## S Supporting Information

**ABSTRACT:** Detection of H<sub>2</sub>O<sub>2</sub> is important for the applications in environmental protection, pharmaceutical industries, food production, and clinical control. Current colorimetric assay of H<sub>2</sub>O<sub>2</sub> based on enzyme or nanomaterials always needs TMB or other peroxidase substrate as coloration species. Furthermore, the corresponding response time including incubation process is in order of minute. In this study, we report on the synthesis of heavily Ti<sup>3+</sup>-doped TiO<sub>2</sub> composed of spherulike nanoparticles by pulsed laser ablation method. This TiO<sub>2</sub> can directly detect H<sub>2</sub>O<sub>2</sub> without using TMB or any other peroxidase substrate and is free from incubation process. In addition, the detection sensitivity is compatible with or better than that of the natural enzyme or other nanomaterials. Hence, the self-doped TiO<sub>2</sub> nanoparticles provide a novel, direct, ultrafast approach for H<sub>2</sub>O<sub>2</sub> assay application.

**KEYWORDS:** H<sub>2</sub>O<sub>2</sub> assay, Ti<sup>3+</sup> self-doping, titanium oxide, absorption, nanotechnology

## 1. INTRODUCTION

Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) is an indispensable intermediate product in most of the environmental and biological circulation processes so that rapid and accurate detection of H<sub>2</sub>O<sub>2</sub> is essential for environmental protection pharmaceutical industries, food production, and clinical control.<sup>1,2</sup> Therefore, the development of rapid, efficient and sensitive methodologies for H<sub>2</sub>O<sub>2</sub> detection is of great interest and extensive attention has been concentrated on the realization of novel H<sub>2</sub>O<sub>2</sub> assay. Horseradish peroxidase (HRP), which is a natural enzyme, has been utilized to assay H<sub>2</sub>O<sub>2</sub>. This is because HRP is sensitive to the presence of H<sub>2</sub>O<sub>2</sub> and selectively in catalyzing H<sub>2</sub>O<sub>2</sub> reduction in biological solutions.<sup>3</sup> However, the reaction time of enzymes with H<sub>2</sub>O<sub>2</sub> is usually very long (i.e., in tens of minutes) and the preparation/purification cost of enzymes is expensive. In addition, enzymes may malfunction in harsh environment and tend to denature under normal detection conditions. Hence, despite the high detection sensitivity of HRP, artificial enzyme mimics were developed to replace natural enzymes for the assay of H<sub>2</sub>O<sub>2</sub>.

Up to now, various nanomaterials including iron oxide-based nanocomposite,<sup>1–5</sup> carbon nanotubes,<sup>6</sup> graphene oxide,<sup>7</sup> BiFeO<sub>3</sub> NPs,<sup>8</sup> polymer-coated CeO<sub>2</sub> NPs,<sup>9</sup> Au NPs,<sup>10</sup> V<sub>2</sub>O<sub>5</sub> nanowires,<sup>11</sup> and FeS sheet<sup>12</sup> had been developed for the assay of H<sub>2</sub>O<sub>2</sub>. However, there are major drawbacks for the current colorimetric detection of H<sub>2</sub>O<sub>2</sub> by using either natural enzymes or nanomaterials: (1) The need of peroxidase substrate as the

chromogenic reagent in acidic condition (i.e., 3,3',5,5'-tetramethylbenzidine (TMB) at pH 4.0) renders all the available assay of H<sub>2</sub>O<sub>2</sub> to be performed in an indirect way. (2) The incubation time of the coloration based on the nanomaterials is in a range of minutes. Therefore, new technology or materials are needed to achieve rapid, direct and facile assay of H<sub>2</sub>O<sub>2</sub>.

