(Received 19 September 1974; accepted 21 September 1974)

Abstract.

$\{(C_5H_5)_2Mo(NH_3)[HNC(CH_3)(C_2H_5)]\}(PF_6)_2$, $C_{14}H_{23}F_{12}MoN_2P_2$, $M=605.2$, monoclinic, space group $P2_1/c$ (C_{2h}^5 , No. 14); $a=9.647(6)$, $b=18.394(10)$, $c=13.988(8)\text{ \AA}$, $\beta=121.05(5)^\circ$, $U=2126.4\text{ \AA}^3$, $D_x=1.88$, $D_c=1.89\text{ g cm}^{-3}$, $Z=4$. The structure demonstrates the ability of a ketimine to form an unchelated, σ -bonded complex with molybdenum.

Introduction. The dark-red material was provided by Dr F. W. S. Benfield and recrystallized from an acetone–water mixture. A crystal of prismatic habit, approximately $0.4 \times 0.3 \times 0.2$ mm, was mounted about its

longest dimension (100) in a nitrogen-filled Lindemann-glass capillary and set up on a Hilger and Watts PDP8-controlled four-circle diffractometer. Cell dimensions and orientation matrix were obtained by a least-squares fit to the setting angles of 20 reflexions.

The intensities of two equivalents of each independent reflexion with $\sin \theta/\lambda < 0.7$ were measured with an $\omega/2\theta$ scan and the ordinate analysis method (Watson, Shotton, Cox & Muirhead, 1970). Mo $K\alpha$ radiation was used from a graphite monochromator. Reflexions with intensity less than 3σ , where σ is the standard deviation derived from simple counting statistics, or whose apparent centre was more than 0.2° from the

Table 1. *Fractional coordinates ($\times 10^4$) of non-hydrogen atoms with anisotropic temperature-factor components ($\times 10^3$)*

The anisotropic temperature factor has the form:

$$\exp\{-2\pi^2(U_{11}h^2a^{*2} + U_{22}k^2b^{*2} + U_{33}l^2c^{*2} + 2U_{23}klb^{*}c^{*} + 2U_{13}hla^{*}c^{*} + 2U_{12}hka^{*}b^{*})\}.$$

predicted position were not included in subsequent calculations. Lorentz and polarization corrections, together with an empirical absorption correction (North, Phillips & Mathews, 1968), were applied, leading to a final set of 3305 independent structure amplitudes.

The structure was solved by conventional Patterson and Fourier techniques; hydrogen atoms were located from difference syntheses. Refinement was by least-squares calculations, with a large-block approximation to the normal matrix: a 2×2 block was calculated from the derivatives of the scale and dummy overall temperature factor, three blocks from those of the positional parameters of the cation and two anions respectively, and a further three blocks from those of the corresponding temperature factors. In the final cycles, non-hydrogen atoms were permitted anisotropic temperature factors, whilst hydrogen atoms were refined isotropically; in addition, the carbon–hydrogen and nitrogen–hydrogen bond lengths were constrained (Waser, 1963; Rollett, 1969) to their respective means with a standard deviation of 0.02 Å. The final values of these means were C–H = 1.00, N–H = 0.94 Å.

Each reflexion was assigned a weight $w^{-1} = 1 + \{(|F_o| - 12)/50\}^2$ and the final R was 0.055. All calculations were performed on the Oxford University ICL 1906A computer with the Oxford package of crystallographic programs (Carruthers & Rollett, 1973). Complex neutral-atom scattering factors were taken from *International Tables for X-ray Crystallography* (1962).

Final atomic parameters are given in Tables 1 and 2, and Table 3 shows bond lengths and angles involving

non-hydrogen atoms, with estimated standard deviations calculated from the full variance-covariance matrix.*

Discussion. Complexes of chelating ligands containing an imino-nitrogen, such as salicylaldimine, are well known, but it has been suggested (see, for example, Smith, 1970) that a double-bonded nitrogen is not sufficiently basic to form simple unchelated complexes. However, Benfield & Green (1974) have recently characterized products obtained from the reactions between $[(\eta\text{-C}_5\text{H}_5)_2\text{Mo}(\text{SMe}_2)\text{Br}](\text{PF}_6)$ and ammonia in ketones, $\text{RR}'\text{CO}$, as $[(\eta\text{-C}_5\text{H}_5)_2\text{Mo}(\text{NH}_3)(\text{HCNRR}')](\text{PF}_6)_2$, postulating a

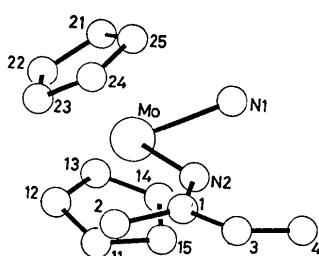

Fig. 1. The cation in projection down *a*. For clarity, carbon atoms are labelled by their serial numbers only and hydrogen atoms have been omitted.

σ -bonded rather than a π -bonded ketimine ligand. King & Douglas (1973) have also reported the existence of $(\text{CH}_3)_2\text{CN}(\text{H})\text{Cr}(\text{CO})_5$. In view of these developments, the crystal structure of Benfield & Green's product from ethyl methyl ketone was determined and is described here.

The observed structure consists of an array of discrete organometallic cations (Fig. 1), in which the presence of a σ -bonded ethyl methyl ketimine ligand is confirmed, and hexafluorophosphate anions. The cations adopt the configuration familiar in many bent bis- η -cyclopentadienyl-metal complexes, with approximate local C_{2v} symmetry at the molybdenum. The molybdenum atom lies 1.98 Å from the best planes of the cyclopentadienyl rings, and the angle between the ring normals is 134°: typical results for $(\eta-\text{C}_5\text{H}_5)_2\text{MoX}_2$ systems (Prout, Cameron, Forder, Critchley, Denton & Rees, 1974). A projection on to the $\text{MoN}(1)\text{N}(2)$ plane shows that the rings adopt a staggered conformation. The $\text{N}-\text{Mo}-\text{N}$ angle (79.1°) and $\text{Mo}-\text{N}$ bond lengths (2.216 and 2.192 Å) are in accord with previous results on, for example, amino acid complexes of molybdenum (Prout, Allison, Delbaere & Gore, 1972; Drew & Kay, 1971; Delbaere & Prout, 1971).

The ketimine ligand itself is essentially planar, the only exceptional feature being the short $\text{C}(3)-\text{C}(4)$ bond. $\text{C}(4)$, however, has a large component of ap-

parent thermal motion perpendicular to the ketimine plane and appears elongated in appropriate Fourier syntheses. It therefore seems likely that there is some disordering of $\text{C}(4)$ about the plane (the local potential energy field would certainly be nearly symmetrical here) with the result that the mean, refined position is too close to $\text{C}(3)$.

As is usually observed with ions having spherical symmetry, the hexafluorophosphate groups have large temperature factors and show considerable apparent distortion.
