The Crystal Structure of a Benzocyclopropapyran*

BY LLOYD J. GUGGENBERGER† AND ROBERT A. JACOBSON

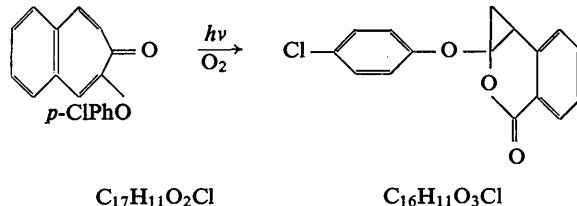

Institute for Atomic Research and Department of Chemistry, Iowa State University, Ames, Iowa U.S.A.

(Received 3 May 1968)

Crystals of 1a-(*p*-chlorophenoxy)-1a,7b-dihydrobenzo[*d*]cyclopropa[*b*]pyran-3(1*H*)one, $C_{16}H_{11}O_3Cl$, belong to the orthorhombic space group $P2_12_12_1$ with four molecules in a unit cell of dimensions $a=13.21$, $b=13.80$, and $c=7.33$, all ± 0.01 Å. The crystal structure was determined by a three-dimensional X-ray analysis of counter data using weighted Patterson superposition techniques and was refined by least-squares methods to a conventional *R* index of 6.9%. The combined benzene and lactone rings are nearly planar and the dihedral angles between this plane and the phenoxy group and cyclopropane ring are 64 and 70°, respectively.

Introduction

One of the photolysis products found by Stoner (1964) on the irradiation of 2-(*p*-chlorophenoxy)-4,5-benzotropone is 1a-(*p*-chlorophenoxy)-1a,7b-dihydrobenzo[*d*]cyclopropa[*b*]pyran-3(1*H*)one, $C_{16}H_{11}O_3Cl$.

* Work was performed at the Ames Laboratory of the U.S. Atomic Energy Commission. Contribution No. 2306.

† Present address: Central Research Department, E.I. du Pont de Nemours and Company, Wilmington, Delaware, U.S.A.

Elemental analysis indicated the loss of one carbon atom and addition of one oxygen atom; this, along with

spectral evidence, suggested that an unusual photochemical rearrangement had taken place. The crystal structure of $C_{16}H_{11}O_3Cl$ was determined to identify the photolysis product and to characterize its molecular configuration.

Experimental

Crystals of $C_{16}H_{11}O_3Cl$ were supplied by Dr O. L. Chapman of this Laboratory. The orthorhombic cell dimensions obtained from an average of values measured on the diffractometer and diffraction photographs recorded using Mo radiation are $a = 13.21 \pm 0.01$, $b = 13.80 \pm 0.01$, and $c = 7.33 \pm 0.01$ Å. The space group as determined from Weissenberg and precession diffraction photographs is $P2_12_12_1$ with $Z = 4$. The calculated density is 1.38 g.cm^{-3} ; the experimental density was not checked because of the small amount of sample available.

Diffraction intensities were collected on a General Electric XRD-5 diffractometer with Zr-filtered Mo radiation by use of the stationary-crystal stationary-counter technique with a peak count time of 40 seconds and a take-off angle of 8° . Intensity measurements were made with a scintillation counter and a pulse height selector on a crystal fragment of dimensions $0.30 \times 0.25 \times 0.20$ mm mounted with the a axis coincident with the φ axis of the diffractometer. A total of 1377 reflections were measured. Background measurements were taken in various regions of reciprocal space so an average background curve could be constructed and used in correcting all of the data.

Four strong reflections were carefully measured along 2θ to characterize the streaking effect due to noncharacteristic radiation. The assumption was made that the streaking observed on these reflections would be representative of all the data. An average streak curve was constructed so that streaking from reflections $n_i(hkl)$, of order n_i , between the origin of the reciprocal

lattice and some reflection $n(hkl)$, of order n , could be subtracted from the intensity observed for the reflection $n(hkl)$. The streak intensity, I_s , for a given reflection $n(hkl)$ was calculated by

$$I_s[n(hkl)] = \sum_{n_i} \frac{I[n_i(hkl)]L_p[n(hkl)]\cos\theta[n(hkl)]K(\lambda/\lambda_s)}{L_p[n_i(hkl)]\sin\theta[n(hkl)]},$$

where $n/2 < n_i < n$, and L_p and λ are the Lorentz-polarization factor and wavelength, respectively. The values of K were obtained from the average streak curve which was conveniently plotted as a function of λ/λ_s . This type of correction has been discussed previously by Williams & Rundle (1964).

