

## addenda and errata

Systematic prediction of new ferroelec-  
trics in space groups  $P3_1$  and  $P3_2$ .  
Erratum

S. C. Abrahams

Physics Department, Southern Oregon University, Ashland, OR 97520, USA.

Correspondence e-mail: sca@mind.net

The alignment in Tables 1–4 of the paper by Abrahams (2003) was incorrect. The corrected tables are reproduced herein.

Table 1

Atomic positions for  $\text{Cu}_2\text{BaGeS}_4$  at room temperature (Teske, 1979), with hypothetical  $x'$ ,  $y'$  and  $z'$  coordinates and  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  and  $u^{33}$  displacements in Å. $a = 6.215$  and  $c = 15.534$  Å. Uncertainties not reported.  $z^* = z - 0.0907$ ,  $\Delta x = (x - x')a$ ,  $\Delta y = (y - y')a$  and  $\Delta z = (z^* - z')c$ .

	Wyckoff position $P3_1, P3_121$	$x$	$y$	$z^*$	$x'$	$y'$	$z'$	$\Delta x$	$\Delta y$	$\Delta z$	$u^{33}$

# Systematic prediction of new ferroelectrics in space groups $P3_1$ and $P3_2$

**S. C. Abrahams**Physics Department, Southern Oregon  
University, Ashland, OR 97520, USA

Correspondence e-mail: sca@mind.net

Release 2002/2 of the Inorganic Crystal Structure Database (FIZ Karlsruhe, Germany, and Institute Laue–Langevin, Grenoble, France) contains 62 entries in space group  $P3_1$  and ten entries in space group  $P3_2$  for 49 different materials including eight families with two or more isostructural members. The structural criteria for ferroelectricity are satisfied for 16 new structure types at a confidence level that depends on the reliability of each determination. LaBGeO<sub>5</sub>, a mineral with stillwellite structure, was previously reported as ferroelectric and forms an additional family with seven other members or related structures that satisfy the criteria. Ten structures reported in space group  $P3_1$  or  $P3_2$  are dubious or incorrect, with atomic coordinates that satisfy supergroup symmetry. One material is probably pyroelectric but is unlikely to become ferroelectric, and three others are either incompletely solved or incompletely refined. Among the predicted new ferroelectrics are Cu<sub>2</sub>BaGeS<sub>4</sub>, Fe<sub>3</sub>(Fe,Si)O<sub>4</sub>(OH)<sub>5</sub>, Se<sub>4</sub>S<sub>5</sub>, K<sub>2</sub>HCr<sub>2</sub>AsO<sub>10</sub>, IV-RbNO<sub>3</sub>, Rb<sub>2</sub>Sc(NO<sub>3</sub>)<sub>5</sub>, Na<sub>3</sub>ReO<sub>5</sub>, Nd<sub>14</sub>(GeO<sub>4</sub>)<sub>2</sub>(BO<sub>3</sub>)<sub>6</sub>O<sub>8</sub>, CsHgCl<sub>3</sub>, Ba<sub>2</sub>Cu<sub>2</sub>AlF<sub>11</sub>, KYF<sub>4</sub>, SrS<sub>2</sub>O<sub>6</sub>·4H<sub>2</sub>O, Cu<sub>3</sub>PbTeO<sub>6</sub>(OH)<sub>2</sub>, ReH(CO)<sub>4</sub>, Ni<sub>2</sub>(NH<sub>3</sub>)<sub>9</sub>Mo(CN)<sub>8</sub>·2H<sub>2</sub>O and the 6T polytype of Ca<sub>1.89</sub>Ta<sub>1.80</sub>Sm<sub>0.16</sub>Ti<sub>0.10</sub>O<sub>7</sub>, in addition to  $\beta$ -LaBSiO<sub>5</sub>, PbBaAsO<sub>5</sub> and BaBaAsO<sub>5</sub> in the stillwellite family.

