

The Crystal Structure of 2'-Iodobiphenyl-4-carboxylic Acid

By H. H. SUTHERLAND

Physics Department, The University, Hull, England

(Received 30 May 1969)

The crystal structure of 2'-iodobiphenyl-4-carboxylic acid, $C_{13}H_9O_2I$, has been determined from three-dimensional X-ray diffraction data. The crystals are triclinic, space group $P\bar{1}$, with unit-cell dimensions $a=4.15$, $b=7.73$, $c=17.79$ Å, $\alpha=99^\circ 4'$, $\beta=91^\circ 23'$, $\gamma=97^\circ 34'$. The structure, which consists of centrosymmetrical hydrogen-bonded dimers, was refined by block-diagonal least-squares refinement with anisotropic thermal parameters to a residual of 9% for the 1758 observed structure factors. The angle between the two phenyl rings and the angle between the carboxyl group and the phenyl ring to which it is attached were found to be 51.3 and 5.2° respectively.

Introduction

X-ray analyses of several simple derivatives of biphenyl with 2 and 2' fluorine or chlorine substitutions have been shown to have interplanar angles of around 48°. As biphenyl in the solid phase is planar (Dhar, 1932; Trotter, 1961; Hargreaves & Rizvi, 1962) it was of interest to determine the interplanar angle with iodine in the 2' substituted position as this angle would be expected to be greater than that obtained for the chlorine derivatives. This paper describes the crystal and molecular structure of 2'-iodobiphenyl-4-carboxylic acid, the sixth in a series of related compounds being investigated by the author.

Experimental

2'-Iodobiphenyl-4-carboxylic acid was crystallized from toluene, producing transparent platelets. The observed density at 17°C was measured by the method of flotation using aqueous cadmium n-dodecatungstaborate.

Crystal data

$C_{13}H_9O_2I$	$M = 324.1$	triclinic
$a = 4.15 \pm 0.01$	$b = 7.73 \pm 0.01$	$c = 17.79 \pm 0.02$ Å
$\alpha = 99^\circ 4' \pm 5'$	$\beta = 91^\circ 23' \pm 5'$	$\gamma = 97^\circ 34' \pm 5'$
$U = 558.1$ Å ³	$D_m = 1.90$ g.cm ⁻³	$D_c = 1.93$ g.cm ⁻³
$Z = 2$	$F(000) = 312$	$Cu K\alpha (\lambda = 1.5418$ Å)

No absent spectra: space group $P\bar{1}$ (no. 2)

In order to minimize absorption effects a crystal of approximately square cross section was chosen for intensity data collection about the a axis. Data for the $0kl$, $1kl$, $2kl$, $3kl$ and $h0l$ levels of reciprocal space were collected by the multiple-film equi-inclination Weissenberg technique, using $Cu K\alpha$ radiation. The $h0l$ intensity data were collected using a crystal cut from one of the platelets.

Intensities of the spots were measured on a Joyce-Loebl Flying Spot Densitometer. The data were brought to the same arbitrary scale and finally on to an approximately absolute scale by applying the method of Wilson (1942) to the $0kl$ level.

Determination and refinement of the structure

The $0kl$ projection of the unit cell was solved from the sharpened Patterson projection and refined by a combination of electron density distribution and block-diagonal least-squares to a residual of $R=0.10$ where $R=\sum|F_0|-|F_c|/\sum|F_0|$. The calculations were carried out on an Elliot 803B computer using the programs of Daly, Stephens & Wheatley (1963).

The $h0l$ projection of the Patterson function gave provisional x coordinates for the atoms.

A structure factor calculation using full three-dimensional data gave a residual of $R=0.22$. For this the average value of $F(hkl)$ and $F(\bar{h}\bar{k}\bar{l})$ was used. The scattering factor for iodine was taken to be $f=\{(f_0+f')^2 + 4f''^2\}^{1/2}$ where f_0 is the scattering factor appropriate to a wavelength far from an absorption edge, f' is the real part of the correction due to anomalous scattering and $4f''$ is the imaginary part of the correction term. Due to the poor quality of the crystals it was decided to use this throughout this investigation.

