Abstract

The electric conductivities of aqueous solutions of nonsteroidal anti-inflammatory drugs salicylate, naproxen, ibuprofen sodium and diclofenac sodium salts and diclofenac potassium salt were measured in the temperature range from 278.15 K to 313.15 K (in steps of 5 K) and in the concentration range $3 \times 10^{-4} < c(\text{mol/dm}^{-3}) < 0.007$. Data analysis based on the low concentration chemical model of electrolyte solutions yielded the limiting molar conductivity, $\Lambda^{\circ\circ}$, and the association constant, K_A . Using the known data of the limiting conductivities of sodium and potassium ions the limiting conductivities of the salicylate, naproxen, diclofenac and ibuprofen anions were evaluated, and the radii of anions in water were estimated. Total dissociation of the investigated salts in water is evident and the considerable differences in the anion mobilities are observed. They are discussed in terms of possible hydration and hydrophobic interactions.

Keywords: Electrolyte conductivity, electrolyte solution, sodium salicylate, naproxen sodium salt, diclofenac sodium salt, diclofenac potassium salt, ibuprofen sodium salt, chemical model

1. Introduction

Nonsteroidal anti-inflammatory drugs (NSAIDs) are among the most commonly prescribed categories of drugs worldwide in the treatment of pain, inflammation and some of them even fever in many conditions. Their mechanism for action likely relates to the inhibition of prostaglandin synthesis¹ Although they are now used widely in therapeutics, physicochemical information about them are rather scarce.

However, the effects of a drug in a biological system is the ultimate consequence of physicochemical interactions between a drug and functionally important molecules in the living organism. The dominant fluid media in the biological systems through which the drugs are transported and in which they interact are water and lipids. The drugs usually undergo a number of complicated interactions in solution which may cause not only structural changes of biological fluids but also metabolic and structural changes of drugs. Therefore drug-drug and drug-solvent interactions may be of great importance to understand their physiological action.

The temperature and concentration dependence of the electrolyte conductance has been proved as one of the most appropriate methods for studying ion-ion, ion-solvent and solvent-solvent interactions in solutions.²

Recently a conductivity study of some drugs in acetonitrile at 298.15 K has been carried out³ but there is no literature data on the drug ion mobility in water so far. In the present work electrical conductivity measurements of aqueous solutions of some NSAIDs: sodium salicylate (Na-Sal), naproxen sodium salt (NaNap), diclofenac sodium salt (NaDic), diclofenac potassium salt (KDic), and ibuprofen sodium salt (NaIbu) at the temperatures from 278.15 K to 313.15 K (in steps of 5 K) in the concentration range $3 \times 10^{-4} < c \text{ (mol/dm}^{-3}) < 0.007$ were carried out. Data analysis is done in the framework of the low concentration chemical model (lcCM)⁴ giving the information on the ion association and mobility of ions in aqueous solutions.

2. Experimetal

2.1. Materials

Sodium salicylate (2-Hydroxybenzoic acid sodium salt, HOC₆H₄COONa, puriss. p.a., ≥99.5%, Fluka, Germany), naproxen sodium ((S)-6-Methoxy-α-methyl-2naphthaleneacetic acid sodium salt, C₁₄H₁₃NaO₃, ≥98%, Sigma-Aldrich, Germany), diclofenac sodium (2-[(2,6-Dichlorophenyl)amino]benzeneacetic acid sodium salt, $C_{14}H_{10}Cl_2NNaO_2$, > 99.7%, Titan Pharma, India) diclofenac potassium salt (2-[(2,6-Dichlorophenyl)amino]benzeneacetic acid potassium salt, $C_{14}H_{10}Cl_2NKO_2$, > 99.7%, Titan Pharma, India), and ibuprofen sodium salt (α -Methyl-4-(isobutyl)phenylacetic acid, C₁₃H₁₇O₂Na, Sigma, Germany) were stored in a desiccator over P_2O_5 and used without further purification. Stock solutions were prepared by weighing pure compounds and demineralized distilled water.

Demineralized water was distilled two times in a quartz bidistillation apparatus (Destamat Bi 18E, Heraeus). The final product with specific conductivity $< 6 \times$ 10⁻⁷ S cm⁻¹ was distilled into a flask permitting storage under an atmosphere of nitrogen.