## 1. Introduction

### 1.1. Previous results reported in point group 3

Analysis of all contemporaneous entries under point groups  $6mm$ ,  $6$ ,  $4mm$  and  $4$  in the Inorganic Crystal Structure Database (ICSD; FIZ Karlsruhe/ILL, 2002) has led to the identification of over 170 materials that satisfy the structural criteria for ferroelectricity (Abrahams, 1988, 1990, 1996, 1999). However, presentation of the analysis of all entries in point group 3, with 57 in space group  $P3$ , 62 in  $P3_1$ , ten in  $P3_2$  and 124 in  $R3$ , would have been unwieldy. Analysis of the 21 candidates for ferroelectricity in space group  $P3$  was hence presented separately (Abrahams, 2000), with each entry under space groups  $P3_1$  and  $P3_2$  considered here, and those in space group  $R3$  considered later. The introduction to the analysis of all entries in space group  $P3$  presented by Abrahams (2000) can also be considered as the introduction to the present set of results. The order in which materials are presented follows the ICSD Collection Code sequence in these two space groups, with the exception that subsequent entries for the same substance or family are grouped with the first entry, as are isostructural and enantiomorphic materials, unless noted otherwise.

### 1.2. Structural criteria for the prediction of ferroelectricity

The criteria that are used to determine whether a structure reported in a polar space group is likely to be ferroelectric have been presented previously (*e.g.* Abrahams, 2000). These criteria are briefly (*a*) that the *i*th atom forming the shortest and least-ionic bonds in the unit cell undergoes no polar displacement,  $\Delta z_i$ , greater than  $\sim 1 \text{ \AA}$  between the location reported at  $x_i y_i z_i$  and that at which the resulting spontaneous polarization,  $P_s$ , vanishes and (*b*) that the largest displacement,  $\Delta \xi_i$ , exceeds  $\sim 0.1 \text{ \AA}$  or the r.m.s. thermal or static displacement,  $u_i$ , of that atom.

A recent study of the atomic displacements undergone at the four separate phase transitions in ferroic  $\text{Pb}_5\text{Al}_3\text{F}_{19}$  (Abrahams *et al.*, 2003) over the temperature range 120–670 K has revealed individual  $\Delta \xi$  magnitudes as large as  $\sim 1.2 \text{ \AA}$ . The upper limit for  $\Delta \xi$  at ferroelectric phase transitions, which was taken to be  $\sim 1.0 \text{ \AA}$  for many years, may hence be revised upward.

The predicted Curie temperature,  $T_c$ , in structures for which the *i*th atom occupies an octahedron of O or F atoms is related (Abrahams *et al.*, 1968) to  $\Delta z_i$  by

$$T_c = (\kappa/2k)(\Delta z_i)^2 \text{ K}, \quad (1)$$

where the force constant  $\kappa$  is  $\sim 5.52 \text{ kPa}$ ,  $k$  is Boltzmann's constant,  $\Delta z_i$  is the largest displacement of the *i*th atom along the polar *c* axis as defined in criterion (*a*) and  $\kappa/2k = 2.00 (9) \times 10^4 \text{ K \AA}^{-2}$ .

### 1.3. Dielectric properties at the subgroup–supergroup transition

The minimal non-isomorphic supergroups of  $P3_1$  in the trigonal system are  $P3_112$ ,  $P3_121$  and  $R3$ ; those of  $P3_2$  are  $P3_212$ ,  $P3_221$  and  $R3$ . The phase transition at  $T_c$  reduces the active piezoelectric moduli,  $d_{15}$ ,  $d_{16}$ ,  $d_{21}$ ,  $d_{22}$ ,  $d_{24}$ ,  $d_{31}$ ,  $d_{32}$  and  $d_{33}$ , of the subgroup to zero in the supergroup, the related  $d_{26} = 2d_{12} = -2d_{11}$  and  $d_{14} = -d_{25}$  moduli remaining active. The permittivity coefficients are active above and below the phase transition, but the single pyroelectric coefficient,  $p_3$ , is reduced to zero in the supergroups, together with the possibility of ferroelectricity. By contrast, all piezoelectric and pyroelectric moduli become zero at the ferroelectric phase transitions in the four point groups previously considered, as a result of the generation of inversion centers (see Abrahams, 1994).