The structure was refined by two cycles of three-dimensional electron density distributions and structure factor calculations and thereafter by block-diagonal least squares applied to positional parameters, overall scale factor and individual isotropic thermal parameters, to a residual of $R=0.13$. After three cycles incorporating anisotropic thermal parameters defined as $\exp[-2\pi^2(U_{11}h^2a^{\ast 2} + U_{22}k^2b^{\ast 2} + U_{33}l^2c^{\ast 2} + 2U_{23}klb^{\ast}c^{\ast} + 2U_{31}lh c^{\ast}a^{\ast} + 2U_{12}hk a^{\ast}b^{\ast})]$ (Cruickshank, Pilling, Bujsa, Lovell & Truter, 1961), a three-dimensional difference electron density distribution was calculated; this showed regions of density at the positions where the eight hydrogen atoms attached to the phenyl rings would be expected and a region of density between the oxygen atoms involved in the hydrogen bonding indicating that the hydrogen was probably attached to O(1).

During the subsequent refinement the hydrogen atoms were fixed at distances of 1.08 Å for those attached to the phenyl rings and at 0.97 Å for that bonded to O(1). Individual scale factors for the batches of data were included in the refinement and a weighting scheme,

STRUCTURE OF 2'-IODOBIPHENYL-4-CARBOXYLIC ACID

$$w = 1/\left\{2|F_{\min}| + |F_0| + \frac{2|F_0|^2}{|F_{\max}|} + \frac{5|F_0|^3}{|F_{\max}|^2}\right\},$$

employed. The final residual for the observed reflexions was $R=0.09$. A final three-dimensional electron density distribution and a difference electron density distribu-

STRUCTURE OF 2'-IDOBIPHENYL-4-CARBOXYLIC ACID

was obtained from a *c*-axis photograph but because of the poor crystal shape was not included in the refinement. Table 2 gives the heavy atom coordinates and Table 3 their thermal parameters. The hydrogen atom

parameters are quoted in Table 4. The numbering of the atoms in the molecule and the arrangement of the molecules in the unit-cell viewed along the *a* axis are shown in Fig. 1. All intermolecular contacts of less

Table 1 (cont.)

Discussion

The angle of $51.3 \pm 1.2^\circ$ between the two phenyl rings is smaller than had been expected if a simple treatment of setting the I to H(12) distance equal to the sum of their respective van der Waals radii is used. A similar discrepancy has been observed in the case of 2'-chlorobiphenyl-4-carboxylic acid (Sutherland, 1969), 4-acetyl-2'-chlorobiphenyl (Sutherland & Hoy, 1968), and 2-chlorobiphenyl-4-carboxylic acid (Sutherland & Hoy, 1969).

In common with these structures not only is there a rotation of one ring with respect to the other by an angle φ_1 about C(1)—C(7) but also two other rotations, which are a rotation φ_2 of the ring C(1)—C(6) about an axis which is in the plane of that ring and passes through C(1) perpendicular to C(1)—C(7) and a rotation φ_3 of ring C(7)—C(12) about an axis which is in the plane of that ring and passes through C(7) perpendicular to C(1)—C(7), the notation used being that of Chawdhury, Hargreaves & Sullivan (1968).

In the present structure the angles φ_2 and φ_3 are respectively 2.5 ± 0.7 and $1.7 \pm 0.7^\circ$. The angle φ_2 is somewhat larger than the values of 0.4 and 0.5° in 2'-chlorobiphenyl-4-carboxylic acid and 4-acetyl-2'-chlorobiphenyl respectively. In the case of 2'-chlorobiphenyl-4-carboxylic acid the Cl—C(2) bond was displaced out of the plane of the biphenyl ring C(1)—C(6) by 1.8° . No significant displacement was observed in the case of the I—C(2) bond and this may account for the increased value of φ_2 . The I—C(2) bond length of 2.122 ± 0.017 Å is possibly significantly longer than the value of 2.05 ± 0.01 Å quoted in *International Tables for X-ray Crystallography* (1962).

The C(1)—C(7) bond length of 1.519 ± 0.023 Å is similar to that of 1.502 ± 0.010 Å for 2'-chlorobiphenyl-4-carboxylic acid and 1.506 ± 0.017 Å for biphenyl (Hargreaves & Rizvi, 1962) and is not significantly different from the biphenyl bond lengths of 1.487 ± 0.010 Å in 2-chlorobiphenyl-4-carboxylic acid, 1.490 ± 0.010 Å in 4-acetyl-2'-chlorobiphenyl and 1.479 ± 0.010 Å in 4-acetyl-2'-fluorobiphenyl.

