The Crystal Structures of Free Radical Salts and Complexes. III.
(N,N'-Dibenzyl-4,4'-bipyridylium)²⁺-(7,7,8,8-Tetracyanoquinodimethane)₄²⁻

BY T. SUNDARESAN AND S. C. WALLWORK

Department of Chemistry, University of Nottingham, England

The 4:1 complex formed between tetracyanoquinodimethane (TCNQ) and dibenzylbipyridylium (DBBP) crystallizes in the triclinic system with the space group $P\bar{1}$ and lattice constants $a = 7.15$, $b = 16.82$, $c = 12.10$ Å, $\alpha = 99.5°$, $\beta = 83.8°$, $\gamma = 91.8°$ and having $Z = 1$. The structure was solved by Patterson methods and refined by block-diagonal least squares using 1936 reflexions measured on a linear diffractometer. The four TCNQs are packed plane-to-plane to form a column along the b axis. The characteristic overlap and short interplanar spacings indicate charge transfer interaction between the four TCNQ moieties stacked as tetramers.

Introduction

Molecular complexes containing TCNQ ions and molecules include some of the best electrically conducting organic compounds known. TCNQ is a powerful electron acceptor and forms $TCNQ^{\dot-}$ by accepting an additional electron. The $TCNQ^{\dot-}$ forms simple salts with cations of many types and complexes containing neutral TCNQ in addition to $TCNQ^{\dot-}$. These complexes of the type $M^+TCNQ^{\dot-}$ TCNQ have been found to exhibit higher electrical conductivity than most simple salts M^+TCNQ^-. In most crystal structure determinations of this type of complex the TCNQs have been found to be indistinguishable moieties with a formal charge $\frac{1}{2}-$. The 4:1 TCNQ DBBP complex salt is a member of the same series of complexes since it has equal numbers of $TCNQ^0$ and $TCNQ^{\dot-}$. Its structure determination was undertaken to see how it is related structurally to M^+ $TCNQ^{\dot-}$ $TCNQ^0$ complexes and in general to provide data for relating structures to conductivity.

Experimental

Crystal data

$(C_{24}H_{22}N_2)$ $(C_{12}H_4N_4)_4$, M.W. 1155·2.
Triclinic,
$a = 7.15 \pm 0.03$, $b = 16.82 \pm 0.04$, $c = 12.10 \pm 0.04$ Å,
$\alpha = 99.5 \pm 0.1°$, $\beta = 83.8 \pm 0.1°$, $\gamma = 91.8 \pm 0.5°$;
$U = 1422.8$ Å³;

$D_m = 1.341$ g.cm⁻³, $Z = 1$, $D_c = 1.348$ g.cm⁻³,
$F(000) = 596$.
Mo $K\alpha$ $(\lambda = 0.7107$ Å$)$, $\mu = 0.91$ cm⁻¹.
Space group $P\bar{1}$ (assumed).

Black plate-like crystals of the complex were deposited when equimolar solutions of Li^+TCNQ^- and TCNQ were dissolved in a minimum qunatity of hot acetonitrile, and added to a concentrated solution of DBBP Cl_2 in water, the mixture being allowed to cool very slowly. The space group and the cell constants were obtained initially from oscillation and Weissenberg photographs taken with the crystals rotating about all the three crystallographic axes using Cu $K\alpha$ radiation and were subsequently refined on a Hilger and Watts linear diffractometer. Intensity data for the layers $0kl$ to $7kl$ were collected with the crystal rotating about the a axis on the diffractometer using a scintillation counter and molybdenum $K\alpha$ radiation with balanced filters. Out of the 4750 reflexions measured, significant counts were recorded for 1936. No absorption corrections were made because of the small size of the crystal, $(1 \times 0.5 \times 0.1$ mm$)$. The intensities were corrected for Lorentz and polarization factors.

