# On the Complex Formation in the Lead(II) (Ethylthio) acetate System

#### ARVID SANDELL

Division of Inorganic Chemistry 1, Chemical Center, University of Lund, P.O.B. 740, S-220 07 Lund 7, Sweden

The complex formation in aqueous solution between the lead(II) ion and the (ethylthio)acetate ion has been studied at 25.0°C by central ion measurements and by ligand measurements.

Both methods indicated the formation of at least two mononuclear complexes, for which the following gross stability constants were calculated:

from the central ion measurements:  $\beta_1 = (52.5 \pm 0.7) \text{ M}^{-1}$ ,

 $\beta_2 = (670 \pm 30) \text{ M}^{-2};$ 

from the ligand measurements:  $\beta_1 = (52.7 \pm 0.4) \text{ M}^{-1}$ ,

 $\beta_2 = (670 \pm 10) \text{ M}^{-2}$ .

The constants refer to an ionic strength of 1.0 M (NaClO<sub>4</sub>).

The existence of anionic complexes could not be established with any certainty.

A sparingly soluble phase separated from solutions with large central ion concentration.

A comparison is made between the complex formation in the present system and in the lead(II) ethoxyacetate system.

Investigations of the formation of ethoxyacetate and (ethylthio)acetate complexes of bivalent nickel, copper, and cadmium have been reported earlier. The results indicate that the (ethylthio)acetate ion in forming mononuclear complexes in aqueous solution acts mainly bidentately with copper(II), but mainly monodentately with the other metal ions.

In this paper, an investigation of the complex formation in the lead(II) (ethylthio)acetate system is reported. As in an earlier investigation of the lead(II) ethoxyacetate system,<sup>5</sup> two independent electrometric methods have been used, viz. (1) indirect determination of the concentration of free ligand in buffer solutions by means of a glass electrode, and (2) direct determination of the concentration of free central ion by means of a lead amalgam electrode.

The formation of lead(II) (ethylthio)acetate complexes in 50 % dioxane at 30°C has earlier been studied by Irving and Fernelius.

#### CALCULATIONS AND NOTATIONS

The stability constants have been obtained by graphical treatment of the data according to Fronzeus.7 A numerical method 4 has also been used with the data from the central ion measurements.

In this paper, the following notations are used:

```
C_{\mathbf{M}} = total concentration of Pb<sup>2+</sup>-ion
```

$$[\tilde{\mathbf{M}}]$$
 = concentration of free Pb<sup>2+</sup>-ion

$$C_{L}'$$
 = stoichiometric total concentration of ligand L

$$C_{\rm L}$$
,  $C_{\rm HL}$  = corrected total concentration of ligand L, acid HL

$$C_{\rm L}'$$
 = stoichiometric total concentration of ligand L  $C_{\rm L}$ ,  $C_{\rm HL}$  = corrected total concentration of ligand L, acid HL  $\delta$  = buffer quotient in the ligand buffer. The stoichiometric concentration of the acid HL is  $\delta C_{\rm L}'$ 

$$K_a = [\mathrm{H_3O^+}] [\mathrm{L}]/[\mathrm{HL}]$$

$$N =$$
maximum coordination number

$$\beta_n = [ML_n]/([M][L]^n) = \text{gross stability constant}$$

$$K_{\mathbf{a}} = [\mathbf{H}_{\mathbf{3}}\mathbf{O}^{+}] [\mathbf{L}]/[\mathbf{H}\mathbf{L}]$$
 $N = \text{maximum coordination number}$ 
 $\beta_{\mathbf{n}} = [\mathbf{M}\mathbf{L}_{\mathbf{n}}]/([\mathbf{M}][\mathbf{L}]^{n}) = \text{gross stability constant}$ 
 $K_{\mathbf{n}} = [\mathbf{M}\mathbf{L}_{\mathbf{n}}]/([\mathbf{M}\mathbf{L}_{\mathbf{n}-1}][\mathbf{L}]) = \text{stepwise stability constant}$ 