A correction was applied to the data so that the peak height intensities would correspond to integrated intensities. A correction curve was calculated using the apparent source width, the 2θ separation of $K\alpha_1-K\alpha_2$, and the correction curve given by Alexander & Smith (1962). For molybdenum radiation with the large take-off angle used and small 2θ 's ($< 50^\circ$), this correction is small.

No absorption correction was applied because the linear absorption coefficient is small (2.8 cm^{-1}). The weights applied to the structure factors were calculated from the estimated errors in intensities after the method of Williams & Rundle (1964). Reflections for which F_o was less than $1.5\sigma(F_o)$ were called unobserved. About 700 reflections remained as observed reflections.

Structure determination and refinement

The structure was solved by Patterson superposition techniques used in conjunction with the minimum function. The Patterson synthesis was sharpened after the method of Jacobson, Wunderlich & Lipscomb (1961). The coordinates of 19 out of the 20 nonhydrogen atoms were read directly from the weighted

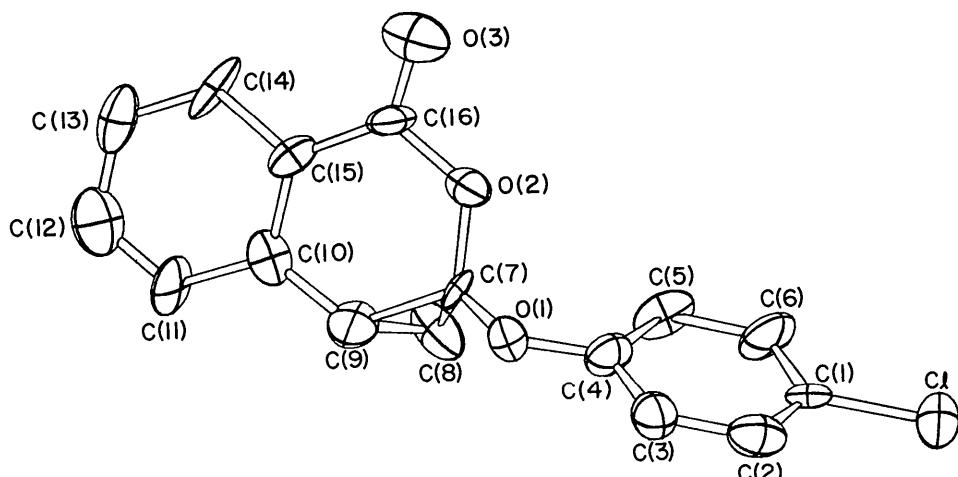

Fig. 1. The molecular configuration of $C_{16}H_{11}O_3Cl$.

$M_7(u)$ function. The $M_7(u)$ function was calculated by use of 3Cl-Cl vectors and 4Cl-O vectors where the 4Cl-O superpositions were weighted according to $Z_{\text{Cl}}/Z_{\text{O}}$. The procedure used here in the interpretation of the Patterson function has been described previously (Jacobson & Guggenberger, 1966; Jacobson, 1966).

