RESUME NEXT   Execution resumes at the
statement immediately fol-
lowing the one which
caused the error.

RESUME <line number> Execution resumes at
<line number>.

A RESUME statement that is not in an error trap
routine causes a "RESUME without error" message
to be printed.

Example: 10 ON ERROR GOTO 900
       •
       •
       •
     900 IF (ERR=230)AND(ERL=90) THEN PRINT "TRY
     AGAIN":RESUME 80
       •
       •
       •

2.59 RUN

Format 1:   RUN [<line number>]

Versions: 8K, Extended, Disk

Purpose: To execute the program currently in memory.

Remarks: If <line number> is specified, execution begins
             on that line. Otherwise, execution begins at
             the lowest line number. BASIC-80 always returns
             to command level after a RUN is executed.

Example: RUN

Format 2:   RUN <filename>[,R]

Version: Disk

Purpose: To load a file from disk into memory and run it.

Remarks: <filename> is the name used when the file was
             SAVEd. (With CP/M and ISIS-II, the default
             extension .BAS is supplied.)

             RUN closes all open files and deletes the
             current contents of memory before loading the
             designated program. However, with the "R"
             option, all data files remain OPEN.

Example: RUN "NEWFIL",R

             See also Appendix B.

NOTE: The BASIC Compiler supports the RUN and RUN LINE
             number> forms of the RUN statement. The BASIC
             Compiler does not support the "R" option with
             RUN. If you want this feature, the CHAIN
             statement should be used.

2.60   SAVE

Format: SAVE <filename>[,A | ,P]

Version: Disk

Purpose: To save a program file on disk.

Remarks: <filename> is a quoted string that conforms to
             your operating system's requirements for
             filenames. (With CP/M, the default extension
             .BAS is supplied.) If <filename> already exists,
             the file will be written over.

             Use the A option to save the file in ASCII
             format. Otherwise, BASIC saves the file in a
             compressed binary format. ASCII format takes
             more space on the disk, but some disk access
             requires that files be in ASCII format. For
             instance, the MERGE command requires and ASCII
             format file, and some operating system commands
             such as LIST may require an ASCII format file.

             Use the P option to protect the file by saving
             it in an encoded binary format. When a
             protected file is later RUN (or LOADed), any
             attempt to list or edit it will fail.

Examples: SAVE"COM2",A
             SAVE"PROG",P

             See also Appendix B.

2.61 STOP

Format: STOP

Versions: 8K, Extended, Disk

Purpose: To terminate program execution and return to command level.

Remarks: STOP statements may be used anywhere in a program to terminate execution. When a STOP is encountered, the following message is printed:

             Break in line nnnnn

             Unlike the END statement, the STOP statement does not close files.

             BASIC-80 always returns to command level after a STOP is executed. Execution is resumed by issuing a CONT command (see Section 2.8).

Example: 10 INPUT A,B,C
             20 K=A^2*5.3:L=B^3/.26
             30 STOP
             40 M=C*K+100:PRINT M
             RUN
             ? 1,2,3
             BREAK IN 30
             Ok
             PRINT L
              30.7692
             Ok
             CONT
              115.9
             Ok

2.62 SWAP

Format: SWAP <variable>,<variable>

Versions: Extended, Disk

Purpose: To exchange the values of two variables.

Remarks: Any type variable may be SWAPped (integer,
             single precision, double precision, string), but
             the two variables must be of the same type or a
             "Type mismatch" error results.

Example: LIST
             10 A$=" ONE " : B$=" ALL " : C$="FOR"
             20 PRINT A$ C$ B$
             30 SWAP A$, B$
             40 PRINT A$ C$ B$
             RUN
             Ok
              ONE FOR ALL
              ALL FOR ONE
             Ok

2.63 TRON/TROFF

Format: TRON

            TROFF

Versions: Extended, Disk

Purpose: To trace the execution of program statements.

Remarks: As an aid in debugging, the TRON statement
            (executed in either the direct or indirect mode)
            enables a trace flag that prints each line
            number of the program as it is executed. The
            numbers appear enclosed in square brackets. The
            trace flag is disabled with the TROFF statement
            (or when a NEW command is executed).

Example: TRON
            Ok
            LIST
            10 K=10
            20 FOR J=1 TO 2
            30 L=K + 10
            40 PRINT J;K;L
            50 K=K+10
            60 NEXT
            70 END
            Ok
            RUN
            [10][20][30][40] 1 10   20
            [50][60][30][40] 2 20   30
            [50][60][70]
            Ok
            TROFF
            Ok

2.64 WAIT

Format: WAIT <port number>, I[,J]
            where I and J are integer expressions

Versions: 8K, Extended, Disk

Purpose: To suspend program execution while monitoring
            the status of a machine input port.

Remarks: The WAIT statement causes execution to be
            suspended until a specified machine input port
            develops a specified bit pattern. The data read
            at the port is exclusive OR'ed with the integer
            expression J, and then AND'ed with I. If the
            result is zero, BASIC-80 loops back and reads
            the data at the port again. If the result is
            nonzero, execution continues with the next
            statement. If J is omitted, it is assumed to be
            zero

CAUTION: It is possible to enter an infinite loop with
            the WAIT statement, in which case it will be
            necessary to manually restart the machine.

Example: 100 WAIT 32,2

2.65 WHILE...WEND

Format: WHILE <expression>
                  .
                  .
               [<loop statements>]
                  .
                  .
               WEND

Versions: Extended, Disk

Purpose: To execute a series of statements in a loop as
               long as a given condition is true.

Remarks: If <expression> is not zero (i.e., true), <loop
               statements> are executed until the WEND
               statement is encountered. BASIC then returns to
               the WHILE statement and checks <expression>. If
               it is still true, the process is repeated. If
               it is not true, execution resumes with the
               statement following the WEND statement.

               WHILE/WEND loops may be nested to any level.
               Each WEND will match the most recent WHILE. An
               unmatched WHILE statement causes a   "WHILE
               without WEND" error, and an unmatched WEND
               statement causes a "WEND without WHILE" error.

Example: 90 'BUBBLE SORT ARRAY A$
               100 FLIPS=1 'FORCE ONE PASS THRU LOOP
               110 WHILE FLIPS
               115   FLIPS=0
               120   FOR I=1 TO J-1
               130   IF A$(I)>A$(I+1) THEN
                                       SWAP A$(I),A$(I+1):FLIPS=1
               140   NEXT I
               150 WEND

2.66 <u>WIDTH</u>

Format: WIDTH [LPRINT] <integer expression>

Versions: Extended, Disk

Purpose: To set the printed line width in number of
                characters for the terminal or line printer.

Remarks: If the LPRINT option is omitted, the line width
                is set at the terminal. If LPRINT is included,
                the line width is set at the line printer.

                <integer expression> must have a value in the
                range 15 to 255.   The default width is 72
                characters.

                If <integer expression> is 255, the line width
                is "infinite," that is, BASIC never inserts a
                carriage return. However, the position of the
                cursor or the print head, as given by the POS or
                LPOS function, returns to zero after position
                255.

Example: 10 PRINT "ABCDEFGHIJKLMNOPQRSTUVWXYZ"
                RUN
                ABCDEFGHIJKLMNOPQRSTUVWXYZ
                Ok
                WIDTH 18
                Ok
                RUN
                ABCDEFGHIJKLMNOPQR
                STUVWXYZ
                Ok

2.67 <u>WRITE</u>

Format: WRITE[<list of expressions>]

Version: Disk

Purpose: To output data at the terminal.

Remarks: If <list of expressions> is omitted, a blank
              line is output. If <list of expressions> is
              included, the values of te expressions are
              output at thee terminal. The expressions in the
              list may be numeric and/or string expressions,
              and they must be separated by commas.

              When the printed items are output, each item
              will be separated from the last by a comma.
              Printed strings will be delimited by quotation
              marks. After the last item in the list is
              printed, BASIC inserts a carriage return/line
              feed.

              WRITE outputs numeric values using the same
              format as the PRINT statement, Section 2.49.

Example: 10 A=80:B=90:C$="THAT'S ALL"
              20 WRITE A,B,C$
              RUN
               80, 90,"THAT'S ALL"
              Ok

2.68 WRITE#

Format: WRITE#<file number>,<list of expressions>

Version: Disk

Purpose: To write data to a sequential file.

Remarks: <file number> is the number under which the file
             was OPENed in "O" mode. The expressions in the
             list are string or numeric expressions, and they
             must be separated by commas.

             The difference between WRITE# and PRINT# is that
             WRITE# inserts commas between the the items as
             they are written to disk and delimits strings
             with quotation marks.   Therefore, it is not
             necessary for the user to put explicit
             delimiters in the list. A carriage return/line
             feed sequence is inserted after the last item in
             the list is written to disk.

Example: Let A$="CAMERA"   and   B$="93604-1".   The
             statement:

             WRITE#1,A$,B$

             writes the following image to disk:

             "CAMERA","93604-1"

             A subsequent INPUT# statement, such as:

             INPUT#1,A$,B$

             would input "CAMERA" to A$ and "93604-1" to B$.

CHAPTER 3

BASIC-80 FUNCTIONS

The intrinsic functions provided by BASIC-80 are presented
in this chapter. The functions may be called from any
program without further definition.

Arguments to functions are always enclosed in parentheses.
In the formats given for the functions in this chapter, the
arguments have been abbreviated as follows:

   X and Y   Represent any numeric expressions

   I and J   Represent integer expressions

   X$ and Y$ Represent string expressions

If a floating point value is supplied where an integer is
required, BASIC-80 will round the fractional portion and use
the resulting integer.

NOTE

     With the BASIC-80 and BASIC-86
     interpreters, only integer and
     single precision resullts are
     returned by funtions. Double
     precision functions are
     supported only by the BASIC
     compiler.

3.1 ABS

Format: ABS(X)

Versions: 8K, Extended, Disk

Action: Returns the absolute value of the expression X.

Example: PRINT ABS(7*(-5))
              35
             Ok

3.2 ASC

Format: ASC(X$)

Versions: 8K, Extended, Disk

Action: Returns a numerical value that is the ASCII code
             of the first character of the string X$. (See
             Appendix M for ASCII codes.) If X$ is null, an
             "Illegal function call" error ·is returned.

Example: 10 X$ = "TEST"
             20 PRINT ASC(X$)
             RUN
              84
             Ok

             See the CHR$ function   for   ASCII-to-string
             conversion.

3.3 ATN

Format: ATN(X)

Versions: 8K, Extended, Disk

Action: Returns the arctangent of X in radians.   Result
              is in the range -pi/2 to pi/2. The expression X
              may be any numeric type, but the evaluation of
              ATN is always performed in single precision.

Example: 10 INPUT X
              20 PRINT ATN(X)
              RUN
              ? 3
               1.24905
              Ok

3.4 CDBL

Format: CDBL(X)

Versions: Extended, Disk

Action: Converts X to a double precision number.

Example: 10 A = 454.67
              20 PRINT A;CDBL(A)
              RUN
               454.67   454.6700134277344
              Ok

3.5 CHR$

Format: CHR$(I)

Versions: 8K, Extended, Disk

Action: Returns a string whose one element has ASCII
             code I. (ASCII codes are listed in Appendix M.)
             CHR$ is commonly used to send a special
             character to the terminal. For instance, the
             BEL character could be sent (CHR$(7)) as a
             preface to an error message, or a form feed
             could be sent (CHR$(12)) to clear a CRT screen
             and return the cursor to the home position.

Example: PRINT CHR$(66)
             B
             Ok
             See the ASC function for ASCII-to-numeric
             conversion.

3.6 CINT

Format: CINT(X)

Versions: Extended, Disk

Action: Converts X to an integer by rounding the
             fractional portion. If X is not in the range
             -32768 to 32767, an "Overflow" error occurs.

Example: PRINT CINT(45.67)
              46
             Ok

             See the CDBL and CSNG functions for converting
             numbers to the double precision and single
             precision data type. See also the FIX and INT
             functions, both of which return integers.

3.7 COS

Format: COS(X)

Versions: 8K, Extended, Disk

Action: Returns the cosine of X in radians. The
            calculation of COS(X) is performed in single
            precision.

Example: 10 X = 2*COS(.4)
            20 PRINT X
            RUN
             1.84212
            Ok

3.8 CSNG

Format: CSNG(X)

Versions: Extended, Disk

Action: Converts X to a single precision number.

Example: 10 A# = 975.3421#
            20 PRINT A#; CSNG(A#)
            RUN
             975.3421   975.342
            Ok

            See the CINT and CDBL functions for converting
            numbers to the integer and double precision data
            types.

3.9 <u>CVI</u>, <u>CVS</u>, <u>CVD</u>

Format: CVI(<2-byte string>)
             CVS(<4-byte string>)
             CVD(<8-byte string>)

Version: Disk

Action: Convert string values to numeric values.
             Numeric values that are read in from a random
             disk file must be converted from strings back
             into numbers. CVI converts a 2-byte string to
             an integer. CVS converts a 4-byte string to a
             single precision number. CVD converts an 8-byte
             string to a double precision number.

Example: .
               .
               .
             70 FIELD #1,4 AS N$, 12 AS B$, ...
             80 GET #1
             90 Y=CVS(N$)
               .
               .
               .

             See also MKI$, MKS$, MKD$, Section 3.25 and
             Appendix B.

3.10 <u>EOF</u>

Format: EOF(<file number>)

Version: Disk

Action: Returns -1 (true) if the end of a sequential
             file has been reached. Use EOF to test for
             end-of-file while INPUTting, to avoid "Input
             past end" errors.

Example: 10 OPEN "I",1,"DATA"
             20 C=0
             30 IF EOF(1) THEN 100
             40 INPUT #1,M(C)
             50 C=C+1:GOTO 30
               .
               .
               .

3.11 EXP

Format: EXP(X)

Versions: 8K, Extended, Disk

Action: Returns e to the power of X.   X must be
             <=87.3365.   If EXP overflows, the "Overflow"
             error message is displayed, machine infinity
             with the appropriate sign is supplied as the
             result, and execution continues.

Example: 10 X = 5
             20 PRINT EXP (X-1)
             RUN
              54.5982
             Ok

3.12 FIX

Format: FIX(X)

Versions: Extended, Disk

Action: Returns the truncated integer part of X. FIX(X)
             is equivalent to SGN(X)*INT(ABS(X)).   The major
             difference between FIX and INT is that FIX does
             not return the next lower number for negative X.

