Abstract

5-Bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]dec-8-ene 3,3-dioxide (BOTCDO) was synthesized from the reaction between 2-(2-bromoallylsulfanyl methyl)-furan and *m*-chloroperbenzoic acid in dichloromethane. The molecular structure and vibrational frequencies of BOTCDO in the ground state have been investigated with ab initio (HF) and density functional theory methods (B3LYP, B3PW91 and MPW1PW91) implementing the standard 6-31G(d) basis set. The optimized geometric bond lengths and bond angles obtained by using HF and DFT methods show the best agreement with the experimental data. Comparison of the observed fundamental vibrational frequencies of title compound and calculated results by HF and DFT methods indicate that MPW1PW91 is superior to the scaled HF approach for molecular problems. Optimal uniform scaling factors calculated for the title compound are 0.8920, 0.9553, 0.9518 and 0.9452 for HF, B3LYP, B3PW91 and MPW1PW91 methods, respectively.

Keywords: HF; DFT; FT-IR spectrum; quantum chemical calculations; furans; sulfoxide.

1. Introduction

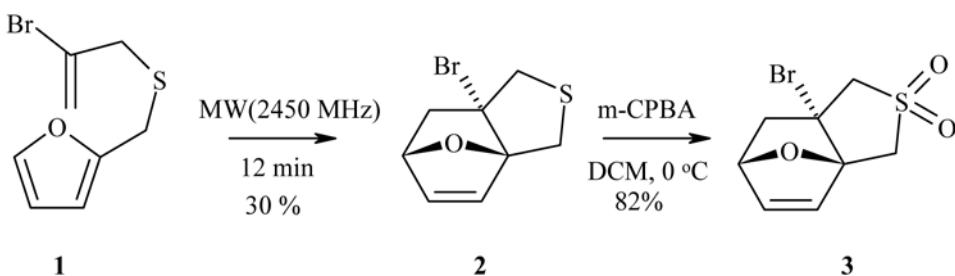

The renewal of interest in cycloaromatization reactions over the last decade has clearly intensified due to the elegant mode of action of the enediyne natural products.^{1,2} In particular, the intramolecular Diels–Alder (IMDA) cycloaddition has been extensively used for assembly of complex molecular architectures of designed or natural products origin.^{3–5} Biosynthetic pathways incorporating IMDA reactions have been recognized and examples of biomimetic total synthesis of natural products by using a key IMDA cycloaddition are known.^{5–7} IMDA reactions between unactivated furans and dienophiles take place generally at lower temperature compared to their intermolecular counterparts,⁸ and thus, they have a much higher scope with respect to the necessary activation of the reaction partners.⁹ Furthermore, success of IMDA cycloaddition critically depends on the length of the tether connecting the furan with the dienophile unit.^{10,11}

The utility of sulfoxide have received great attention in point of chemical and biological properties.^{2,13} The sulfonyl functional group has recently been shown to potentially inhibit a variety of enzymatic processes providing unique properties for drug design and medicinal chem-

istry.^{14,15} Furthermore, alkenyl sulfones are well known for their ability to inhibit many types of cycteine proteases.^{16,1} The alkenyl sulfones are reversible inhibitors of these enzymes through conjugate addition of the thiol of the active site cycteine residue, mimicking the initial covalent adduct in normal proteolytic turnover. Particularly, Hanzlick¹⁸ proposed alkenyl sulfone series as potential cycteine protease inhibitors targeting the plant protease papain.

In the point of chemical properties view, sulfoxides used as dienophiles in a Diels–Alder reaction and their 1,4-cycloadditon have attracted considerable attention¹⁹. The sulfonyl group has versatile functionality in organic synthesis and can be conveniently eliminated resulting in an alkene.^{20,21} Moreover sulfonyl group can also be converted to the corresponding ketone by oxidative desulfonylation.²² From synthetic and medicinal chemistry point of view, tricyclicsulfone, 5-bromo-10-oxa-3-thia-tricyclo[5.2.1.0^{1,5}]dec-8-ene-3,3-dioxide (BOTCDO) might be a convenient route for the development of combinatorial furan chemistry.