Because of high chemical and physical stability in ambient conditions, easy preparation, low fabrication cost, nontoxicity, excellent biocompatibility, and environmental friendliness, TiO<sub>2</sub> has been widely used in energy and environmental science and technologies, such as photocatalysis, self-cleaning, solar cells, etc.<sup>13–18</sup> Zuo and co-workers have shown that the Ti<sup>3+</sup>-doped TiO<sub>2</sub> (i.e., self-doped titania) can enhance the performance of hydrogen generation.<sup>19</sup> This implies that the presence of Ti<sup>3+</sup> may transform TiO<sub>2</sub> as a reducing agent to directly assay H<sub>2</sub>O<sub>2</sub>. Here, we reported a one-step method to prepare heavily Ti<sup>3+</sup> self-doped TiO<sub>2</sub> NPs (herein after, TiO<sub>2</sub>:Ti<sup>3+</sup> NPs), which unexpectedly possess rapid and high sensitivity for determining H<sub>2</sub>O<sub>2</sub> without using any peroxidase substrate. The coloration response is instantaneous (<1 s), the sensitive concentration range is as large as 1 × 10<sup>-6</sup> to 1 M, and

Accepted: November 27, 2013

Published: November 27, 2013

the detection limitation can reach to  $5 \times 10^{-7}$  M, even lower than that of the HRP.

## 2. RESULTS AND DISCUSSION

TiO<sub>2</sub>:Ti<sup>3+</sup> NPs were fabricated by ablating rutile TiO<sub>2</sub> powder dispersed in deionized water (concentration: 10 mg/mL) via a 355 nm nanosecond pulsed Nd:YAG laser (6 ns, 10 Hz, typical laser fluence:  $\sim 1$  J/(pulse cm<sup>2</sup>)). Blue color was instantly appeared in the white emulsion containing TiO<sub>2</sub> powders after 355 nm laser irradiation for  $\sim 1$  min. The emulsion eventually became transparent with blue color after  $\sim 10$  min of irradiation.

The calculated laser fluence for anatase TiO<sub>2</sub> to heat an individual spherical particle (diameter: 60 nm) to full melting is  $\sim 0.6$  J/(pulse cm<sup>2</sup>).<sup>20</sup> The rutile TiO<sub>2</sub> has similar physical parameters with anatase; we assume the laser fluence threshold is same to that of anatase. The 355 nm Nd:YAG laser fluence used in this study is about  $\sim 1$  J/pulse-cm<sup>2</sup>, which is high enough to fully melt the TiO<sub>2</sub> nanoparticles. During the ablation process, TiO<sub>2</sub> nanoparticles were generated by heat evaporation arisen from the absorption of laser light.<sup>20,21</sup> After 10 min of irradiation, a blue and transparent solution without any precipitate was obtained. The zeta potential of the TiO<sub>2</sub> nanoparticles colloidal solution is about  $-59$  mV. The as-prepared TiO<sub>2</sub> NPs is spherulike with average size of about 30 nm, as shown in Figure 1c. According to the electron

**Figure 1.** (a) Ti 2p XPS spectra and (b) EPR spectra at 2 K for rutile TiO<sub>2</sub> before and after 355 nm laser irradiation; (c) TEM of TiO<sub>2</sub>:Ti<sup>3+</sup> NPs.

diffraction, the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs is amorphous, as shown in Figure S1 in the Supporting Information. The atomic percentage of O and Ti determined from energy-dispersive X-ray spectrometer (EDX) is 67.84 and 32.16%, respectively. These values are consistent with the atomic constitution of TiO<sub>2</sub>, as shown in Figure S1b in the Supporting Information. It is noted that the solution is stable in ambient conditions for more than 3 months without any evident color variation or deposit formation.

The high resolution Ti 2p X-ray photoelectron spectra (XPS) of the TiO<sub>2</sub> powders before and after laser irradiation are shown in Figure 1a. For the pristine TiO<sub>2</sub>, the binding energy peaks at 458.9 and 464.7 eV are assigned to the 2p<sub>3/2</sub> and 2p<sub>1/2</sub> core levels of Ti<sup>4+</sup>. After laser irradiation, the 2p<sub>3/2</sub> and 2p<sub>1/2</sub> peaks shift to a lower energy side. The fitting of the Ti 2p<sub>1/2</sub> peak reveals the presence of two peak energies at 463.7 and 464.5 eV. The Ti 2p<sub>3/2</sub> peak can also be resolved into two Gaussian peaks with peak energy at 458.2 and 458.7 eV. The binding energy of 458.2 and 462.5 eV can attribute to the 2p<sub>1/2</sub> and 2p<sub>3/2</sub> core level of Ti<sup>3+</sup> respectively. On the other hand, the peak energies at 458.7 and 463.7 eV are related to the 2p<sub>1/2</sub> and