2. 2. Conductivity Measurement

The conductivities of solutions were determined with the help of a three-electrode measuring cell, described elsewhere.² The cell was calibrated with dilute potassium chloride solutions⁵ and immersed in the high precision thermostat described previously⁶ The temperature dependence of the cell constant was taken into account.⁵

The oil bath can be set to each temperature of a temperature program with a reproducibility within 0.005 K. The temperature in the precision thermostat bath was additionally checked with calibrated Pt100 resistance thermometer (MPMI 1004/300 Merz) in connection with a HP 3458 A. The resistance measurements of solutions in the cell were performed using a precision LCR Meter Agilent 4284 A.

At the beginning of every measuring cycle the cell was filled with a weighed amount (~660 g) of water. After the measurement of the solvent conductivity at all temperatures of the program a weighed amount of a stock solution was added using a gas-tight syringe. After every addition the temperature program was run and all measured data (frequency dependent resistance, temperature) were stored by the computer and partially shown on a display to track the measuring process.⁶ The measuring procedure, including corrections and the extrapolation of the sample conductivity to infinite frequency, is described in the literature.^{5,6}

From the weights and the corresponding solution densities d the molar concentrations c were determined. A linear change of d with increasing salt content for diluted solutions was assumed, $d = d_s + b\tilde{m}$, where d_s is the density of water, given in Table 1, and \tilde{m} is the molonity of

^a Units: \widetilde{m} , mol · kg⁻¹; T, K; Λ , $S \cdot \text{cm}^2 \cdot \text{mol}^{-1}$; b, kg² · dm⁻³ · mol⁻¹

the electrolyte (moles of electrolyte per kilogram of solution). The densities of the solutions were determined by the method of Kratky et al.¹¹ using a Paar densimeter (DMA 60, DMA 601 HT) at 298.15 K combined with a precision thermostat. As usual the density gradient *b* is considered to be independent of temperature, see Table 2.

The measured conductivity data of all investigated salts are given in Table 2 as a function of the temperature independent molonities. They can be converted to the temperature-dependent molarities by using the relationship $c = \tilde{m}d$.

Taking into account the sources of error (calibration, measurements, impurities) the molar conductivities are accurate to within 0.1%.

3. Data Analysis

The analysis of the conductivity data in the framework of the low concentration chemical model (lcCM) given in Ref.⁴ and the literature cited there, uses the set of equations

$$\frac{\Lambda}{\alpha} = \Lambda^{\infty} - S\sqrt{\alpha c} + E\alpha c \ln(\alpha c) + J_1 \alpha c - J_2 (\alpha c)^{\frac{3}{2}}$$
(1)

$$K_{\rm A} = \frac{1-\alpha}{c\alpha^2 y_{\pm}^{\prime 2}}; \quad y'_{\pm} = exp\left(-\frac{\kappa q}{1+\kappa R}\right); \tag{2a-b}$$

$$\kappa^2 = 16\pi N_A qac; \qquad q = \frac{e_o^2}{8\pi\varepsilon\varepsilon_o kT} \tag{3}$$

where Λ and Λ^{∞} are the molar conductivities at molarity cand in the infinite dilution, respectively, $(1-\alpha)$ is the fraction of oppositely charged ions acting as ion pairs, and K_A is the equilibrium constant of the lcCM with upper association limit R; $\mathbf{y'}_{\pm}$ is the corresponding activity coefficient of the free ions, $(\mathbf{y'}_{\pm})^2 = \mathbf{y'}_{+} \mathbf{y'}_{-}$, κ is the Debye parameter, e_0 is the proton charge, ε is the relative permittivity of the solvent, ε_o is the permittivity of vacuum and T the absolute temperature. The other symbols have their usual meaning. W^* is a step function for the potential of mean force between cation and anion due to non-Coulombic interactions.

The coefficients of Eq. (1) are given in Ref.⁴ The limiting slope S and the parameter E are completely calculable when the solvent data are available (Table 1). The coefficients J_1 and J_2 are also functions of the distance parameter R, representing the distance to which oppositely charged ions can approach as freely moving particles in solution.