In our further systematic studies on IMDA cycloadditon of furans,^{23,24} we have recently synthesized the

Scheme 1

tricyclicsulfones (**3**) by oxidizing the thermal intramolecular Diels-Alder cycloadduct, (**2**)^{25,26} (Scheme 1). 2-{[(2-bromoprop-2-en-1-yl)thio]methyl}furan (**1**) was derived from furfurylmercaptanol by employing Williamson ether synthesis.²⁷ Irradiation of thioether, 2-{[(2-bromoprop-2-en-1-yl)thio]methyl}furan in a commercial microwave oven (2450 MHz) in solvent-free condition for 12 min underwent [4+2] cycloaddition and gave 5-bromo-10-oxa-3-thia-tricyclo[5.2.1.0^{1,5}]dec-8-ene, (**2**) with modest yield. The tricyclic cycloadduct, (**2**) was then oxidized to sulfones, 5-bromo-10-oxa-3-thia-tricyclo[5.2.1.0^{1,5}]dec-8-ene-3,3-dioxide (**3**), using *m*-chloroperbenzoic acid (*m*-CPBA) in dichloromethane at 0 °C giving 78% yield.^{25,26}

Several theoretical methods are useful in analyzing vibrational spectra of organic molecules. These methods can be roughly divided into the following groups: classical mechanics, semi-empirical quantum mechanical methods, ab initio quantum mechanical method and ab initio followed by empirical scaling of the force constants. Ab initio molecular orbital calculation is relatively successful approaches to the calculation of vibrational spectrum of closed shell organic molecules. However, raw frequency values computed at the Hartree–Fock level contain known systematic errors due to neglecting electron correlation. Therefore, it is necessary to scale frequencies predicted at the Hartree–Fock level.

DFT methods are gaining popularity recently as a cost-effective general procedure for studying the physical properties of molecules.²⁸ Much effort has been devoted to refining the methodology and exploring the limits of its applicability.^{29,30} In the recent theoretical studies,^{31,32} the harmonic vibrational frequencies for a large number of molecules were computed with Hartree–Fock and Density functional methods. On the basis of a comparison of computed and observed fundamental vibrational frequencies, the scaled DFT methods were found to be reliable.

In the present study, we have, therefore, calculated the vibrational frequencies and geometric parameters of the title compound in the ground state to distinguish the fundamentals from the experimental vibrational frequencies and geometric parameters, by using the Hartree–Fock,³³ density functional using Becke's three-parameter hybrid method³¹ with the Lee, Yang, and Parr correlation functional methods,³² the Barone and Adamo's Becke-style one-parameter functional using the modified Perdew-Wang exchange and Perdew-Wang 91 correlation

method,^{34,35} Becke's three parameter exchange functional combined with gradient corrected correlation functional of Perdew and Wang's 1991,^{36,37} with the standard 6-31G(d) basis set. Furthermore, we interpreted the calculated spectra of in terms of potential energy distributions (PEDs) and made the assignment of the experimental bands due to PED analysis results. In continuation of our theoretical studies, in the present work we checked the relative performance of B3LYP, B3PW91 and MPW 1PW91 methods, as well as of HF for comparison, at the 6-31G(d) level taking as a test compound 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]dec-8-ene 3,3-dioxide.

2. Experimental

2.1. Synthesis of 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]dec-8-ene 3,3-dioxide

To a solution of *meta*-chloroperbenzoic acid (*m*-CPBA) (300 mg, 1.2 mmol) which was previously purified and recrystallized in dry diethyl ether, in dichloromethane (10 mL), cooled to 0 °C, was added dropwise a solution of 2-(2-bromo-allylsulfanyl)methyl-furan (140 mg, 0.6 mmol) in dichloromethane (10 mL) over 3 min. The reaction mixture was stirred at room temperature for 4 h and the diluted with cold 4% sodium bicarbonate solution (4 mL). The organic layer was separated, washed with water (20 mL) and concentrated in *vacuo*. The crude solid residue was subjected to flash column chromatography to afford titled compound. EtOAc / *n*-Hexane (3:7) [*R*_f 0.27] was used as eluent to provide pure dioxide. Off pale yellow crystals (for re-crystallization, 1:1 Ether / DCM): yield 120 mg (78%); m.p. 142–144 °C; δ_H (300 MHz CDCl₃): 6.57 (dd, 1H, *J*₁ 1.8 Hz, *J*₂ 5.7 Hz, AB), 6.35 (d, 1H, *J* 5.7 Hz, AB), 5.13 (dd, 1H, *J*₁ 1.8 Hz, *J*₂ 4.8 Hz), 3.93 (d, 1H, *J* 12.3 Hz, AB), 3.86 (d, 1H, *J* 12.5 Hz, AB), 3.65 (d, 1H, *J* 12.3 Hz, AB), 3.59 (d, 1H, *J* 12.5 Hz, AB), 2.53 (dd, 1H, *J*₁ 4.8 Hz, *J*₂ 12.0 Hz, AB), 1.98 (d, 1H, *J* 12.0 Hz, AB). δ_C (75 MHz CDCl₃): 135.0, 131.1, 128.5, 119.2 (q), 76.5 (q), 67.4, 52.3, 50.9, 46.7. m/z : 266 [M⁺⁸¹Br], % 16], 264 [M⁺⁷⁹Br], % 16], 184.9 [M⁺⁸¹Br]–(C₅H₅O), % 10], 121 [M⁺–(SO₂+Br), % 16], 81 [(C₅H₅O)⁺, % 16], 55 [(C₃H₃O)⁺, % 40]. E. A. Required for C₈H₉O₃SBr: C, 36.24%; H, 3.42%. Found: C, 36.48%; H, 3.21%.

