## Structure of Diaquatetrakis(urea)magnesium Bromide

BY LUKASZ LEBIODA AND KRZYSZTOF LEWINSKI

Institute of Chemistry, Jagiellonian University, ul. Karasia 3, 30-060 Kraków, Poland

(Received 30 June 1979; accepted 17 October 1979)

**Abstract.** [Mg{CO(NH<sub>2</sub>)<sub>2</sub>}<sub>4</sub>(H<sub>2</sub>O)<sub>2</sub>]Br<sub>2</sub>, C<sub>4</sub>H<sub>20</sub>MgN<sub>8</sub>O<sub>6</sub><sup>2+</sup>·2Br<sup>-</sup>, monoclinic, *P*2<sub>1</sub>/*c*, *a* = 8.455 (1), *b* = 11.206 (1), *c* = 9.127 (1) Å,  $\beta$  = 103.52 (2)°, *Z* = 2, *D*<sub>x</sub> = 1.818, *D*<sub>m</sub> = 1.804 Mg m<sup>-3</sup>. The Mg<sup>2+</sup> ions are octahedrally coordinated by the O atoms of the four urea and two water molecules. The urea molecules form a pseudotetragonal arrangement with intra-complex hydrogen bonds.

**Introduction.** Crystals of the title compound were obtained by slow evaporation of an aqueous solution of

magnesium bromide and urea in the molar ratio 1:4. This is probably the same compound as that described as MgBr<sub>2</sub>·4urea·H<sub>2</sub>O by Suleimankulov, Nogoev, Dushenaliewa & Naumova (1964) in their study of the magnesium bromide–urea–water system.

A crystal ground to a sphere of diameter 0.38 mm was used to collect intensity data on an Enraf–Nonius CAD-4 diffractometer. Variable  $\omega$ –2θ scans in the  $\theta$  range 0–27° and graphite-monochromatized Mo *Kα* radiation were used. The cell parameters were obtained from a least-squares fit of the setting angles for 15

reflections. The space group was determined from systematic absences to be  $P2_1/c$ . Lorentz, polarization and absorption corrections were applied in the usual manner. Of the 1956 intensities measured, 1902 were positive and yielded 1789 unique  $|F|$  values giving an internal consistency factor of 1.6% in a sort-merge procedure. The structure was determined by the heavy-atom method and refined by a full-matrix least-squares procedure using weights  $w^{-1} = \sigma^2(|F|)$ .

All H atoms were identified in difference Fourier maps and refined using isotropic temperature factors. Neutral-atom scattering factors were used (*International Tables for X-ray Crystallography*, 1974).

Discrepancy indices were  $R = 2.9\%$  and  $R_w = 2.3\%$  for all structure factors. On the final difference Fourier map the highest peak of  $0.5 \text{ e \AA}^{-3}$  was of no chemical significance. The final atomic coordinates and their standard deviations are given in Table 1.\* Most of the calculations were performed with the systems of programs written by Sheldrick (1976) and Roberts & Sheldrick (1972).

**Discussion.** This structure was examined in order to compare it with those of  $[\text{Mg}(\text{urea})_6\text{Br}_2] \cdot 4\text{urea}$  (MBD) (Lebioda, Stadnicka & Sliwinski, 1979) and

\* Lists of structure factors, thermal parameters and distances and angles involving the H atoms have been deposited with the British Library Lending Division as Supplementary Publication No. SUP 34845 (12 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

$[\text{Mg}(\text{urea})_6\text{Br}_2 \cdot \text{MgBr}_2$  (3:1) (MBH) (Lebioda & Lewinski, 1979). The coordination of the  $\text{Mg}^{2+}$  ion is shown in Fig. 1. The complex cation is in a special position  $(0, \frac{1}{2}, \frac{1}{2})$  of symmetry  $\bar{1}$ . The  $\text{Mg}^{2+}$  ion is approximately in the planes of both urea molecules, which form an angle of  $20.4^\circ$  with each other. The  $\text{Mg}-\text{O}=\text{C}$  angles of  $139^\circ$  are close to the expected value of  $138^\circ$  (Lebioda, 1980). The  $\text{O}=\text{C}-\text{N}$  angles nearest to the cation are  $121.6 (2)$  and  $121.4 (2)^\circ$  while those on the opposite side are  $120.2 (2)$  and  $120.0 (2)^\circ$ ; these differences are accompanied by differences in the lengths of the  $\text{C}-\text{N}$  bonds:  $1.323 (3)$  and  $1.320 (3) \text{ \AA}$  at the greater angle,  $1.341 (3)$  and  $1.340 (3) \text{ \AA}$  at the smaller. Both these distortions reflect the asymmetrical polarization of the urea molecules.