$$X = C_{\mathbf{M}}/[\mathbf{M}] = 1 + \sum_{n=1}^{N} \beta_n [\mathbf{L}]^n$$

$$X' = dX/d[L]$$

$$\bar{n} = (C_{\tau} - [L])/C_{\tau} = \text{the ligand number}$$

$$X_i = (X_{i-1} - \beta_{i-1})/[L]; (1 \le i \le N; X_0 = X; \beta_0 = 1)$$

$$\begin{split} & \overline{h} &= (C_{\mathbf{L}} - [\mathbf{L}])/C_{\mathbf{M}} = \text{the ligand number} \\ & X_i = (X_{i-1} - \beta_{i-1})/[\mathbf{L}]; \ (1 \leq i \leq N; \ X_0 = X; \ \beta_0 = 1) \\ & h_{\mathbf{m}} \text{ and } h_0 = [\mathbf{H}_3 \mathbf{O}^+] \text{ in solutions with the same } C_{\mathbf{L}}' \text{-value, } h_0 \text{ referring to a} \\ & \text{solution with } C_{\mathbf{M}} = 0 \\ & h_{\mathbf{R}} = [\mathbf{H}_3 \mathbf{O}^+] \text{ in a reference buffer} \\ & E_0 = 59.16 \log (h_0/h_{\mathbf{R}}) \text{ mV} \\ & E_{\mathbf{m}} = 59.16 \log (h_{\mathbf{m}}/h_{\mathbf{R}}) \text{ mV} \\ & E_{\mathbf{L}} = E_{\mathbf{m}} - E_0 = 59.16 \log (h_{\mathbf{m}}/h_{\mathbf{0}}) \text{ mV} \\ & E_{\mathbf{L}} = e \text{mf of cell } (1) = 29.58 \log (X) \text{ mV} \\ & D_{\mathbf{m}} = \text{by prothetical correction torm} \ (\mathbf{m} \mathbf{V}) \end{split}$$

$$D^{\rm M} = \text{hypothetical correction term (mV)}$$

I = ionic strength

### **EXPERIMENTAL**

Chemicals. The (ethylthio)acetic acid supplied by Eastman Organic Chemicals was not pure. It was rectified by vacuum distillation. A portion constantly boiling at 122.0°C (16 mbar) had the equivalent weight 120.3 (calc. 120.2). The buffer solutions prepared from the pure acid and carbonate free sodium hydroxide were analysed with the aid of a cation exchange resin.

The lead(II) perchlorate stock solution, the sodium perchlorate, and the lead amalgam were the same as used in an earlier investigation.5

All other chemicals used were of pro analysi grade.

Methods. The same two experimental methods were applied as in the investigation of the lead(II) ethoxyacetate system. A description of these methods was given in the report of that investigation,5 and will not be repeated here.

To obtain favourable conditions for a comparison of the lead(II) complex formation with ethoxyacetate and with (ethylthio)acetate, the same measurement equipment and, as far as possible, the same chemicals were used in the two investigations.

Table 1. Corresponding values of [L] and  $\bar{n}/[L]$  in the lead(II) (ethylthio)acetate system. Buffer with  $\delta = 0.258$ . The values of  $E_0$  refer to  $h_{\rm R} = 6.0 \times 10^{-6} \, {\rm M}$ .

<sup>a</sup> Supersaturated solution. <sup>b</sup> Precipitation.

#### MEASUREMENTS AND RESULTS

The ligand measurements. As in the corresponding measurements with ethoxyacetate buffers,<sup>5</sup> the experimental reproducibility was the same as the precision of the voltmeter, viz.  $\pm 0.1$  mV. The experimental results from the main part of the investigation, in which a ligand buffer solution with  $\delta = 0.258$  was used, are collected in Table 1.

For  $C_{\rm M}=60.0\,$  mM and 50.0 mM, measurements could be made in the slightly supersaturated solutions at  $C_{\rm L}{}'=198.6\,$  mM and 375 mM, resp. At higher  $C_{\rm L}{}'$ -values, precipitation occurred immediately. The precipitate was not dissolved, at least not completely, at  $C_{\rm L}{}'=750\,$  mM. The precipitate was a heavy, viscous, greyish liquid, forming large drops on standing. An estimate of the lead content of the substance was obtained in the following way. The precipitate was washed with water and kept at 80°C for 1 h. The drops were then transparent and very viscous. After some weeks in a desiccator over silica gel, the substance was light brown and had a horny consistence. Samples were dissolved in very dilute nitric acid and titrated with EDTA with xylenolorange as indicator.8 (Found: Pb 47.0  $\pm$  0.5. Calc. for Pb( $C_2H_5$ .S.CH<sub>2</sub>.COO)<sub>2</sub>: Pb 46.5.)