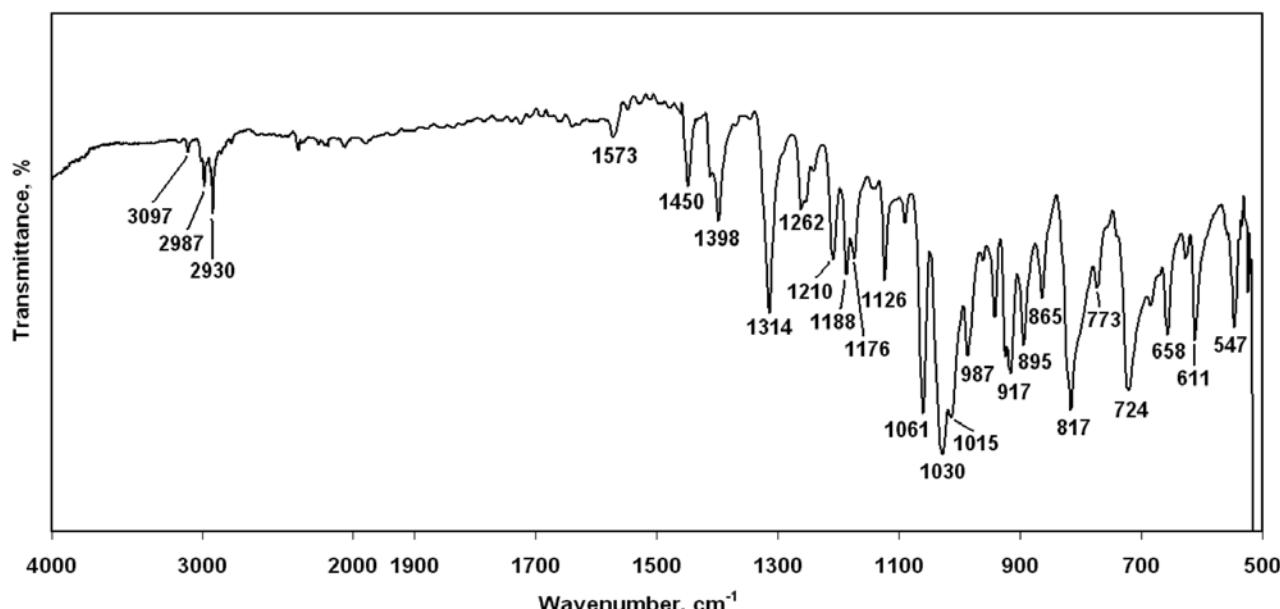

Figure 1: FT-IR spectrum of 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]-dec-8-ene 3,3-dioxide recorded at room temperature.

2.2. Instrumentation

The room temperature attenuated total reflection Fourier transform infrared (FT-IR ATR) solid state spectrum of the 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]-dec-8-ene 3,3-dioxide was registered using Varian FTS1000 FT-IR spectrometer with Diamond/ZnSe prism (4000–525 cm⁻¹; number of scans: 250; resolution: 1 cm⁻¹) (Fig. 1).