Examples: PRINT FIX(58.75)
              58
             Ok

             PRINT FIX(-58.75)
             -58
             Ok

3.13 FRE

Format: FRE(0)
             FRE(X$)

Versions: 8K, Extended, Disk

Action: Arguments to FRE are dummy arguments. FRE
             returns the number of bytes in memory not being
             used by BASIC-80.

             FRE("") forces a garbage collection before
             returning the number of free bytes. BE
             PATIENT: garbage collection may take 1 to 1-1/2
             minutes.   BASIC will not initiate garbage
             collection until all free memory has been used
             up.   Therefore, using FRE("") periodically will
             result in shorter delays for each garbage
             collection.

Example: PRINT FRE(0)
              14542
             Ok

3.14 HEX$

Format: HEX$(X)

Versions: Extended, Disk

Action: Returns   a   string   which   represents   the
             hexadecimal value of the decimal argument. X is
             rounded to an integer before HEX$(X)   is
             evaluated.

Example: 10 INPUT X
             20 A$ = HEX$(X)
             30 PRINT X "DECIMAL IS " A$ " HEXADECIMAL"
             RUN
             ? 32
              32 DECIMAL IS 20 HEXADECIMAL
             Ok

             See the OCT$ function for octal conversion.

3.15 INKEY$

Format: INKEY$

Action: Returns either a one-character string containing
               a character read from the terminal or a null
               string if no character is pending at the
               terminal.   No characters will be echoed and all
               characters are passed through tto the program
               except   for Control-C, which terminates the
               program. (With the BASIC Compiler, Control-C is
               also passed through to the program.)

Example: 1000 'TIMED INPUT SUBROUTINE
               1010 RESPONSE$=""
               1020 FOR I%=1 TO TIMELIMIT%
               1030 A$=INKEY$: IF LEN(A$)=0 THEN 1060
               1040 IF ASC(A$)=13 THEN TIMEOUT%=0 : RETURN
               1050 RESPONSE$=RESPONSE$+A$
               1060 NEXT I%
               1070 TIMEOUT%=1 : RETURN

3.16 INP

Format: INP(I)

Versions: 8K, Extended, Disk

Action: Returns the byte read from port I. I must be in
               the range 0 to 255. INP is the complementary
               function to the OUT statement, Section 2.47.

Example: 100 A=INP(255)

3.17 INPUT$

Format: INPUT$(X[,[#]Y])

Version: Disk

Action: Returns a string of X characters, read from the
            terminal or from file number Y. If the terminal
            is used for input, no characters will be echoed
            and all control characters are passed through
            except Control-C, which is used to interrupt the
            execution of the INPUT$ function.

Example 1: 5 'LIST THE CONTENTS OF A SEQUENTIAL FILE IN
            HEXADECIMAL
            10 OPEN"I",1,"DATA"
            20 IF EOF(1) THEN 50
            30 PRINT HEX$(ASC(INPUT$(1,#1)));
            40 GOTO 20
            50 PRINT
            60 END

Example 2:   .
              .
              .
            100 PRINT "TYPE P TO PROCEED OR S TO STOP"
            110 X$=INPUT$(1)
            120 IF X$="P" THEN 500
            130 IF X$="S" THEN 700 ELSE 100
              .
              .
              .

3.18 <u>INSTR</u>

Format: INSTR([I,]X$,Y$)

Versions: Extended, Disk

Action: Searches for the first occurrence of string Y$
             in X$ and returns the position at which the
             match is found.   Optional offset I sets the
             position for starting the search. I must be in
             the range 1 to 255.   If I>LEN(X$) or if X$ is
             null or if Y$ cannot be found, INSTR returns 0.
             If Y$ is null, INSTR returns I or 1. X$ and Y$
             may be string variables, string expressions or
             string literals.

Example: 10 X$ = "ABCDEB"
             20 Y$ = "B"
             30 PRINT INSTR(X$,Y$);INSTR(4,X$,Y$)
             RUN
              2 6
             Ok

NOTE: If I=0 is specified, error message "ILLEGAL
             ARGUMENT IN <line number>" will be returned.

3.19 <u>INT</u>

Format: INT(X)

Versions: 8K, Extended, Disk

Action: Returns the largest integer <=X.

Examples: PRINT INT(99.89)
             99
            Ok

            PRINT INT(-12.11)
            -13
            Ok

            See the FIX and CINT functions which also return
            integer values.

3.20 <u>LEFT$</u>

Format: LEFT$(X$,I)

Versions: 8K, Extended, Disk

Action: Returns a string comprised of the leftmost I
            characters of X$.   I must be in the range 0 to
            255.   If I is greater than LEN(X$), the entire
            string (X$) will be returned. If I=0, the null
            string (length zero) is returned.

Example: 10 A$ = "BASIC-80"
            20 B$ = LEFT$(A$,5)
            30 PRINT B$
            BASIC
            Ok

            Also see the MID$ and RIGHT$ functions.

3.21 <u>LEN</u>

Format: LEN(X$)

Versions: 8K, Extended, Disk

Action: Returns the number of characters in X$.
             Non-printing characters and blanks are counted.

Example: 10 X$ = "PORTLAND, OREGON"
             20 PRINT LEN(X$)
              16
             Ok

3.22 <u>LOC</u>

Format: LOC(<file number>)

Version: Disk

Action: With random disk files, LOC returns the record
             number just read or written from a GET or PUT.
             If the file was opened but no disk I/O has been
             performed yet, LOC returns a 0. With sequential
             files, LOC returns the number of sectors (128
             byte blocks) read from or written to the file
             since it was OPENed.

Example: 200 IF LOC(1)>50 THEN STOP

3.23 LOG

Format: LOG(X)

Versions: 8K, Extended, Disk

Action: Returns the natural logarithm of X. X must be
             greater than zero.

Example: PRINT LOG(45/7)
              1.86075
             Ok

3.24 LPOS

Format: LPOS(X)

Versions: Extended, Disk

Action: Returns the current position of the line printer
             print head within the line printer buffer. Does
             not necessarily give the physical position of
             the print head. X is a dummy argument.

Example: 100 IF LPOS(X)>60 THEN LPRINT CHR$(13)

3.25 MID$

Format: MID$(X$,I[,J])

Versions: 8K, Extended, Disk

Action: Returns a string of length J characters from X$
             beginning with the Ith character. I and J must
             be in the range 1 to 255. If J is omitted or if
             there are fewer than J characters to the right
             of the Ith character, all rightmost characters
             beginning with the Ith character are returned.
             If I>LEN(X$), MID$ returns a null string.

Example: LIST
             10 A$="GOOD "
             20 B$="MORNING EVENING AFTERNOON"
             30 PRINT A$;MID$(B$,9,7)
             Ok
             RUN
             GOOD EVENING
             Ok

             Also see the LEFT$ and RIGHT$ functions.

NOTE: If I=0 is `specified, error message "ILLEGAL
             ARGUMENT IN <line number>" will be returned.

3.26 MKI$, MKS$, MKD$

Format: MKI$(<integer expression>)
             MKS$(<single precision expression>)
             MKD$(<double precision expression>)

Version: Disk

Action: Convert numeric values to string values. Any
             numeric value that is placed in a random file
             buffer with an LSET or RSET statement must be
             converted to a string. MKI$ converts an integer
             to a 2-byte string. MKS$ converts a single
             precision number to a 4-byte string. MKD$
             converts a double precision number to an 8-byte
             string.

Example: 90 AMT=(K+T)
             100 FIELD #1, 8 AS D$, 20 AS N$
             110 LSET D$ = MKS$(AMT)
             120 LSET N$ = A$
             130 PUT #1
               .
               .

             See also CVI, CVS, CVD, Section 3.9 and Appendix
             B.

3.27 OCT$

Format: OCT$(X)

Versions: Extended, Disk

Action: Returns a string which represents the octal
             value of the decimal argument. X is rounded to
             an integer before OCT$(X) is evaluated.

Example: PRINT OCT$(24)
              30
             Ok

             See the HEX$ function for hexadecimal
             conversion.

3.28 PEEK

Format: PEEK(I)

Versions: 8K, Extended, Disk

Action: Returns the byte (decimal integer in the range 0
             to 255) read from memory location I. With the
             8K version of BASIC-80, I must be less than
             32768. To PEEK at a memory location above
             32768, subtract 65536 from the desired address.
             With Extended and Disk BASIC-80, I must be in
             the range 0 to 65536. PEEK is the complementary
             function to the POKE statement, Section 2.48.

Example: A=PEEK(&H5A00)

3.29 <u>POS</u>

Format: POS(I)

Versions: 8K, Extended, Disk

Action: Returns the current cursor position. The
             leftmost position is 1. X is a dummy argument.

Example: IF POS(X)>60 THEN PRINT CHR$(13)

             Also see the LPOS function.

3.30 <u>RIGHT$</u>

Format: RIGHT$(X$,I)

Versions: 8K, Extended, Disk

Action: Returns the rightmost I characters of string X$.
             If I=LEN(X$), returns X$.   If I=0, the null
             string (length zero) is returned.

Example: 10 A$="DISK BASIC-80"
             20 PRINT RIGHT$(A$,8)
             RUN
             BASIC-80
             Ok

             Also see the MID$ and LEFT$ functions.

3.31 RND

Format: RND[(X)]

Versions: 8K, Extended, Disk

Action: Returns a random number between 0 and 1. The
            same sequence of random numbers is generated
            each time the program is RUN unless the random
            number generator is reseeded (see RANDOMIZE,
            Section 2.53). However, X<0 always restarts the
            same sequence for any given X.

            X>0 or X omitted generates the next random
            number in the sequence. X=0 repeats the last
            number generated.

Example: 10 FOR I=1 TO 5
            20 PRINT INT(RND*100);
            30 NEXT
            RUN
             24 30 31 51 5
            Ok

3.32 SGN

Format: SGN(X)

Versions: 8K, Extended, Disk

Action: If X>0, SGN(X) returns 1.
            If X=0, SGN(X) returns 0.
            If X<0, SGN(X) returns -1.

Example: ON SGN(X)+2 GOTO 100,200,300 branches to 100 if
            X is negative, 200 if X is 0 and 300 if X is
            positive.

3.33 <u>SIN</u>

Format: SIN(X)

Versions: 8K, Extended, Disk

Action: Returns the sine of X in radians. SIN(X) is
             calculated   in   single   precision.
             COS(X)=SIN(X+3.14159/2).

Example: PRINT SIN(1.5)
              .997495
             Ok

3.34 <u>SPACE$</u>

Format: SPACE$(X)

Versions: Extended, Disk

Action: Returns a string of spaces of length X.   The
             expression X is rounded to an integer and must
             be in the range 0 to 255.

Example: 10 FOR I = 1 TO 5
             20 X$ = SPACE$(I)
             30 PRINT X$;I
             40 NEXT I
             RUN
               1
                2
                 3
                  4
                   5
             Ok

             Also see the SPC function.

3.35 SPC

Format: SPC(I)

Versions: 8K, Extended, Disk

Action: Prints I blanks on the terminal. SPC may only
             be used with PRINT and LPRINT statements. I
             must be in the range 0 to 255. A';' is assumed
             to follow the SPC(I) command.

Example: PRINT "OVER" SPC(15) "THERE"
             OVER   THERE
             Ok

             Also see the SPACE$ function.

3.36 SQR

Format: SQR(X)

Versions: 8K, Extended, Disk

Action: Returns the square root of X.   X must be >=0.

Example: 10 FOR X = 10 TO 25 STEP 5
             20 PRINT X, SQR(X)
             30 NEXT
             RUN
              10   3.16228
              15   3.87298
              20   4.47214
              25   5
             Ok

3.37 <u>STR$</u>

Format: STR$(X)

Versions: 8K, Extended, Disk

Action: Returns a string representation of the value of
              X.

Example: 5 REM ARITHMETIC FOR KIDS
              10 INPUT "TYPE A NUMBER";N
              20 ON LEN(STR$(N)) GOSUB 30,100,200,300,400,500
                   .
                   .
                   .

              Also see the VAL function.

3.38 <u>STRING$</u>

Formats: STRING$(I,J)
              STRING$(I,X$)

Versions: Extended, Disk

Action: Returns a string of length I whose characters
              all have ASCII code J or the first character of
              X$.

Example: 10 X$ = STRING$(10,45)
              20 PRINT X$ "MONTHLY REPORT" X$
              RUN
              ----------MONTHLY REPORT----------
              Ok

3.39 TAB

Format: TAB(I)

Versions: 8K, Extended, Disk

Action: Spaces to position I on the terminal. If the
            current print position is already beyond space
            I, TAB goes to that position on the next line.
            Space 1 is the leftmost position, and the
            rightmost position is the width minus one.   I
            must be in the range 1 to 255. TAB may only be
            used in PRINT and LPRINT statements.

Example: 10 PRINT "NAME" TAB(25) "AMOUNT" : PRINT
            20 READ A$,B$
            30 PRINT A$ TAB(25) B$
            40 DATA "G. T. JONES","$25.00"
            RUN
            NAME   AMOUNT

            G. T. JONES $25.00
            Ok

3.40 TAN

Format: TAN(X)

Versions: 8K, Extended, Disk

Action: Returns the tangent of X in radians. TAN(X) is
            calculated in single precision.   If TAN
            overflows, the "Overflow" error message is
            displayed, machine infinity with the appropriate
            sign is supplied as the result, and execution
            continues.

Example: 10 Y = Q*TAN(X)/2

3.41 <u>USR</u>

Format :   USR[<digit>](X)

Versions: 8K, Extended, Disk

Action: Calls the user's assembly language subroutine
            with the argument X. <digit> is allowed in the
            Extended and Disk versions only. <digit> is in
            the range 0 to 9 and corresponds to the digit
            supplied with the DEF USR statement for that
            routine.   If   <digit> is omitted, USR0 is
            assumed. See Appendix x.

Example: 40 B = T*SIN(Y)
            50 C = USR(B/2)
            60 D = USR(B/3)
               .
               .
               .

3.42 <u>VAL</u>

Format: VAL(X$)

Versions: 8K, Extended, Disk

Action: Returns the numerical value of string X$.   The
            VAL function also strips leading blanks, tabs,
            and linefeeds from the argument string.   For
            example,

            VAL(" -3)

            returns -3.