With  $C_{\rm M} = 40.0$  mM and 20.0 mM, the measurements were extended to  $C_{\rm L}' = 750$  mM, without precipitation being observed. The  $E_{\rm L}$ -values obtained at  $C_{\rm L}' > 375$  mM, however, were too small to allow calculation of reliable [L]-values, and were not used in the calculation of the stability constants.

[L]-values, and were not used in the calculation of the stability constants. Titrations were also made at  $C_{\rm M}\!=\!40.0$  mM with a ligand buffer with  $\delta\!=\!0.418$ . The results showed that, within the experimental reproducibility,  $\bar{n}/[{\rm L}]$  was independent of  $\delta$ . Hence it is likely that the hydrolysis of the lead(II) ion is negligible under the present experimental conditions, and that no complex formation occurs between the lead(II) ion and the free (ethylthio)-acetic acid.

As can be seen in Fig. 1,  $\bar{n}/[L]$  was not quite independent of  $C_{\rm M}$ . A limiting curve representing  $\bar{n}/[L]$  at  $C_{\rm M}=0$  as a function of [L] was obtained by linear

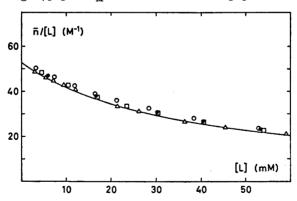

Fig. 1. Some  $\tilde{n}/[\text{L}]$ -values from the ligand measurements. The main investigation,  $\delta=0.258$ :  $C_{\text{M}}=60$  mM (O),  $C_{\text{M}}=40$  mM ( $\square$ ),  $C_{\text{M}}=20$  mM ( $\triangle$ ). Buffer with  $\delta=0.418$ , and  $C_{\text{M}}=40$  mM ( $\blacksquare$ ). The full-drawn curve is calculated from the  $\beta_n$ -values obtained in the ligand investigation.

extrapolation of  $\bar{n}/[L]$  as a function of  $C_{\rm M}$  at constant [L]. From this curve, X-values were obtained by graphical integration.

The variation of  $\bar{n}/[L]$  with  $C_{\rm M}$  may indicate the existence of polynuclear complexes. By extrapolation of the different  $\bar{n}/[L]$ -plots to [L]=0, the stability constant  $\beta_{12}=[{\rm M_2L}]/([{\rm M}]^2[{\rm L}])$  could be estimated <sup>2,7</sup> to about 40 M<sup>-2</sup>. However, the effect is very small and might as well be attributed to variations in the liquid junction potential and in the activity coefficients.

The maximum value of  $\bar{n}$ , obtained directly from the measurements, was about 2. As can be found from Table 3,  $\bar{n}$  calculated from  $\bar{n}/[L]$  at  $C_{\rm M}=0$  reached a value of 1.8. Thus it is likely that at least two mononuclear complexes are formed.

The  $X_1$ -plot was linear for  $[L] \le 70$  mM (corresponding to  $\bar{n} \le 1.4$ ). Applying the least squares principle in this region resulted in the estimates of  $\beta_1$  and

 $\beta_2$  given below, with 99 % confidence limits. The slope of the  $X_2$ -graph indicated the existence of a very weak third complex. The stability constant of this third complex could be estimated only within wide limits of error. The following stability constants were obtained:

$$\begin{array}{ll} \beta_1 = (52.7 \pm 0.4) & \quad M^{-1} \\ \beta_2 = (670 \ \pm 10) & \quad M^{-2} \\ \beta_3 = (200 \pm 100) & \quad M^{-3} \end{array}$$

A check with the experimental data obtained at  $C_{\rm L}' > 375$  mM showed these to be consistent with the results obtained at lower  $C_{\rm L}'$ -values. The preci-

a cf. Discussion.

sion of the value of  $\beta_3$  could not be improved. Formation of a fourth complex was not indicated.

With the aid of the stability constants, the product [M] [L]<sup>2</sup> was calculated to  $5 \times 10^{-5}$  M³ for the two slightly supersaturated solutions mentioned above. Considering the result of the analysis of the precipitate, this value can be

regarded as a rough estimate of the solubility product of the compound  $ML_2$ , in the medium in question.