The exocyclic C(10)—C(13) bond was found to be 1.462 ± 0.028 Å. Neither the C(1)—C(7) bond nor the C(10)—C(13) bond differ significantly from the theoret-

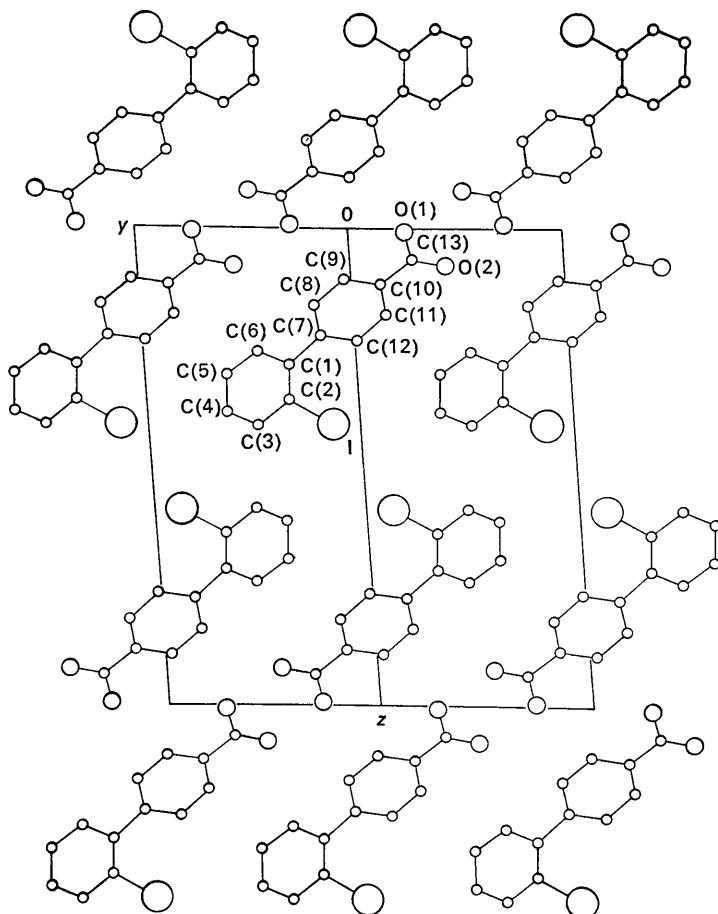

Fig. 1. The arrangement of the molecules in the unit-cell viewed along the α axis.

ical value of 1.477 \AA quoted by Dewar & Schmeising (1959) and Cruickshank & Sparks (1960) for the (sp^2) single-bond length between trigonally linked carbon atoms.

The carboxyl group is rotated about the C(10)-C(13) bond through an angle φ_4 of $5.2 \pm 1.3^\circ$. Associated with this is a second rotation φ_5 of the group C(10), C(13), O(1) and O(2) about an axis which is in the plane of that group and passes through C(10) perpendicular to C(7)-C(10). The angle of φ_5 was found to be $4.8 \pm 0.8^\circ$. These are comparable with the angles of 5.6 and 7.1° for φ_4 and φ_5 respectively obtained for 2'-chlorobiphenyl-4-carboxylic acid.

In the solid phase biphenyl is planar. The introduction of an iodine atom in the 2' position causes a strain which results in a twisting of the rings about the biphenyl bond, φ_1 , together with the additional small rotations of φ_2 and φ_3 . It is probable that there is a relayed steric effect which results in the rotation and displacement of the carboxyl group. Similar effects have been observed in other 2, 2' and 3' halogen derivatives of biphenyl investigated by the author.

The C(13)-O(1) bond of $1.264 \pm 0.026 \text{ \AA}$ and the C(13)-O(2) bond of $1.250 \pm 0.026 \text{ \AA}$ were respectively

shorter and longer than had been expected. The bond lengths are similar to those obtained in 2'-chlorobiphenyl-4-carboxylic acid of 1.289 ± 0.010 and $1.261 \pm 0.010 \text{ \AA}$ respectively.

The O-H...O bond of 2.60 \AA , which is the shortest intermolecular distance, is similar to the values quoted for 2-chlorobiphenyl-4-carboxylic acid of 2.62 \AA and orthochlorobenzoic acid of 2.63 \AA (Ferguson & Sim, 1961). The bond angles C(10)-C(13)-O(1), C(10)-C(13)-O(2) and O(1)-C(13)-O(2) are comparable with those found in similar compounds.

