#### Abstract

Cu}\left(\mathrm{C}_{13} \mathrm{H}_{27} \mathrm{~N}_{4} \mathrm{O}_{2}\right) \mathrm{CN}\right] \cdot \frac{1}{2} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}\), $[\mathrm{Cu}(\mathrm{CN})-$ (pnao-H)]. $\frac{1}{2} \mathrm{CH}_{3} \mathrm{CN}$, orthorhombic, Fdd $2, a=$ 18.993 (2), $b=32.352$ (2), $c=11.799$ (1) $\AA, V=$ $7250.0 \AA^{3}, M_{r}=381.48, Z=16, \rho_{\text {calc }}=1.40(1)$, $\rho_{\text {obs }}=1.41$ (1) $\mathrm{Mg} \mathrm{m}^{-3}$. Three-dimensional counter X-ray data were used to solve and refine the structure to a final $R\left(F^{2}\right)$ of 0.054 for 2600 independent reflections. The structure consists of discrete monomeric square-pyramidal Cu complex molecules with a strong intramolecular hydrogen bond. The a-amine-oxime ligand is quadridentate with an average $\mathrm{Cu}-\mathrm{N}$ (amine) distance $=2.043(3) \AA$ and $\mathrm{Cu}-\mathrm{N}$ (oxime) $=$ 1.978 (3) $\AA$. The cyanide ion is carbon bonded at the apical position with a $\mathrm{Cu}-\mathrm{C}$ bond distance of $2 \cdot 154$ (5) $\AA$. The strong $\mathrm{Cu}-\mathrm{CN}$ bond pulls the $\mathrm{Cu}^{2+}$ ion out of the plane of the four N atoms by 0.499 (6) $\AA$. The short intramolecular hydrogen bond of $2.475(4) \AA$ is not appreciably modified by the presence of $\mathrm{CN}^{-}$. The acetonitrile molecule is not coordinated to the $\mathrm{Cu}^{11}$ atom, but packs between the Cu complexes as solvent of crystallization.

Introduction. The deep-purple crystals (Murmann \& Monzyk, 1978) were consistently twinned when grown from aqueous media but gave satisfactory crystals from anhydrous acetonitrile. They crystallize with primarily $\{010\}$, $\{011\}$, and $\{110\}$ facial development. The crystal selected was semi-spherical and had a volume of about $0.023 \mathrm{~mm}^{3}$. The space group and cell dimensions were first determined by precession film data, and the final cell dimensions were obtained with a Picker diffractometer from a least-squares refinement of the
setting angles of 18 manually centered reflections. Intensity data were collected for 4094 reflections by the $\theta-2 \theta$ scan method using Mo $K \_$radiation ( $\lambda=$ $0.7107 \AA$ ) filtered with Nb . The data were corrected for background, Lp and absorption ( $\mu=1.27 \mathrm{~mm}^{-1}$ ).* The transmission factor ranged from 0.89 to 0.73 . Standards monitored about every 75 reflections showed no significant systematic variation with time.

The structure was solved by Patterson and Fourier methods. The acetonitrile was revealed by a difference Fourier map and its occupancy factor refined to 0.5 . After a few cycles of least-squares refinement with all non-hydrogen atoms present, a difference Fourier map revealed most of the H atoms. When ambiguities occurred, idealized positions for these H atoms were calculated and were found to be consistent with difference Fourier peaks. Refinement was made using anisotropic temperature factors for all non-hydrogen atoms, with fixed H atoms. H atoms on the $\mathrm{CH}_{3} \mathrm{CN}$ molecule were treated as disordered around the twofold axis. Full-matrix refinement minimizing $\sum w\left(F_{o}^{2}-\right.$ $\left.k F_{c}^{2}\right)^{2}$, using 2600 independent reflections, 213 variables, scattering factors of Cromer \& Waber (1962), and anomalous scattering for Cu (Cromer, 1962), gave

[^0]Table 1. Atomic positional parameters for nonhydrogen atoms

Estimated standard deviations from the least-squares refinement are given in parentheses here and elsewhere in this paper.

