S Supporting Information

ABSTRACT: A one-pot three-component reaction, involving condensation of 2-aminopyridines, aldehydes, and ketones/aldehydes under trifluoromethanesulfonic acid catalysis, provides rapid access to highly substituted novel 4*H*-pyrido[1,2-*a*]pyrimidines.

KEYWORDS: MCRs, multicomponent reactions, three-component reaction, 2-aminopyridine, 4*H*-pyrido[1,2-*a*]pyrimidine

INTRODUCTION

Pyridopyrimidines make up an important class of nitrogen-containing heterocycles because many of them exhibit a plethora of interesting biological activities.^{1–10} For example, pyrido[1,2-*a*]pyrimidine constitutes the core structure of some marketed drugs, including the antiasthmatic agent pemirolast,¹¹ the tranquilizer pirenperone,¹² and the antiallergic agent barmastine.¹³ Other pyrido[1,2-*a*]pyrimidine derivatives are known for their antidepressant,¹⁴ gastrointestinal protective,¹⁵ neurotropic and stress-protecting,¹⁶ and anticancer¹⁷ properties.

Over the past several decades, a number of approaches to the synthesis of 4*H*-pyrido[1,2-*a*]pyrimidines have been described, and these methodologies focused on the traditional two-component condensation of 2-aminopyridines with a variety of bifunctional electrophiles.^{10,18–26} Multicomponent reactions (MCRs) have emerged as powerful methods for creating molecular complexity and diversity and are recognized as important tools for a successful drug discovery program in accessing druglike molecules in a rapid and efficient manner.^{27–31} However, multicomponent reactions for the synthesis of 4*H*-pyrido[1,2-*a*]pyrimidines are scarce in general.^{32,33} To the best of our knowledge, there is no report of the synthesis of 4-alkyl/aryl-substituted 4*H*-pyrido[1,2-*a*]pyrimidines via MCRs.

The Biginelli reaction is a commonly used three-component reaction involving one-pot condensations of urea, aldehydes, and β -ketoesters.³⁴ Recently, we reported a versatile three-component reaction of 4-aminopyrimidines, aldehydes, and β -ketoesters leading to 4*H*-pyrimido[1,6-*a*]pyrimidines (Scheme 1).³⁵ As part of our ongoing efforts to develop methodologies to prepare libraries of novel heterocycles,^{36–41} we set out to discover and develop novel reactions to extend the scope of the well-known Biginelli reaction through the use of readily available ketones/aldehydes in place of β -ketoesters (active

methylene compound) in 2-aminopyridine systems as shown in Scheme 2. Herein, the details of these studies are presented.

Scheme 2. Three-Component Reaction of 2-Aminopyridines 1, Aldehydes 2, and Ketones/Aldehydes 3**RESULTS AND DISCUSSION**

Initially, 2-aminopyridine 1{1}, 4-chlorobenzaldehyde 2{1}, and cyclohexanone 3{1} were selected to investigate the reaction conditions suitable to generate product 4{1,1,1} (Scheme 3). First, the previously reported conditions for the pyrimidine system were studied, and an only 41% yield of the desired product 4{1,1,1} was obtained by heating 0.5 equiv of $\text{CF}_3\text{SO}_3\text{H}$, 1.0 equiv of 1{1}, 3.0 equiv of 2{1}, and 3.0 equiv of 3{1} for 46 h at 110 °C; another product was also isolated and identified as compound 5{1,1,1} (13%).⁴² These results prompted us to screen for an optimized condensation condition, and the results are summarized in Table 1. Treatment of compound 1{1} (1.0 equiv) with compounds

Figure 1. Diversity elements employed during library synthesis: 2-aminopyridines 1{1–4}, aldehydes 2{1–15}, and ketones/aldehydes 3{1–9}.

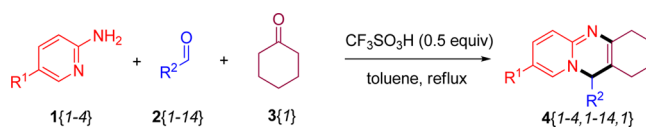

2{1} (1.1 equiv) and 3{1} (1.1 equiv) in the presence of $\text{CF}_3\text{SO}_3\text{H}$ (0.5 equiv) in refluxing acetonitrile for 130 h gave the desired product 4{1,1,1} in 45% yield and side product 5{1,1,1} in 17% yield (Table 1, entry 2). Variation of solvents (Table 1, entries 3–5) did not lead to significant improvement in the yield of compound 4{1,1,1}, but using toluene as the solvent did shorten the reaction time possibly because of the higher reaction temperature (Table 1, entry 5). Next, other acids, including pTsOH, TFA, AcOH, and PPA, were screened, but none produced a higher yield of compound 4{1,1,1} or reduced the amount of side product 5{1,1,1} (Table 1, entries 6–9). The reaction concentration was also investigated: conducting the reaction at a dilute concentration of compound 1{1} (0.5 M, Table 1, entry 10) or under a solvent-free condition (Table 1, entry 11) did not increase the yield of compound 4{1,1,1}. Formation of side product 5{1,1,1} indicates that two molecules of aldehyde 2{1} participated in the reaction; therefore, optimization of the stoichiometry of reactants could minimize the formation of compound 5{1,1,1}, leading to the higher yield of product 4{1,1,1}. As expected, an increasing level of ketone 3{1} produced more desired product 4{1,1,1} and less side product 5{1,1,1} (Table 1, entries 13–15), while reducing the amount of ketone 3{1} led to even more side product 5{1,1,1} (Table 1, entry 12). An acceptable condition was discovered as heating a mixture of 0.5 equiv of $\text{CF}_3\text{SO}_3\text{H}$, 1.0 equiv of 1{1}, 1.1 equiv of 2{1}, and 3.0 equiv of 3{1} in toluene for 21 h at reflux (Table 1, entry 14), which gave product 4{1,1,1} in 69% yield and side product 5{1,1,1} in only 8% yield. Therefore, the reaction condition of entry 14 was used in further studies.