**1.3.1. Validation of predicted state.** Confirmation of ferroelectricity in structures satisfying the criteria in §1.2 is most direct if dielectric hysteresis is observed at room temperature and is supported by the dielectric permittivity thermal dependence. Characterization of the phase transition through the Curie temperature is most readily determined calorimetrically. Structural reinvestigation is generally advisable.

### 1.4. Subgroup–supergroup atomic distributions and equivalent positions

Pyroelectricity in a crystal is a necessary condition for the development of ferroelectricity and becomes sufficient if, in addition, the atomic distribution approaches supergroup symmetry (see §§1.2 and 1.3). The number of structures reported in nonpyroelectric supergroups generally exceeds that in related pyroelectric subgroups; thus, the 2002/2 release of the ICSD lists 366 entries in nonpyroelectric  $P3_112$ ,  $P3_121$ ,  $P3_212$  and  $P3_221$  but only 72 entries in the pyroelectric space groups  $P3_1$  and  $P3_2$ . It may hence be an indication of difficulties associated with structural determination in space groups  $P3_1$  and  $P3_2$  that the symmetry of at least one-third of the structure types reported therein can be regarded as dubious. Remarkably, the atomic distribution in only one of the remaining reports departs substantially from supergroup symmetry.

Atomic locations in structures that can undergo a phase transition from ferroelectric to nonferroelectric are related to equivalent positions in the resulting supergroup. Hypothetical supergroup coordinates, which are indicated by primes (') in the tables that follow, are obtained by averaging the experimental values in the subgroup. The component axial displacements,  $\Delta \xi$ , of each atom at the structure determination temperature ( $T$ ) to a hypothetical nonpyroelectric phase, with spontaneous polarization  $P_s = 0$ , may thereby be determined.  $P_s$  reversal at  $T$  requires the *z* coordinate of each atom to undergo a total displacement of  $2\Delta z$  that also reverses the sense of *c*; nonzero *x* and *y* coordinates are without symmetry restriction and may relax to the original values. All  $|\Delta \xi|$  values are probably temperature dependent. The equivalent positions in space groups  $P3_1$  and  $P3_2$  and in their supergroups are given in the footnote below as an aid in clarifying these tables.<sup>1</sup> Consideration of the atomic paths followed under ferroelectric switching or in the approach to the supergroup at the phase transition would be of most interest once the predicted ferroelectric property has been confirmed.

## 2. New inorganic ferroelectrics predicted in space groups $P3_1$ and $P3_2$

### 2.1. $\text{Cu}_2\text{SrSnS}_4$ family

The  $\text{Cu}_2\text{ABS}_4$  family ( $A = \text{Sr}$  or  $\text{Ba}$ , and  $B = \text{Ge}$  or  $\text{Sn}$ ) includes  $\text{Cu}_2\text{SrSnS}_4$ ,  $\text{Cu}_2\text{BaGeS}_4$ ,  $\text{Cu}_2\text{SrGeS}_4$  and  $\text{Cu}_2\text{BaGeSe}_4$ .