2.3. Calculations Details

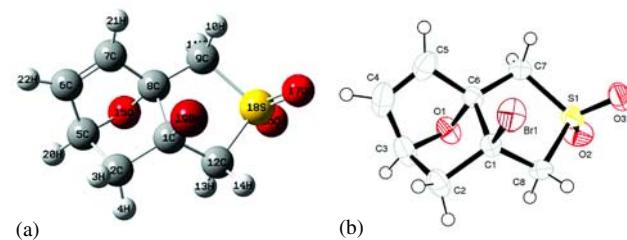

All the calculations were performed with the Gaussian 03W program package on a double Xeon/3.2 GHz processor with 8 GB Ram.³⁸ The molecular structure of the BOTCDO, in the ground state are optimized by using the Hartree-Fock (HF),³³ density functional using Becke's three-parameter hybrid method³¹ with the Lee, Yang, and Parr correlation functional methods³² (B3LYP), the Barone and Adamo's Becke-style one-parameter functional using the modified Perdew-Wang exchange and Perdew-Wang 91 correlation method, (mPW1PW91),^{34,35} Becke's three parameter exchange functional combined with gradient corrected correlation functional of Perdew and Wang's 1991 (B3PW91),^{6,37} and 6-31G(d) basis set. The vibrational frequencies were also calculated with these methods. The frequency values computed at these levels contain known systematic errors.³⁹ Therefore, we have used the scaling factor values of 0.8992, 0.9614, 0.9573 and 0.9500 for HF, B3LYP, B3PW91 and MPW1PW91, respectively.^{40,41} We have also calculated optimal scaling factors for all investigated methods. The assignment of the calculated wave numbers is aided by the animation option of GaussView 3.0 graphical interface

for gaussian programs, which gives a visual presentation of the shape of the vibrational modes.⁴² Furthermore, theoretical vibrational spectra of the title compound were interpreted by means of PEDs using VEDA 4 program.⁴³

3. Results and Discussion

3.1. Geometry Optimization

The crystal and molecular structure of 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]-dec-8-ene 3,3-dioxide have been reported.²⁶ The structure parameters is orthorhombic, the space group *Pbca*, with the cell dimensions *a* = 10.1723 (6) Å, *b* = 10.3446 (9) Å, *c* = 17.6278 (10) Å and *V* = 1854.9 (2) Å³. In this work, we performed full geometry optimization of the title compound. The crystal and optimized structure of BOTCDO with the labelling of atoms is given in Fig. 2. The optimized geometrical parameters (bond length and angles) by HF, B3LYP, B3P W91 and MPW1PW91 methods with 6-31G(d) as basis

set are listed in Table 1. Also, Table 1 compares the calculated geometrical parameters with the experimental data. As follows from this comparison, the bond lengths and angles calculated for the title compound show quite good agreement with experimental values. However, owing to our calculations, DFT method correlates well for the bond

length and angle in comparison to the HF method. The largest difference between experimental and calculated DFT bond length and angle is about 0.049 Å and 2.8°. In the intermolecular hydrogen bond distances for a Donor-Hydrogen…Acceptor system, D-H distance is typically ~1.1 Å, whereas HA distance is ~1.6 to 2.0 Å. The crys-

^a Harmonic frequencies (in cm^{-1}), IR intensities (km mol^{-1}), reduced masses (amu) and force constants (m dyn \AA^{-1}). ^b Scaling Factor calculated in this research. ^c Scaling factor obtained from Ref.⁴⁰ ^d v, stretching; δ , bending; ipb, in-plane bending; γ , out-of-plane bending; τ , torsion; sym, symmetric; asym, asymmetric; wagg, wagging; twist, twisting; rock, rocking; sciss, scissoring; PED less than 10% are not shown.

taline form of the title compound has two intermolecular interactions (C7-H7A…O2ⁱ, with H…O = 2.42 Å ($i = 1/2 + x, y, 1/2-z$) and C8-H8A…O3ⁱⁱ, with H…O = 2.42 Å ($ii = -1/2 + x, y, 1/2-z$)). According to these crystalline geometrical parameters, we can say that the title compound has too weak molecular interactions. The good correlation between the experimental and calculated structure parameters confirmed these weak intermolecular interactions. As a result, the optimized bond lengths and angles by DFT method show the best agreement with the experimental values.

3.2. Vibrational Frequencies

The literature search has revealed that DFT calculations and vibrational analysis have not been reported so far on 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]dec-8-ene 3,3-dioxide. Therefore, we have calculated the theoretical vibrational spectra of 5-bromo-10-oxa-3-thiatricyclo[5.2.1.0^{1,5}]dec-8-ene 3,3-dioxide by using HF, B3LYP, B3PW91 and MPW1PW91 methods with 6-31G(d) basis set. Theoretical and experimental results of the title compound are shown in Table 2 and supplementary materials as Table S1–S3. The vibrational bands assignments have

been made by using both the animation option of GaussView 3.0 graphical interface for gaussian programs⁴² and VEDA 4 program.⁴³ All the calculated spectra are in a good agreement with the experimental one. All three hybrid functions are superior to HF in terms of realistic reproduction of both band intensity distribution and general spectral features.