The central ion measurements. The concentration of free (ethylthio)acetic acid did not influence  $E_{\rm M}$ . This was found by measurements of the same kind as in the investigation of the ethoxyacetate complexes (see cell (4) in Ref. 5). Results:  $C_{\rm HL}/{\rm mM}$ , emf/mV - 554; 0, 0.26; 25.4, 0.26; 47.9, 0.27; 77.0, 0.25; 101.7, 0.26; 129.4, 0.26; 153, 0.29; 178, 0.28; 203, 0.27;

A ligand buffer with  $\delta = 0.247$  was used in the main part of this investigation. In calculating  $C_{\rm L}$  from  $C_{\rm L}$ , the earlier <sup>4</sup> found value of  $2.26 \times 10^{-4}$  M was used for the acid constant of (ethylthio)acetic acid.

The experimental results are collected in Tables 4 and 5. The mean value of the difference between the  $E_{\rm M}$ -values obtained in repeating the measurements was 0.02 mV.

Representative values from the graphical determination of the stability constants are collected in Table 6.

The  $X_1$ -plot was linear only for [L] < 35 mM, which meant an unfavourable situation in calculating both  $\beta_1$  and  $\beta_2$  from this plot. The  $X_2$ -plot, however, having no linear portion, offered still more unfavourable conditions for a determination of  $\beta_2$ . Fairly reliable values of  $X_3$  could be calculated only at [L] > 200 mM.

Below are stated estimates of the stability constants (with 99 % confidence limits) obtained by application of the principle of least squares;  $\beta_1$  and  $\beta_2$  from the linear portion of  $X_1$  at [L] < 35 mM,  $\beta_3$  and  $\beta_4$  from  $X_3$  at [L] > 210 mM:

$$\begin{array}{ll} \beta_1 = (52.5 \pm 0.7) & \quad M^{-1} \\ \beta_2 = (670 \pm 30) & \quad M^{-2} \\ \beta_3 = (900 \pm 300) & \quad M^{-3} \\ \beta_4 = (2000 \pm 1000) & \quad M^{-4} \end{array}$$

The entire experimental material was also treated by the numerical method earlier described.<sup>4</sup> The result agreed well with that obtained by the graphical method.

The calculations are founded on  $E_{\rm M}$ , which is the emf of the galvanic cell (1).

$$-\operatorname{Pb}(\operatorname{Hg}) \quad \left| \begin{array}{c} [\operatorname{M}] = C_{\operatorname{M}}/X \\ [\operatorname{L}] < C_{\operatorname{L}'} \\ [\operatorname{HL}] \approx \delta \ C_{\operatorname{L}'} \\ \operatorname{NaClO}_4 \ \operatorname{to} \ I \approx 1 \ \operatorname{M} \end{array} \right| \quad \left| \begin{array}{c} [\operatorname{M}] = C_{\operatorname{M}} \\ [\operatorname{H}_3\operatorname{O}^+] \approx 2 \times 10^{-4} \ \operatorname{M} \\ \operatorname{NaClO}_4 \ \operatorname{to} \ I = 1 \ \operatorname{M} \end{array} \right| \quad \operatorname{Pb}(\operatorname{Hg}) + \quad (1)^*$$

As earlier pointed out,<sup>5</sup> the emf of this cell includes a liquid junction potential which is not likely to be negligible at large [L]-values. Hence it is open to doubt whether useful information regarding the formation of weak complexes can be derived directly from the  $E_{\rm M}$ -values obtained at high  $C_{\rm L}$ '-values. An estimate of the uncertainty in this matter can perhaps be obtained with the aid of the  $E_0$ -values from the ligand measurements. It is observed (see Table 1) that  $E_0$  at low  $C_{\rm L}$ ' increases to a constant value - 0.6 mV. In this region (0 <  $C_{\rm L}$ ' < 40 mM), the  $K_a$ -value calculated from  $E_0$  is constant,  $2.3 \times 10^{-4}$  M. At higher  $C'_{\rm L}$ -values, both  $E_0$  and the calculated  $K_a$  decrease.

<sup>\*</sup> In the present paper the double lines symbolize a salt bridge with 1.000 M NaClO4.