Example: 10 READ NAME$,CITY$,STATE$,ZIP$
            20 IF VAL(ZIP$)<90000 OR VAL(ZIP$)>96699 THEN
            PRINT NAME$ TAB(25) "OUT OF STATE"
            30 IF VAL(ZIP$)>=90801 AND VAL(ZIP$)<=90815 THEN
            PRINT NAME$ TAB(25) "LONG BEACH"
               .
               .
               .

            See the STR$ function for numeric to string
            conversion.

3.43 VARPTR

Format 1:   VARPTR(<variable name>)

Versions: Extended, Disk

Format 2:   VARPTR(#<file number>)

Version: Disk

Action: Format 1: Returns the address of the first byte
             of data identified with <variable name>. A
             value must be assigned to <variable name> prior
             to execution of VARPTR. Otherwise an "Illegal
             function call" error results. Any type variable
             name may be used (numeric, string, array), and
             the address returned will be an integer in the
             range 32767 to -32768. If a negative address is
             returned, add it to 65536 to obtain the actual
             address.

             VARPTR is usually used to obtain the address of
             a variable or array so it may be passed to an
             assembly language subroutine. A function call
             of the form VARPTR(A(0)) is usually specified
             when passing an array, so that the
             lowest-addressed element of the array is
             returned.

NOTE: All simple variables should be assigned before
             calling VARPTR for an array, because the
             addresses of the arrays change whenever a new
             simple variable is assigned.

             Format 2: For sequential files, returns the
             starting address of the disk I/O buffer assigned
             to <file number>. For random files, returns the
             address of the FIELD buffer assigned to <file
             number>.

             In Standalone Disk BASIC, VARPTR(#<file number>)
             returns the first byte of the file block. See
             Appendix H.

Example: 100 X=USR(VARPTR(Y))

APPENDIX A

New Features in BASIC-80, Release 5.0

The execution of BASIC programs written under Microsoft BASIC, release 4.51 and earlier may be affected by some of the new features in release 5.0. Before attempting to run such programs, check for the following:

1. New reserved words: CALL, CHAIN, COMMON, WHILE, WEND, WRITE, OPTION BASE, RANDOMIZE.

2. Conversion from floating point to integer values results in rounding, as opposed to truncation. This affects not only assignment statements (e.g., I%=2.5 results in I%=3), but also affects function and statement evaluations (e.g., TAB(4.5) goes to the 5th position, A(1.5) yeilds A(2), and X=11.5 MOD 4 yields 0 for X).

3. The body of a FOR...NEXT loop is skipped if the initial value of the loop times the sign of the step exceeds the final value times the sign of the step. See Section 2.22.

4. Division by zero and overflow no longer produce fatal errors. See Section 1.8.1.2.

5. The RND function has been changed so that RND with no argument is the same as RND with a positive argument. The RND function generates the same sequence of random numbers with each RUN, unless RANDOMIZE is used. See Sections 2.53 and 3.30.

6. The rules for PRINTing single precision and double precision numbers have been changed. See Section 2.49.

7. String space is allocated dynamically, and the first argument in a two-argument CLEAR statement sets the end of memory. The second argument sets the amount of stack space. See Section 2.4.

8. Responding to INPUT with too many or too few items, or with non-numeric characters instead of digits, causes the message "?Redo from start" to be printed. If a single variable is requested, a carriage return may be entered to indicate the default values of 0 for numeric input or null for string input. However, if more than one variable is requested, entering a carriage return will cause the "?Redo from start" message to be printed because too few items were entered. No assignment of input values is made until an acceptable response is given.

9. There are two new field formatting characters for use with PRINT USING. An ampersand is used for variable length string fields, and an underscore signifies a literal character in a format string.

10. If the expression supplied with the WIDTH statement is 255, BASIC uses an "infinite" line width, that is, it does not insert carriage returns. WIDTH LPRINT may be used to set the line width at the line printer. See Section 2.66.

11. The at-sign and underscore are no longer used as editing characters.

12. Variable names are significant up to 40 characters and can contain embedded reserved words. However, reserved words must now be delimited by spaces. To maintain compatibility with earlier versions of BASIC, spaces will be automatically inserted between adjoining reserved words and variable names. WARNING: This insertion of spaces may cause the end of a line to be truncated if the line length is close to 255 characters.

13. BASIC programs may be saved in a protected binary format. See SAVE, Section 2.60.

APPENDIX B

BASIC-80 Disk I/O

Disk I/O procedures for the beginning BASIC-80 user are examined in this appendix. If you are new to BASIC-80 or if you're getting disk related errors, read through these procedures and program examples to make sure you're using all the disk statements correctly.

Wherever a filename is required in a disk command or statement, use a name that conforms to your operating system's requirements for filenames. The CP/M operating system will append a default extension .BAS to the filename given in a SAVE, RUN, MERGE or LOAD command.

B.1 PROGRAM FILE COMMANDS

Here is a review of the commands and statements used in program file manipulation.

SAVE <filename>[,A] Writes to disk the program that is currently residing in memory. Optional A writes the program as a series of ASCII characters. (Otherwise, BASIC uses a compressed binary format.)

LOAD <filename>[,R] Loads the program from disk into memory. Optional R runs the program immediately. LOAD always deletes the current contents of memory and closes all files before LOADing. If R is included, however, open data files are kept open. Thus programs can be chained or loaded in sections and access the same data files.

RUN <filename>[,R]   RUN <filename> loads the program from
                            disk into memory and runs it. RUN
                            deletes the current contents of memory
                            and closes all files before loading
                            the program. If the R option is
                            included, however, all open data files
                            are kept open.

MERGE <filename>   Loads the program from disk into
                            memory but does not delete the current
                            contents of memory. The program line
                            numbers on disk are merged with the
                            line numbers in memory. If two lines
                            have the same number, only the line
                            from the disk program is saved. After
                            a MERGE command, the "merged" program
                            resides in memory, and BASIC returns
                            to command level.

KILL <filename>   Deletes the file from the disk.
                            <filename> may be a program file, or a
                            sequential or random access data file.

NAME <old filename>   To change the name of a disk file,
    AS<new filename>   execute the NAME statement, NAME
                            <oldfile> AS <newfile>. NAME may be
                            used with program files, random files,
                            or sequential files.

B.2 PROTECTED FILES

If you wish to save a program in an encoded binary format,
use the "Protect" option with the SAVE command. For
example:

    SAVE "MYPROG",P

A program saved this way cannot be listed or edited. You
may also want to save an unprotected copy of the program for
listing and editing purposes.

B.3 DISK DATA FILES - SEQUENTIAL AND RANDOM I/O

There are two types of disk data files that may be created
and accessed by a BASIC-80 program: sequential files and
random access files.

B.3.1 Sequential Files

Sequential files are easier to create than random files but
are limited in flexibility and speed when it comes to
accessing the data.   The data that is written to a
sequential file is stored, one item after another
(sequentially), in the order it is sent and is read back in
the same way.

The statements and functions that are used with sequential
files are:

     OPEN   PRINT#   INPUT#   WRITE#
             PRINT# USING LINE INPUT#

     CLOSE   EOF   LOC

The following program steps are required to create a
sequential file and access the data in the file:

1. OPEN the file in "O" mode.   OPEN "O",#1,"DATA"

2. Write data to the file   PRINT#1,A$;B$;C$
    using the PRINT# statement.
    (WRITE# may be used instead.)

3. To access the data in the   CLOSE #1
    file, you must CLOSE the file   OPEN "I",#1,"DATA"
    and reOPEN it in "I" mode.

4. Use the INPUT# statement to   INPUT#1,X$,Y$,Z$
    read data from the sequential
    file into the program.

Program B-1 is a short program that creates a sequential
file, "DATA", from information you input at the terminal.

```
10 OPEN "O",#1,"DATA"
20 INPUT "NAME";N$
25 IF N$="DONE" THEN END
30 INPUT "DEPARTMENT";D$
40 INPUT "DATE HIRED";H$
50 PRINT#1,N$;",";D$;",";H$
60 PRINT:GOTO 20
RUN
NAME? MICKEY MOUSE
DEPARTMENT? AUDIO/VISUAL AIDS
DATE HIRED? 01/12/72

NAME? SHERLOCK HOLMES
DEPARTMENT? RESEARCH
DATE HIRED? 12/03/65

NAME? EBENEEZER SCROOGE
DEPARTMENT? ACCOUNTING
DATE HIRED? 04/27/78

NAME? SUPER MANN
DEPARTMENT? MAINTENANCE
DATE HIRED? 08/16/78

NAME? etc.
```

PROGRAM B-1 - CREATE A SEQUENTIAL DATA FILE

Now look at Program B-2. It accesses the file "DATA" that was created in Program B-1 and displays the name of everyone hired in 1978.

```
10 OPEN "I",#1,"DATA"
20 INPUT#1,N$,D$,H$
30 IF RIGHT$(H$,2)="78" THEN PRINT N$
40 GOTO 20
RUN
EBENEEZER SCROOGE
SUPER MANN
Input past end in 20
Ok
```

PROGRAM B-2 - ACCESSING A SEQUENTIAL FILE

Program B-2 reads, sequentially, every item in the file. When all the data has been read, line 20 causes an "Input past end" error. To avoid getting this error, insert line 15 which uses the EOF function to test for end-of-file:

15 IF EOF(1) THEN END

and change line 40 to GOTO 15.

A program that creates a sequential file can also write formatted data to the disk with the PRINT# USING statement. For example, the statement

PRINT#1,USING"####.##,";A,B,C,D

could be used to write numeric data to disk without explicit delimiters. The comma at the end of the format string serves to separate the items in the disk file.

The LOC function, when used with a sequential file, returns the number of sectors that have been written to or read from the file since it was OPENed. A sector is a 128-byte block of data.

B.3.1.1 Adding Data To A Sequential File -
If you have a sequential file residing on disk and later want to add more data to the end of it, you cannot simply open the file in "O" mode and start writing data. As soon as you open a sequential file in "O" mode, you destroy its current contents. The following procedure can be used to add data to an existing file called "NAMES".

1. OPEN "NAMES" in "I" mode.

2. OPEN a second file called "COPY" in "O" mode.

3. Read in the data in "NAMES" and write it to "COPY".

4. CLOSE "NAMES" and KILL it.

5. Write the new information to "COPY".

6. Rename "COPY" as "NAMES" and CLOSE.

7. Now there is a file on disk called "NAMES" that includes all the previous data plus the new data you just added.

Program B-3 illustrates this technique. It can be used to create or add onto a file called NAMES. This program also illustrates the use of LINE INPUT# to read strings with embedded commas from the disk file. Remember, LINE INPUT# will read in characters from the disk until it sees a carriage return (it does not stop at quotes or commas) or until it has read 255 characters.

```
10 ON ERROR GOTO 2000
20 OPEN "I",#1,"NAMES"
30 REM IF FILE EXISTS, WRITE IT TO "COPY"
40 OPEN "O",#2,"COPY"
50 IF EOF(1) THEN 90
60 LINE INPUT#1,A$
70 PRINT#2,A$
80 GOTO 50
90 CLOSE #1
100 KILL "NAMES"
110 REM ADD NEW ENTRIES TO FILE
120 INPUT "NAME";N$
130 IF N$="" THEN 200 'CARRIAGE RETURN EXITS INPUT LOOP
140 LINE INPUT "ADDRESS? ";A$
150 LINE INPUT "BIRTHDAY? ";B$
160 PRINT#2,N$
170 PRINT#2,A$
180 PRINT#2,B$
190 PRINT:GOTO 120
200 CLOSE
205 REM CHANGE FILENAME BACK TO "NAMES"
210 NAME "COPY" AS "NAMES"
2000 IF ERR=53 AND ERL=20 THEN OPEN "O",#2,"COPY":RESUME 120
2010 ON ERROR GOTO 0
```

PROGRAM B-3 - ADDING DATA TO A SEQUENTIAL FILE

The error trapping routine in line 2000 traps a "File does
not exist" error in line 20. If this happens, the
statements that copy the file are skipped, and "COPY" is
created as if it were a new file.

B.3.2 Random Files

Creating and accessing random files requires more program
steps than sequential files, but there are advantages to
using random files. One advantage is that random files
require less room on the disk, because BASIC stores them in
a packed binary format. (A sequential file is stored as a
series of ASCII characters.)

The biggest advantage to random files is that data can be
accessed randomly, i.e., anywhere on the disk -- it is not
necessary to read through all the information, as with
sequential files. This is possible because the information
is stored and accessed in distinct units called records and
each record is numbered.

The statements and functions that are used with random files
are:

```
OPEN     FIELD     LSET/RSET     GET

PUT      CLOSE     LOC

MKI$     CVI
MKS$     CVS
MKD$     CVD
```

B.3.2.1 Creating A Random File -
The following program steps are required to create a random
file.

1.   OPEN the file for random   OPEN "R",#1,"FILE",32
     access ("R" mode). This example
     specifies a record length of 32
     bytes. If the record length is
     omitted, the default is 128
     bytes.

2.   Use the FIELD statement to   FIELD #1 20 AS N$,
     allocate space in the random   4 AS A$, 8 AS P$
     buffer for the variables that
     will be written to the random
     file.

3.   Use LSET to move the data   LSET N$=X$
     into the random buffer.   LSET A$=MKS$(AMT)
     Numeric values must be made   LSET P$=TEL$
     into strings when placed in
     the buffer. To do this, use the
     "make" functions: MKI$ to
     make an integer value into a
     string, MKS$ for a single
     precision value, and MKD$ for
     a double precision value.

4.   Write the data from   PUT #1,CODE%
     the buffer to the disk
     using the PUT statement.

Look at Program B-4. It takes information that is input at
the terminal and writes it to a random file. Each time the
PUT statement is executed, a record is written to the file.
The two-digit code that is input in line 30 becomes the
record number.

NOTE

Do not use a FIELDed string
variable in an INPUT or LET
statement. This causes the
pointer for that variable to
point into string space
instead of the random file
buffer.

```
10  OPEN "R",#1,"FILE",32
20  FIELD #1,20 AS N$, 4 AS A$, 8 AS P$
30  INPUT "2-DIGIT CODE";CODE%
40  INPUT "NAME";X$
50  INPUT "AMOUNT";AMT
60  INPUT "PHONE";TEL$:PRINT
70  LSET N$=X$
80  LSET A$=MKS$(AMT)
90  LSET P$=TEL$
100 PUT #1,CODE%
110 GOTO 30
```

PROGRAM B-4 - CREATE A RANDOM FILE

B.3.2.2 Access A Random File -
The following program steps are required to access a random
file:

1. OPEN the file in "R" mode.   OPEN "R",#1,"FILE",32

2. Use the FIELD statement to   FIELD #1 20 AS N$,
    allocate space in the random   4 AS A$, 8 AS P$
    buffer for the variables that
    will be read from the file.