2p<sub>3/2</sub> core level of Ti<sup>4+</sup> respectively. These resolutions of peaks are well consistent with the recently reported on the binding energy value of TiO<sub>2</sub> nanostructures containing Ti<sup>3+</sup> synthesized by chemical method.<sup>22,23</sup> These quantitative analysis of the XPS data indicates that the Ti<sup>3+</sup>/(Ti<sup>3+</sup>+Ti<sup>4+</sup>) atomic ratio is about 49%, i.e., nearly half of the titanium species in TiO<sub>2</sub>:Ti<sup>3+</sup> are presented in the form of Ti<sup>3+</sup>. The existence of Ti<sup>3+</sup> can also be verified by the EPR spectrum, as shown in Figure 1b. The dried TiO<sub>2</sub>:Ti<sup>3+</sup> blue powder gives rise to a very strong electron paramagnetic resonance (EPR) signal, while no evident signal is seen for the pristine rutile TiO<sub>2</sub> powder. The g-value signal can be attributed to originate from the surface and subsurface paramagnetic Ti<sup>3+</sup> centers, which has also been previously reported in Ti<sup>3+</sup>-doped TiO<sub>2</sub> grown by chemical method.<sup>24–26</sup>

The blue coloration was also reported previously in the reduced TiO<sub>2</sub> (TiO<sub>2-x</sub>),<sup>19,27–30</sup> nonaqueous-synthesized TiO<sub>2</sub> nanocrystals,<sup>24</sup> and raw TiO<sub>2</sub> irradiated by ultraviolet light in an inert atmosphere.<sup>25,31</sup> The observation of blue coloration can be attributed to the Ti<sup>3+</sup> species formed in TiO<sub>2</sub>. In the reduced TiO<sub>2</sub> (TiO<sub>2-x</sub>), additional electrons (i.e., blue color) are resulted from the titanium interstitials or oxygen vacancies arisen during the synthetic process. In the nonaqueous-synthesized TiO<sub>2</sub> NPs, the blue coloration is stable in air for several months without any noticeable change in the absorbance.<sup>24</sup> For the TiO<sub>2</sub> under ultraviolet light irradiation, bandgap absorption produces conduction band electrons which localize on the surface of Ti atoms, and this coloration can be rapidly extinguished upon exposure to oxygen.<sup>25</sup> In this study, the dried TiO<sub>2</sub>:Ti<sup>3+</sup> blue powder can be stable in air more than 1 month.

Figure 2a shows the typical absorption spectra and photo images of the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs with and without adding H<sub>2</sub>O<sub>2</sub>.

**Figure 2.** (a) Typical absorption spectra of TiO<sub>2</sub>:Ti<sup>3+</sup> before (solid line) and after (dashed line) adding of H<sub>2</sub>O<sub>2</sub>. (b) Typical absorbance kinetic of TiO<sub>2</sub>:Ti<sup>3+</sup> NPs and H<sub>2</sub>O<sub>2</sub> at 450 nm. Inset shows schematic images of TiO<sub>2</sub>:Ti<sup>3+</sup> NPs without (left) and with (right) adding of H<sub>2</sub>O<sub>2</sub> solution. Error bar: standard deviation.

