## The Structure of *trans-p,p'*-Dichloroazobenzene

BY HÅKON HOPE AND DILNA VICTOR\*

Department of Chemistry, University of California, Davis, California 95616, U.S.A.

(Received 18 November 1968)

Crystals of *trans-p,p'*-dichloroazobenzene are monoclinic, space group  $P2_1/c$ ,  $a=9.817(5)$ ,  $b=4.708(2)$ ,  $c=11.710(3)$  Å,  $\beta=91.12(5)^\circ$ , with two molecules in the unit cell. Intensity data (Cu  $K\alpha$ ) were obtained with a Picker automatic diffractometer. The structure was refined to  $R=0.049$  for 941 observed reflections. The centrosymmetric molecules are nearly planar. A slight deviation from planarity is discussed. Observed bond distances are: N=N, 1.252; C-N, 1.443; C-Cl, 1.737 Å ( $\sigma \sim 0.005$  Å). Observed angles: N=N-C, 112.6°; N-C-C (*cis* relative to N=N), 125.9°; C-C(Cl)-C, 121.7°.

### Introduction

Earlier reports of structure determinations of aromatic azo compounds include the crystal structures of *trans*-azobenzene (Brown, 1966a), *trans*-azotoluene (Brown, 1966b), *trans*-4,4'-azopyridine N-oxide (Eichhorn, 1959), and *trans-p,p'*-dibromoazobenzene (Amit & Hope, 1966). The structures of azobenzene and azotoluene are disordered, making it difficult to obtain accurate results, and the reported standard deviations for distances in the other two compounds are rather large (0.015–0.02 Å).

Since dichloroazobenzene was known to be chemically stable, and since the Cl atoms were expected not to be too heavy to preclude a fairly accurate determination of the parameters for the other atoms, we felt that a structure determination of *trans-p,p'*-dichloroazobenzene might provide more reliable data for the geometry of the azo group.

### Experimental and structure determination

*trans-p,p'*-Dichloroazobenzene was prepared by oxidation of *p*-chloroaniline with sodium perborate in acetic acid (Mehta & Vakilwala, 1952). Crystals were obtained without recrystallization in the form of thin,

brittle, orange needles. Oscillation and Weissenberg photographs taken with Cu  $K\alpha$  radiation at room temperature showed monoclinic symmetry, with  $b$  parallel to the needle axis. The systematically absent reflections are  $h0l$  with  $l$  odd and  $0k0$  with  $k$  odd, uniquely indicating the space group  $P2_1/c$ . Preliminary cell dimensions obtained from the photographs suggested the compound to be nearly isomorphous with azotoluene (Brown, 1966b) and a survey of the intensity distribution in the  $h0l$  zone gave further indication of this.

Since azotoluene was known to be disordered we decided not to collect a full three-dimensional data set unless *p,p'*-dichloroazobenzene was found not to exhibit disorder. The intensities of the  $h0l$  reflections below  $2\theta = 133^\circ$  were therefore measured rapidly using a Picker automatic diffractometer, and the  $x$  and  $z$  parameters for the Cl atom were determined from a sharpened Patterson function. A Fourier synthesis based on the Cl phases clearly showed the C and N atoms, with no indication of disorder. One cycle of least-squares refinement of the  $x$  and  $z$  parameters and individual isotropic temperature factors gave an  $R$  index of 0.17.

Cell dimensions determined by a least-squares procedure from diffractometer angle measurements are  $a = 9.817(5)$ ,  $b = 4.708(2)$ ,  $c = 11.710(3)$  Å,  $\beta = 91.12(5)^\circ$  [ $\lambda(\text{Cu } K\alpha_1) = 1.54051$  Å,  $t = 23^\circ\text{C}$ ]. The observed density is 1.55 g.cm<sup>-3</sup>, and the calculated density is 1.54 g.cm<sup>-3</sup>, for two molecules per unit cell. (Indexed as azotoluene the cell dimensions would be  $a = 11.710$ ,  $b = 4.708$ ,  $c = 9.817$  Å and  $\beta = 88.88^\circ$ .)

Three-dimensional intensity data were recorded on the automatic diffractometer with Ni-filtered Cu  $K\alpha$  radiation. The crystal, of dimensions  $0.04 \times 0.07 \times 0.2$  mm, was mounted with its long direction (**b**) along the diffractometer  $\varphi$  axis. The intensities of 1115 unique reflections with  $2\theta$  less than  $160^\circ$  were measured with the  $2\theta-\theta$  technique at a scan speed of  $0.5^\circ \text{ min}^{-1}$ , with the scan range given by  $[2\theta(\alpha_1) - 1.1^\circ] - [2\theta(\alpha_2) + 1.1^\circ]$ . Background counts were taken for 100 sec at each end of the scan range. Automatic attenuators were used to keep the count rate below 10,000 c.p.s. The intensities of two check reflections (102 and 106) were measured

every 10 hours; all deviations from the means were less than  $\pm 2\%$ .