Table 2 shows the distances and angles in the  $\text{Mg}^{2+}$  coordination polyhedra.

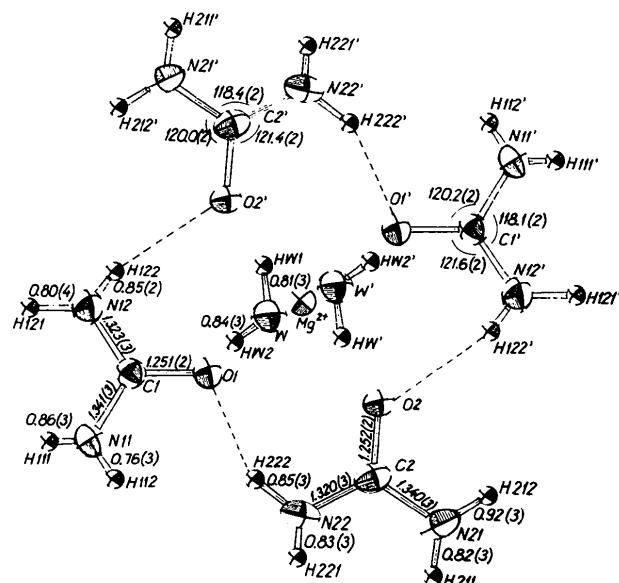

Fig. 1. The  $[\text{Mg}(\text{urea})_4(\text{H}_2\text{O})_2]^{2+}$  complex cation with some distances ( $\text{\AA}$ ) and angles ( $^\circ$ ). Standard deviations are in parentheses. The figure was drawn with the ORTEP program (Johnson, 1965) using arbitrary temperature factors for the H atoms.

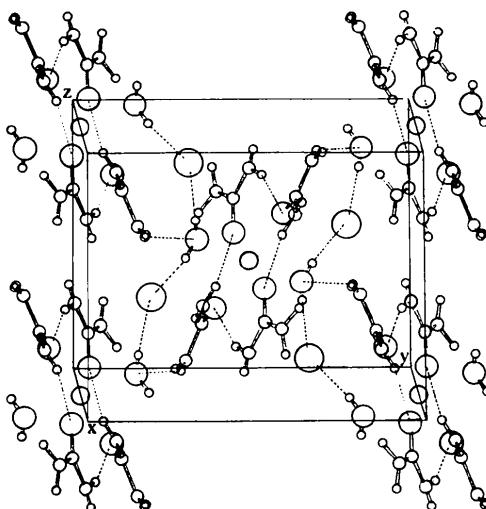

Fig. 2. Hydrogen bonding in the structure.

Hydrogen bonding at the carbonyl groups reflects well the  $sp^2$  hybridization at the O atoms as shown in Fig. 1. The O atoms of the urea molecules are acceptors of intracomplex hydrogen bonds from neighbouring molecules forming a pseudotetragonal arrangement. This situation is different from that found in MBD, where there is only a pair of intracomplex hydrogen bonds, and that in MBH where there are six intracomplex hydrogen bonds of symmetry  $\bar{3}$ . A similar pseudotetragonal arrangement of urea ligands was found in  $\text{CaSO}_4\cdot 4\text{urea}$  (de Villiers & Boeyens, 1975).

The water molecule is positioned with one of its free electron pairs directed towards the cation; the

$H(112)\cdots W$  distance of 2.44 (4)  $\text{\AA}$  is too long for a hydrogen bond, so it can be placed in type J of the hydrate-classification scheme of Ferraris & Franchini-Angela (1972).

The hydrogen bonding is shown in Fig. 2 and described in Table 3. All available H atoms form or tend to form hydrogen bonds to  $\text{Br}^-$  ions thus connecting complex cations and anions in a three-dimensional network.

We thank SLAFiBS, Kraków, for making the diffractometer available.