The spectrum of the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs (without H<sub>2</sub>O<sub>2</sub>) shows a sharp absorption edge at 390 nm (3.18 eV) corresponding to band-to-band transition. As the particle size ( $\sim 30$  nm) is much shorter than the wavelength of visible light (400–800 nm), light scattering caused by the NPs do not contribute to any absorbance in the absorption spectrum. The weak absorption in the visible region may be due to the Ti<sup>3+</sup>-ion-related level in the band gap.<sup>24</sup> The TiO<sub>2</sub>:Ti<sup>3+</sup> NPs have negligible light absorption over the wavelength between 440 and 530 nm. As shown in Figure 2b, the TiO<sub>2</sub>:Ti<sup>3+</sup> NP solution produces an orange-yellow color after introducing H<sub>2</sub>O<sub>2</sub>. The solution remained transparent, and there is no deposition formed even adding excessive H<sub>2</sub>O<sub>2</sub>. The absorbance of the TiO<sub>2</sub> NP-H<sub>2</sub>O<sub>2</sub> system in the visible light and near UV ranges is dramatically enhanced when compared to the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs. The resulting solution shows a maximum absorbance at 450 nm, which corresponds to

the orange-yellow color of the systems. It should be pointed out that the blue solution instantly produce orange-yellow color after mixing the TiO<sub>2</sub> NPs with H<sub>2</sub>O<sub>2</sub>, as shown in the Supporting Information (video).

For H<sub>2</sub>O<sub>2</sub> detection based on other nanomaterials, such as V<sub>2</sub>O<sub>5</sub>,<sup>11</sup> Fe<sub>3</sub>O<sub>4</sub>,<sup>1,2</sup> and Au,<sup>10</sup> the coloration reaction needs TMB as the peroxidase substrate, the mixture of nanomaterials, TMB substrate and H<sub>2</sub>O<sub>2</sub> is generally required to be incubated for some "time interval" in acidic environment at about 45 °C before the corresponding absorption spectra are recognized as a valid measurement.<sup>1,2,4</sup> See Table 1 for the required "time

**Table 1. Comparison of Typical Nanomaterials for H<sub>2</sub>O<sub>2</sub> Detection**

nanomaterials	chromogenic peroxidase substrates <sup>a</sup>	incubation time (s)	pH	detection limit (μM)

<sup>a</sup>ABTS, 2,2-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid; TMB, 3,3',5,5'-tetramethyl-benzidine; DAB, diazo-aminobenzene; OPD, *o*-phenylenediamine.

interval" for different types of nanomaterials for the detection of H<sub>2</sub>O<sub>2</sub>. In our case, no chemical is added to the mixture TiO<sub>2</sub>:Ti<sup>3+</sup> NPs and H<sub>2</sub>O<sub>2</sub> so that incubation process is not required to detect H<sub>2</sub>O<sub>2</sub> and the "time interval" is zero. Figure 2b illustrates the variation of absorbance at wavelength of 450 nm with time after the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs and H<sub>2</sub>O<sub>2</sub> were mixed together. The absorbance at ~450 nm quickly increases with time and becomes stable after ~30 s.

It was reported that similar yellow color solution was also produced in the hydrogen peroxide solution treated with titanium(IV) sulfate reagent with the presence of dilute sulphuric acid<sup>32</sup> or gray TiH<sub>2</sub> powders.<sup>33</sup> The yellow species were tentatively attributed to the formation of pertitanic acid H<sub>2</sub>TiO<sub>4</sub>.<sup>32</sup> The elemental analysis obtained from the EDX in TEM shows that the atomic ratio of O to Ti is about 4.8/1, which is close to the Ti and O elemental constitution in H<sub>2</sub>TiO<sub>4</sub>. See also the measured data of H<sub>2</sub>TiO<sub>4</sub> given in the Supporting Information. Hence, a possible chemical reaction is tentatively proposed below to explain the reaction between TiO<sub>2</sub>:Ti<sup>3+</sup> NPs and H<sub>2</sub>O<sub>2</sub>:<sup>34,35</sup>