$R\left(F^{2}\right)=\sum\left|F_{o}^{2}-k F_{c}^{2}\right| / \sum F_{o}^{2}=0.081, R_{w}\left(F^{2}\right)=$ $\left[\sum w\left(F_{o}^{2}-k F_{c}^{2}\right)^{2} / \sum w F_{o}^{4}\right]^{1 / 2}=0.127$ and the standard deviation of an observation of unit weight was 2.51. Refinement with N -bonded CN gave a significantly poorer agreement factor $R\left(F^{2}\right)=0.083$ and improbable temperature factors ( N greater than C ). A least-squares evaluation of the extinction parameter showed it to be very small and negative; so it was set to zero. Since $F d d 2$ is a noncentrosymmetric space group the signs of $h, k$ and $l$ were reversed to distinguish the direction of the polar axis. Refinement of the same parameters using the alternate data set led to a significantly lower $R\left(F_{o}^{2}\right)$ of 0.057 vs 0.083 using the same number of variables (213), so the second model was chosen for final refinement. Several least-squares cycles with all non-hydrogen atoms anisotropic, but H atoms held at chemically reasonable positions ( $B=5$ to $6 \AA^{2}$ ), gave $R\left(F_{o}^{2}\right)=0.054, R_{w}\left(F_{o}^{2}\right)=0.81$ and the e.s.d. of an observation of unit weight $=1.60 . R(F)$ conventional $=0.033$. The weighting in the least squares was based on $\sigma^{2}\left(F_{o}^{2}\right)=\sigma^{2}$ (counting) $+\left(0.035 F_{o}^{2}\right)^{2}$. The shifts in the last cycle were all less than $5 \%$ of the corresponding standard deviations. A difference Fourier map

Discussion. The primary interest in the structure of this molecule was a comparison of the bond distances and

[^1]$\left[\mathrm{Cu}\left(\mathrm{C}_{13} \mathrm{H}_{27} \mathrm{~N}_{4} \mathrm{O}_{2}\right) \mathrm{CN}\right] \cdot \frac{1}{2} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}$

Fig. 1. Perspective view of $[\mathrm{Cu}(\mathrm{CN})($ pnao- H$)]$ showing the labeling of the atoms and selected bond angles $\left(^{\circ}\right.$ ).

Fig. 2. Perspective view of $\lfloor\mathrm{Cu}(\mathrm{CN})($ pnao- H$) \mid$ showing bond distances ( $\AA$ ).
angles with those of the analogous $[\mathrm{Cu}($ pnao- H$)$ $\left.\left(\mathrm{OReO}_{3}\right)\right]$ (Liss \& Schlemper, 1975). This comparison contrasts the strongest unidentate ligand ( $\mathrm{CN}^{-}$) which has $\pi$-bonding capability with a very weak ligand ( $\mathrm{ReO}_{4}^{-}$) which has only $\sigma$-bond characteristics. The major features of interest are the extent of metal displacement from the $\mathrm{N}_{4}$ plane, and the intramolecular hydrogen-bond modification caused by the bonding change at the apical position.

A previous study (Murmann \& Monzyk, 1978) investigated the thermodynamic quantities involved in