NOTE:
In a program that performs both
input and output on the same random
file, you can often use just one
OPEN statement and one FIELD
statement.

3. Use the GET statement to move   GET #1,CODE%
    the desired record into the
    random buffer.

4. The data in the buffer may   PRINT N$
    now be accessed by the program.   PRINT CVS(A$)
    Numeric values must be converted
    back to numbers using the
    "convert" functions: CVI for
    integers, CVS for single
    precision values, and CVD
    for double precision values.

Program B-5 accesses the random file "FILE" that was created
in Program B-4. By inputting the three-digit code at the
terminal, the information associated with that code is read
from the file and displayed.

```
10 OPEN "R",#1,"FILE",32
20 FIELD #1, 20 AS N$, 4 AS A$, 8 AS P$
30 INPUT "2-DIGIT CODE";CODE%
40 GET #1, CODE%
50 PRINT N$
60 PRINT USING "$$###.##";CVS(A$)
70 PRINT P$:PRINT
80 GOTO 30
```

PROGRAM B-5 - ACCESS A RANDOM FILE

The LOC function, with random files, returns the "current
record number." The current record number is one plus the
last record number that was used in a GET or PUT statement.
For example, the statement

        IF LOC(1)>50 THEN END

ends program execution if the current record number in
file#1 is higher than 50.

Program B-6 is an inventory program that illustrates random
file access. In this program, the record number is used as
the part number, and it is assumed the inventory will
contain no more than 100 different part numbers. Lines
900-960 initialize the data file by writing CHR$(255) as the
first character of each record. This is used later (line
270 and line 500) to determine whether an entry already
exists for that part number.

Lines 130-220 display the different inventory functions that
the program performs. When you type in the desired function
number, line 230 branches to the appropriate subroutine.

```
120 OPEN"R",#1,"INVEN.DAT",39
125 FIELD#1,1 AS F$,30 AS D$, 2 AS Q$,2 AS R$,4 AS P$
130 PRINT:PRINT "FUNCTIONS:":PRINT
135 PRINT 1,"INITIALIZE FILE"
140 PRINT 2,"CREATE A NEW ENTRY"
150 PRINT 3,"DISPLAY INVENTORY FOR ONE PART"
160 PRINT 4,"ADD TO STOCK"
170 PRINT 5,"SUBTRACT FROM STOCK"
180 PRINT 6,"DISPLAY ALL ITEMS BELOW REORDER LEVEL"
220 PRINT:PRINT:INPUT"FUNCTION";FUNCTION
225 IF (FUNCTION<1)OR(FUNCTION>6) THEN PRINT
        "BAD FUNCTION NUMBER":GO TO 130
230 ON FUNCTION GOSUB 900,250,390,480,560,680
240 GOTO 220
250 REM BUILD NEW ENTRY
260 GOSUB 840
270 IF ASC(F$)<>255 THEN INPUT"OVERWRITE";A$:
        IF A$<>"Y" THEN RETURN
280 LSET F$=CHR$(0)
290 INPUT "DESCRIPTION";DESC$
300 LSET D$=DESC$
310 INPUT "QUANTITY IN STOCK";Q%
320 LSET Q$=MKI$(Q%)
330 INPUT "REORDER LEVEL";R%
340 LSET R$=MKI$(R%)

```

PROGRAM B-6 - INVENTORY

APPENDIX C

Assembly Language Subroutines

All versions of BASIC-80 have provisions for interfacing
with assembly language subroutines. The USR function allows
assembly language subroutines to be called in the same way
BASIC's intrinsic functions are called.

NOTE

The addresses of the DEINT,
GIVABF, MAKINT and FRCINT
routines are stored in
locations that must be
supplied individually for
different implementations of
BASIC.

C.1 MEMORY ALLOCATION

Memory space must be set aside for an assembly language
subroutine before it can be loaded. During initialization,
enter the highest memory location minus the amount of memory
needed for the assembly language subroutine(s). BASIC uses
all memory available from its starting location up, so only
the topmost locations in memory can be set aside for user
subroutines.

When an assembly language subroutine is called, the stack
pointer is set up for 8 levels (16 bytes) of stack storage.
If more stack space is needed, BASIC's stack can be saved
and a new stack set up for use by the assembly language
subroutine. BASIC's stack must be restored, however, before
returning from the subroutine.

The assembly language subroutine may be loaded into memory by means of the system monitor, or the BASIC POKE statement, or (if the user has the MACRO-80 or FORTRAN-80 package) routines may be assembled with MACRO-80 and loaded using LINK-80.

C.2   USR FUNCTION CALLS - 8K BASIC

The starting address of the assembly language subroutine must be stored in USRLOC, a two-byte location in memory that is supplied individually with different implementations of BASIC-80.   With 8K BASIC, the starting address may be POKEd into USRLOC. Store the low order byte first, followed by the high order byte.

The function USR will call the routine whose address is in USRLOC.   Initially USRLOC contains the address of ILLFUN, the routine that gives the "Illegal function call" error. Therefore, if USR is called without changing the address in USRLOC, an "Illegal function call" error results.

The format of a USR function call is

        USR(argument)

where the argument is a numeric expression. To obtain the argument, the assembly language subroutine must call the routine DEINT. DEINT places the argument into the D,E register pair as a 2-byte, 2's complement integer. (If the argument is not in the range -32768 to 32767, an "Illegal function call" error occurs.)

To pass the result back from an assembly language subroutine, load the value in register pair [A,B], and call the routine GIVABF. If GIVABF is not called, USR(X) returns X. To return to BASIC, the assembly language subroutine must execute a RET instruction.

For example, here is an assembly language subroutine that multiplies the argument by 2:

```
USRSUB: CALL DEINT        ;put arg in D,E
        XCHG              ;move arg to H,L
        DAD H             ;H,L=H,L+H,L
        MOV A,H           ;move result to A,B
        MOV B,L
        JMP GIVABF        ;pass result back and RETurn
```

Note that valid results will be obtained from this routine for arguments in the range $-16384 <= x <= 16383$. The single instruction JMP GIVABF has the same effect as:

```
CALL GIVABF
RET
```

To return additional values to the program, load them into
memory and read them with the PEEK function.

There are several methods by which a program may call more
than one USR routine. For example, the starting address of
each routine may be POKEd into USRLOC prior to each USR
call, or the argument to USR could be an index into a table
of USR routines.

C.3 USR FUNCTION CALLS - EXTENDED AND DISK BASIC

In the Extended and Disk versions, the format of the USR
function is

    USR[<digit>](argument)

where DIGIT> is from 0 to 9 and the argument is any numeric
or string expression. <digit> specifies which USR routine
is being called, and corresponds with the digit supplied in
the DEF USR statement for that routine. If <digit> is
omitted, USR0 is assumed. The address given in the DEF USR
statement determines the starting address of the subroutine.

When the USR function call is made, register A contains a
value that specifies the type of argument that was given.
The value in A may be one of the following:

Value in A	Type of Argument
2	Two-byte integer (two's complement)
3	String
4	Single precision floating point number
8	Double precision floating point number

If the argument is a number, the [H,L] register pair points
to the Floating Point Accumulator (FAC) where the argument
is stored.

If the argument is an integer:

    FAC-3 contains the lower 8 bits of the argument and
    FAC-2 contains the upper 8 bits of the argument.

If the argument is a single precision floating point number:

    FAC-3 contains the lowest 8 bits of mantissa and

FAC-2 contains the middle 8 bits of mantissa and
FAC-1 contains the highest 7 bits of mantissa
with leading 1 suppressed (implied). Bit 7 is
the sign of the number (0=positive, 1=negative).
FAC is the exponent minus 128, and the binary
point is to the left of the most significant
bit of the mantissa.

If the argument is a double precision floating point number:

FAC-7 through FAC-4 contain four more bytes
of mantissa (FAC-7 contains the lowest 8 bits).

If the argument is a string, the [D,E] register pair points
to 3 bytes called the "string descriptor." Byte 0 of the
string descriptor contains the length of the string (0 to
255).   Bytes 1 and 2, respectively, are the lower and upper
8 bits of the string starting address in string space.

CAUTION: If the argument is a string literal in the
program, the string descriptor will point to program text.
Be careful not to alter or destroy your program this way.
To avoid unpredictable results, add +"" to the string
literal in the program. Example:

    A$ = "BASIC-80"+""

This will copy the string literal into string space and will
prevent alteration of program text during a subroutine call.

Usually, the value returned by a USR function is the same
type (integer, string, single precision or double precision)
as the argument that was passed to it. However, calling the
MAKINT routine returns the integer in [H,L] as the value of
the function, forcing the value returned by the function to
be integer.   To execute MAKINT, use the following sequence
to return from the subroutine:

    PUSH   H   ;save value to be returned
    LHLD   xxx   ;get address of MAKINT routine
    XTHL   ;save return on stack and
                         ;get back [H,L]
    RET   ;return

Also, the argument of the function, regardless of its type,
may be forced to an integer by calling the FRCINT routine to
get the integer value of the argument in [H,L]. Execute the
following routine:

    LXI   H   ;get address of subroutine
                         ;continuation
    PUSH   H   ;place on stack
    LHLD   xxx   ;get address of FRCINT
    PCHL
SUB1: . . . . .

C.4 CALL STATEMENT

Extended and Disk BASIC-80 user function calls may also be made with the CALL statement. The calling sequence used is the same as that in Microsoft's FORTRAN, COBOL and BASIC compilers.

A CALL statement with no arguments generates a simple "CALL" instruction. The corresponding subroutine should return via a simple "RET." (CALL and RET are 8080 opcodes - see an 8080 reference manual for details.)

A subroutine CALL with arguments results in a somewhat more complex calling sequence. For each argument in the CALL argument list, a parameter is passed to the subroutine. That parameter is the address of the low byte of the argument. Therefore, parameters always occupy two bytes each, regardless of type.

The method of passing the parameters depends upon the number of parameters to pass:

1. If the number of parameters is less than or equal to 3, they are passed in the registers. Parameter 1 will be in HL, 2 in DE (if present), and 3 in BC (if present).

2. If the number of parameters is greater than 3, they are passed as follows:

    1. Parameter 1 in HL.

    2. Parameter 2 in DE.

    3. Parameters 3 through n in a contiguous data block. BC will point to the low byte of this data block (i.e., to the low byte of parameter 3).

Note that, with this scheme, the subroutine must know how many parameters to expect in order to find them. Conversely, the calling program is responsible for passing the correct number of parameters. There are no checks for the correct number or type of parameters.

If the subroutine expects more than 3 parameters, and needs to transfer them to a local data area, there is a system subroutine which will perform this transfer. This argument transfer routine is named $AT (located in the FORTRAN library, FORLIB.REL), and is called with HL pointing to the local data area, BC pointing to the third parameter, and A containing the number of arguments to transfer (i.e., the total number of arguments minus 2). The subroutine is

responsible for saving the first two parameters before
calling $AT. For example, if a subroutine expects 5
parameters, it should look like:

```
SUBR:   SHLD    P1          ;SAVE PARAMETER 1
        XCHG
        SHLD    P2          ;SAVE PARAMETER 2
        MVI     A,3         ;NO. OF PARAMETERS LEFT
        LXI     H,P3        ;POINTER TO LOCAL AREA
        CALL    $AT         ;TRANSFER THE OTHER 3 PARAMETERS
        .
        .
        .
        [Body of subroutine]
        .
        .
        .
        RET                 ;RETURN TO CALLER
P1:     DS      2           ;SPACE FOR PARAMETER 1
P2:     DS      2           ;SPACE FOR PARAMETER 2
P3:     DS      6           ;SPACE FOR PARAMETERS 3-5
```

A listing of the argument transfer routine $AT follows.

```
00100   ;           ARGUMENT TRANSFER
00200   ;[B,C]   POINTS TO 3RD PARAM.
00300   ;[H,L]   POINTS TO LOCAL STORAGE FOR PARAM 3
00400   ;[A]     CONTAINS THE # OF PARAMS TO XFER (TOTAL-2)
00500
00600
00700           ENTRY   $AT
00800   $AT:    XCHG                ;SAVE [H,L] IN [D,E]
00900           MOV     H,B
01000           MOV     L,C         ;[H,L] = PTR TO PARAMS
01100   AT1:    MOV     C,M
01200           INX     H
01300           MOV     B,M
01400           INX     H           ;[B,C] = PARAM ADR
01500           XCHG                ;[H,L] POINTS TO LOCAL STORAGE
01600           MOV     M,C
01700           INX     H
01800           MOV     M,B
01900           INX     H           ;STORE PARAM IN LOCAL AREA
02000           XCHG                ;SINCE GOING BACK TO AT1
02100           DCR     A           ;TRANSFERRED ALL PARAMS?
02200           JNZ     AT1         ;NO, COPY MORE
02300           RET                 ;YES, RETURN
```

When accessing parameters in a subroutine, don't forget that they are <u>pointers</u> to the actual arguments passed.

NOTE

It is entirely up to the programmer to see to it that the arguments in the calling program match in <u>number</u>, <u>type</u>, and <u>length</u> with the parameters expected by the subroutine. This applies to BASIC subroutines, as well as those written in assembly language.

C.5 <u>INTERRUPTS</u>

Assembly language subroutines can be written to handle interrupts. All interrupt handling routines should save the stack, register A-L and the PSW. Interrupts should always be re-enabled before returning from the subroutine., since an interrupt automatically disables all further interrupts once it is received. The user should be aware of which interrupt vectors are free in the particular version of BASIC that has been supplied. (Note to CP/M users: In CP/M BASIC, all interrupt vectors are free.)

APPENDIX D

BASIC-80 with the CP/M Operating System

The CP/M version of BASIC-80 (MBASIC) is supplied on a
standard size 3740 single density diskette. The name of the
file is MBASIC.COM.   (A 28K or larger CP/M system is
recommended.)