The presence of Ti<sup>3+</sup> ions and high surface-to-volume area of NPs greatly enhance the reducibility of TiO<sub>2</sub>:Ti<sup>3+</sup> NPs, and can be directly oxidized by H<sub>2</sub>O<sub>2</sub>. As a result, the Ti<sup>3+</sup> ions in TiO<sub>2</sub>:Ti<sup>3+</sup> NPs can directly react with H<sub>2</sub>O<sub>2</sub>, and the resultant pertitanic acid is orange-yellow. Furthermore, the small size NPs with high surface-to-volume ratio accelerate the above chemical reaction. The pertitanic acid can be written as TiO<sub>2</sub>·H<sub>2</sub>O<sub>2</sub>, showing a true peroxide structure. As a comparison, the precursor of white rutile TiO<sub>2</sub> powders without Ti<sup>3+</sup> ions was also treated with H<sub>2</sub>O<sub>2</sub> solution, however, there is no evident

change of color, as shown in Figure S3 in the Supporting Information.

To investigate the reduction capability of H<sub>2</sub>O<sub>2</sub> by TiO<sub>2</sub>:Ti<sup>3+</sup> NPs, H<sub>2</sub>O<sub>2</sub> with different concentration was added to the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs solution with concentration of 10 mg/mL, as shown in Figure 3 and Figure S6 in the Supporting

**Figure 3.** (a) Relationship between absolute absorbance  $\Delta A$  at 450 nm and concentration of H<sub>2</sub>O<sub>2</sub> over a range between  $1 \times 10^{-6}$  and 1 M. The blue solid line is the fitted curve. (b) Linear fitting of absolute absorbance at 450 nm versus H<sub>2</sub>O<sub>2</sub> concentration over a range between 1 and 10 mM. Error bar: standard deviation.

Information. The absorbance at 450 nm was selected as the calibration wavelength. The absolute absorbance  $\Delta A$  is defined as  $\Delta A = A(\text{TiO}_2\text{-H}_2\text{O}_2) - A(\text{TiO}_2)$ , where  $A(\text{TiO}_2\text{-H}_2\text{O}_2)$  and  $A(\text{TiO}_2)$  are the absorbance at 450 nm of TiO<sub>2</sub>:Ti<sup>3+</sup> NP-H<sub>2</sub>O<sub>2</sub> system and the corresponding TiO<sub>2</sub>:Ti<sup>3+</sup> NPs solution with same concentration respectively. The  $\Delta A$  of the system (TiO<sub>2</sub>-H<sub>2</sub>O<sub>2</sub>) increases with the increase of H<sub>2</sub>O<sub>2</sub> concentration. As shown in Figure 3a, the absorbance at 450 nm versus H<sub>2</sub>O<sub>2</sub> concentration can be well fitted by logarithmic function (with the *R* value is equal to 0.998) over a wide range of H<sub>2</sub>O<sub>2</sub> concentration between  $1 \times 10^{-6}$  and  $6 \times 10^{-5}$  M as well as  $1 \times 10^{-4}$  and 1 M. The detection limit is as low as  $5 \times 10^{-7}$  M. In a small concentration range of 1 mM to 10 mM, the  $\Delta A$  has a linear relationship (*R* = 0.989) with H<sub>2</sub>O<sub>2</sub> concentration.

HCl, NaClO, ethanol, and acetone were selected as the control reagents to verify the coloration of TiO<sub>2</sub>:Ti<sup>3+</sup> NPs solution. The blue transparent solutions became muddy white after adding with HCl and NaClO. This observation is different to that from adding H<sub>2</sub>O<sub>2</sub> to the TiO<sub>2</sub>:Ti<sup>3+</sup> NPs solution (i.e., formation of orange-yellow transparent solution; see the inset of Figure 4, the absorption spectra are shown in Figure S5 in the Supporting Information). On the other hand, the adding of ethanol and acetone has shown no evidence of changing in TiO<sub>2</sub>:Ti<sup>3+</sup> NPs solution except the blue color turn light. The absorbance of TiO<sub>2</sub>:Ti<sup>3+</sup> NPs solution with H<sub>2</sub>O<sub>2</sub> is much

**Figure 4.** Selectivity analysis for H<sub>2</sub>O<sub>2</sub> detection by monitoring the relative absorbance. Inset: the analyte concentrations are as follows: 1 M sodium hypochlorite (NaClO), 2 M hydrochloric acid (HCl), 1 M ethanol, 1 M acetone, 0.5 M hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>). Error bar: standard deviation.

higher than that with HCl, NaClO, ethanol, and acetone, as shown in Figure 4. This control experiment indicates that the  $\text{TiO}_2\text{:Ti}^{3+}$  NPs shows high selectivity in detection of  $\text{H}_2\text{O}_2$ .

