The Crystal Structure of Lithium Maleate Dihydrate

BY W. G. TOWN* AND R. W. H. SMALL

The Chemistry Department, The University, Lancaster, England

(Received 16 April 1973; accepted 17 April 1973)

The structure of $Li_2C_4H_2O_4 \cdot 2H_2O$, with cell dimensions $a = 9.6306$, $b = 12.1307$, $c = 12.7051 \text{ \AA}$, $\beta = 107.96^\circ$, has been determined with counter-measured X-ray intensities (1535 planes). The maleate ion is non-planar and unsymmetrical, the principal bond distances (\AA) being C(1)-C(2) 1.495 (3), C(2)-C(3) 1.330 (3), C(3)-C(4) 1.505 (3), C(1)-O(1) 1.277 (2), C(1)-O(2) 1.252 (2), C(4)-O(3) 1.273 (2), C(4)-O(4) 1.252 (2). Each lithium ion has an approximately tetrahedral coordination of oxygen atoms.

Experimental

(a) Preparation

The compound was prepared by the neutralization

of an aqueous solution of maleic acid with equivalent amounts of lithium hydroxide. Crystals obtained from the aqueous solution were monoclinic prisms, usually showing the forms {010}, {110}, {001} and occasionally elongated parallel to a . A melting point could not be determined as dehydration occurred at 160°C. The composition was confirmed by elemental chemical analysis (C, H, and Li).

* Present address: Crystallographic Data Centre, Lensfield Road, Cambridge, England.

(b) Crystallographic

Weissenberg photographs, taken with Cu $K\alpha$ radiation ($\lambda=1.5418 \text{ \AA}$) were used to determine approximate cell dimensions and to show that the space group

Main & Woolfson were used with 250 of the largest E values. An E map, computed with one of the sets of signs, gave positions of all the atoms except those of hydrogen. Refinement of the positional parameters and anisotropic temperature factors was carried out with the program *FMLS* of Bracher & Taylor (1967). At an intermediate stage of the refinement all the hydrogen atoms were located from a three-dimensional difference synthesis.

During the refinement it became apparent that, for planes of high intensity, the observed structure factors were appreciably less than those calculated. On the assumption that the differences were due to extinction, a correction was calculated and applied to the observed structure factors. Following the method described by Larson (1970) the correction was calculated as a modification of the calculated structure factors in the form

$$F_c^* = k |F_c| \left\{ 1 + r |F_c|^2 \left[\frac{1 + \cos^4 2\theta}{\sin 2\theta (1 + \cos^2 2\theta)} \right] T \right\}^{-1/4}$$

where k is a scale factor, r is a constant involving the extinction parameter and T is the mean path length for a particular reflexion. The parameters k and r were

refined by a separate least-squares procedure involving all values of F_o and F_c^* , the latter being derived from the F_c values output from the *FMLS* program. The correction factors derived in this way were applied inversely to the F_o values and refinement of the structural parameters by least-squares calculations (*FMLS*) resumed. As a result of this correction the conventional R fell from 0.064 to a final value of 0.041. The calculated value of F_{040} , although improved by this proce-

dure, was still considerably greater than that observed and it was therefore omitted from the last refinement cycles. The atomic scattering factors used throughout were those listed in *International Tables for X-ray Crystallography* (1962). The final values of F_o and F_c (including 040) are given in Table 2. The coordinates of all atoms in the structural unit are given in Table 3 and the b_{ij} values in Table 4.

Interpretation of the thermal vibration parameters

On the assumption that the anions in this compound behave as rigid bodies, the three tensors T , ω and S described by Schomaker & Trueblood (1968) were evaluated from b_{ij} values with the program MGTL of Gantzel & Trueblood. These three tensors and their estimated standard deviations referred to orthogonal axes a , b , c^* are listed in Table 5. The validity of the rigid-body model of the anion may be conveniently tested by a comparison of the U_{ij} values of each atom derived from the b_{ij} values with those values calculated

from the rigid-body parameters T , ω and S . The two sets are listed side by side in Table 6. The r.m.s. ΔU_{ij} between the two sets is 0.0021 \AA^2 and the mean σU_{ij} of those obtained from the b_{ij} values is 0.007 \AA^2 . Bond distances and angles within the anion have been corrected for librational motion and are given in Table 7.

Description and discussion of the structure

(a) General arrangement

A projection of the structure along \mathbf{b} is shown in Fig. 1. The main plane of each maleate ion is approximately parallel to (001). The water molecules are sandwiched between layers of maleate ions and the lithium ions lie between the water molecules and the anions. The structure is continuously bonded in three dimensions by either ionic or hydrogen bonds. Each lithium ion forms bonds to four oxygen atoms and each maleate ion is bonded by its four oxygen atoms to lithium ions and water molecules.

(b) Lithium ion environment

The approximately tetrahedral coordination of both the crystallographically distinct lithium ions is made up of one water oxygen and three anion oxygen atoms as depicted in Fig. 2(a) and (b). The angles and distances involved are given in Table 8. It will be noted that one of the lithium ions, Li(1), has two oxygen neighbours from the same anion.

