

Un angle endocyclique des phényles diffère peut-être significativement de 120°: c'est l'angle C<sub>o</sub>—C(7)—C<sub>o</sub> dont le sommet est le carbone C(7) lié à l'azote N(6). Il vaut 118,3 (3)° dans le composé (I) et 117,5 (4)° dans le composé (II). De telles déformations dans le cycle benzénique par rapport à la géométrie hexagonale idéale ont été mises au compte du pouvoir électrocapteur du groupement attaché au benzène (Domenicano, Vaciago & Coulson, 1975).

JPD et MH marquent leur gratitude respectivement au Fonds National (Belge) de la Recherche Scientifique et à l'Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture pour les mandat et bourse dont ils ont bénéficié. Le diffractomètre a été acquis grâce à une subvention du Fonds de la Recherche Fondamentale Collective.

### 3-Coumaric Acid\*

BY S. RAGHUNATHAN AND VASANTHA PATTABHI

Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Madras-600025, India

(Received 12 November 1980; accepted 5 January 1981)

**Abstract.** C<sub>9</sub>H<sub>8</sub>O<sub>3</sub>, monoclinic, P2<sub>1</sub>/n, *a* = 5.402 (3), *b* = 18.693 (11), *c* = 7.973 (4) Å, β = 98.28 (2)°, *V* = 796.8 Å<sup>3</sup>, *Z* = 4, *D*<sub>m</sub> = 1.395, *D*<sub>c</sub> = 1.388 Mg m<sup>-3</sup>, *M*<sub>r</sub> = 164.2. *R* = 0.072 for 1236 reflections. O—H···O hydrogen bonds link the molecules to form dimers. The interplanar angle between the phenyl ring and the carboxyl group is 6.5 (8)°.

**Introduction.** The spatial relationship between the ring and the side chain is an important factor in the activity of auxin molecules. After a study of structure and activity, it was suggested (Veldstra, 1944) that, for an auxin molecule to be active, the ring and the carboxyl group should lie in different planes. The crystal structure of 3-coumaric acid (3-hydroxy-*trans*-cinnamic acid) was investigated as part of the project on the structure and function of plant hormones. Cinnamic acid exists in *cis* and *trans* forms. *cis*-Cinnamic acid demonstrates good auxin activity and its *trans* isomer does not.

Crystals were obtained by evaporation from a mixture of chloroform, hexane and ether. The cell parameters were refined by least squares (Main & Woolfson, 1963) from 24 reflections. Intensities for 1236 reflections with 2θ ≤ 130° were measured with a θ/2θ scan, Ni-filtered Cu Kα radiation ( $\lambda$  = 1.5418 Å) and a 2° min<sup>-1</sup> scan speed. The scan range was 2° and the background was measured on either side of the peak for 10 s. The data were corrected for Lorentz and polarization factors but not for absorption. Each reflection was assigned a weight ( $\sigma_F$ ) by calculating the reciprocal of the variance of observation (Stout & Jensen, 1968).

The structure was solved by symbolic addition (Karle & Karle, 1963). 158 reflections with |*E*| ≥ 1.5 were used to generate triplets and phase propagation was carried out by hand with the  $\sum_2$  formula (Hauptman & Karle, 1953). An *E* map revealed all 12 non-H atoms (*R* = 0.45). Block-diagonal least-squares refinement of these atoms (Shiono, 1968), with isotropic temperature factors, reduced *R* to 0.17. A difference synthesis computed at this stage revealed all

\* The average e.s.d. in  $B$  is  $1.1 \text{ \AA}^2$ .

eight H atoms which were assigned the isotropic temperature factors of the atoms to which they were bonded. Full-matrix least-squares refinement was carried out (Gantzel, Sparks & Trueblood, 1961) with isotropic temperature factors for H, anisotropic temperature factors for the non-H atoms and weight  $w = 1/\sigma_F^2$  for each reflection giving a final  $R$  of 0.072.

Scattering factors for C, O and H were taken from *International Tables for X-ray Crystallography* (1962). The final positional parameters are listed in Tables 1 and 2.\*

**Discussion.** The bond lengths and angles are shown in Fig. 1. The average e.s.d.'s in the bond lengths and angles not involving H atoms are  $0.004 \text{ \AA}$  and  $0.2^\circ$  respectively. The average bond length in the benzene ring is  $1.388 (5) \text{ \AA}$ . C(1)—C(2) and C(3)—C(4) exhibit partial double-bond character with lengths  $1.473 (4)$ ,

\* Lists of structure factors and anisotropic thermal parameters of the non-H atoms have been deposited with the British Library Lending Division as Supplementary Publication No. SUP 35890 (8 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