To explore the scope of this one-pot three-component reaction, various 2-aminopyridines 1{1–4}, aldehydes 2{1–15}, and ketones/aldehydes 3{1–9} were employed under the optimized reaction conditions described above (Scheme 2 and Figure 1). The results are summarized in Tables 2 and 3.

The scope of aldehydes (R^2CHO) was investigated using cyclohexanone, and the results are disclosed in Table 2. Various benzaldehydes are suitable substrates leading to the desired products in good to high yields (Table 2, entries 1–7). Both electron-withdrawing and electron-donating groups are tolerated, although 2-methylbenzaldehyde (Table 2, entry 6) gave a slightly lower yield compared to benzaldehyde (Table 2, entry 1), indicating possible steric hindrance effects. Other aryl and heteroaryl aldehydes (Table 2, entries 8–10) are also tolerated but gave the desired products in yields lower than that of benzaldehyde (Table 2, entry 1). Aliphatic aldehydes were also studied, and the desired products were obtained in good to high yields. It is interesting to note that simple straight chain aliphatic aldehydes gave moderate yields (Table 2, entries 11 and 12), while cyclic aliphatic aldehydes produced excellent yields (Table 2, entries 13 and 14). To test the electronic effects of the substituents of the 2-aminopyridines, both electron-donating and electron-withdrawing groups were tested (Table 2, entries 15–17). Tuning the electron density of the 2-amino group had little effect on product yields, but it appears that the reaction proceeded faster when there is an electron-donating group on 2-aminopyridines (Table 2, entry 15 vs entries 16 and 17). Having completed the investigation of the scope of aldehydes 2{1–14}, we studied various carbonyl compounds 3{2–9}, and the results are summarized in Table 3.

As seen in Table 3, acyclic ketones ($\text{R}^3\text{COCH}_2\text{R}^4$) are also compatible in terms of these reactions yielding the expected products (Table 3, entries 1, 3, and 4) with the exception of

acetophenone. The reaction of acetophenone led to complex reaction mixtures that might be due to the instability of product 4{1,1,3} under the reaction conditions described here. It is noteworthy that the reaction also can be extended to aliphatic aldehydes, although moderate yields were obtained for reactions involving phenylacetaldehyde and pentanal (Table 3, entries 5–7).⁴³ The self-condensation reactions of phenylacetaldehyde on treatment with 2-aminopyridine 1{1} were

also investigated, which produced the desired product 4{1,15,6} in 62% yield (Table 3, entry 8). The case of cyclopentanone was surprising and failed to give the desired product 4{1,1,8} (Table 3, entry 9). On the other hand, the reaction of cycloheptanone proceeded smoothly to form desired product 4{1,1,9} in good yield (Table 3, entry 10). To unambiguously identify the structures of compound 4, 4{1,1,6}, X-ray crystallographic analysis was performed (Figure 2).⁴⁴

Figure 2. ORTEP diagram of compound 4{1,1,6}.

Mechanistically, several reaction pathways could be envisioned to generate products 4 in the current MCR. After carefully examining our experimental results and considering existing literature reports,^{21,24,43,45–47} we propose two potential mechanistic pathways as shown in Scheme 4 to account for the current MCRs. The first step of the current MCR is the formation of intermediate 6 through CF₃SO₃H-promoted Knoevenagel condensation of aldehyde 2 and ketone/aldehyde 3. Intermediate 6 was indeed detected and identified in the reaction mixture by mass spectroscopy and thin layer chromatography analysis during the reaction. Subsequently, 2-aminopyridine 1 can react with intermediate 6 via two reaction pathways. For pathway a, condensation of 2-aminopyridine 1 with intermediate 6 under acid-catalyzed conditions gave imine 7,^{21,24} and then imine 7 underwent an intramolecular cyclization reaction to generate product 4. On the other hand, it is plausible that the current MCR could follow reaction pathway b: Michael addition by the nucleophilic pyridine ring

N atom of intermediate 6 to afford ketone intermediate 8,⁴⁵ then an intramolecular cyclization of the imine group of intermediate 8 onto the keto moiety to give 9, and finally an acid-catalyzed elimination of water to afford product 4.

CONCLUSIONS

In summary, we have demonstrated that 2-aminopyridines, aldehydes, and ketones/aldehydes undergo a productive three-component reaction to provide 4*H*-pyrido[1,2-*a*]pyrimidines in moderate to high yields. This new MCR proved to have a broad scope because many aliphatic aldehydes, aromatic aldehydes, heterocyclic aldehydes, cyclic ketones, and acyclic ketones are suitable substrates for the current MCR. Moreover, the current MCR is operationally simple; therefore, this new methodology should allow the rapid assembly of heterocyclic scaffolds with highly substituted 4*H*-pyrido[1,2-*a*]pyrimidines. This synthetic methodology complements the well-known Biginelli reaction and existing pyridine chemistry by allowing access to libraries of the pyridine-fused heterocycles.