Structure determination

If the space group is $P\bar{1}$, the single DBBP ion in the cell must occupy a centre of symmetry, while the four TCNQ moieties may lie in general positions as two

centrosymmetrically related pairs. A three-dimensional Patterson map was computed using F_o^2 as coefficients. Vectors typical of TCNQ were recognized round the origin and round peaks at (1) $x=0.000$, $y=0.230$, $z=0.043$; (2) $x=0.014$, $y=0.296$, $z=-0.120$ and (3) $x=-0.014$, $y=0.452$, $z=0.085$. These peaks could all be interpreted in terms of a trial structure in which the TCNQs are stacked along the b axis, spaced roughly $b/4$, as shown in Fig. 2. The strong peak at (1) was taken to represent the combined vectors between the two crystallographically independent TCNQ moieties (A and B) and also the centrosymmetrically related pair of TCNQs (A' and A), while the peak at (2) was taken to represent the vectors between the other pair (B and B') of centrosymmetrically related TCNQs. The relatively weaker peak at (3) was taken to represent the vectors between the TCNQs A' and B. The presence of strong vectors between the two crystallographically independent TCNQs (A and B) suggests that the TCNQs are packed parallel to each other and thus the common orientation of the TCNQs was deduced from the vector pattern around the origin.

Using the signs of the structure factors calculated on the basis of the trial structure for the TCNQs, a three-dimensional Fourier electron density map was computed. This confirmed the positions of TCNQs and showed six of the thirteen atoms of the DBBP ion. Three subsequent structure factor calculations followed by Fourier maps showed the remaining seven atoms of the DBBP ion. Four cycles of least-squares refinement of the positional and isotropic thermal parameters of all the 45 atoms gave an R value of

0.161. The weighting scheme used was:

$$\sqrt{w} = 1 \text{ if } |F_o| \le F^* \text{ or}$$

$$\sqrt{w} = \frac{F^*}{|F_o|} \text{ if } |F_o| > F^*$$

where F^* was given a value of 300 on the scale of Table 2.

The 19 hydrogen atom positions were calculated and peaks were found at these positions in a difference Fourier synthesis. A further six cycles of least-squares refinement of all the non-hydrogen atoms with anisotropic temperature factors gave the final residual $R = 0.080$. Hydrogen atoms were given temperature factors 0.5 Å^2 greater than the atoms to which they are attached and were included in the final structure factor calculation. The scattering factor curves of Cromer & Waber (1965) were used throughout. The final positional and thermal atomic parameters for the non-hydrogen atoms together with their standard deviations are given in Table 1. Final observed and calculated structure factors are listed in Table 2. Least-squares planes calculated through each of the TCNQ moieties and through the bipyridylium and benzyl groups of the DBBP ion are shown in Table 3.

Description and discussion of the structure

Fig. 1(*a*) shows the dimensions of the two crystallographically independent types of TCNQ moiety. Averaged bond lengths of chemically similar bonds of both the TCNQs are summarized in Table 4. Owing to rather large standard deviations of atomic coordinates it is difficult to decide from these dimensions whether the