Analysis of the conductivity data of associated electrolytes are carried out by setting the coefficients *S*, *E* and J_1 of Eq. (1) to their calculated values⁴ and then usually using three-parameter fits to obtain the limiting values of

molar conductivity Λ^{∞} , the association K_A and the coefficient J_2 by non-linear least squares iterations. A three-parameter evaluation is reduced to a two-parameter procedure for nonassociating electrolytes,² where usually coefficient J_2 is also fixed. The input data for the calculation of the coefficients are the known solvent properties (Table 1) and the distance parameter R. The lower limit a of the association integral is the distance of closest approach of cation and anion (contact distance), $a = a_1 + a_2$. It was calculated from the ionic radii of the cations; ${}^{4}a_{\perp} = 0.098$ nm for Na⁺ and 0.133 nm for K⁺. Organic anions such as carboxylates, sulfonates, etc., bear their negative charge in an oxygen atom on the surface of the ionic molecule. The "radius" of such ions may be taken to be the effective van der Waals radius of the carboxylate or sulfonate group.⁴ We used the value a = 0.162 nm which was estimated for formic acid⁴ assuming that the radicals in the anions of the investigated drugs do not change the interionic distance between the cation and the basic oxygen atom in their structure.

From extended investigations of electrolyte solutions in amphiprotic hydroxylic solvents (water, alcohols) it is known that the upper limit of association is given by an expression of the type R = a + ns, where *s* is the length of an oriented solvent molecule, n is an integer, n = 0, 1, 2,... Here, *s* is the length of an OH-group, d_{OH} , and $s = d_{OH}$ = 0.28 nm. In this study we fixed the distance parameter *R* at R = 0.820 nm for sodium and 0.855 nm for potassium salts, allowing thus three types of ion pairs in the solutions: contact ion pairs, solvent-shared and solvent-separated ion pairs.

4. Results and Discussion

Figure 2 shows a comparison of the experimental data for molar conductivities, Λ , of the NaNap aqueous

Figure 2. Molar conductivities, Λ , of aqueous NaNap solutions from 278.15 to 318.15 K (steps of 5 K). (Δ) experiment, full line: lcCM calculations.

Bešter-Rogač: Nonsteroidal Anti-Inflammatory Drugs Ion Mobility: ...

solutions given in Table 2 and the results of the lcCM calculations executed using Eqs. (1-3). All other investigated systems show similar dependence.

In Figure 3 the conductivity data for sodium salts (salicylate, naproxen, ibuprofen, diclofenac) and potassium diclofenac at 298.15 K are presented. For NaIbu solutions the experiment was performed in the same concentration range as for other salts but for unknown reason the experimental data can only be satisfactorily fitted over a narrow range of concentration.

Table 3 gives a comparison of the calculated lcCM data for all investigated salts. The limiting conductivities are dependent on the structure of the anions, as can be expected. The values of the association constants are very low and all the investigated salts could be regarded as completely dissociated in water solutions ("strongelectrolytes"). The values of K_A for NaCl aqueous solutions obtained from precise conductance measurements by using the lcCM, are in the range $0.6 < K_A < 2.6$ in the temperature range between 278.15 and 303.15 K.¹² Whereas the temperature coefficient dK_A/dT is usually positive for the alkali salt water solutions, no reliable evidence for the temperature dependence of the association process of aqueous solutions of the discussed drugs was found except at NaSal and NaIbu where slightly higher ion association at lower temperatures can be assumed.

Figure 3. Molar conductivities of KDic ($\mathbf{\nabla}$), NaSal ($\mathbf{\diamondsuit}$), NaNap (\triangle) , NaDic (\bigtriangledown) and NaIbu (\bullet) in water at 25 °C.

Combining the limiting conductivities Λ^{∞} of Table 3 and the known limiting values of cations $\lambda^{\infty}(M^+)$, $M^+ =$ Na^+ , K^+ (Table 1)

$$\lambda^{\infty}(T, \mathbf{A}^{-}) = \Lambda^{\infty}(T, \mathbf{M}\mathbf{A}) - \lambda^{\infty}(T, \mathbf{M}^{+})$$
(4)

yields the limiting anion conductivities $\lambda^{\infty}(A^{-})$ and their temperature dependence; see Table 4.

Table 4. Limiting conductance of anions of investigated drugs in water as a function of temperature^a

^a Units: *T*, K; λ^{∞} , $S \cdot cm^2 \cdot mol^{-1}$

From the Walden rule⁴

$$\lambda^{\infty}(T)\eta(T) = \frac{Fe|z|}{6\pi a_{i}^{(\eta)}}$$
(5)

the solvent dependent ionic radii $a_i^{(\eta)}$ were estimated (*F* is the Faraday constant and *z* the ionic charge). In water $a_i^{(\eta)}$ are usually called hydrodynamic radii, r_h . Values for the hydrodynamic radii of the ions of investigated salts are collected in Table 5. It is well known that comparison of the values of the hydrodynamic radii and the crystal radii of cations show large difference for Na⁺ ions, whereas the ion size parameter of K⁺ are close together.