<sup>1</sup> Each subgroup atom occupies the general 3(*a*) Wyckoff position with coordinates  $x, y, z; \bar{y}, x - y, z + \frac{1}{3}; \bar{x} + y, \bar{x}, z + \frac{2}{3}$  in space group  $P3_1$ , and  $x, y, z; \bar{y}, x - y, z + \frac{2}{3}; \bar{x} + y, \bar{x}, z + \frac{1}{3}$  in space group  $P3_2$ . In supergroup  $P3_112$ , the special 3(*a*) positions are  $x, \bar{x}, \frac{1}{3}; x, 2x, \frac{2}{3}; 2\bar{x}, \bar{x}, 0$ , and the 3(*b*) positions are  $x, \bar{x}, \frac{2}{3}; x, 2x, \frac{1}{3}; 2\bar{x}, \bar{x}, \frac{1}{3}$ , with the 6(*c*) positions as in  $P3_1 + (x, x - y, \bar{z}; \bar{x} + y, y, \bar{z} + \frac{1}{3}; \bar{y}, \bar{x}, \bar{z} + \frac{2}{3})$ . In  $P3_121$ , the special 3(*a*) positions are  $x, 0, \frac{1}{3}; 0, x, \frac{2}{3}; \bar{x}, \bar{x}, 0$ , and the 3(*b*) positions are  $x, 0, \frac{2}{3}; 0, x, \frac{1}{3}; \bar{x}, \bar{x}, \frac{1}{3}$ , with the 6(*c*) positions as in  $P3_1 + (y, x, \bar{z}; \bar{x}, \bar{x} + y, \bar{z} + \frac{1}{3}; x - y, \bar{y}, \bar{z} + \frac{2}{3})$ . In  $P3_212$ , the special 3(*a*) positions are  $x, \bar{x}, \frac{2}{3}; x, 2x, \frac{1}{3}; 2\bar{x}, \bar{x}, 0$ , and the 3(*b*) positions are  $x, \bar{x}, \frac{1}{3}; x, 2x, \frac{2}{3}; 2\bar{x}, \bar{x}, \frac{1}{3}$ , with the 6(*c*) positions as in  $P3_2 + (x, x - y, \bar{z}; \bar{y}, \bar{x}, \bar{z} + \frac{1}{3}; \bar{x} + y, y, \bar{z} + \frac{2}{3})$ . In  $P3_221$ , the special 3(*a*) positions are  $x, 0, \frac{2}{3}; 0, x, \frac{1}{3}; \bar{x}, \bar{x}, 0$ , and the 3(*b*) positions are  $x, 0, \frac{1}{3}; 0, x, \frac{2}{3}; \bar{x}, \bar{x}, \frac{1}{3}$ , with the 6(*c*) positions as in  $P3_2 + (y, x, \bar{z}; x - y, \bar{y}, \bar{z} + \frac{1}{3}; \bar{x} + y, y, \bar{z} + \frac{2}{3})$ .

**Table 1**

Atomic positions for  $\text{Cu}_2\text{BaGeS}_4$  at room temperature (Teske, 1979), with hypothetical  $x'$ ,  $y'$  and  $z'$  coordinates and  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  and  $u^{33}$  displacements in Å.

$a = 6.215$  and  $c = 15.534$  Å. Uncertainties not reported.  $z^* = z - 0.0907$ ,  $\Delta x = (x - x')a$ ,  $\Delta y = (y - y')a$  and  $\Delta z = (z^* - z')c$ .

	Wyckoff position $P3_1, P3_121$	$x$	$y$	$z^*$	$x'$	$y'$	$z'$	$\Delta x$	$\Delta y$	$\Delta z$	$u^{33}$

† See footnote 1 for equivalent positions.

