# Structure and Hydrogen Bonding of $\boldsymbol{\alpha}$ - $\mathrm{NaHSO}_{4}$ 

By E. J. Sonneveld and J. W. Visser<br>Technisch Physische Dienst TNO-TH, PO Box 155, 2600 AD Delft, The Netherlands

(Received 22 February 1979; accepted 9 May 1979)

#### Abstract

$\alpha-\mathrm{NaHSO}_{4}$ is triclinic, space group $P \overline{1}$, with $a=$ $7.005(1), b=7 \cdot 125(1), c=6.712(1) \AA, \quad a=$ 95.94 (2), $\beta=87.69$ (2), $\gamma=104.48$ (2) ${ }^{\circ}, V=322.5$ (1) $\AA^{3}, Z=4$. The final $R=0.059$ for 514 counter reflections. Disorder of one of the H atoms was deduced from $\mathrm{S}-\mathrm{O}$ bond lengths and $\mathrm{O} \ldots \mathrm{O}$ distances. The disorder causes a peculiar hydrogen-bonding scheme, with one of the hydrogen bonds across a centre of symmetry.

## 1. Introduction

Recently, a new modification of $\mathrm{NaHSO}_{4}$ was found and its crystal structure, which is monoclinic, space group $P 2_{1} / n$, determined by powder work (Sonneveld \& Visser, 1978).

The purpose of the present determination of the triclinic form of $\mathrm{NaHSO}_{4}$ was to compare it with the structure of the monoclinic modification. The triclinic phase was called $\alpha-\mathrm{NaHSO}_{4}$, the monoclinic form $\beta$ $\mathrm{NaHSO}_{4}$.

## 2. Experimental

Cell constants were determined from Guinier-de Wolff powder photographs, calibrated with corundum as an internal standard. The powder pattern of $\alpha-\mathrm{NaHSO}_{4}$ could be indexed from the isomorphism with $\mathrm{CaHPO}_{4}$ (Langmuir, 1919). The procedure for growing crystals was derived from a phase diagram (Landolt-Börnstein, 1962): they were grown from a saturated solution of $\mathrm{NaHSO}_{4}$ in concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ at 353 K . This solution contained equal molar amounts of $\mathrm{NaHSO}_{4}$ and $\mathrm{H}_{2} \mathrm{SO}_{4}$ and just enough water to dissolve all $\mathrm{NaHSO}_{4}$ at this temperature. By cooling the solution slowly from 353 to 343 K , well developed plate-like crystals were formed. Since anhydrous $\mathrm{NaHSO}_{4}$ is hygroscopic, the crystals were stored under paraffin oil. A crystal $0.7 \times 0.5 \times 0.3 \mathrm{~mm}$ was mounted in a glass capillary, which was filled on both sides of the crystal with paraffin oil. The capillary was closed at both ends by melting. To confirm the identity of the crystal and to
make sure that it was a single crystal, precession photographs were taken. The cell constants determined in this way agreed well with the values resulting from the powder work.

In the subsequent measurements on a CAD-3 diffractometer at room temperature with Mo $K \alpha$ radiation, the intensities of 2860 independent reflections were determined. For economic reasons we used only the 514 reflections with $h^{2}+k^{2}+l^{2}<40$ for the structure determination (49 parameters).

## 3. Structure determination

$\alpha-\mathrm{NaHSO}_{4}$ is isomorphous with $\mathrm{CaHPO}_{4}$ (Langmuir, 1919). As starting values for the positional parameters we took the positional values of $\mathrm{CaHPO}_{4}$ (Jones \& Cruickshank, 1961).

Least-squares refinement was carried out with the XRAY system (1972). The refinement included individual isotropic temperature factors and weights $w=$ $1 / \sigma^{2}(F)$.

An absorption correction was applied, but no correction for extinction was made. The contribution of H atoms was neglected. The final $R$ was 0.059 for 514 reflections.*

* A list of structure factors has been deposited with the British Library Lending Division as Supplementary Publication No. SUP 34456 ( 12 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

## 4. Discussion

### 4.1. General

The final positions are given in Table 1, distances and angles in Table 2. A projection of the structure is given in Fig. 1. The distances in the $\mathrm{S}(1) \mathrm{O}_{4}$ tetrahedron are in good agreement with those found in other structures which contain $\mathrm{HSO}_{4}^{-}$ions (Ashmore \& Petch,

Fig. 1. A projection down $c$ of the structure of $a-\mathrm{NaHSO}_{4}$. Hydrogen bonds are indicated by broken lines.