Table 5. Hydrodynamic radii, r_h , of the investigated salts in water from Walden rule as a function of temperature

			r_h

^a Units: T, K; r_h, nm

Sodium ion is relatively small and has, therefore, an exceptionally high charge to radius ratio (charge density) and tends to orient the water molecules in its vicinity. Contrarily, its hydrated radius is much larger than similar ions and the large solvation shell around the ion also causes its low mobility and low limiting conductivities λ^{∞} in solution.

The potassium ion has low charge densities and consequently ions are surrounded by water molecules which are more mobile. For the sodium ion the hydration number, h, obtained from transport process measurements, is reported in the literature as h (Na⁺, 298.15 K) = 5. The obtained hydrodynamic radii for the anions are ranked in Sal⁻ < Nap⁻ < Dic⁻ < Ibu⁻ what is not expected from their molar van der Waals volumes, V_{vdw} , calculated from the optimized geometries using the Winmostar program¹³ and summarized in Table 6.

Table 6. Van der Waals volumes, V_{vdw} , van der Waals radii, r_{vdw} , of the anions and the ratio between van der Waals radii and the hydrodynamic radii at 298.15 K.^a

	V_{vdw}	<i>r</i> _{vdw}	r_{vdw}/r_h
Sal ⁻	67.9	0.300	1.123
Nap⁻	125.1	0.367	0.973
Dic ⁻	137.4	0.379	0.828
Ibu [_]	119.2	0.362	0.532

^a Units: V_{vdw} , cm³ · mol⁻¹; r_{vdw} , nm

The van der Waals radii, r_{vdw} , were calculated assuming spherical shapes of anions and Walden rule treats the ionic migration as a movement of a rigid spherical ion through viscous continuum also. The structures of the investigated ions (Figure 1) hardly express the spherical symmetry. Therefore values listed in Tables 5 and 6 can be discussed only as the rough estimation of real dimensions of the drug's anions in water. Nevertheless, values of r_h and r_{vdw} for Sal⁻ and Nap⁻ are close together. It appears that no explicit hydration of these anions can be assumed.

Larger differences between r_h and r_{vdw} for Dic⁻ and Ibu⁻ may lead to the assumption that here the hydration is more pronounced. Despite the fact that chlorine and nitrogen atoms reduce the hydrophobicity of the radical in Dic⁻ anion the hydration can be predicted hardly even here. For Ibu⁻ possessing higly hydrophobic alkyl chain bound to the aromatic ring this is even less likely. Rather it can be assumed that the anions are more extended and the assumption of the spherical symmetry is far from more realistic dimensions obtained by Walden rule.

From Table 5 it is evident that r_h of Sal⁻ is almost temperature insensitive whereas at all other anions r_h is decreasing perceivably with increasing temperature. This again may lead to the conclusion that hydration – which is more pronounced at lower temperatures – may take place.

Finally, the hydrodynamic radii of Sal⁻ and Nap⁻ ions have been found to be smaller than 0.4 nm, a common pore size of membranes so that the direct passage of the drug through the pores of the membranes is possible. The opposite is true for the Dic⁻ and Ibu⁻ and these drugs probably penetrate by partition mechanism.

For Dic⁻ anion in acetontrile the value of $a_i^{(\eta)} = 0.521$ nm at 298.15 K has been found recently³ showing completely different interactions of this anion with the solvent. It is known that solvents forming three-dimensional networks (water, alcohols) surround hydrophobic organic ions in clathrate-like structures⁴ and therefore here the radii of complex organic anions are significantly different from that in organic solvents. Moreover, for the complex hydrophobic organic anions in aqueous solutions coiled configuration can be assumed.

The temperature-dependence of limiting conductivity yields Eyring's enthalpy of activation of charge transport¹⁴

$$\ln\lambda^{\infty} + \frac{2}{3}\ln d_s = -\frac{\Delta H^*}{RT} + \mathbf{B}, \qquad (6)$$

where B is the integration constant.

Values $\Delta H^* = 16.50$, 14.72, 17.40, 17.94, 19.02 and 19.03 kJ/mol for Na⁺, K⁺, Sal⁻, Nap⁻, Dic⁻and Ibu⁻, respectively, were obtained (Figure 4).