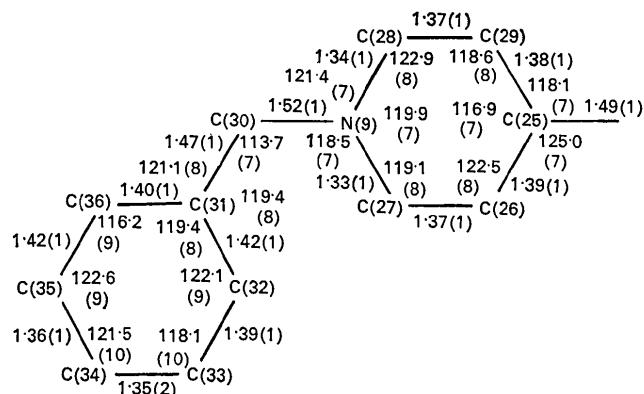

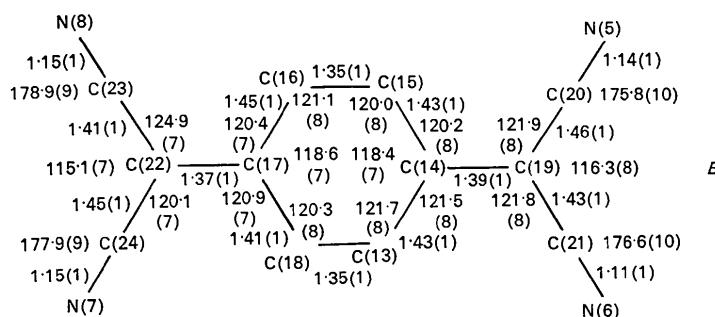

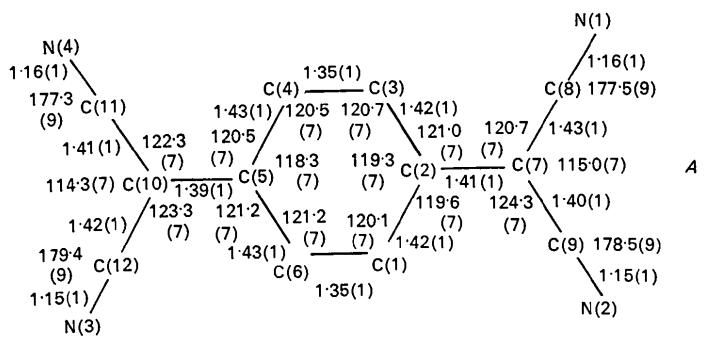

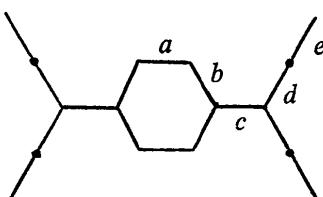

Fig. 1. (a) Bond lengths (Å) and bond angles (°), with their standard deviations (in parentheses), for the two independent TCNQ moieties (b) Bond lengths (Å) and bond angles (°) with their standard deviations (in parentheses) for the DBBP ion.

TCNQs occur as $TCNQ^0$ and $TCNQ^-$ or whether they are really indistinguishable as $TCNQ^{1/2-}$. The bond lengths mostly tend towards the interpretation of molecule A as TCNQ and molecule B as $TCNQ^0$ but a multivariate significance test (Cruickshank & Robert-

son, 1953) of the differences in dimensions between the the two TCNQ moieties gave a value of $T^2 = 0.31$ which is not significant for five degrees of freedom. There is also evidence from the ultraviolet, visible and infrared spectra of the complex that the TCNQs are indistinguishable.

The least-squares planes through the TCNQs indicate that they are not quite planar, the $C-(CN)_2$ groups being twisted out of the planes so as to increase the short contacts $N(1)\cdots C(30) = 3.43$, $N(5)\cdots C(34) = 3.48$ and $N(8)\cdots C(32) = 3.46$ Å with the benzyl group of the DBBP ion. The contact $N(5)\cdots C(34)$ probably contributes also to the non-linearity of the $C-(CN)_2$ group $C(19)-C(20)-N(5)$ and $C(19)-C(21)-N(6)$, the bends being mainly in the plane of the molecule in such a direction as to reduce the distance between the nitrogen atoms of the $C-(CN)_2$ group.

The dimensions of the DBBP ion [Fig. 1(b)] are in agreement with values reported in the structure of DBBP diiodide (Russell & Wallwork, 1971). The dihedral angle between the planes through the benzyl group and the pyridylium ring of the ion is 66.9°.

The structure viewed along the a axis is illustrated in Fig. 2. It consists of columns of TCNQs packed almost parallel to each other (dihedral angle between molecules A and B is 1.6°) along the b axis which is 16.82 Å long. The average interplanar spacings between $A\cdots B$ and $A\cdots A'$ are 3.16 and 3.24 Å respectively, indicating charge-transfer interaction between the pairs, but the separation $B\cdots B'$ is 3.62 Å suggesting that here there is no appreciable molecular interaction.