To run MBASIC, bring up CP/M and type the following:

    A>MBASIC <carriage return>

The system will reply:

    xxxx Bytes Free
    BASIC-80 Version 5.0
    (CP/M Version)
    Copyright 1978 (C) by Microsoft
    Created: dd-mmm-yy
    Ok

MBASIC is the same as Disk BASIC-80 as described in this
manual, with the following exceptions:

D.1 INITIALIZATION

The initialization dialog has been replaced by a set of
options which are placed after the MBASIC command to CP/M.
The format of the command line is:

A>MBASIC [<filename>][/F:<number of files>][/M:<highest memory location>]
     [/S:<maximum record size>]

If <filename> is present, MBASIC proceeds as if a RUN
<filename> command were typed after initialization is
complete. A default extension of .BAS is used if none is
supplied and the filename is less than 9 characters long.
This allows BASIC programs to be executed in batch mode
using the SUBMIT facility of CP/M. Such programs should
include a SYSTEM statement (see below) to return to CP/M
when they have finished, allowing the next program in the

batch stream to execute.

If /F:<number of files> is present, it sets the number of disk data files that may be open at any one time during the execution of a BASIC program. Each file data block allocated in this fashion requires 166 bytes of memory. If the /F option is omitted, the number of files defaults to 3.

The /M:<highest memory location> option sets the highest memory location that will be used by MBASIC. In some cases it is desirable to set the amount of memory well below the CP/M's FDOS to reserve space for assembly language subroutines. In all cases, <highest memory location> should be below the start of FDOS (whose address is contained in locations 6 and 7). If the /M option is omitted, all memory up to the start of FDOS is used.

/S:<maximum record size> may be added at the end of the command line to set the maximum record size for use with random files. The default record size is 128 bytes.

NOTE

<number of files>, <highest memory location>, and <maximum record size> are numbers that may be either decimal, octal (preceded by &O) or hexadecimal (preceded by &H).

Examples:

A>MBASIC PAYROLL.BAS   Use all memory and 3 files,
                             load and execute PAYROLL.BAS.

A>MBASIC INVENT/F:6   Use all memory and 6 files,
                             load and execute INVENT.BAS.

A>MBASIC /M:32768   Use first 32K of memory and
                             3 files.

A>MBASIC DATACK/F:2/M:&H9000
                             Use first 36K of memory, 2
                             files, and execute DATACK.BAS.

D.2 DISK FILES

Disk filenames follow the normal CP/M naming conventions. All filenames may include A: or B: as the first two characters to specify a disk drive, otherwise the currently selected drive is assumed. A default extension of .BAS is

used on LOAD, SAVE, MERGE and RUN <filename> commands if no
"." appears in the filename and the filename is less than 9
characters long.

For systems with CP/M 2.x, large random files are supported.
The maximum logical record number is 32767. If a record
size of 256 is specified, then files up to 8 megabytes can
be accessed.

D.3 FILES COMMAND

Format: FILES[<filename>]

Purpose: To print the names of files residing on the
            current disk.

Remarks: If <filename> is omitted, all the files on the
            currently selected drive will be listed.
            <filename> is a string formula which may contain
            question marks (?) to match any character in the
            filename or extension. An asterisk (*) as the
            first character of the filename or extension
            will match any file or any extension.

Examples: FILES
            FILES "*.BAS"
            FILES "B:*.*"
            FILES "TEST?.BAS"

D.4 RESET COMMAND

Format: RESET

Purpose: To close all disk files and write the directory
            information to a diskette before it is removed
            from a disk drive.

Remarks: Always execute a RESET command before removing a
            diskette from a disk drive. Otherwise, when the
            diskette is used again, it will not have the
            current directory information written on the
            directory track.

            RESET closes all open files on all drives and
            writes the directory track to every diskette
            with open files.

D.5 LOF FUNCTION

Format: LOF(<file number>)

Action: Returns the number of records present in the
             last extent read or written. If the file does
             not exceed one extent (128 records), then LOF
             returns the true length of the file.

Example: 110 IF NUM%>LOF(1) THEN PRINT "INVALID ENTRY"

D.6 EOF

With CP/M, the EOF function may be used with random files.
If a GET is done past the end of file, EOF will return -1.
This may be used to find the size of a file using a binary
search or other algorithm.

D.7 MISCELLANEOUS

1. CSAVE and CLOAD are not implemented.

2. To return to CP/M, use the SYSTEM command or
   statement. SYSTEM closes all files and then
   performs a CP/M warm start. Control-C always
   returns to MBASIC, not to CP/M.

3. FRCINT is at 103 hex and MAKINT is at 105 hex.
   (Add 1000 hex for ADDS versions, 4000 for SBC CP/M
   versions.)

APPENDIX E

BASIC-80 with the ISIS-II Operating System

With ISIS-II, BASIC-80 is the same as described in this manual, with the following exceptions:

E.1 INITIALIZATION

The initialization dialog has been replaced by a set of options which are placed after the MBASIC command to ISIS-II. The format of the command line is:

-MBASIC [<filename>][/F:<number of files>][/M:<highest memory location>]
    [/S:<maximum record size>]

If <filename> is present, BASIC proceeds as if a RUN <filename> command were typed after initialization is complete. A default extension of .BAS is used if none is supplied.

If /F:<number of files> is present, it sets the number of disk data files that may be open at any one time during the execution of a BASIC program. The maximum is six and the default is three. The /M:<highest memory location> option sets the highest memory location that will be used by BASIC. Use this option to reserve memory locations above BASIC for assembly language subroutines. /S:<maximum record size> may be added at the end of the command line to set the maximum record size for use with random files. The default record size is 128 bytes.

At initialization, the system will reply:

    xxxx Bytes Free
    BASIC-80 Version x.x
    (ISIS-II Version)
    Copyright 1978 (C) by Microsoft

E.2 LINE PRINTER I/O

To send output to the printer during execution of a BASIC program, open the line printer as if it were a disk file:

```
50 N=4
100 OPEN "O",N,":LP:"
    .
    .
    .
120 PRINT #N,A,B,C
```

Since BASIC buffers disk I/O, you may want to force buffers out by CLOSEing the printer channel.

To LIST a program on the line printer, use:

```
SAVE":LP:",A
```

E.3 ATTRIB STATEMENT

In ISIS-II BASIC-80, the ATTRIB statement sets file attributes. The format of the statement is:

```
ATTRIB <filename string>,<attribute string>
```

The attribute string consists of F, W, S or I for the attribute, followed by a 1 to set the attribute or a 0 to reset.

Examples:

```
ATTRIB "INFO.DAT","W1"
ATTRIB "GHOST.BAS","I1"
ATTRIB ":F1:SYSFIL","W1F1S1I1"
ATTRIB A$,B$
```

E.4 MISCELLANEOUS

Note these other differences for ISIS-II BASIC:

1. MAKINT is located at 3903 hex, and GIVINT is located at 3905 hex.

2. There is no FILES command in ISIS-II BASIC. Filenames do not default to .BAS on SAVEs, LOADs, and MERGEs.

APPENDIX F

BASIC-80 with the TEKDOS Operating System

The operation of BASIC-80 with the TEKDOS operating system is the same as described in this manual with the following exceptions:

1. At initialization, BASIC asks MEMORY SIZE? If you respond with a carriage return, BASIC will use all available memory. If you respond with a memory location (in decimal), BASIC will use memory only up to that location. This lets you reserve space at the top of memory for assembly language subroutines.

2. The number of disk files that may be open at one time defaults to 5.

3. LPRINT and LLIST are not implemented. Instead, open a file to the printer.

4. TEKDOS does not support random disk I/O. The corresponding BASIC-80 statements (PUT, GET, OPEN"R", etc.) are inoperable under TEKDOS.

5. Control-C works only once due to a bug in TEKDOS. If you interrupt a running program or a LIST command with Control-C, BASIC appears to be in "single statement" mode. To clear this condition, exit BASIC with a SYSTEM command and re-enter BASIC with an XEQ BASIC. Avoid using the AUTO command, since it requires a Control-C to return to BASIC command level.

APPENDIX G

BASIC-80 with the INTEL SBC and MDS Systems

G.1 INITIALIZATION

The paper tape of BASIC-80 supplied for SBC and MDS systems
is in Intel-compatible hex format.   Use the monitor's R
command to load the tape, then execute the G command to
start BASIC-80. The command is:

    .G4000

BASIC will respond:

    Memory size?

If you want BASIC to use all available RAM, just type a
carriage return. If you want to reserve space at the top of
memory for machine language subroutines, enter the highest
memory address (in decimal) that BASIC may use.

    Terminal Width?

(8K versions only) Respond with the number of characters for
the output line width in PRINT statements. The default is
72 characters. (Extended versions use WIDTH command.)

    Want SIN-COS-TAN-ATN?

Type Y to retain these functions, type N to delete them, or
type A to delete ATN only.

G.2 SUBROUTINE ADDRESSES

In the 8K version of SBC and MDS BASIC-80, DEINT is located
at 0043 hex and GIVABF is located at 0045 hex. USRLOC is at
xxxx hex. In the Extended version, FRCINT is located at
xxxx hex, and MAKINT is located at xxxx hex.

G.3 LLIST AND LLPRINT

LLIST and LPRINT are not implemented.

APPENDIX H

Standalone Disk BASIC

Standalone Disk BASIC is an easily implemented, self-contained version of BASIC-80 that runs on almost any 8080 or Z80 based disk hardware without an operating system. Standalone Disk BASIC incorporates several unique disk I/O methods that make faster and more efficient use of disk access and storage.

Random access with Standalone BASIC is faster than other disk operating systems because the file allocation table is kept in memory and updated periodically on the diskette. Therefore, there is no need for index blocks for random files, and there is no need to distinguish between random and sequential files. Because there are no index blocks, there is no large per-file-overhead either in memory or on disk. Binary SAVEs and LOADs are also faster because they are optimized by cluster, i.e., an entire cluster is read or written at one time, instead of a single sector.

To initialize Standalone Disk BASIC, insert the BASIC diskette and power up the system. In one- or two-drive systems, BASIC asks if there are two drives. In systems with more than two drives, BASIC asks for the number of drives. BASIC then asks how many files, i.e., how many disk files may be open at one time. Answer with a number from 0 to 15, or, for a default of 1 file per drive, just enter a carriage return.

The operation of Standalone Disk BASIC is the same as Disk BASIC-80 as described in this manual, with the following exceptions:

H.1 FILENAMES

The format for disk filenames is:

        [drive#:]filename[.extension]

The first drive is 1.

Disk filenames are six characters with an optional three-character extension that is preceded by a decimal point. If a decimal point appears in a filename after fewer than six characters, the name is blank-filled to six characters and the next three characters are the extension. If the filename is six or fewer characters with no decimal point, there is no extension. If the filename is more than six characters, BASIC inserts a decimal point after the sixth character and uses the next three characters as an extension. (Any additional characters are ignored.)

H.2 DISK FILES

The FILES command prints the names of the files residing on a disk. The format is: [L]FILES[<drive number>]
LFILES outputs to the line printer. In addition to the filename, the size of each file, in clusters, is output. A cluster is the minimum unit of allocation for a file -- it is one-half of a track. Filenames of files created with OPEN or ASCII SAVE are listed with a space between the name and extension. Filenames of binary files created with binary SAVE are listed with a decimal point between the name and extension. The protected file option with SAVE is not supported in Standalone Disk BASIC.

H.3 FPOS

The FPOS function:

        FPOS(<file number>)

is the same as BASIC-80's LOC function except it returns the number of the physical sector where <filenumber> is located. (BASIC-80's LOC function and CP/M BASIC-80's LOF function are also implemented.)

H.4 DSKI$/DSKO$

The DSKO$ statement:

        DSKO$<drive>,<track>,<sector>,<string expression>

writes the string on the specified sector. The maximum length for the string is 128 characters. A string of fewer than 128 characters is zero-filled at the end to 128 characters.

DSKI$ is the complementary function to the DSKO$ statement. DSKI$ returns the contents of a sector to a string variable name. The format is:

    DSKI$(<drive>,<track>,<sector>)

Example: A$=DSKI$(0,I,J)

H.5   MOUNT COMMAND

Before a diskette can be used for file operations (i.e., any disk I/O besides DSKI$, DSKO$, or IBM or USR modes), it must be MOUNTed. The format of the command is:

    MOUNT[<drive>[,<drive>...]]

MOUNT with no arguments mounts all drives. When a diskette is mounted, BASIC reads the File Allocation Table (see Section H.11.2) from the diskette into memory and checks it for errors. If there are no errors, the disk is mounted. If an error is found, BASIC reads one or both of the back-up allocation tables from the diskette in an attempt to mount the disk; and a warning message, "x copies of allocation bad on drive y", is issued. x is 1 or 2 and y is the drive number. When a warning occurs, it is a good idea to make a new copy of the diskette. If all copies of the allocation table are bad or if a free entry is encountered in the file chain, a fatal error--"bad allocation table"--is given and the diskette will not be mounted.

While a disk is mounted, BASIC occasionally writes the allocation table to the directory track, but it does not check for errors unless the read after write attribute is set for that drive (see SET statement).

H.6   REMOVE COMMAND

REMOVE is the complement of MOUNT. Before a diskette can be taken out of the drive, a REMOVE command must be executed. The format of the command is:

    REMOVE[<drive>[,<drive>...]]

REMOVE writes three copies of the current allocation table to disk and follows the same error-check procedure as MOUNT. MOUNT and REMOVE replace the RESET command that is in BASIC-80.

NOTE

ALWAYS do a REMOVE before
taking a diskette out of a
drive. If you do not, the
diskette you took out will not
have an updated and checked
allocation table, and the data
on the next diskette inserted
will be destroyed when the
wrong allocation table is
written to the directory
track.

H.7 SET STATEMENT

The SET statement determines the attributes of the currently
mounted disk drive, a currently open file, or a file that
need not be open. The format of the SET statement is:

SET<drive> | #<file> | <filename>,<attribute string>

<attribute string> is a string of characters that determines
what attributes are set. Any characters other than the
following are ignored:

R   Read after write
P   Write protect
E   EBCDIC conversion (if available)

Attributes are assigned in the following order:

1. MOUNT command
    When a MOUNT is done for a particular drive, the
    first byte of the information sector on the
    diskette (track 35, sector 20 for floppy; track
    18, sector 13 for minifloppy) contains the
    attributes for the disk. (octal values: R=100,
    P=20, E=40)

2. SET<drive>,<attribute string> Statement
    This statement sets the current attributes for the
    disk, in memory, while it is mounted. The
    attributes are not permanently recorded and apply
    only while the disk is mounted.