The author wishes to thank Dr P. J. Wheatley and Monsanto Research S. A. for kindly providing the least-squares and Fourier programs, Dr G. W. Gray for providing the crystals used in the investigations, and the S.R.C. for the provision of a grant to purchase the Joyce-Loebl Flying Spot Densitometer.

Crystallography of the Silver-Rich Rare-Earth-Silver Intermetallic Compounds

BY O. D. McMASTERS, K. A. GSCHNEIDNER, JR AND R. F. VENTEICHER

Institute for Atomic Research and Department of Metallurgy, Iowa State University, Ames, Iowa 50010, U.S.A.

(Received 8 July 1969)

The crystal structures of the silver-rich compounds in the rare-earth-silver systems were determined by means of X-ray powder diffraction methods. Metallographic methods were used to confirm the stoichiometries. The low temperature form of LaAg₅ crystallizes in a 'substituted' MgZn₂ (C14) type Laves-phase structure. The high temperature polymorph of LaAg₅ and the phases CeAg₅, PrAg₅ and YbAg₅ were found to be isotypic but the crystal structure was not established. EuAg₅ crystallizes in the CaCu₅ (D2_a) type structure; LuAg₄ and ScAg₄ of the MoNi₄ (D1_a) type were found. R₁₄Ag₅₁ phases of the Gd₁₄Ag₅₁ type exist for R=Y, La, Ce, Pr, Nd, Sm, Gd, Tb, Dy, Ho and Er. Yb₂Ag₇ crystallizes in the Ca₂Ag₇ type structure. TmAg₃ was found to exist in both the AuCu₃ (L1₂) type and the TiCu₃ (D0₆) type structures. The crystallographic data for these phases are given and their structural relationships are discussed.

Introduction

During an investigation of the solubility limits of the rare earths in silver, it became necessary to determine the stoichiometry of the first silver-rich compound in the rare-earth-silver systems (Gschneidner, McMasters, Alexander & Venteicher, 1970). Since most of these compounds are new, their structural properties and crystallographic data were determined and are the subject of this paper.

All of the rare earths except europium form the RAg compound with the cubic CsCl (B2) type structure. These phases have been studied by several investigators and most of their results are given in Pearson (1967) and McMasters & Gschneidner (1964). For YbAg and YAg the data are given by Moriarty, Humphreys, Gordon & Baenziger (1966). Iandelli & Palenzona (1969) have shown that YbAg crystallizes in both the CsCl and FeB type structures. Köster & Meixner (1965) reported that EuAg exists but the structure was not established.

For R=La, Ce, Pr, Nd, Eu and Yb the phase RAg₂ crystallizes in the orthorhombic CeCu₂ (KHg₂) type structure according to Iandelli & Palenzona (1968) and Köster & Meixner (1965) in the case of EuAg₂. For R=Gd, Tb, Dy, Ho, Er, Tm, Lu, Sc and Y the

RAg₂ phase of the tetragonal MoSi₂ (C11_b) type structure has been reported by several investigators: Baenziger & Moriarty (1961), Moriarty, Gordon & Humphreys (1965), Dwight, Downey & Conner (1967), Kusma & Laube (1965), Ferro, Capelli, Borsese & Delfino (1967), Iandelli & Palenzona (1968), and Steeb, Godel & Lohr (1968). Different structures have been reported for SmAg₂ by Iandelli & Palenzona (1968), for YbAg₂ by Moriarty, Humphreys, Gordon & Baenziger (1966), and for YAg₂ by Gebhardt, von Erdberg & Lütz (1964).

The structure data for the RAg₃ phases reported by Steeb, Godel & Lohr (1968) and Donalato & Steeb (1969) will be discussed later in connection with the results of our investigation.

Lattice parameters and structure types for Yb₅Ag₃ (Cr₅B₃ type) and Yb₃Ag₂ (U₃Si₂ type) were determined by Iandelli & Palenzona (1969). Palenzona (1967) and Köster & Meixner (1965) reported EuAg₅ as being of the hexagonal CaCu₅ (D2_a) type structure. The latter also reported that the phases EuAg₄ and Eu₅Ag₃ exist but did not determine the structures.

Experimental procedures

The purity of the metals used in this investigation and alloy preparation procedures are described by Gschnei-