We now make the simplifying assumptions that  $K_{\rm a}$  in reality is constant also for  $C_{\rm L}'>40$  mM and that the non-constancy of  $E_{\rm 0}$  is due solely to the liquid junction potential. Then the variable quantity  $D=(-0.6~{\rm mV}-E_{\rm 0})$  should be an estimate of the liquid junction potential at high values of  $C_{\rm L}'$  for the element

$$-\frac{\text{glass}}{\text{electrode}} \quad \begin{vmatrix} C_{\text{HClO}_4} \approx 5.0 \times 10^{-4} \text{ M} \\ \text{NaClO}_4 \text{ to } I = 1 \text{ M} \end{vmatrix} \begin{vmatrix} [L] \approx C_{\text{L}}' \\ [HL] \approx \delta C_{\text{L}}' \\ \text{NaClO}_4 \text{ to } I = 1 \text{ M} \end{vmatrix} \qquad \frac{\text{glass}}{\text{electrode}} + \quad (2)$$

since  $h_{\rm R}$  in the reference buffer (see cell (3) in Ref. 5) was determined by emf measurements which can be expressed by the cell

$$-\frac{\mathrm{glass}}{\mathrm{electrode}} \quad \left| \begin{array}{c} C_{\mathrm{HClO_4}} \approx 5.0 \times 10^{-4} \, \mathrm{M} \\ \mathrm{NaClO_4} \, \mathrm{to} \, I = 1 \, \mathrm{M} \end{array} \right| \quad \begin{array}{c} \mathrm{reference \ buffer} \\ [\mathrm{H_3O^+}] = h_R \\ \mathrm{NaClO_4} \, \mathrm{to} \, I = 1 \, \mathrm{M} \end{array} \right| \quad \begin{array}{c} \mathrm{glass} \\ \mathrm{electrode} + \end{array} \quad (3)$$

Since the solutions in the half-cells of (1) and (2) are very much alike, it is assumed that the quantity D also represents a rough estimate of the liquid junction potential of cell (1). Thus the X-values in the central ion investigation should be calculated from  $E_{\rm M}-D$ . Values of D are inserted in Table 5.

With application of this correction term, the total experimental material was re-analysed by the computer method. It was found that the X-function in the entire [L]-region ([L]  $\leq$  274 mM) could be very well represented by a polynomial of the second degree, giving the stability constants (with 99 % confidence limits):

$$\begin{array}{ll} \beta_1 = (52.5 \pm 0.4) & \quad M^{-1} \\ \beta_2 = (672 \pm 5) & \quad M^{-2} \end{array}$$

The same kind of  $E_{\rm M}$ -correction was applied to the data of the investigation of the lead(II) ethoxyacetate system,<sup>5</sup> in which the difficulties in interpreting the central ion measurements at higher  $C_{\rm L}$ '-values were similar to those encountered in the present investigation. The calculations, which were restricted to  $C_{\rm L}$ '  $\leq$  300 mM, showed that the X-function in this case too could be well represented by a polynomial of the second degree in [L]. The stability constants found in this case were (with 99 % confidence limits):

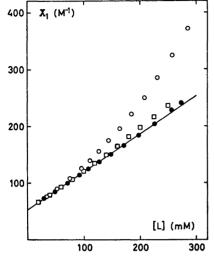

$$\beta_1 = (52.7 \pm 0.2)$$
  $M^{-1}$   
 $\beta_2 = (435 \pm 3)$   $M^{-2}$ 

The influence of the correction term upon the  $X_1$ -functions of the two systems is illustrated in Figs. 2 and 3.

It should be emphasized that the correction of  $E_{\rm M}$  made above is merely an attempt to show, by means of the data on hand, the limited possibility of drawing reliable conclusions from  $E_{\rm M}$ -data at high  $C_{\rm L}$ '-values in the present investigation. No systematic investigation has yet been made regarding the influence of the exchange of electrolytes upon the activity coefficients of the particles involved in the cell reactions in question.

Some support was obtained to the assumption that the liquid junction potential should be the dominating systematic error in the central ion measurements, by measuring the emf  $E_{\rm F}$  (mV) of the cell (4) at 25.0°C.

Û

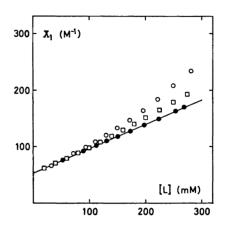

Fig. 2. The  $X_1$ -functions for the lead(II) (ethylthio)acetate system obtained by: central  $\cdot$  ion measurements (O), ligand measurements ( $\square$ ), central ion measurements with application of a correction term ( $\bullet$ ). The line is  $X_1/M^{-1}=53+670$  [L]/M.