(c) *The water molecules*

The shape and environment of each water molecule is shown in Fig. 2(c), (d), and the distances and angles involved are given in Table 9. Each water molecule has its oxygen atom coordinated to a lithium ion and in one of the molecules both hydrogen atoms, H(3), H(4), are hydrogen bonded to anion oxygens. Only one hydrogen atom H(5) in the other molecule of water can be considered to be involved in a hydrogen bond. The other H(6) is 2.15 Å from the nearest oxygen atom O(1), a distance considerably in excess of that usually interpreted as constituting a hydrogen bond. The large thermal vibration of O(6) (Table 4) may be explained by the weaker bonding in which it is involved.

(d) *The maleate ion*

The ion is illustrated in Fig. 2(e). The distances of all atoms from the plane defined by the four carbon atoms are given in Table 10. Apart from O(3) and O(4) the anion is approximately planar; in terms of torsion angles the plane of one carboxylate group, C(2)O(1)O(2), is rotated 7.0° from the plane of the

carbon atoms whilst for the opposite carboxylate group the rotation is 81.4°. This unsymmetrical configuration may be contrasted with the planar arrangement found in maleic acid (Shahat, 1952) and in the hydrogen maleate ion (Darlow & Cochran, 1961). In both these structures the planarity is due to internal hydrogen bonding; in the maleate ion, with no corresponding hydrogen bond, repulsion between oxygen atoms of the opposite carboxylate groups leads to a non-planar configuration. The nearest approach of these oxygen atoms, 2.999 Å O(1)-O(3), is quite close to the sum of the

van der Waals 'radii' for carbonyl oxygens in directions parallel and perpendicular to the bond (1.35 and 1.63 Å respectively) (Bondi, 1964).

Bond distances and angles within the maleate ion are given in Table 7. The carbon–carbon double bond, C(2)C(3), is of the expected length and differs slightly from that found in the hydrogen maleate ion, 1.348 (4) Å. The bonds C(1)C(2) and C(3)C(4) have lengths which are not significantly different nor do they differ from the comparable bond in the hydrogen maleate ion, 1.498 (3) Å. Since C(1)C(2) and C(3)C(4) involve greatly different degrees of torsion of the carboxylate planes relative to the carbon atom plane, they can be considered to be free from double-bond character. The bond angles C(1)–C(2)–C(3) (125.1°) and C(2)–C(3)–C(4) (127.4°) are smaller than the strained value of 130.4 (2)° found in the hydrogen maleate ion but considerably greater than the value of 121.5° assumed by Darlow (1961) to represent the strain-free angle for this type of carbon framework. Further evidence of strain due to oxygen–oxygen repulsion is found in the significant non-planarity of the group C(3)C(4)O(3)O(4) (Table 11). The two carboxylate groups are closely similar in shape and dimensions and in each of them one C–O bond is significantly larger than the other. There is no obvious explanation of this difference and no similar effect has been found in comparable structures.

We are indebted to the S.R.C. for the award of a Research Studentship to one of us (W.G.T.).

Stéréochimies du Zirconium et du Cuivre dans les Fluorozirconates de Cuivre Hydratés. I. Structure Cristalline de CuZrF₆.4H₂O

PAR J. FISCHER ET R. WEISS

Institut de Chimie, Université Louis Pasteur, BP 296/R8, 67008 Strasbourg Cedex, France*

(Reçu le 19 mars 1973, accepté le 10 avril 1973)

The crystal structure of CuZrF₆.4H₂O has been solved using three-dimensional X-ray diffraction data recorded on a automatic diffractometer. The crystals are monoclinic with $a=5.691$, $b=10.030$, $c=7.592$ Å, $\beta=103.53^\circ$, $Z=2$, space group $P2_1/c$. The structure is built up from infinite $\cdots[\text{ZrF}_6]^{2-}\cdots[\text{Cu}(\text{H}_2\text{O})_4]^{2+}\cdots[\text{ZrF}_6]^{2-}\cdots$ chains linked by hydrogen bonds.

Introduction

Dans le cadre d'une étude générale des fluorozirconates de cuivre hydratés, et dans le but de déterminer les stéréochimies du zirconium et du cuivre dans ce type de composés, les structures cristallines de CuZrF₆.4H₂O, K₂Cu(ZrF₆)₂·6H₂O, Cu₃(ZrF₇)₂·16H₂O et

Cu₂ZrF₈·12H₂O ont été déterminées. Le présent mémoire rend compte de la structure cristalline de CuZrF₆.4H₂O.

Partie expérimentale

CuZrF₆.4H₂O se forme comme premier composé lors de la préparation à chaud de Cu₃(ZrF₇)₂·16H₂O (Maignac, 1860) en retirant les cristaux de la solution mère à une température supérieure à 50°C à mesure qu'ils se forment pour éviter leur redissolution et la forma-