**2.1.1.  $\text{Cu}_2\text{SrSnS}_4$ .** Structural determination by Teske (1976), on the basis of 1552 independent reflections, resulted in a best fit with  $R = 0.06$  for the Sn atom fixed at  $\frac{1}{3}, \frac{2}{3}, \frac{1}{4}$  and all remaining position coordinates and anisotropic  $u^{ij}$  parameters were allowed to vary; neither  $u_{\text{iso}}$  nor  $u^{33}$  values were reported.<sup>2</sup> The final atomic coordinates, following an origin displacement of  $-0.0814$  that minimizes  $\Sigma \Delta z_i$  for all  $i$  atoms, where  $\Delta z_i$  is the difference between adjusted experimental and hypothetical  $z_i$  coordinates, are given in Table S1(a).<sup>3</sup> No atom is further than  $\sim 1.1$  Å from the corresponding Wyckoff position in supergroup  $P3_121$ , and hence the revised criteria for structural ferroelectricity given in §1.2 are clearly satisfied. The polarization,  $P_s$ , in  $\text{Cu}_2\text{SrSnS}_4$ , however, is expected to be small, since  $\Delta z \leq 0.030$  Å for all  $i$  atoms;  $u_{\text{max}}^{33}$  displacements are unstated for  $\text{Cu}_2\text{SrSnS}_4$  but are likely to be in the range given for  $\text{Cu}_2\text{BaGeS}_4$  (see Table 1). Individual  $\Delta x$  or  $\Delta y$  displacement components in  $\text{Cu}_2\text{SrSnS}_4$  between subgroup atom positions and the corresponding locations in the nonpyroelectric supergroup are as large as  $0.73$  Å for the S1/S2 pair,  $0.72$  Å for the S3/S4 pair and  $0.64$  Å for  $\Delta x(\text{Sr})$ . Average bond distances in the structure are normal, with  $\langle d_{\text{Cu-S}} \rangle = 2.337$  Å,  $\langle d_{\text{Sr-S}} \rangle = 3.199$  Å and  $\langle d_{\text{Sn-S}} \rangle = 2.389$  Å.

The potential barrier in  $\text{Cu}_2\text{SrSnS}_4$  to polar displacement may be low enough to allow reversal of the sense of  $P_s$  under the application of small electric fields at room temperature, as  $x$ ,  $y$ ,  $z$  atomic coordinates change to  $y$ ,  $x$ ,  $\bar{z}$  etc.; dielectric measurement is necessary in order to determine if the  $x$  and  $y$  coordinates can undergo the displacements necessary for polarization switching. If the field required for domain-wall motion is small then this material may have useful applications.

**2.1.2.  $\text{Cu}_2\text{BaGeS}_4$ .** Refinement in space group  $P3_1$ , on the basis of 1210 independent reflections with  $F_{\text{obs}} > 6\sigma(F_{\text{obs}})$ , led to  $R = 0.067$  (Teske, 1979). The atomic coordinates (after an

origin shift of  $-0.0907$  to minimize  $\Sigma \Delta z_i$ ) are given in Table 1, together with the  $u^{33}$  parameters. Note that all  $\Delta z_i$  magnitudes in  $\text{Cu}_2\text{BaGeS}_4$  are significantly larger than those in  $\text{Cu}_2\text{SrSnS}_4$ , with  $\Delta z(\text{S1})$  and  $\Delta z(\text{S2})$  equal to  $0.33$  Å and no other  $\Delta z$  magnitude being less than  $\sim 0.09$  Å; the maximum  $\Delta x$  and  $\Delta y$  displacements ( $\sim 0.75$  Å), however, are comparable to those in  $\text{Cu}_2\text{SrSnS}_4$ .

**2.1.3.  $\text{Cu}_2\text{SrGeS}_4$ .** Teske (1979) reported the structure in the enantiomorphic space group  $P3_2$ , based on 1030 independent reflections with  $F_{\text{obs}} > 6\sigma(F_{\text{obs}})$ . The atomic coordinates in Table S1(b) (an origin shift of  $0.0839$  minimizes  $\Sigma \Delta z_i$ ) correspond to a final  $R$  value of  $0.056$ . All atoms are close to the Wyckoff position  $6(c)$ ,  $3(a)$  or  $3(b)$ , as is the case for both  $\text{Cu}_2\text{SrSnS}_4$  and  $\text{Cu}_2\text{BaGeS}_4$ , but are in the nonpyroelectric space group  $P3_221$  rather than  $P3_121$ . The largest  $\Delta \xi$  displacements between sub- and supergroups in  $\text{Cu}_2\text{SrGeS}_4$  are  $\Delta x(\text{S3,S4})$  and  $\Delta y(\text{S3,S4})$  at  $0.72$  Å and  $\Delta x(\text{S1,S2})$  at  $0.70$  Å.