3. When a file is created, the permanent file
    attributes recorded on the disk will be the same as
    the current drive attributes.

4. SET<filename>,<attribute string> Statement
   This statement changes the permanent file attributes that are stored in the directory entry for that file. It does not affect the drive attributes.

5. When an existing file is OPENed, the attributes of the file number are those of the directory entry.

6. SET#<file number>,<attribute string> Statement
   This statement changes the attributes for that file number but does not change the directory entry.

Examples:

SET 1,"R"   Force read after write checking on all output to drive 1

SET #1,"R"   Force read after write for all output to file 1 while it is open

SET #1,"P"   Give write protect error if any output is attempted to file 1

SET "TEST","P"   Protect TEST from deletion and modification

SET 1,""   Turn off all attributes for drive 1

H.8 ATTR$ FUNCTION

ATTR$ returns a string of the current attributes for a drive, currently open file, or file that need not be open. The format of ATTR$ is:

    ATTR$(<drive> | #<file number> | <filename>)

For example:

    SET 1,"R":A$=ATTR$(1):PRINT A$
    R
    Ok

H.9 OPEN STATEMENT

The format for the OPEN statement in Standalone BASIC is:

    OPEN <filename> [FOR <mode>] AS [#]<file number>

where <mode> is one of the following:

    INPUT
    OUTPUT
    APPEND
    IBM
    USR

The mode determines only the initial positioning within the file and the actions to be taken if the file does not exist. The action taken in each mode is:

INPUT   The initial position is at the start of the file. An error is returned if the file is not found.

OUTPUT   The initial position is at the start of the file. A new file is always created.

APPEND   The initial position is at the end of the file. An error is returned if the file is not found.

IBM   The initial position is after the last DSKI$ or DSKO$. The file is then set up to write contiguous. No file search is done. (The same effect may be achieved in many cases by altering the FORMAT program. See Section H.11.2.1.)

USR   Same as IBM mode except, instead of write contiguous, USR0 is called and returns the next track/sector number. The USR0 routine should read the current track/sector from B,C and return the next location in B,C. When USR0 is first called, B,C contains the track and sector number of the previous DSKI$ or DSKO$.

If the FOR <mode> clause is omitted, the initial position is at the start of the file. If the file is not found, it is created.

Note that variable length records are not supported in Standalone Disk BASIC. All records are 128 bytes in length.

USR mode is especially useful for creating diskettes that require sector mapping. This is the case if the diskette is intended for use on another system, for example, a CP/M system. Instead of opening the file for write contiguous (IBM mode), the USR0 routine may be used to map the sectors logically, as required by the other system.

When a file is OPENed FOR APPEND, the file mode is set to APPEND and the record number is set to the last record of the file. The program may subsequently execute disk I/O statements that move the pointer elsewhere in the file. When the last record is read, the file mode is reset to FILE and the pointer is left at the end of the file. Then, if you wish to append another record, execute:

        GET#n,LOF(n)

This positions the pointer at the end of the file in preparation for appending.

At any one time, it is possible to have a particular

filename OPEN under more than one file number. This allows
different attributes to be used for different purposes. Or,
for program clarity, you may wish to use different file
numbers for different methods of access. Each file number
has a different buffer, so changes made under one file are
not accessible to (or affected by) the other numbers until
that record is written (e.g., GET#n,LOC(n)).

H.10 DISK I/O

A GET or PUT (i.e., random access) cannot be done on a file
that is OPEN FOR IBM or OPEN FOR USR. Otherwise, GET/PUT
may be executed along with PRINT#/INPUT# on the same file,
which makes midfile updating possible. The statement
formats for GET, PUT, PRINT#, and INPUT# are the same as
those in BASIC-80. The action of each statement in
Standalone BASIC is as follows:

GET   If the "buffer changed" flag is set, write the
buffer to disk. Then execute the GET (read the
record into the buffer), and reset the position
for sequential I/O to the beginning of the buffer.

PUT   Execute the PUT (write the buffer to the specified
record number), and set the "sequential I/O is
illegal" flag until a GET is done.

INPUT#   If the buffer is empty, write it if the "buffer
changed" flag is set, then read the next buffer.

PRINT#   Set the "buffer changed" flag. If the buffer is
full, write it to disk. Then, if end of file has
not been reached, read the next buffer.

H.10.1 File Format

For a single density floppy, each file requires 137 bytes:
9 bytes plus the 128-byte buffer. Because the File
Allocation Table keeps random access information for all
files, random and sequential files are identical on the
disk. The only distinction is that sequential files have a
Control-Z (32 octal) as the last character of the last
sector. When this sector is read, it is scanned from the
end for a non-zero byte. If this byte is Control-Z, the
size of the buffer is set so that a PRINT overwrites this
byte. If the byte is not Control-Z, the size is set so the
last null seen is overwritten.

Any sequential file can be copied in random mode and remain
identical. If a file is written to disk in random mode

(i.e., with PUT instead of PRINT) and then read in
sequential mode, it will still have proper end of file
detection.

H.11 DISK ALLOCATION INFORMATION

With Standlone Disk BASIC, storage space on the diskette is
allocated beginning with the cluster closest to the current
position of the head. (This method is optimized for
writing. Custom versions can be optimized for reading.)
Disk allocation information is placed in memory when the
disk is mounted and is periodically written back to the
disk. Because this allocation information is kept in
memory, there is no need for index blocks for random files,
and there is no need to distinguish between random and
sequential files.

H.11.1 Directory Format

On the diskette, each sector of the directory track contains
eight file entries. Each file entry is 16 bytes long and
formatted as follows:

Bytes	Usage
0-8	Filename, 1 to 9 characters. The first character may not be 0 or 255.
9	Attribute: Octal 200 Binary file 100 Force read after write check 40 EBCDIC file 20 Write protected file Excluding 200, these bits are the same for the disk attribute byte which is the first byte of the information sector.
10	Pointer into File Allocation Table to the first cluster of the file's cluster chain.
11-15	Reserved for future expansion.

If the first byte of a filename is zero, that file entry
slot is free. If the first byte is 255, that slot is the
last occupied slot in the directory, i.e., this flags the
end of the directory.

H.11.2 Drive Information

For each disk drive that is MOUNTed, the following information is kept in memory:

1. Attributes
   Drive attributes are read from the information sector when the drive is mounted and may be changed with the SET statement. Current attributes may be examined with the ATTR$ function.

2. Track Number
   This is the current track while the disk is mounted. Otherwise, track number contains 255 as a flag that the disk is not mounted.

3. Modification Counter
   This counter is incremented whenever an entry in the File Allocation Table is changed. After a given number of changes has been made, the File Allocation Table is written to disk.

4. Number of Free Clusters
   This is calculated when the drive is mounted, and updated whenever a file is deleted or a cluster is allocated.

5. File Allocation Table
   The File Allocation Table has a one-byte entry for every cluster allocated on the disk. If the cluster is free, this entry is 255. If the cluster is reserved, this entry is 254. If the cluster is the last cluster of the file, this entry is 300 (octal) plus the number of sectors from this cluster that were used. Otherwise, the entry is a pointer to the next cluster of the file. The File Allocation Table is read into memory when the drive is mounted, and updated:

   1. When a file is deleted

   2. When a file is closed

   3. When modifications to the table total twice the number of sectors in a cluster (this can be changed in custom versions)

   4. When modifications to the table have been made and the disk head is on (or passes) the directory track.

H.11.2.1 FORMAT Program - Before mounting a
drive with a new diskette, run BASIC's FORMAT program to
initialize the directory (set all bytes to 255), set the
information sector to 0, and set all the File Allocation
Table entries (except the directory track entry (254)) to
"free" (255).

The FORMAT program is:

```
10 CLEAR 1500
20 A$=STRING$(128,255)
30 B$=STRING$(35*2,255)+STRING$(2,254)+STRING$(56,255)
40 FOR S=1 TO 19:DSKO$ 1,35,S,A$:NEXT
50 FOR S=21 TO 25 STEP 2:DSKO$ 1,35,S,B$
60 DSKO$ 1,35,S+1,A$:NEXT
70 DSKO$ 1,35,20,CHR$(0)
```

After running FORMAT and MOUNTing the drive, files will be
allocated as usual, i.e., on either side of the directory
track.

The FORMAT program may be altered to pre-allocate selected
files. For instance, you may wish to use the FORMAT program
to pre-allocate files contiguously (as they would be
allocated in IBM mode). Then IBM and BASIC files may both
exist on the diskette. The altered FORMAT program must also
write the name of the file(s) to the directory track (i.e.,
files 1-8 in sector 1, files 9-16 in sector 2, etc.), so
BASIC knows where the files start.

H.11.3 File Block

Each file on the disk has a file block that contains the
following information:

1. File Mode (byte 0)
   This is the first byte (byte 0) of the file block,
   and its location may be read with
   VARPTR(#filenumber). The location of any other
   byte in the file block is relative to the file mode
   byte. The file mode byte is one of the following:

   (octal)
1	Input only
2	Output only
4	File mode
10	Append mode
20	Delete file
40	IBM mode
100	Special format (USR)
200	Binary save

NOTE

     It is not recommended that the user attempt
     to modify the next four bytes of the File
     Allocation Table. Many unforeseen
     complications may result.

2. Pointer to the File Allocation Table entry for the
    first cluster allocated to the file (+1)

3. Pointer to the File Allocation Table entry for the
    last cluster accessed (+2)

4. Last sector accessed (+3)

5. Disk number of file (+4)

6. The size of the last buffer read (+5). This is 128
    unless the last sector of the file is not full
    (i.e., Control-Z).

7. The current position in the buffer (+6). This is
    the offset within the buffer for the next print or
    input.

8. File flag (+7), is one of the following:
    Octal
      100   Read after write check
       40   Read/Write EBCDIC, not ASCII
              (Not available in all versions.)
       20   File write protected
       10   Buffer changed by PRINT
        4   PUT has been done. PRINT/INPUT are
              errors until a GET is done.
              (See Section H.10.)
        2   Flags buffer is empty

9. Terminal position for TAB function and comma in
    PRINT statements (+8)

10. Beginning of sector buffer (+9), 128 bytes in
    length

H.12 ADVANCED USES OF FILE BUFFERS

1. Information may be passed from one program to
    another by FIELDing it to an unopened file number
    (not #0). The FIELD buffer is not cleared as long
    as the file is not OPENed.

2. The FIELDed buffer for an unopened file can also be used to format strings. For example, an 80-character string could be placed into a FIELDed buffer with LSET. The strings could then be accessed as four 20-character strings using their FIELDed variable names. For example:

```
100 FIELD#1, 80 AS A$
200 FIELD#1, 20 AS A1$, 20 AS A2$, 20 AS A3$, 20 AS A4$
300 LINE INPUT "CUSTOMER INFORMATION: ";B$
400 LSET A$=B$
500 PRINT "NAME ";A1$;"SSN: ";A2$
```

3. FIELD#0 may be used as a temporary buffer, but note that this buffer is cleared after each of the following commands: FILES, LOAD, SAVE, MERGE, RUN, DSKO$, MOUNT, OPEN.

4. The effect of PRINT[USING]# into a string may be achieved by printing to a FIELDed buffer and then accessing it without reopening the file. To assure that this temporary buffer is not written to the disk, return the pointer to the beginning of the buffer and reset the "buffer changed" flag as follows:

```
10 OPEN "D" FOR IBM AS 1:REM THIS DOESN'T USE SPACE
20 PRINT USING#1 ...
30 P=PEEK(6+VARPTR(#1)):REM OPTIONAL, TO GET LENGTH OF PRINT
USING
40 FIELD#1 ... AS ...
50 Y=7+VARPTR(#1)
60 POKE Y,PEEK(Y AND &360):REM RESET BUFFER CHANGED FLAG
70 POKE 6+VARPTR,0:REM CLEAR POSITION IN BUFFER
```

H.13 STANDALONE BASIC DISK ERRORS

```
50    FIELD overflow
51    Internal error
52    Bad file number
53    File not found
54    File already open
55    Disk not mounted
56    Disk I/O error
57    File already exists
59    Disk already mounted
61    Input past end
62    Bad file name
63    Direct statement in file
64    Bad allocation table
65    Bad drive number
66    Bad track/sector
67    File write protected
68    Disk offline
69    Deleted record
70    Rename across disks
71    Sequential after PUT
72    Sequential I/O only
73    File not OPEN
```

H.14 DOUBLE DENSITY, DOUBLE SIDED DISKETTES

For diskettes with 256-byte sectors, DSKI\$ and DSKO\$ are modified.

The DSKI\$ function returns as its value the first 255 bytes of the sector read.