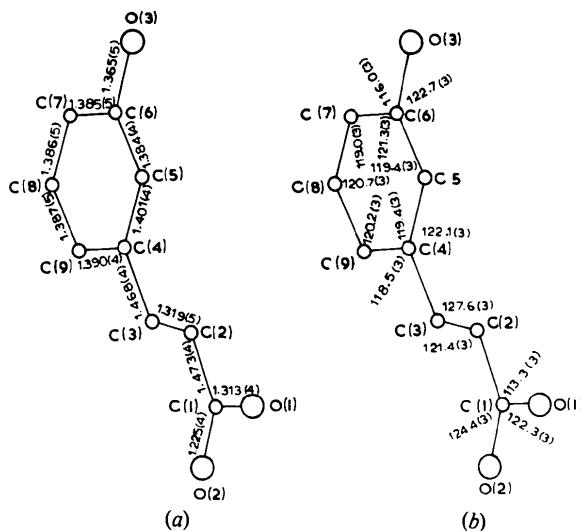

Fig. 1. (a) Bond lengths ( $\text{\AA}$ ) and (b) angles ( $^\circ$ ) with e.s.d.'s in parentheses.

$1.468 (4) \text{ \AA}$ . To minimize steric interaction, C(4)—C(3)—C(2) expands (Zabel, Watson, Cassels & Langs, 1980) to  $127.6 (3)^\circ$  consistent with those in *p*-coumaric acid ( $126.1^\circ$ ) (Utsumi, Fujii, Irie, Furusaki & Nitta, 1970) and 2-coumaric acid [ $126.1 (3)^\circ$ ] (Raghunathan & Pattabhi, 1979).

Least-squares planes are given in Table 3. The angle between the two planes is  $6.5 (8)^\circ$ . This is comparable to the angle between the ring and the carboxyl group planes in other related structures such as *p*-coumaric acid ( $5^\circ$ ) (Utsumi *et al.*, 1970), 2-coumaric acid ( $4.8^\circ$ ) (Raghunathan & Pattabhi, 1979) and  $\beta$ -chloro-*trans*-cinnamic acid ( $11.7^\circ$ ) (Fillipakis, Leiserowitz, Rabinovich & Schmidt, 1972) but differs significantly from that in  $\beta$ -chloro-*cis*-cinnamic acid ( $65.4^\circ$ ) and  $\beta$ -methyl-*cis*-cinnamic acid ( $83^\circ$ ) (Fillipakis *et al.*, 1972).

C(4) is *trans* to C(1) with torsion angle C(1)—C(2)—C(3)—C(4) =  $179.4 (3)^\circ$ . Table 4 lists the corresponding torsion angle and the interplanar angle observed in other plant hormones. The table shows that

\* Torsion angle about the bond connecting the benzene ring and the carboxyl group.

† Angle between the benzene ring and carboxyl group.

the interplanar angle is always close to  $0^{\circ}$  when this torsion angle is *trans*, probably due to steric interactions. On the other hand the carboxyl group takes a perpendicular conformation when this angle is close to *gauche*.

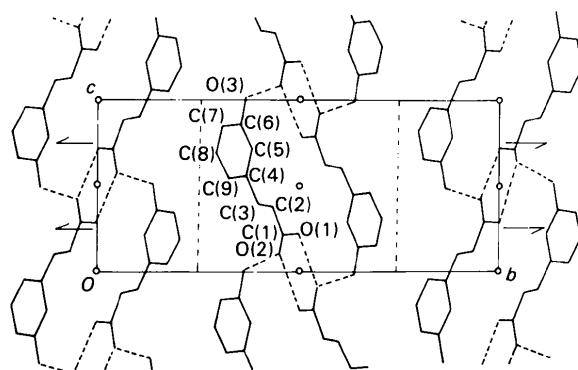

Fig. 2. The crystal structure of 3-coumaric acid viewed down [100]. Hydrogen bonds are shown by broken lines.

Table 5. Hydrogen-bond lengths ( $\text{\AA}$ ) and angles ( $^{\circ}$ )

$D-H \cdots A$	$D-H$	$D \cdots A$	$H \cdots A$	$D-H \cdots A$
$O(1)-H(O1) \cdots O(2)^l$	1.06 (7)	2.65 (1)	1.60 (7)	169.3 (2.1)
$O(3)-H(O3) \cdots O(2)^l$	0.94 (7)	2.80 (1)	1.89 (7)	163.0 (2.1)

Symmetry code: (i)  $-1 - x, 1 - y, -z$ ; (ii)  $x, y, 1 + z$ .

The packing of the molecules is illustrated in Fig. 2 as viewed down **a**. The molecules translated along **c** are cross-linked by  $O-H \cdots O$  hydrogen bonds [ $2.80$  (1)  $\text{\AA}$ ] involving the terminal carboxyl  $O(2)$  and the central hydroxyl  $O(3)$  to form an infinite zig-zag chain. These chains are linked by  $O-H \cdots O$  hydrogen bonds [ $2.65$  (1)  $\text{\AA}$ ] around the centre of symmetry forming dimers involving  $O(1)$  and  $O(2)$  of the carboxyl group. The hydrogen bonds help the chains to form a set of parallel sheets which are held together by van der Waals forces. The hydrogen-bonding scheme is given in Table 5.

One of us (SR) thanks the University Grants Commission and the CSIR, India, for financial assistance.