**2.1.4.  $\text{Cu}_2\text{BaGeSe}_4$ .** The atomic coordinates, given in Table S1(c), were recently determined by Tampier & Johrendt (2001) in space group  $P3_1$  and refined with 982 independent reflections with  $I_{\text{obs}} > 2\sigma(I_{\text{obs}})$  to  $R = 0.024$  and  $wR = 0.048$ ;  $\text{Cu}_2\text{BaGeSe}_4$  is a new member of the  $\text{Cu}_2\text{SrSnS}_4$  family. With the largest  $\Delta x(\text{Se3,Se4})$  and  $\Delta y(\text{Se3,Se4})$  values being  $\sim 0.76$  Å, the ferroelectricity criteria in §1.2 are satisfied. All four quaternary thio- or selenostannate or germanate members of the  $\text{Cu}_2\text{SrSnS}_4$  family are hence ferroelectric candidates (but see §1.3.1).

## 2.2. Cronstedtite-3T

The first structural determination and refinement of the cronstedtite-3T polytype, with idealized composition  $\text{Fe}_3(\text{Fe,Si})\text{O}_4(\text{OH})_5$  (ACCRA 16 1),<sup>4</sup> was noted as incomplete by Smrčok *et al.* (1994), who measured a carefully selected crystal of the formula  $\text{Fe}_{2.96}\text{Al}_{0.02}\text{Mg}_{0.02}[(\text{Si}_{1.26}\text{Fe}_{0.74})\text{O}_5](\text{OH})_4$  by the use of Ag  $K\alpha$  radiation. Refinement of 1336 indepen-

<sup>2</sup> All tables contain the displacement  $u^{33}$ ,  $u_{\text{eq}}$  or  $u_{\text{iso}}$  for each atom, if reported, for comparison with the corresponding  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  magnitudes. Following the recommendations of Trueblood *et al.* (1996), the atomic displacement parameters are assigned the dimension of length, whereas the mean-square displacements  $U^{33}$  etc. have the dimension length squared.

<sup>3</sup> Tables S1–S31 have been deposited. Supplementary data for this paper are available from the IUCr electronic archives (Reference: BK0135). Services for accessing these data are described at the back of the journal.

<sup>4</sup> Coden-type references are given throughout this paper for most structure determinations for which atomic coordinates are not reproduced (see Notes for Authors, 1985). The ICSD omits the final check letter of the journal abbreviation, providing only five letters in each coden. The year of publication is given implicitly in the coden by the volume number following the journal's modified acronym; the final entry in the coden is the number of the first page.

**Table 2**

Atomic positions for  $K_2HCr_2AsO_{10}$  at room temperature (Averbuch-Pouchot *et al.* 1978), with hypothetical  $x'$ ,  $y'$  and  $z'$  coordinates and  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  and  $u_{eq}$  displacements in Å.

$a = 7.712$  (3) and  $c = 14.644$  (8) Å.  $z^* = z - 0.0046$ ,  $\Delta x = (x - x')a$ ,  $\Delta y = (y - y')a$  and  $\Delta z = (z^* - z')c$ .