After one cycle of least-squares the conventional reliability index was 0.30. Further study of the $M_7(u)$ map indicated that four of the phenoxy carbon atoms had been misplaced. After correcting these positions and locating the last nonhydrogen atom on an electron density map the refinement proceeded normally. An $R(\Sigma |F_o| - |F_c|)/\Sigma |F_o|$ of 0.135 was obtained on varying the isotropic thermal parameters. Since it was important to prove that an oxygen atom had been introduced by the photochemical reaction, the lactone oxygen, O(2), was replaced by a carbon atom and a cycle of least-squares run. The isotropic temperature factor of this atom went to -1.5, indicating that the oxygen assignment was correct. A cycle of least-squares with anisotropic thermal parameters was run after

excluding 9 reflections because of suspected errors resulting from incorrectly positioned angles in the data collection. Hydrogen atoms were then placed in their calculated positions, 1 Å from the associated carbon, which corresponded to peak positions in the electron density difference synthesis. The hydrogen atoms were assigned an isotropic temperature factor of 4.0 and their positions were not refined. A small correction was made in the weighting scheme since the average values of $w(|F_o| - |F_c|)^2$ in low $\sin \theta/\lambda$ regions were systematically too high (Cruickshank & Pilling, 1961). The form factors for all atoms were those of Hansen, Herman, Lea & Skillman (1964). Local least-squares and Fourier programs written by D.R. Fitzwater were used.

The refinement converged with a final R of 0.069 for the observed reflections and 0.171 for all reflections. The maximum peak in the final electron density difference map was 0.5 e.Å⁻³. The large R value for all the data results from the large block of weak high order, unobserved reflections. Although the data were meas-

Table 1. *Atomic coordinates and thermal parameters*

ured out to a maximum 2θ of 50° it is clear that most of the high order data from the crystal used were too weak to be considered observed. The relatively poor agreement for the unobserved data probably results from errors in estimating the backgrounds for many of these reflections. Some small background fluctuations were observed for different χ and ϕ instrument settings. Noteworthy here is the fact that the weighted R index, $\{\sum w(|F_o| - |F_c|)^2 / \sum w|F_o|^2\}^{1/2}$, for all the data is much better at 0.090. The lack of good high order data is also reflected to some extent in the errors in the atom positional parameters. It was not possible to obtain better statistics by choosing a different crystal, since the total available supply of this compound was five crystals and the best of these was chosen for this study. In retrospect it is clear that Cu radiation would have given us more usable data without increasing the absorption appreciably and hence would have been a better radiation choice.

The molecular configuration with the anisotropic thermal ellipsoids included (Johnson, 1965) is depicted in Fig. 1. The refined parameters and their standard deviations are given in Table 1. The calculated hydrogen atom positions are given in Table 2. The bond lengths and bond angles are given in Table 3. Estimated standard errors were calculated by use of the variance-covariance matrix and the program of Busing & Levy (1959). The observed and calculated structure factors are listed in Table 4 where asterisks are used to denote unobserved data.

Least-squares planes were calculated for several regions of the molecule. The equations of the least-squares planes and the displacements of the atoms from these planes are given in Table 5.

Discussion

The bond distances and angles are normal in view of the known molecular geometries of other organic compounds. The average benzene carbon-carbon distance is 1.39 Å. The cyclopropane distances found here are similar to those found in a recent structure determination (MacDonald & Trotter, 1965). The C(15)-C(16) distance is the same as that observed in salicylic acid (Sundaralingam & Jensen, 1965).

The C(4)-O(1)-C(7) angle of 115.6° suggests that O(1) is sp^2 hybridized; the driving force for this might be some electron delocalization with the benzene ring.