The IR bands at 3156 and 3097 cm^{-1} in FT-IR spectrum of the title compound have been designated to symmetric and asymmetric ν_{CH} stretching fundamentals of C6 and C7 atoms, respectively.^{44,45} The wave numbers corresponding to the aliphatic ν_{CH} stretching are listed in Table 2 and Table S1–S3. A good coincidence of theoretical wave numbers with that of experimental evaluations is found in the symmetric and asymmetric stretching vibrations of the –CH₂– moieties. The vibrational spectra show five bands in the aliphatic ν_{CH} stretching region and are evident overlap between the different C–H stretching modes. Seven bands at 3042, 3039, 3020, 3016, 2973, 2967 and 2954 cm^{-1} were calculated in this research (MPW1PW91). First three is asymmetric $\nu_{\text{C}-\text{H}}$ stretching band and the last three bands symmetric $\nu_{\text{C}-\text{H}}$ stretching band for –CH₂– group. These assignments were also supported by the literature.^{44,46}

Table 3: Mean deviation, mean absolute deviation, correlation coefficient, root mean square and average absolute error between the calculated and observed fundamental vibrational frequencies for the title compound.

^a Harmonic frequencies (in cm^{-1}), IR intensities (km mol^{-1}), reduced masses (amu) and force constants (m dyn Å^{-1}). ^b Scaling Factor calculated in this research. ^c Scaling factor obtained from Ref. ⁴¹.

Calculations of the vibrational spectra of hydrogen bonded systems are extremely demanding since their potential energy hyper surfaces are highly anharmonic; therefore, calculations of the vibrational spectra in the harmonic approximation are of very limited value. Some methods have been developed for solving this problem such as variational solving of the Schrödinger equation⁴⁷. However, according to single crystal X-ray diffraction data, the title compound has not got any strong hydrogen bond. Therefo-

re, we did not focus on the hydrogen bonds for the title compound. The crystalline form of the title compound has two weak molecular interactions (C7-H7A...O2 and C8-H8A...O3). The biggest difference between calculated and experimental $\nu_{\text{C}-\text{H}}$ stretching vibrations of the $-\text{CH}_2-$ moieties is 33 and 30 cm^{-1} for $\nu_{\text{C9}-\text{H}}$ and $\nu_{\text{C12}-\text{H}}$ stretching, respectively. These discrepancies for $\nu_{\text{C9}-\text{H}}$ and $\nu_{\text{C12}-\text{H}}$ stretching vibrational modes come from the formation of weak intermolecular hydrogen bonding with C–H.

The biological effects are often connected with the capability of contributing into intermolecular interactions during formation of supramolecular compounds with biomacromolecules. Hydrogen bonds are implicated in regulating dioxygen activation in methane monooxygenase,^{48,49} and hydrogen atom abstraction in lipoxygenase.^{50–54} As the inhibition of some enzymes by derivatives of the title compound can be attributed to weak intermolecular interactions, the title compound may itself possess same biological activity due to the presence of these interactions.

The peaks appearing in the region (600–1500 cm⁻¹) are associated with the scissoring, rocking, wagging and twisting modes of methylene groups. The vibrational modes of scissoring, rocking, wagging and twisting are well defined in all the calculations. The bands observed at 1450, 1413 and 1398 cm⁻¹ in FT-IR spectrum correspond to scissoring deformation of –C(2)H₂–, –C(9)H₂– and –C(12)H₂– group in the title compound.^{44,45} The wagging, twisting and rocking vibrational modes are distributed in a wide range.^{44–46,55,56} The rocking –CH₂– is assigned in the wave number range of 950–800 cm⁻¹ and the wave number shift of these bands is due to the atom nature in which the –CH₂– group is bonded. The –CH₂– rocking vibrational modes are intensive bands in which can be appreciating the vibrational coupling with other vibrational modes.^{55,56} All these bands are assigned using calculated potential energy distribution.