Fig. 3 shows the three types of overlap, B on A, A' on A and B' on B. The first two overlaps are virtually

(b) Molecule A to molecule A'

$C(1^i)-C(11^{ii})$	3.36 Å
$C(2^i)-C(10^{ii})$	3.22
$C(2^i)-C(11^{ii})$	3.39
$C(3^i)-C(10^{ii})$	3.39
$C(3^i)-C(12^{ii})$	3.36
$C(4^i)-C(6^{ii})$	3.21
$C(5^i)-C(5^{ii})$	3.33

(c) Other intermolecular contacts

$C(6^i)-N(3^{iii})$	3.35
$C(18^i)-N(1^{iv})$	3.35
$C(20^i)-N(5^v)$	3.31
$C(27^i)-N(8^i)$	3.35
$C(27^i)-N(2^{vi})$	3.36
$C(28^i)-N(1^{vi})$	3.34
$C(28^i)-N(2^{vii})$	3.27
$C(29^i)-N(4^{viii})$	3.36
$N(5^i)-N(5^v)$	3.18

Superscripts indicate equivalent positions as follows:

i	x, y, z	v	$(1-x), (1-y),$	$\bar{z}$
ii	$\bar{x}, \bar{y}, \bar{z}$	vi	$x,$	$y,$ $(1+z)$
iii	$(-1-x), \bar{y}, \bar{z}$	vii	$(1+x),$	$y,$ $(1+z)$
iv	$(-1+x), y, z$	viii	$(1-x),$	$\bar{y},$ $(1-z)$

identical and similar to that found in most of the TCNQ complexes. But the overlap B' on B is a new type of overlap involving a diagonal shift of centres. Thus the different modes of overlap combined with different interplanar spacings suggest that the TCNQs are packed as tetramers with a gap between B' and B. This situation has been observed in crystal structures of N-(n-propyl)-quinolinium 2TCNQ (Sundaresan & Wallwork, 1972), triethylammonium 2TCNQ (Kobayashi, Ohashi, Marumo & Saito, 1970) and 1,3,3-trimethyl-2-(p-N-methyl-N-β-chloroethylstyryl)indoleninium 2TCNQ (Shibaeva, Atovmyan & Rozenberg, 1971). In the last complex quoted, however, the 4TCNQs tend to form two dimers. The short intermolecular contacts are listed in Table 5.

We wish to thank the Science Research Council for the provision of the linear diffractometer, Dr F. R. Ahmed for the computer programs used, the Director of the Cripps Computing Centre of the University of Nottingham for computing facilities and Mr G. J. Ashwell for preparing the crystals.

The crystal structure of bis-(4-bromophenylsulphonyl)methane has been determined from diffractometer intensity measurements (779 reflexions) by means of the heavy-atom technique and refined by the full-matrix least-squares method, with anisotropic thermal parameters, to an R of 0·06. Crystals are orthorhombic with $a = 30·05$, $b = 5·015$, $c = 11·455$ Å, $\beta = 118°$, space group $C2/c$ (No. 15), $Z = 4$. The binary axis of the molecule coincides with the twofold axis of the space group. The molecules form layers approximately parallel to planes {001}. The slightly different surroundings of the two oxygen atoms of the SO_2 groups may explain some features of the infrared spectrum of the substance.

La détermination de la stéréochimie préférentielle du carbanion α-sulfonyle $RSO_2C^-R_1R_2$ a donné lieu à de nombreux travaux, depuis la mise en évidence de l'aptitude du groupement SO_2 à retenir la configuration, sur un carbone adjacent saturé, dans les réactions de substitution électrophile (Cram, 1965; Wolfe, Rank & Csizmadia, 1969). Le cas du carbanion bis(sulfonyle)-méthanique $(RSO_2)_2C^-H$, a été discuté dans le cadre de ces études (Cram, 1965; Corey, König & Lowry,

1962). Cependant, la structure moléculaire des β-disulfones n'a jamais été examinée avec précision.

Au cours d'une étude dans l'infrarouge moyen des composés $(X$-C_6H_4-$SO_2)_2CH_2$ (Jéminet, 1969), nous avons observé une structure complexe des bandes de vibration de valence du groupement SO_2, dans la région 1100–1350 cm^{-1}, en solution ou à l'état solide. La recherche d'une explication sur l'origine théorique de ce phénomène nous a conduits à préciser les con-