The DSKO\$ statement does not use the <string expression> field. The format is:

    DSKO\$ <drive>,<track>,<sector>

In order to specify the data to write with DSKO\$ and to retrieve all 256 bytes of the data read by DSKI\$, the user must FIELD two or more variables (for a total of 256 bytes) to the file#0 buffer. The FIELDed variables will be identical to the data read with DSKI\$ and written with DSKO\$. For example:

    FIELD#0,128 AS A\$,128 AS B\$

For double-sided diskettes, the formats of DSKI\$ and DSKO\$ must also include the surface number:

    DSKI\$(<drive>,<surface>,<track>,<sector>)

    DKSO\$ <drive>,<surface>,<track>,<sector>
     or
    DKSO\$ <drive>,<surface>,<track>,<sector>,<string exp>
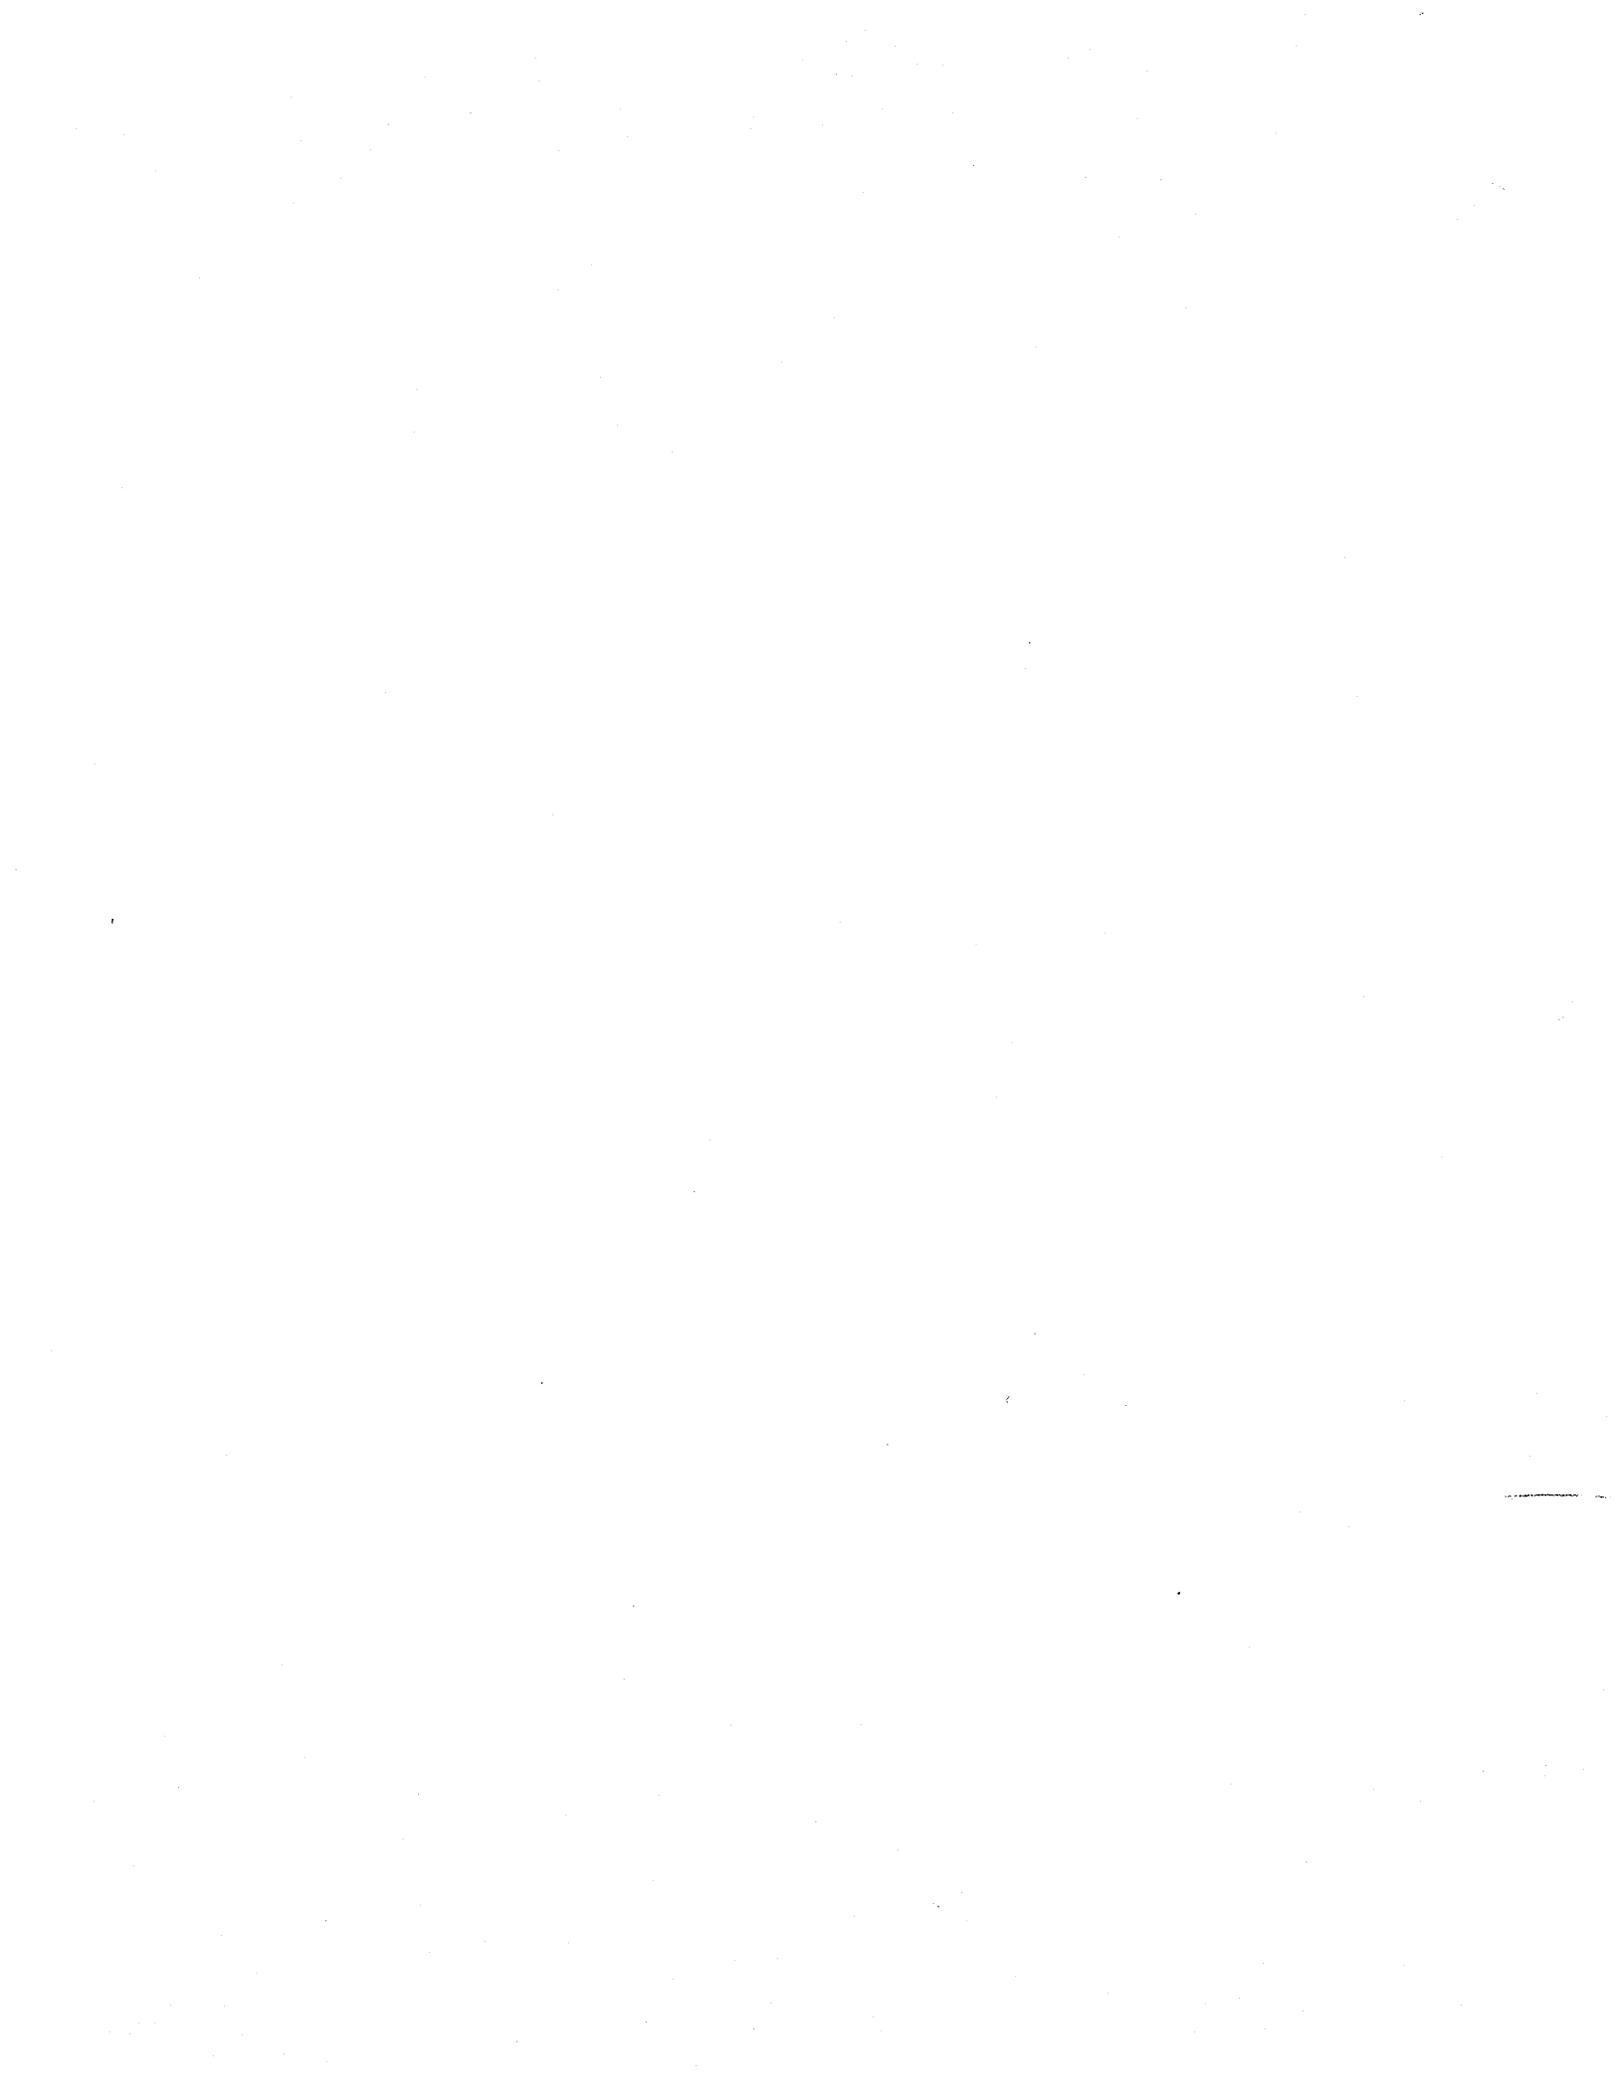

APPENDIX I

Converting Programs to BASIC-80

If you have programs written in a BASIC other than BASIC-80, some minor adjustments may be necessary before running them with BASIC-80. Here are some specific things to look for when converting BASIC programs.

I.1 STRING DIMENSIONS

Delete all statements that are used to declare the length of strings. A statement such as DIM A$(I,J), which dimensions a string array for J elements of length I, should be converted to the BASIC-80 statement DIM A$(J).

Some BASICs use a comma or ampersand for string concatenation. Each of these must be changed to a plus sign, which is the operator for BASIC-80 string concatenation.

In BASIC-80, the MID$, RIGHT$, and LEFT$ functions are used to take substrings of strings. Forms such as A$(I) to access the Ith character in A$, or A$(I,J) to take a substring of A$ from position I to position J, must be changed as follows:

Other BASIC	BASIC-80
X$=A$(I)	X$=MID$(A$,I,1)
X$=A$(I,J)	X$=MID$(A$,I,J-I+1)

If the substring reference is on the left side of an assignment and X$ is used to replace characters in A$, convert as follows:

Other BASIC	8K BASIC-80
A$(I)=X$	A$=LEFT$(A$,I-1)+X$+MID$(A$,I+1)
A$(I,J)=X$	A$=LEFT$(A$,I-1);X$;MID$(A$,J+1)

	Ext. and Disk BASIC-80
A$(I)=X$	MID$(A$,1,1)=X$
A$(I,J9=X$	MID$(A$,I,J-I+1)=X$

I.2   MULTIPLE ASSIGNMENTS

Some BASICs allow statements of the form:

    10 LET B=C=0

to set B and C equal to zero. BASIC-80 would interpret the
second equal sign as a logical operator and set B equal to
-1 if C equaled 0. Instead, convert this statement to two
assignment statements:

    10 C=0:B=0

I.3   MULTIPLE STATEMENTS

Some BASICs use a backslash (\) to separate multiple
statements on a line. With BASIC-80, be sure all statements
on a line are separated by a colon (:).

I.4   MAT FUNCTIONS

Programs using the MAT functions available in some BASICs
must ¯ be   rewritten using FOR...NEXT loops to execute
properly.

APPENDIX J

Summary of Error Codes and Error Messages

Code	Number	Message
NF	1	**NEXT without FOR** A variable in a NEXT statement does not correspond to any previously executed, unmatched FOR statement variable.
SN	2	**Syntax error** A line is encountered that contains some incorrect sequence of characters (such as unmatched parenthesis, misspelled command or statement, incorrect punctuation, etc.).
RG	3	**Return without GOSUB** A RETURN statement is encountered for which there is no previous, unmatched GOSUB statement.
OD	4	**Out of data** A READ statement is executed when there are no DATA statements with unread data remaining in the program.
FC	5	**Illegal function call** A parameter that is out of range is passed to a math or string function. An FC error may also occur as the result of:

1. a negative or unreasonably large subscript

2. a negative or zero argument with LOG

3. a negative argument to SQR

4. a negative mantissa with a non-integer exponent

5. a call to a USR function for which the starting address has not yet been given

6. an improper argument to MID$, LEFT$, RIGHT$, INP, OUT, WAIT, PEEK, POKE, TAB, SPC, STRING$, SPACE$, INSTR, or ON...GOTO.

OV   6   Overflow
The result of a calculation is too large to be represented in BASIC-80's number format. If underflow occurs, the result is zero and execution continues without an error.

OM   7   Out of memory
A program is too large, has too many FOR loops or GOSUBs, too many variables, or expressions that are too complicated.

UL   8   Undefined line
A line reference in a GOTO, GOSUB, IF...THEN...ELSE or DELETE is to a nonexistent line.

BS   9   Subscript out of range
An array element is referenced either with a subscript that is outside the dimensions of the array, or with the wrong number of subscripts.

DD   10   Redimensioned array
Two DIM statements are given for the same array, or a DIM statement is given for an array after the default dimension of 10 has been established for that array.

/0   11   Division by zero
A division by zero is encountered in an expression, or the operation of involution results in zero being raised to a negative power. Machine infinity with the sign of the numerator is supplied as the result of the division, or positive machine infinity is supplied as the result of the involution, and execution continues.

ID   12   Illegal direct
A statement that is illegal in direct mode is entered as a direct mode command.

TM   13   Type mismatch
A string variable name is assigned a numeric value or vice versa; a function that expects a numeric argument is given a string argument or vice versa.

OS   14   Out of string space
                String variables have caused BASIC to exceed
                the amount of free memory remaining. BASIC
                will allocate string space dynamically, until
                it runs out of memory.