1975; Cruickshank, 1964; Grimvall, 1971; Pringle \& Broadbent, 1965; Sonneveld \& Visser, 1978). $\mathrm{S}(1)-\mathrm{O}(1)$, which is longer than the remaining $\mathrm{S}(1)-\mathrm{O}$ distances, shows the presence of the H atom bonded to $\mathrm{O}(1)$. As can be seen from Table $2, \mathrm{Na}(1)$ is coordinated by seven O atoms with $\mathrm{Na}(1)-\mathrm{O}$ distances varying from 2.347 to $2.983 \AA$, while $\mathrm{Na}(2)$ is coordinated by eight O atoms with $\mathrm{Na}(2)-\mathrm{O}$ distances in the range $2 \cdot 410$ to $2.667 \AA$.

### 4.2. Hydrogen and hydrogen bonding

From the $\mathrm{S}-\mathrm{O}$ distances in the $\mathrm{S}(2) \mathrm{O}_{4}$ tetrahedron, it is not clear which O atom is bonded to H .

Both $\mathrm{S}(2)-\mathrm{O}(5)$ and $\mathrm{S}(2)-\mathrm{O}(6)$ are close to the values expected for $\mathrm{S}-\mathrm{O}$ distances in the $\mathrm{HSO}_{4}^{-}$ion. Though both $\mathrm{S}(2)-\mathrm{O}(7)$ and $\mathrm{S}(2)-\mathrm{O}(8)$ are significantly longer, they are not as long as expected for $\mathrm{S}-\mathrm{OH}$. The short distance $\mathrm{O}(6)-\mathrm{O}\left(8^{\prime}\right)$ seems to point to hydrogen bonding of these O atoms, which suggests that the H atom is bonded to $\mathrm{O}(8)$.

However, this assumption does not explain the large value of $S(2)-O(7)$, nor does it explain the value of $O(7)-O\left(7^{\prime}\right)$, which is even shorter than is expected for hydrogen-bonded O atoms in this kind of compound. A similar anomaly has been encountered in $\mathrm{CaHPO}_{4}$ (Dickens, Bowen \& Brown, 1972; Catti, Ferraris \& Filhol, 1977). The $\mathrm{P}(1)-\mathrm{O}$ distances found in these determinations are as expected, $\mathrm{P}(1)-\mathrm{O}(1)$ being considerably longer than the other $\mathrm{P}(1)-\mathrm{O}$ distances. Both $\mathrm{P}(2)-\mathrm{O}(6)$ and $\mathrm{P}(2)-\mathrm{O}(7)$ are longer than $\mathrm{P}(2)-\mathrm{O}(5)$ and $\mathrm{P}(2)-\mathrm{O}(8)$, while $\mathrm{O}(7)-\mathrm{O}\left(7^{\prime}\right)$, as in $\alpha-$ $\mathrm{NaHSO}_{4}$, is very short. (Atom identification is similar in both compounds.)

These phenomena have been explained as disorder of one of the H atoms. In $\mathrm{CaHPO}_{4}$ (Dickens et al., 1972) the H atom was found to be distributed between O (6) and $O(7)$, which makes it possible that hydrogen bonding exists between $O(6)$ and $O\left(8^{\prime}\right)$ as well as between $O(7)$ and $O\left(7^{\prime}\right)$. Since the purpose of our determination was to obtain global structural knowledge of $\alpha-\mathrm{NaHSO}_{4}$, no attempt was made to determine the H -atom positions. Because of the similarity of the anomaly in the $\mathrm{S}-\mathrm{O}$ and $\mathrm{O} \cdots \mathrm{O}$ distances in $\alpha-$ $\mathrm{NaHSO}_{4}$ and the $\mathrm{P}-\mathrm{O}$ and $\mathrm{O} \cdots \mathrm{O}$ distances in the isomorphous $\mathrm{CaHPO}_{4}$, it is assumed that the H atom of the $\mathrm{HS}(2) \mathrm{O}_{4}^{-}$ion is disordered. However, a remarkable difference with respect to $\mathrm{CaHPO}_{4}$ is that the H atom is distributed between $O(7)$ and $O(8)$, and not between $\mathrm{O}(6)$ and $\mathrm{O}(7)$ as in $\mathrm{CaHPO}_{4}$. An indication that disorder of H atoms is present in more compounds of this structure type is found in a-SrHPO (Boudjada, Masse \& Guitel, 1978). Although the authors do not discuss the positions of the H atoms, the $\mathrm{P}(2)-\mathrm{O}$ distances in that structure may well be explained by disorder of one of the H atoms.