Fig. 3. Stereoscopic view of one quarter of the unit cell (without $H$ atoms and ligand methyl groups).
the reaction of $\mathrm{CN}^{-}$with $[\mathrm{Cu}(\text { pnao- } \mathrm{H})]^{+}$in aqueous media. In contrast to an upper-limit formation-constant estimate (based on the lack of spectral changes in solution) of $20 \mathrm{~mol}^{-1}$ for $\mathrm{ReO}_{4}^{-}$the CN formation constant ( 298 K ) was found to be remarkably large, $1.25 \times 10^{3} \mathrm{~mol}^{-1}$. As is well established in copper(II)CN chemistry, the association is often so strong that oxidation-reduction rapidly proceeds giving $\mathrm{Cu}^{1}$ and $(\mathrm{CN})_{2}$. However, with the stoichiometric ratio $1 / 1$ ( $\mathrm{CN}^{-} /$complex) both the solid and aqueous solutions of the title complex are highly stable. Slight excesses of $\mathrm{CN}^{-}$produce $\mathrm{Cu}(\mathrm{CN})_{3}^{2-}$ and oxidized products from pnao at a relatively rapid rate.

The structure consists of discrete mononuclear neutral Cu complex molecules with the Cu atom in a square-pyramidal configuration (Figs. 1, 2). The Cu coordination consists of four N atoms from the quadridentate amine-oxime ligand and the cyano group (C-bonded) occupying the fifth position. The $\mathrm{C}-\mathrm{N}$ distance of $1 \cdot 112$ (6) $\AA$ is about normal for a coordinated CN group. The acetonitrile is in a vacant position in the lattice and is not coordinated to the metal, nor is it hydrogen bonded to the neutral complex (for a stereoview of the unit cell, see Fig. 3).

The structure of the complex is basically the same as that of $\left[\mathrm{Cu}(\right.$ pnao- H$\left.)\left(\mathrm{OReO}_{3}\right)\right]$ (Liss \& Schlemper, 1975). The $\mathrm{Cu}-\mathrm{C}(\mathrm{CN})$ distance is $2 \cdot 154$ (5) $\AA$, appreciably shorter than the $\mathrm{Cu}-\mathrm{O}\left(\mathrm{ReO}_{4}\right)$ distance of 2.40 (1) $\AA$, and the $\mathrm{Cu}-\mathrm{C}-\mathrm{N}$ bond angle is slightly bent $\left[175.6(4)^{\circ}\right]$. The square pyramid about the Cu atom is significantly distorted. The Cu atom is displaced by 0.50 (1) $\AA$ out of the plane (Table 3) through the four N atoms toward $\mathrm{CN}^{-}$. With the $\mathrm{OReO}_{3}^{-}$complex, the displacement was only $0.24 \AA$ and for $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{OH}_{2}\right)\right] \mathrm{SO}_{4}$ (Morosin, 1969) a $0 \cdot 19 \AA$ movement was noted. A similar effect has been observed (Anderson \& Packard, 1979) for a related complex, $\left[\mathrm{Cu}\right.$ (cyclops) $\left.\left(\mathrm{OH}_{2}\right)\right] \mathrm{ClO}_{4}$, where the $\mathrm{Cu}^{\mathrm{II}}$ ion is found to be displaced only $0.10 \AA$ above the $\mathrm{N}_{4}$ plane. Because of the $0.5 \AA$ displacement of the Cu atom from the plane of the four N atoms, the $\mathrm{N}(X)-\mathrm{Cu}-\mathrm{C}(14)$ angles are all much larger than $90^{\circ}$ $\left[X=1,103 \cdot 2(2)^{\circ} ; X=2,102 \cdot 6(2)^{\circ} ; X=3\right.$, $106 \cdot 0(2)^{\circ}$; and $\left.X=4,105 \cdot 5(2)^{\circ}\right]$.

$$
\left[\mathrm{Cu}\left(\mathrm{C}_{13} \mathrm{H}_{27} \mathrm{~N}_{4} \mathrm{O}_{2}\right) \mathrm{CN}\right] \cdot \frac{1}{2} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}
$$