LS   15   String too long
                An attempt is made to create a string more
                than 255 characters long.

ST   16   String formula too complex
                A string expression is too long or too
                complex. The expression should be broken
                into smaller expressions.

CN   17   Can't continue
                An attempt is made to continue a program
                that:

                1. has halted due to an error,

                2. has been modified during a break in
                    execution, or

                3. does not exist.

UF   18   Undefined user function
                A USR function is called before the function
                definition (DEF statement) is given.

                Extended and Disk Versions Only

        19   No. RESUME
                An error trapping routine is entered but
                contains no RESUME statement.

        20   RESUME without error
                A RESUME statement is encountered before an
                error trapping routine is entered.

        21   Unprintable error
                An error message is not available for the
                error condition which exists. This is
                usually caused by an ERROR with an undefined
                error code.

        22   Missing operand
                An expression contains an operator with no
                operand following it.

        23   Line buffer overflow
                An attempt is made to input a line that has
                too many characters.

26   FOR without NEXT
        A FOR was encountered without a matching
        NEXT.

29   WHILE without WEND
        A WHILE statement does not have a matching
        WEND.

30   WEND without WHILE
        A WEND was encountered without a matching
        WHILE.

        Disk Errors

50   Field overflow
        A FIELD statement is attempting to allocate
        more bytes than were specified for the record
        length of a random file.

51   Internal error
        An internal malfunction has occurred in Disk
        BASIC-80. Report to Microsoft the conditions
        under which the message appeared.

52   Bad file number
        A statement or command references a file with
        a file number that is not OPEN or is out of
        the range of file numbers specified at
        initialization.

53   File not found
        A LOAD, KILL or OPEN statement references a
        file that does not exist on the current disk.

54   Bad file mode
        An attempt is made to use PUT, GET, or LOF
        with a sequential file, to LOAD a random file
        or to execute an OPEN with a file mode other
        than I, O, or R.

55   File already open
        A sequential output mode OPEN is issued for a
        file that is already open; or a KILL is
        given for a file that is open.

57   Disk I/O error
        An I/O error occurred on a disk I/O
        operation. It is a fatal error, i.e., the
        operating system cannot recover from the
        error.

58   File already exists
        The filename specified in a NAME statement is
        identical to a filename already in use on the
        disk.

61   Disk full
        All disk storage space is in use.

62   Input past end
        An INPUT statement is exeucted after all the
        data in the file has been INPUT, or for a
        null (empty) file. To avoid this error, use
        the EOF function to detect the end of file.

63   Bad record number
        In a PUT or GET statement, the record number
        is either greater than the maximum allowed
        (32767) or equal to zero.

64   Bad file name
        An illegal form is used for the filename with
        LOAD, SAVE, KILL, or OPEN (e.g., a filename
        with too many characters).

66   Direct statement in file
        A direct statement is encountered while
        LOADing an ASCII-format file. The LOAD is
        terminated.

67   Too many files
        An attempt is made to create a new file
        (using SAVE or OPEN) when all 255 directory
        entries are full.

APPENDIX K

Mathematical Functions

Derived Functions

Functions that are not intrinsic to BASIC-80 may be calculated as follows.

Function	BASIC-80 Equivalent
SECANT	SEC(X)=1/COS(X)
COSECANT	CSC(X)=1/SIN(X)
COTANGENT	COT(X)=1/TAN(X)
INVERSE SINE	ARCSIN(X)=ATN(X/SQR(-X*X+1))
INVERSE COSINE	ARCCOS(X)=-ATN (X/SQR(-X*X+1))+1.5708
INVERSE SECANT	ARCSEC(X)=ATN(X/SQR(X*X-1)) +SGN(SGN(X)-1)*1.5708
INVERSE COSECANT	ARCCSC(X)=ATN(X/SQR(X*X-1)) +(SGN(X)-1)*1.5708
INVERSE COTANGENT	ARCCOT(X)=ATN(X)+1.5708
HYPERBOLIC SINE	SINH(X)=(EXP(X)-EXP(-X))/2
HYPERBOLIC COSINE	COSH(X)=(EXP(X)+EXP(-X))/2
HYPERBOLIC TANGENT	TANH(X)=EXP(-X)/EXP(X)+EXP(-X))*2+1
HYPERBOLIC SECANT	SECH(X)=2/(EXP(X)+EXP(-X))
HYPERBOLIC COSECANT	CSCH(X)=2/(EXP(X)-EXP(-X))
HYPERBOLIC COTANGENT	COTH(X)=EXP(-X)/(EXP(X)-EXP(-X))*2+1
INVERSE HYPERBOLIC SINE	ARCSINH(X)=LOG(X+SQR(X*X+1))
INVERSE HYPERBOLIC COSINE	ARCCOSH(X)=LOG(X+SQR(X*X-1)
INVERSE HYPERBOLIC TANGENT	ARCTANH(X)=LOG((1+X)/(1-X))/2
INVERSE HYPERBOLIC SECANT	ARCSECH(X)=LOG((SQR(-X*X+1)+1)/X)
INVERSE HYPERBOLIC COSECANT	ARCCSCH(X)=LOG((SGN(X)*SQR(X*X+1)+1)/X
INVERSE HYPERBOLIC COTANGENT	ARCCOTH(X)=LOG((X+1)/(X-1))/2

APPENDIX L

Microsoft BASIC Compiler

The Microsoft BASIC Compiler package contains the following
software: BASIC   Compiler, MACRO-80 assembler, and LINK-80
loader.   The following manuals are also supplied: BASIC-80
Reference Manual, BASIC Compiler User's Manual, Utility
Software Manual.   The Utility Software Manual is   the
reference manual for MACRO-80 and LINK-80.   The BASIC
Compiler User's Manual describes the use of the compiler,
its command format, compilation switches and error messages.
The BASIC language that is used with the Microsoft BASIC
Compiler is the   same as described in this manual for Disk
BASIC-80 with the following exceptions:

L.1 OPERATIONAL DIFFERENCES

The Compiler interacts with the console only to read
compiler commands.   These specify what files are to be
compiled.   There is no "direct mode," as with   the   BASIC-80
interpreter.   Commands that are usually issued in the direct
mode with the BASIC-80 interpreter are not implemented on
the Compiler.

The following statements and commands are not implemented
and will generate an error message:

     AUTO   CLOAD   CSAVE   CONT   DELETE
     EDIT   ERASE   LIST   LLIST   LOAD
     MERGE   NEW   RENUM   SAVE

Because there is no direct mode for typing in programs or
edit mode for editing programs, use Microsoft's EDIT-80 Text
Editor or BASIC-80 interpreter for creating and editing
programs.   If you use the interpreter, be sure to SAVE the
file with the A (ASCII format) option.

The compiler cannot accept a physical line that is more than
253 characters in length. A logical statement, however, may
contain as may physical lines as desired. Use line feed to
start a new physical line within a logical statement.

To reduce the size of the compiled program, there are no program line numbers included in the object code generated by the compiler unless the /D, /X, or /E switch is set in the compiler command. Error messages, therefore, contain the address where the error occurred, instead of a line number. The compiler listing and the map generated by LINK-80 are used to identify the line that has the error. It is always a good idea to debug programs using the BASIC-80 interpreter before attempting to compile them. See the BASIC Compiler User's Manual for more information.

L.2 LANGUAGE DIFFERENCES

Most programs that run on the Microsoft BASIC-80 interpreter will run on the BASIC Compiler with little or no change. However, it is necessary to note differences in the use of the following program statements:

1. CALL
    The <variable name> field in the CALL statement must contain an External symbol, i.e., one that is recognized by LINK-80 as a global symbol. This routine must be supplied by the user as an assembly language subroutine or a routine from the FORTRAN-80 library.

2. CHAIN and RUN
    The CHAIN statement is used to chain to a new program overlay using the runtime module. The RUN statement is to be used to execute any executable file. (Under CP/M, any .COM file may be RUN.)

3. CLEAR
    The CLEAR statement is only supported in compiled programs using the runtime module.

4. COMMON
    The COMMON statement must appear before any executable statements. See section 2.7 for further details.

5. DEFINT/SNG/DBL/STR
    The compiler does not "execute" DEFxxx statements; it reacts to the static occurrence of these statements, regardless of the order in which program lines are executed. A DEFxxx statement takes effect as soon as its line is encountered. Once the type has been defined for a given variable, it remains in effect until the end of the program or until a different DEFxxx statement with that variable takes effect.

6. DIM and ERASE
   The DIM statement is similar to the DEFxxx
   statement in that it is scanned rather than
   executed. That is, DIM takes effect when its line
   is encountered. If the default dimension (10) has
   already been established for an array variable and
   that variable is later encountered in a DIM
   statement, a "Redimensioned array" error results.

   There is no ERASE statement in the compiler, so
   arrays cannot be erased and redimensioned. An
   ERASE statement will produce a fatal error.

   Also note that the values of the subscripts in a
   DIM statement must be integer constants; they may
   not be variables, arithmetic expessions, or
   floating point values. For example,

        DIM Al(I)
        DIM Al(3+4)

   are both illegal.

7. END
   During execution of a compiled program, an END
   statement closes files and returns control to the
   operating system. The compiler assumes an END
   statement at the end of the program, so "running
   off the end" produces proper program termination.

8. FOR/NEXT and WHILE/WEND
   FOR/NEXT and WHILE/WEND loops must be statically
   nested.

9. ON ERROR GOTO/RESUME <line number>
   If a program contains ON ERROR GOTO and RESUME
   <line number> statements, the /E compilation switch
   must be used. If the RESUME NEXT, RESUME, or
   RESUME 0 form is used, the /X switch must also be
   included. See the BASIC Compiler User's Manual for
   an explanation of these switches.

10. REM
    REM statements or remarks starting with a single
    quotation mark do not take up time or space during
    execution, and so may be used as freely as desired.

11. STOP
    The STOP statement is identical to the END
    statement. Open files are closed and control
    returns to the operating system.

12. TRON/TROFF
    In order to use TRON/TROFF, the /D compilation
    switch must be used. Otherwise, TRON and TROFF are
    ignored and a warning message is generated.

13. USRn Functions
    USRn Functions are significantly different from the
    interpreter versions. The argument to the USRn
    function is ignored and an integer result is
    returned in the HL registers. It is recommended
    that USRn functions be replaced by the CALL
    statement.

14. %INCLUDE
    The %INCLUDE <filename> statement allows the
    compiler to include source from an alternate file.
    The %INCLUDE statement must be the last statement
    on a line. The format of the %INCLUDE statement
    is:

    <line number> %INCLUDE <filename>

    For example,

    999   %INCLUDE SUB1000.BAS

15. Double Precision Transcendental Functions
    SIN, COS, TAN, SQR, LOG, and EXP return double
    precision results if given a double precision
    argument. Exponentiation with double precision
    operands will return a double precision result.

16. String Variables
    The string space is maintained differently with the
    BASIC Compiler than with the interpreter. Using
    PEEK, POKE, VARPTR, or assembly language routines
    to change string descriptors will result in a
    String Space Corrupt error.

L.3 EXPRESSION EVALUATION

During expression evaluation, the operands of each operator
are converted to the same type, that of the most precise
operand. For example,

    QR=J%+A!+Q#

causes J% to be converted to single precision and added to
A!. This result is converted to double precision and added
to Q#.

The Compiler is more limited than the interpreter in
handling numeric overflow. For example, when run on the
interpreter the following program

```
I%=20000
J%=20000
K%=-30000
M%=I%+J%-K%
```

yields 10000 for M%. That is, it adds I% to J% and, because
the number is too large, it converts the result into a
floating point number. K% is then coverted to floating
point and subtracted. The result of 10000 is found, and is
converted back to integer and saved as M%.

The compiler, however, must make type conversion decisions
during compilation. It cannot defer until the actual values
are known. Thus, the compiler would generate code to
perform the entire operation in integer mode. If the /D
switch were set, the error would be detected. Otherwise, an
incorrect answer would be produced.

In order to produce optimum efficiency in the compiled
program, the compiler may perform any number of valid
algebraic transformations before generating the code. For
example, the program

```
I%=20000
J%=-18000
K%=20000
M%=I%+J%+K%
```

could produce an incorrect result when run. If the compiler
actually performs the arithmetic in the order shown, no
overflow occurs. However, if the compiler performs I%+K%
first and then adds J%, an overflow will occur. The
compiler follows the rules for operator precedence and
parenthetic modification of such precedence, but no other
guarantee of evaluation order can be made.

L.4 INTEGER VARIABLES

In order to produce the fastest and most compact object code
possible, make maximum use of integer variables. For
example, this program

```
FOR I=1 TO 10
A(I)=0
NEXT I
```

can execute approximately 30 times faster by simply
substituting "I%" for "I". It is especially advantageous to
use integer variables to compute array subscripts. The
generated code is significantly faster and more compact.

APPENDIX M

ASCII Character Codes

ASCII Code	Character	ASCII Code	Character	ASCII Code	Character
000	NUL	043	+	086	V
001	SOH	044	,	087	W
002	STX	045	−	088	X
003	ETX	046	.	089	Y
004	EOT	047	/	090	Z
005	ENQ	048	0	091	[
006	ACK	049	1	092	\
007	BEL	050	2	093	]
008	BS	051	3	094	^
009	HT	052	4	095	<
010	LF	053	5	096	'
011	VT	054	6	097	a
012	FF	055	7	098	b
013	CR	056	8	099	c
014	SO	057	9	100	d
015	SI	058	:	101	e
016	DLE	059	;	102	f
017	DC1	060	<	103	g
018	DC2	061	=	104	h
019	DC3	062	>	105	i
020	DC4	063	?	106	j
021	NAK	064	@	107	k
022	SYN	065	A	108	l
023	ETB	066	B	109	m
024	CAN	067	C	110	n
025	EM	068	D	111	o
026	SUB	069	E	112	p
027	ESCAPE	070	F	113	q
028	FS	071	G	114	r
029	GS	072	H	115	s
030	RS	073	I	116	t
031	US	074	J	117	u
032	SPACE	075	K	118	v
033	!	076	L	119	w
034	"	077	M	120	x
035	#	078	N	121	y
036	$	079	O	122	z
037	%	080	P	123	{
038	&	081	Q	124		
039	'	082	R	125	}
040	(	083	S	126	~
041	)	084	T	127	DEL
042	*	085	U		

ASCII codes are in decimal.