Fig. 3. The  $X_1$ -functions in the lead(II) ethoxyacetate system <sup>5</sup> as obtained by: central ion measurements (O), ligand measurements ( $\square$ ), central ion measurements with application of a correction term ( $\bigoplus$ ). The straight line is  $X_1/M^{-1} = 53 + 435$  [L]/M.

With the ligand buffer replaced by 5.56 mM  $\mathrm{HClO_4}$ ,  $E_{\mathrm{F}}$  was 688.0 mV. Results:  $C_{\mathrm{L}}'/\mathrm{mM}$ ,  $E_{\mathrm{F}}/\mathrm{mV}-801$ ,  $K_{\mathrm{a}}\times10^4/\mathrm{M}$ ; 30.4, 0.6, 3.1; 41.0, 0.5, 3.1; 61.1, 0.5, 3.1; 79.8, 0.5, 3.1; 100.0, 0.6, 3.1; 126.3, 0.7, 3.1; 150.0, 0.8, 3.1; 175.5, 0.9, 3.1; 200.0, 1.0, 3.1; 240, 1.2, 3.0; 300, 1.5, 3.0.

Thus it was found that the change in  $E_0$  (see Table 3 in Ref. 5) was four times as large as the change in  $E_{\rm F}$  when  $C_{\rm L}$  was increased from 40 mM to 300 mM. According to Brønsted's principle of the specific interaction of ions, the activity coefficient of  ${\rm Cl}^-$  in cell (4) should not be much influenced by the exchange of perchlorate ions against ethoxyacetate ions, since these three ions all have the same charge. However, a considerable part of the perchlorate ions are exchanged, and the experimental material is too small to justify a closer comparison of the changes in  $E_{\rm F}$  and  $E_0$ .

Similar measurements with an (ethylthio)acetate buffer could not be done, owing to the high stability of the silver (ethylthio)acetate complexes.<sup>10</sup>

#### DISCUSSION

Both methods used in the present investigation show that two mononuclear complexes are formed at low [L]-values. The same  $\beta_1$ - and  $\beta_2$ -values are obtained by both methods.

The question whether anionic complexes are formed cannot be answered with certainty, on the basis of the present experimental material. Both methods indicate the formation of a weak third complex at high [L]-values. For reasons earlier mentioned, however, this indication cannot be considered very reliable, especially as the calculations in the ligand investigation involve an extrapolation to  $C_{\rm M}=0$ . Formation of a third complex, with  $\beta_3$  of the order of magnitude indicated by the ligand measurements, seems not to be incompatible with the fact that the sparingly soluble phase is in equilibrium with the solution in a system with  $C_{\rm M}=50.0$  mM, and  $C_{\rm L}'=750$  mM. A closer investigation of the solubility of the precipitate should probably give valuable information.

All the stability constants listed in Table 7 are determined by ligand measurements. The  $\beta_3$ -values of the ethoxyacetate and (ethylthio)acetate systems should be considered as tentative. No thorough investigation on the complex formation in the lead(II) acetate system at 25°C and I = 1 M is known. The set of constants for this system, listed in Table 7, is considered to be the one offering the best conditions for a comparison with the other constants listed in the table, since the  $\beta$ -values of the lead(II) acetate system seem to vary more with the ionic strength 12,13 than with the temperature.14

A comparison of the constants gives the impression that the complex formation in the three systems follows the same principal scheme, and that the two substituted acetates act mainly monodentately. Considering the fact, however, that the p $K_a$ -values of the ethoxyacetic acid and the (ethylthio)acetic acid are 3.51 and 3.65, resp., it seems rather striking that  $\beta_1$  is equal in the corresponding lead(II) systems. This relative stabilisation of the first ethoxyacetate complex may indicate that chelates are formed to a somewhat higher degree by the ethoxyacetate than by the (ethylthio)acetate. If this interpretation is correct, then the effect is a parallel to that found by other workers in investigating the formation of lead(II) complexes with potentially three- and four-dentate ligands 15,16 containing  $-\dot{C}-O-C-$  and  $-\dot{C}-S-C$ groups. However, the effect observed in the present investigation is small, and it seems not possible to draw a definite conclusion in this matter.

Acknowledgements. I wish to thank Professor Sture Fronzeus for a valuable discussion of the results of this investigation. I also thank Miss Kerstin Anderson for her assistance in the preparatory work, and Dr. Peter Sellers for his linguistic revision of the manuscript.