It has been shown that the ionic migration in a nonstructures solvent is very much a solvent property and that the difference in the mobilities of ions is simply the result of different ion sizes.^{14,15} The observed order of the molar ionic enthalpies of activation, ΔH^* , for the cations Na⁺ > K⁺ could be explained by the energy needed for the desolvation and rearrangement of water molecules in the vicinity of the ion. Thus values of ΔH^* may depend on the expressed hydration.

Differences in the Eyring's enthalpy of activation of charge transport of the investigated anions are ranked as Sal⁻< Nap⁻< Dic⁻ \approx Ibu⁻. They could not be ascribed to the differences in the ion sizes only ($r_h(\text{Dic}^-) < r_h(\text{Ibu}^-)$) but also to the specific interaction anions with water.

In water additional strong – hydrophobic – interactions are presented, resulting not only in the size parameters. Therefore it could be assumed that for the jump of the, for example, Ibu⁻ anion to a prepared vacancy in the solvent – or to produce such a vacancy – higher energy is required than for the Sal⁻ anion (and Nap⁻) or cations investigated in this work.

This could be explained by the repulsion of water molecules by the hydrophobic site of the anions and this part is larger at Dic⁻ and Ibu⁻ than at Sal⁻ and Nap⁻. The hydroxyl and ether group in the structure of Sal⁻ and Nap⁻, respectively, reduce the hydrophobicity of these anions obviously. Assuming substantial hydration of Dic⁻ the relatively high value of ΔH^* can be explained by the desolvation and rearrangement of water around the moving ion, whereas at Ibu⁻ the hydrophobicity is crucial.

Figure 4. Plot of $ln\lambda^{\infty} + 2/3 \ lnd_s$ as a function of 1/T for K⁺(\diamondsuit), Na⁺(\bigcirc), Sal⁻(\blacklozenge), Nap⁻(\bigtriangleup), Dic⁻(\bigtriangledown) and Ibu⁻(\blacklozenge) in water at 298.15 K. From the slope the activation energy of the ionic movement, ΔH^* , is obtained.

4. Conclusion

Nonsteroidal anti-inflammatory drugs sodium salicylate, naproxen sodium salt, diclofenac sodium salt, diclofenac potassium salt and ibuprofen sodium salt are completely dissociated in aqueous solutions. Their anions are weakly hydrated due to its hydrophobicity, whereas the hydration of cations depends on their charge densities.

From the Eyring's enthalpy of activation it could be assumed that the repulsion of water molecules by the hydrophobic site of the anion at Ibu⁻ is more pronounced than at Sal⁻ and Nap⁻, where hydroxyl group and/or ether group reduce the hydrophobicity of the anions. At Dic⁻ the hydration could also play an important role.

Despite the fact, that the mechanism of action of NSAIDs is not completely understood,¹ it could be expected that the observed differences should have an influence on their potency, duration of action and the way in which they are eliminated from the body. However, more investigations are needed to enlighten the correlation of their transport behaviour with their pharmacological properties.

5. Acknowledgement

Financial support by the Agency for Research and Development of Slovenia (ARRS) under grant P1-0201 is gratefully acknowledged. The author owes Professor Barthel a great debt of gratitude for all support and his continued interest in her work.

Povzetek

Izmerili smo električne prevodnosti vodnih raztopin salicilat, ibuprofen, diklofenak in naproksen natrijeve soli ter diklofenak kalijeve soli v temperaturnem območju med 278.15 K in 313.15 K v koncentracijskem obsegu $3 \times 10^{-4} < c (mol/dm^{-3}) < 0.007$. Na osnovi kemijskega modela smo določili vrednosti molskih prevodnosti pri neskončnem razredčenju, Λ^{∞} , ter konstante asociacije ionov, K_A , v posameznem sistemu. S pomočjo znanih vrednosti limitnih prevodnosti natrijevega oz. kalijevega iona smo ocenili limitne prevodnosti ter hidrodinamične radije vseh preiskovanih anionov. Ugotovili smo, da je delež ionskih parov v raztopini zanemarljiv in preiskovanim elektrolitom v vodnih raztopinah lahko pripišemo popolno disociacijo v celotnem obravnavanem temperaturnem območju. Opazno razliko v mobilnosti anionov lahko pripišemo različni hidrataciji ter možnim hidrofobnim interakcijam.