Because of the hydrogen bonding assumed in $\alpha$ $\mathrm{NaHSO}_{4}$, between $\mathrm{O}(6)$ and $\mathrm{O}\left(8^{\prime}\right)$ as well as between $\mathrm{O}(7)$ and $\mathrm{O}\left(7^{\prime}\right), \mathrm{HS}(2) \mathrm{O}_{4}^{-}$ions are coupled to form infinite chains in the [110] direction. $\mathrm{HS}(1) \mathrm{O}_{4}^{-}$ions are linked to these chains by means of the hydrogen bonding between $O(1)$ and $O(5)$.

### 4.3. Comparison of $\alpha$ - and $\beta$ - $\mathrm{NaHSO}_{4}$

As was already mentioned in the discussion of the structure of $\beta-\mathrm{NaHSO}_{4}$, one of the differences of $\beta$ $\mathrm{NaHSO}_{4}$ with respect to the structure of $\alpha-\mathrm{NaHSO}_{4}$ can be understood by looking at the configurations of the cations and anions.
In $\alpha-\mathrm{NaHSO}_{4}$ this configuration is of the NaCl type, with each $\mathrm{Na}^{+}$ion coordinated by six $\mathrm{HSO}_{4}^{-}$ions, while in $\beta-\mathrm{NaHSO}_{4}$ the structure can be seen as a distorted CsCl type, each $\mathrm{Na}^{+}$ion being surrounded by eight $\mathrm{HSO}_{4}^{-}$ions.

A further difference is seen by considering the hydro-gen-bonding scheme. While in $\alpha-\mathrm{NaHSO}_{4}$ the hydrogen bonding gives rise to the presence of infinite chains of $\mathrm{HSO}_{4}^{-}$ions, in $\beta-\mathrm{NaHSO}_{4}$ the $\mathrm{HSO}_{4}^{-}$ions are coupled to form dimers.
Furthermore, in $\alpha-\mathrm{NaHSO}_{4}$ one of the Na atoms is eight-coordinated by O atoms. In $\beta$ - $\mathrm{NaHSO}_{4}$, however, there exists only seven-coordination of Na . There is a remarkable similarity between the seven-coordination of Na in $\beta-\mathrm{NaHSO}_{4}$ and the seven-coordination of $\mathrm{Na}(1)$ in $\alpha-\mathrm{NaHSO}_{4}$. In $\beta$ - $\mathrm{NaHSO}_{4}$ six of the $\mathrm{Na}-\mathrm{O}$ distances vary from $2.37-2.56 \AA$ while one $\mathrm{Na}-\mathrm{O}$
distance is much longer ( $2.91 \AA$ ). In $\alpha-\mathrm{NaHSO}_{4}$ six of the $\mathrm{Na}(1)-\mathrm{O}$ distances are in the range 2.347-2.520 $\AA$, while the seventh has a much larger value ( 2.983 A).

We thank Dr H. van Koningsveld, for the use of his CAD-3 diffractometer, and Dr A. L. Spek, who gave assistance in the calculation of the absorption corrections.

#### Abstract

$\mathrm{K}_{3} \mathrm{Na}\left(\mathrm{H}_{2} \mathrm{P}_{2} \mathrm{O}_{7}\right)_{2}$ is monoclinic, space group $C 2 / c$ with $a=16.912$ (8), $b=7.251$ (5), $c=11.015$ (6) $\AA, \beta=$ $100.26(6)^{\circ}$ and $Z=4 ; V=1316.8 \AA^{3}, D_{m}=$ 2.465 (5), $D_{x}=2.459 \mathrm{Mg} \mathrm{m}^{-3}, \mu=1.36 \mathrm{~mm}^{-1}$ for Mo $K \alpha$. The structure was solved by direct methods and refined by least squares ( $R=0.027$ ) with 1753 reflexions measured on an automatic three-circle dif-

0567-7408/79/091977-06\$01.00
fractometer (Mo $K \alpha$ radiation). The three independent H atoms were located on difference maps; they are involved in three $\mathrm{O} \cdots \mathrm{O}$ hydrogen bonds of length 2.609 (3), 2.544 (3) and 2.503 (4) $\AA$. In the two shorter contacts, the proton is required to lie on a crystallographic element of symmetry (centre and twofold axis). The hydrogen bond lying across the twofold axis was found to be anomalous in several structural details, and the electron density difference (C) 1979 International Union of Crystallography