### 3. CONCLUSIONS

In conclusion, we reported that the fabrication of  $\text{TiO}_2\text{:Ti}^{3+}$  composed of uniform nanospheres grown by a one-step method. The  $\text{TiO}_2\text{:Ti}^{3+}$  NPs exhibit excellent detection behavior of  $\text{H}_2\text{O}_2$  with high selectivity and required the usage of no peroxidase substrate, such as TMB. Due to free of incubation process, the response time of  $\text{H}_2\text{O}_2$  detection based on  $\text{TiO}_2\text{:Ti}^{3+}$  NPs is much faster than currently used materials. Detection sensitivity of  $\text{TiO}_2\text{:Ti}^{3+}$  NPs on  $\text{H}_2\text{O}_2$  is ranged from  $1 \times 10^{-6}$  to 1 M with a detection limit at  $5 \times 10^{-7}$  M. The results demonstrate that the  $\text{TiO}_2\text{:Ti}^{3+}$  NPs can act as an direct, ultrafast  $\text{H}_2\text{O}_2$  detection agent. Due to easy preparation, low cost, nontoxicity, excellent biocompatibility and environmentally friendly of  $\text{TiO}_2$ , our findings open up a wide range of new potential applications for  $\text{TiO}_2$  NPs in environmental chemistry, biotechnology, pharmaceutical industry, food production.

### METHODS

**1. Fabrication.** Typically, 50 mg of commercial available rutile  $\text{TiO}_2$  particles (Aladdin Industrial Corporation, 99.8%, with average diameter  $\sim 60$  nm) was poured into a glass bottle containing 5 mL of DI water, and the mixture was stirred for 5 min. A pulsed operation (Nd:YAG, 6 ns, 10 Hz) laser beam, which has a wavelength of 355 nm, a beam diameter of  $\sim 5$  mm, and laser energy fluence of  $1 \text{ J}/(\text{pulse cm}^2)$ , was irradiated onto the mixture of  $\text{TiO}_2$  and water. After 10 min of irradiation, the color of mixture becomes dark blue.

**2. Characterization.** Morphology of the as-prepared  $\text{TiO}_2\text{:Ti}^{3+}$  NPs was investigated by using a JEM-2010 transmission electron microscope (TEM) with accelerating voltage of 200 kV. All the UV-vis absorption and kinetic spectrum was recorded by SHIMADZU UV-2550 spectrometer. The structure of rutile  $\text{TiO}_2$  before and after laser irradiation was measured by HORIBA HR-800 Raman system with an argon ion laser (emitted at 488 nm) operating at a back scattering configuration. X-ray photoelectron spectroscopy (XPS) (Kratos AXIS Ultra DLD, Al  $K\alpha$ ) was used to determine the chemical compositions of the films with calibration of C 1s peak (284.6 eV). Electron paramagnetic resonance (EPR) spectroscopy (Bruker EMX-10/12 plus) was used to examine paramagnetic species on  $\text{TiO}_2$ .

**3.  $\text{H}_2\text{O}_2$  Detection Using the  $\text{TiO}_2\text{:Ti}^{3+}$  NPs.** A typical colorimetric analysis can be realized as follows: 0.03 mL of  $\text{H}_2\text{O}_2$  with different concentrations was added into 0.27 mL of 0.4 mM  $\text{TiO}_2\text{:Ti}^{3+}$  NPs solution. The mixture solution becomes orange-yellow color instantly and holds on for 1 min. After the reaction take place for 60 s, the resulting solution was used for absorption spectroscopy measurement. Each data point was repeatedly measured for five times to obtain the standard deviation.
