

pression for the velocity of the discrete vortices that are used to represent the sheet. I have not compared the results obtained by the Fink-Soh method with those obtained by the simple discrete-vortex method and, therefore, am not able to evaluate or comment on the virtues of their technique. The purpose of this Reply is to point out that their method applies only to those cases where rollup of a continuous vortex sheet is being analyzed, e.g., the tailored and elliptic loading cases presented in Ref. 2. Such a method does then not apply to systems of vortices in general nor to vortex wakes that are composed of discrete vortices such as the stepped and sawtooth loadings in my paper.<sup>2</sup>

Based on the experience with the method of Fink and Soh that Prof. Sarpkaya reported in his Comment, it appears unlikely that inclusion of the logarithmic term in the velocity expression would significantly alter the results presented in Ref. 2 for tailored and elliptic loadings. Also, as noted in Ref. 2, the numerical calculations were monitored with accuracy parameters and then terminated to prevent error growth beyond a specified limit. The resulting wake vortex structure was then found to be in good agreement with Betz' rollup theory (Figs. 6 and 10 of Ref. 2). Therefore, all of the numerical results remain correct as presented in Ref. 2, and the conclusions drawn in the paper need not be modified.

As pointed out in Ref. 2, the erratic character and large magnitude of the excursions predicted for the vortices shed by stepped and sawtooth loadings has been confirmed qualitatively by experiments conducted at NASA Ames Research Center (e.g. Ciffone and Orloff<sup>3</sup>). It still remains however, to apply these loading concepts effectively so that the wake-dispersive motions of the vortices bring about adequate alleviation of the wake hazard behind large aircraft, as well as to compare the alleviation achieved and penalties incurred by the various aerodynamic-alleviation schemes with vortex avoidance systems.