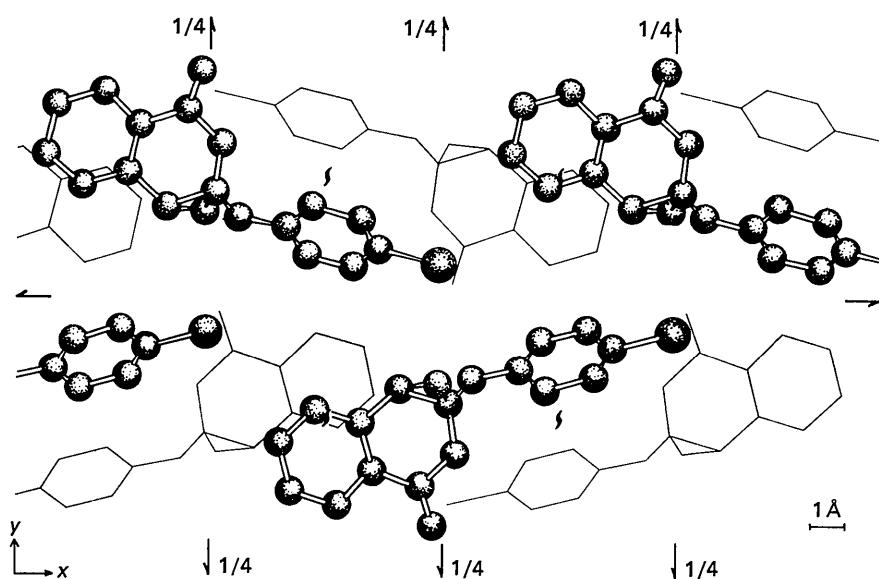

Fig. 2. Projection of the structure along the *c* axis. The shaded layer is *c*/2 above the unshaded layer.

Table 5. Molecular least-squares planes

Description of planes					
I	C(1), C(2), C(3), C(4), C(5), C(6)				
II	C(10), C(11), C(12), C(13), C(14), C(15)				
III	C(9), C(7), O(2), C(16), O(3), C(15), C(10)				
IV	C(9), C(7), O(2), C(16), O(3), C(15), C(10), C(11), C(12), C(13), C(14)				
V	C(7), C(8), C(9)				
Equations, relative to a, b, c					
I	$0.2413X + 0.7815Y - 0.5753Z - 5.231 = 0$				
II	$0.1439X + 0.0227Y + 0.9893Z - 4.299 = 0$				
III	$0.1976X + 0.0701Y + 0.9778Z - 5.030 = 0$				
IV	$0.1768X + 0.0561Y + 0.9826Z - 4.809 = 0$				
V	$-0.2094X + 0.9181Y + 0.3364Z - 6.484 = 0$				
Deviations	I	II	IV	IV	V
C(1)	0.01				
C(2)	-0.02				
C(3)	0.02				
C(4)	0.00				
C(5)	-0.01				
C(6)	0.01				
C(7)		-0.02			
C(8)			0.00		
C(9)			0.00	-0.04	
C(10)		-0.01	0.02	-0.02	
C(11)		-0.01		0.04	
C(12)		0.03		0.08	
C(13)		-0.02		-0.03	
C(14)		-0.01		-0.07	
C(15)		0.02	-0.02	-0.04	
C(16)			0.00	0.02	
O(2)			0.02	0.05	
O(3)			0.00	0.04	

The p_z orbital on O(1) makes an angle of 20.4° with the normal of the phenoxy ring, [plane I]. The C–O distances for O(1) also compare favorably with those involving O(2) in the lactone ring.

It is evident from the deviations in Table 5 that the combined benzene and lactone rings (plane IV) are nearly planar. This plane is tilted 10.7° out of the $x-y$ plane. The angle between the phenoxy plane (I) and the molecular plane (IV) is 64.4° . The cyclopropane ring makes an angle of 69.8° with the molecular plane.

The thermal parameters, U_{ij} , could not be interpreted satisfactorily in terms of rigid-body translational and librational motion. The eight atom phenoxy group was treated as one rigid body and the rest of the molecule as a second rigid body and the center of motion was varied for both groups. Although no good fit could be obtained between the observed and calculated U_{ij} values, several general conclusions could be drawn. The translational oscillations for both groups were not markedly anisotropic; neither were the librational oscillations of the second group. The root mean square librational amplitude of the phenoxy group about the C(1)–C(4) direction was about 7° .

The intermolecular contacts are of the normal van der Waals type. The molecular packing is illustrated in Fig. 2. The shortest non-hydrogen contact is 3.35 \AA and involves C(12) and C(9) on a neighboring molecule. The C(12) atom showed the largest deviations from the least-squares planes and the largest r.m.s. vibrations in the bonding directions. The C(12) atom has probably

been slightly misplaced in this refinement as evidenced by the short C(11)–C(12) distance. This distance remained essentially the same throughout the refinement and probably results from some systematic error in the data. A correction for librational motion increases this bond length by only 0.01 \AA .

We wish to thank Dr A. Schlueter for help with some of the computational aspects of this work.