The two ν_{S=O} stretching modes were calculated at 1294 and 1092 cm⁻¹ and observed in reasonably good agreement at 1322 and 1106 cm⁻¹ in the infrared spectrum of vinylsulfonamide⁵⁷. The band observed at 773 cm⁻¹ in FT-IR spectrum corresponds to ν_{C-S} stretching vibration in the title compound. The calculated DFT/6-31G(d) scaled value for the title compound is 771 cm⁻¹, this value is well in agreement with the experimental wave number. This result was confirmed by Bensebaa et al.⁵⁸

A general better performance of B3LYP, B3PW91 and MPW1PW91 versus HF can be quantitatively characterized by using the mean deviation, mean absolute deviation, average absolute error, root mean square values and coefficients of correlation (cc) between the calculated and observed vibration frequencies and given in Table 2 and Table S1–S3. The root mean square (RMS) values were obtained in this study using the equations (12) and (13) from Ref.⁴¹ The cc values for all three DFT methods were bigger than 0.9998, whereas for HF it was 0.9997: these values are very close to those reported for the literature data.^{40,59–65}

These results indicate that the DFT calculations approximate the observed fundamental frequencies much better than the HF results. Furthermore, the MPW1PW91 method calculations approximate the observed fundamental frequencies much better than the other investigated DFT methods results. The small difference between experimental and calculated vibrational modes is observed. We note that the experimental results belong to solid

phase and theoretical calculations belong to gaseous phase.

Finally, one should mention scaling factors, which are crucial for IR spectral predictions. To calculate optimal scaling factors, λ, we employed a least-square procedure using the equation (10) from Ref.⁴¹:

$$\lambda = \sum_i^{\text{all}} \omega_i^{\text{theor}} v_i^{\text{expt}} / \sum_i^{\text{all}} (\omega_i^{\text{theor}})^2$$

Where ω_i^{theor} and v_i^{expt} are the *i*th theoretical harmonic and *i*th experimental fundamental frequencies (in cm⁻¹), respectively. Only single (uniform) scaling factors were calculated, without discrimination for different vibrations. The values obtained are 0.8920, 0.9452, 0.9518 and 0.9553 for HF, MPW1PW91, B3PW91 and B3LYP, respectively. They are very close to those recommended by Scott & Radom and Kuppens et al.^{40,41} for the same levels of theory and increase in the same order of HF, MPW1PW91, B3PW91 and B3LYP. Thus, for future IR spectral predictions for unknown derivatives of the title compound, one can recommend scaling factors of 0.892, 0.945, 0.952 and 0.955 for HF, MPW1PW91, B3PW91 and B3LYP, respectively.

4. Conclusions

The ground state geometries were optimized using the HF, B3LYP, B3PW91 and MPW1PW91 methods with the 6-31G(d) basis set. The vibrational frequencies were also calculated with these methods. IR spectrum of the title compound computed is in a good agreement with its observed FT-IR spectrum. The correlation between the calculated and experimental vibration frequencies is characterized by the coefficients of bigger than 0.9998 for all three DFT methods and 0.9997 for HF. Optimal uniform scaling factors calculated for the title compound are 0.8920, 0.9452, 0.9518 and 0.9553 for HF, MPW1PW91, B3PW91 and B3LYP, respectively. For IR spectrum predictions for the title compound type derivatives, any of the three hybrid functions can be equally successfully used. Taking into account small variations of the scaling factors for the derivatives of the title compound, for future IR spectral predictions for unknown compounds of this class, one can recommend scaling factors of 0.892, 0.945, 0.952 and 0.955 for HF, MPW1PW91, B3PW91 and B3LYP, respectively.

Povzetek

5-bromo-10-oksa-3-thiatriciklo[5.2.1.0^{1,5}]-dek-8-ene 3,3-dioksid (BOTCDO) je bil sintetiziran na osnovi reakcije med 2-(2-bromoalilsulfanilmetil)-furanom in *m*-kloroperbenzojeve kisline v diklormetanu. Molekularno strukturo in vibracijske frekvence BOTCDO v osnovnem stanju smo raziskovali z metodami *ab initio* (HF) in teorijo gostotnega funkcionala (B3LYP, B3PW91 in MPW1PW91) s pomočjo standardnega 6–31G(d) baznega seta. Dolžine vezi in velikosti kotov geometrije optimirane s HF in DFT kažejo najboljše ujemanje z eksperimentalnimi podatki. Primerjava dejanskih osnovnih vibracijskih frekvenc obravnavanih spojin z izračunanimi (HF in DFT) nakazujejo, da je MPW1PW91 metoda boljša od normalizirane HF metode za molekularne probleme. Najboljši normalizacijski faktorji obravnavanih spojin za metode HF, B3LYP, B3PW91 in MPW1PW91 so 0.8920, 0.9553, 0.9518 in 0.9452.