Corrections were made for Lorentz and polarization effects, but not for absorption or secondary extinction. (With an absorption coefficient of  $51 \text{ cm}^{-1}$  the maxi-

imum and minimum  $\mu r$  will be about 0.18 and 0.10 respectively for the given crystal mounting.) Reflections for which the net intensity was less than three times its standard deviation (counting statistics) were recorded as 'unobserved' with the recorded value of  $I_{\text{obs}}$  equal to the larger of  $I_{\text{net}}$  and  $0.7\sigma(I_{\text{net}})$ . The number of 'observed' reflections is 941.

The positional parameters already obtained from the (*x,z*) projection of *p,p'*-dichloroazobenzene were found to correspond closely to those of the azotoluene position designated 'molecule rotated through  $-5.0^\circ$ ' (Brown, 1966*b*), after the transformation  $x=z'$ ,  $y=y'$ ,  $z=0.5-x'$ . As initial *y* parameters for C and N atoms we therefore used those given for azotoluene, while the *y* parameter for Cl was estimated, assuming the Cl atom to be coplanar with the benzene ring and the C-Cl distance to be 1.74 Å.

These parameters, together with the isotropic temperature factors from the two-dimensional least-squares results, gave an initial *R* index of 0.24. One least-squares cycle lowered *R* to 0.15. Anisotropic temperature factors for the 'heavy' atoms were then introduced, and the hydrogen atoms were placed in 'calculated' positions. The refinement was concluded with a final *R* index of 0.049 after three additional least-squares cycles where all parameters (including individual isotropic temperature factors for hydrogen) were adjusted. The largest shift in the final cycle corresponds to 6% of the corresponding estimated standard deviation.

The final positional and thermal parameters are given in Tables 1 and 2 respectively. Observed and calculated structure factors are listed in Table 3.

The Fourier program used was written by H. Hope. Least-squares refinement was run with a program essentially the same as ACA computer program No. 317, written by P. K. Gantzel, R. A. Sparks, and K. N. Trueblood. The program minimizes the weighted sum of the squares of  $\Delta F$  by a full-matrix routine. The weighting scheme used was that of Hughes (1941) with  $4F_0$  (min)=6.6. The atomic form factors were those of

Hanson, Herman, Lea & Skillman (1964). The isotropic temperature factors are of the form  $\exp(-B \sin^2 \theta/\lambda^2)$  and the anisotropic of the form  $\exp[-(h^2\beta_{11}+k^2\beta_{22}+l^2\beta_{33}+hk\beta_{12}+hl\beta_{13}+kl\beta_{23})]$ . The *R* index is defined as  $R=\sum |F_0|-|F_c|/\sum |F_0|$  including observed reflections only. Standard deviations were obtained from the inverse of the normal equation matrix.

### Description of the structure

Projections of the structure along **a** and **b** are shown in Fig. 1. Bond distances and angles calculated from the positional parameters in Table 1 are given in Fig. 2. A 'rigid body' analysis of the thermal motion was carried out (Schomaker & Trueblood, 1968). The major libration axis coincides with the long axis of the molecule, the corresponding root mean square amplitude being  $4.5^\circ$ . The r.m.s. difference between 'observed' and 'calculated' amplitude parameters is 0.004 Å<sup>2</sup>, indicating that the rigid body approximation is fairly reasonable. Based on the rigid body model, corrected distances and angles were calculated (Cruickshank, 1961). The corrections were small, with none exceeding two estimated standard deviations; the results are therefore not given in full.

The geometry of the azo group is quite similar to that reported earlier. In *trans*-*p,p'*-dichloroazobenzene we find an N=N distance of 1.252 Å ('corrected' 1.255 Å), compared to 1.243 Å in *trans*-azobenzene (Brown, 1966*a*) 1.244 Å in *trans*-azotoluene (Brown, 1966*b*), 1.23 Å in *trans*-4,4'-azopyridine-*N*-oxide (Eichhorn, 1959) and 1.276 Å in *trans*-*p,p'*dibromoazobenzene (Amit & Hope, 1966).

The N=N distance in aromatic azo compounds thus seems to be close to (or perhaps slightly longer than) the distance estimated from the sum of the covalent bond radii (1.24 Å; Pauling, 1960) and certainly longer than the N=N distance in the difluorodiazines (Bohn, 1964; Kuczkowski & Wilson, 1963). The angles N=N-C(5) and N-C(5)-C(4) (112.6 and 125.9° respec-