As observed in $\left[\mathrm{Co}(\right.$ pnao- H$\left.)\left(\mathrm{NO}_{2}\right)_{2}\right]$ (Murmann \& Schlemper, 1973) and $\left[\mathrm{Co}(\mathrm{pnao}-\mathrm{H})\left(\mathrm{OReO}_{3}\right)\right]$ (Liss \& Schlemper, 1975), the $\mathrm{Cu}-\mathrm{N}$ (amine) distances 12.049 , $2.037(3) \AA$ ] are longer than the $\mathrm{Cu}-\mathrm{N}$ (oxime) distances [1.977, 1.979 (3) $\AA$ ], suggesting a stronger $\mathrm{Cu}-\mathrm{N}$ (oxime) bond. At least part of this difference can be attributed to the usual shortening of $0 \cdot 03-0.04 \AA$ on change of hybridization from $s p^{3}$ to $s p^{2}$ for the N atom. The reason for the rest of the shortening is not clear.

The intramolecular hydrogen bond has an $\mathrm{O} \cdots \mathrm{O}$ distance of 2.475 (4) $\AA$ which compares well with the value of 2.46 (2) $\AA$ in the $\mathrm{ReO}_{4}^{-}$complex. Thus, shifting the Cu atom away from the $\mathrm{N}_{4}$ plane does not facilitate a shortening of the $\mathrm{O} \cdots \mathrm{O}$ distance. Both of these are significantly longer than the 2.432 (3) $\AA$ in [Co(pnao-H) $\left.\left(\mathrm{NO}_{2}\right)_{2}\right]$. All of the other bond distances and angles are in reasonable agreement with those of the perrhenate structure. Thus the strong $\mathrm{CN}^{-}$coordination to the $\mathrm{Cu}^{1 \mathrm{I}}$ atom has little effect on the ligand geometry: its main effect is displacing the metal from the plane of the organic ligand.

Financial support from the National Science Foundation (Grant CHE77-08325) is gratefully acknowledged.

#### Abstract

Fe}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}_{3}\right)_{2}(\mathrm{NCS})_{2}\right], \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{FeN}_{8} \mathrm{~S}_{2}, M_{r}=\) $310 \cdot 0$, orthorhombic, $a=7.882$ (1), $b=16.312$ (4), $c=9.890$ (2) $\AA, Z=4, D_{c}=1.620 \mathrm{Mg} \mathrm{m}^{-3} ; R=$ $0.037\left(R_{w}=0.048\right)$ for 963 independent reflexions. The compound is isomorphous with $\left[\mathrm{Co}^{1 \mathrm{I}}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}_{3}\right)_{2}\right.$ $(\mathrm{NCS})_{2} \mathrm{~J}$.

Introduction. Very recently, we reported the crystal structures of $\left[M^{\mathrm{II}}(\mathrm{trz})_{2}(\mathrm{NCS})_{2}\right]$ with $M=\mathrm{Co}, \mathrm{Zn}, \mathrm{Cu}$ and trz $=1,2,4$-triazole (Engelfriet, den Brinker, Verschoor \& Gorter, 1979). Although crystallizing in different space groups, the three compounds exhibit the

^[ * 1,2,4-Triazole Complexes. XI. Part X: Donker, Haasnoot \& Groeneveld (1980). $\dagger$ To whom correspondence should be addressed. ]

same basic features: two-dimensional $M^{\text {II }}$ networks with 2,4 -bridging $\operatorname{trz}$ molecules and $\mathrm{NCS}^{-}$groups, acting as N donors, on either side of the planes. From X-ray powder diffraction the $\mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}$ and $\beta$-Ni members of the series were found to be isomorphous (Haasnoot \& Groeneveld, 1977). Nevertheless, there were several reasons for examining a single crystal of the Fe compound as well: the Mössbauer spectrum of this compound showed a quadrupole doublet with strongly broadened lines, while for a proper refinement of the neutron powder diffraction pattern precise values of the positional parameters are needed (Engelfriet, Groeneveld \& Nap, 1980). Single crystals were prepared in the following way. A solution of $\mathrm{FeCl}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$, slightly acidified with HCl , was added to a solution containing equimolar quantities of trz and