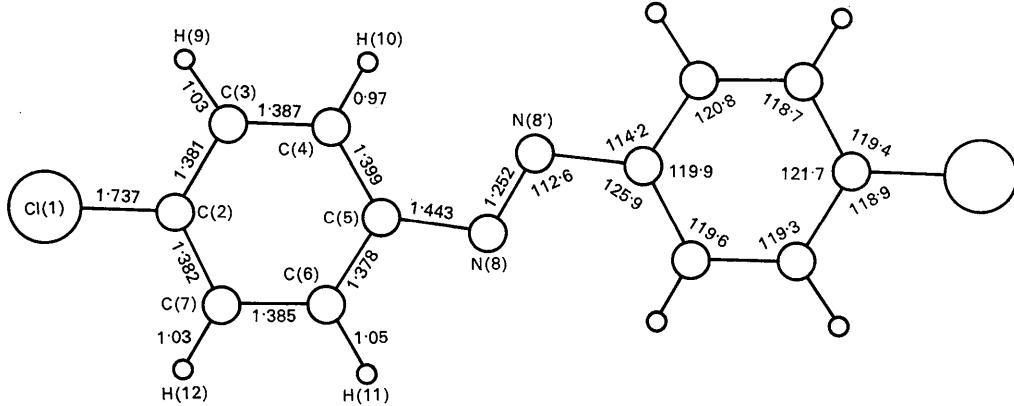

Fig. 2. Bond distances and angles. Estimated standard deviations are 0.004–0.005 Å for distances not involving H, 0.04 Å for C–H distances and 0.3–0.4° for angles not involving H.

tively) are very similar to those found in *p,p'*-dibromoazobenzene ( $112.2^\circ$  and  $125.6^\circ$  respectively). The C–N distance ( $1.443 \text{ \AA}$ ) is nearly the same as the corresponding distance in *p,p'*-dibromoazobenzene ( $1.428 \text{ \AA}$ ). Five of the distances in the benzene ring are very similar, with an average of  $1.384 \text{ \AA}$  (somewhat less than the accepted value of  $1.396 \text{ \AA}$ ) whereas the distance C(4)–C(5), (*cis* to the azo group) is  $1.399 \text{ \AA}$ . The apparent lengthening of this bond relative to the others in the ring may not be significant, but we note that in the benzene rings in *p,p'*-dibromoazobenzene the corresponding distance is also somewhat longer than the other five. The C–Cl distance ( $1.737 \text{ \AA}$ ) is normal (Palenik, Donohue & Trueblood, 1968). The internal angle at C(2), to which Cl is attached, is larger than  $120^\circ$ , in agreement with earlier observations for electron-withdrawing substituents (Carter, McPhail & Sim, 1966; Hope, 1969).

The ‘best’ plane through the entire molecule (defined by the non-hydrogen atoms) has the equation  $-6.230x + 3.420y + 3.229z = 1.615 (\text{\AA})$ . Individual deviations from this plane are (in  $\text{\AA}$ ): Cl(1),  $-0.046$ ; C(2),  $-0.002$ ; C(3),  $0.027$ ; C(4),  $0.028$ ; C(5),  $0.023$ ; C(6),  $0.021$ ; C(7),  $0.009$ ; N(8),  $0.012$ . It is seen that the molecule shows a slight trend towards an ‘S’ shape, with the Cl atoms being displaced from the ring plane by about  $0.05 \text{ \AA}$ , or more than  $50\sigma$ . As indicated by the equation of the molecular plane, the perpendicular distance between the rings packed along **b** is near the normal distance of  $3.4 \text{ \AA}$  for aromatic rings. The shortest distance between Cl(1) and a C atom of a neighboring ring (along **b**) is  $3.65 \text{ \AA}$ , in excess of the van der Waals distance. This means that the ring is locked in place, while the Cl atom has some freedom to move in a direction perpendicular to the

molecular plane. An inducement to do so is provided by a Cl–Cl packing contact. The distance between Cl(1) and Cl at  $1-x, \frac{1}{2}+y, \frac{1}{2}-z$  is  $3.49 \text{ \AA}$ , or about  $0.1 \text{ \AA}$  shorter than the sum of the van der Waals radii ( $3.60 \text{ \AA}$ ); and significantly, the chlorine atom making the contact with Cl(1) is situated on the positive side of the plane given above, while Cl(1) is displaced towards the negative side.

This study has been supported through NSF grant GP-6635.

## Etude par Diffraction de Neutrons à $0.31^\circ\text{K}$ de la Structure Antiferromagnétique des Grenats d’Aluminium-Terbium et d’Aluminium-Holmium

PAR J. HAMMANN

Service de Physique du Solide et de Résonance Magnétique, Centre d’Etudes Nucléaires de Saclay,  
BP 2, 91, Gif-sur-Yvette, France

(Reçu le 22 novembre 1968)

The crystallographic and magnetic structures of the terbium-aluminum and holmium-aluminum garnets have been determined by neutron diffraction measurements at room temperature, at  $4.2^\circ\text{K}$  and  $0.31^\circ\text{K}$ . The terbium-aluminum garnet undergoes an antiferromagnetic transition at  $1.35^\circ\text{K}$  with an effective magnetic moment of  $5.7 \mu_B$  at  $0^\circ\text{K}$ . The holmium-aluminum garnet shows the same antiferromagnetic ordering with a transition temperature of approximately  $0.95^\circ\text{K}$  and an effective moment of  $5.8 \mu_B$  at  $0^\circ\text{K}$ .

Les grenats d’aluminium-terbium (TbAlG) et d’aluminium-holmium (HoAlG) présentent à très basse température un ordre antiferromagnétique mis en évidence

par des mesures de susceptibilité (Cooke, Thorp & Wells, 1967). Ces mesures donnent des températures de transition de  $0.85^\circ\text{K}$  pour HoAlG et de  $1.35^\circ\text{K}$  pour