	Wyckoff position $P3_1, P3_121$	$x$	$y$	$z^*$	$x'$	$y'$	$z'$	$\Delta x$	$\Delta y$	$\Delta z$	$u_{eq}$

† See footnote 1 for equivalent positions.

dent  $F_{meas}$ , with  $I_{meas} > 3\sigma(I_{meas})$ , to which analytical absorption corrections were applied, led to final values of  $R = 0.050$  and  $wR = 0.031$  for the atomic coordinates in Table S2 (an origin shift of 0.02011 has been applied in order to minimize  $\Sigma\Delta z$  for all atoms). The table shows the largest  $|\Delta x|$  and  $|\Delta y|$  values to be  $\sim 0.9$  Å; 16 of the remaining independent  $|\Delta x|$  and  $|\Delta y|$  values are less than  $\sim 0.02$  Å and all other values are between 0.2 and 0.6 Å. The largest  $|\Delta z|$  value is  $\sim 1.1$  Å, and the other  $z$  components range from 0.3 to 0.8 Å, where  $\Delta\xi$  ( $\xi = x, y$  or  $z$ ) is the axial component of the difference between a location in space group  $P3_1$  and that in the corresponding Wyckoff position of space group  $P3_12$ . The diffraction pattern produced by this polytype reveals appreciable diffuse scattering indicative of disorder; the octahedral Fe sites with the largest  $|\Delta z|$  values are occupied by  $\sim 23\%$  Si atoms and  $\sim 2\%$  each of Al and Mg atoms. Nevertheless, the cronstedtite-3T polytype structure fulfills the criteria for ferroelectricity given in §1.2. A transition involving a change from a  $3_1$  to a  $3_2$  screw axis may imply an integral change in the length of the polar axis, for which evidence is presently lacking. Further structural investigation would be of interest (see also §1.3.1).

### 2.3. $S_5Se_4$

The structure of the pressure-induced phase  $S_5Se_4$  was reported by Geller & Lind (1970) in space group  $P3_1$  or  $P3_2$ . The final disordered model was deduced from packing considerations to have three atoms per helix segment. Despite difficulties that included parameter correlation, rotational twinning and positional disorder, the authors claimed that this model fitted the data better than any other model examined. Refinement on the basis of 131 visually estimated reflections gave  $R = 0.11$ , with the atomic coordinates modified by an origin shift of 0.3788 along the polar axis (see Table S3). The six independent sites in Table S3 are related to four sites with Wyckoff positions 3(a), 6(c) and 3(b) in the space group  $P3_12$

by  $\Delta x$  and  $\Delta y$  components of less than  $\sim 0.41$  Å and  $\Delta z$  of less than  $\sim 0.21$  Å for  $u_{iso}(S/Se) = 0.27$  Å. Each site is reported as partially occupied by S/Se atoms at room temperature. Assuming that the original structure determination is correct, the S/Se displacements satisfy the structural criteria for ferroelectricity given in §1.2; since all  $\Delta\xi$  values are less than  $\sim 2u_{iso}$ , however, the possibility also exists that the space group at room temperature is the piezoelectric but nonpyroelectric space group  $P3_112$ . Further investigation is indicated (see §1.3.1).

### 2.4. $K_2HCr_2AsO_{10}$

Averbuch-Pouchot *et al.* (1978) determined the structure of  $K_2HCr_2AsO_{10}$  in space group  $P3_1$  on the basis of 1170 reflections with  $F_{obs} > n\sigma(F_{obs})$ , derived from 2201 independent reflections ( $n$  not stated). An initial model that could not be reduced below  $R = 0.08$  was modified by placing all atoms close to locations in the Wyckoff position 6(c) of the space group  $P3_121$ . Consequently, many correlation coefficients in the least-squares refinement became large, but holding some parameters constant in intermediate cycles led to refinement with a final value of  $R = 0.054$ . The resulting atomic coordinates are given in Table 2, where the origin along the polar axis is shifted by  $-0.0046$  to minimize  $\Sigma\Delta z_i$ . Polar displacements from equivalent positions in the supergroup are  $\Delta z \lesssim u_{eq}$  for all atoms except O9 and O10; the latter have  $\Delta z \simeq 2u_{eq}$ . The criteria for ferroelectricity given in §1.2 are hence satisfied. All thermal/static atomic displacements,  $u_{eq}$ , fall in the range 0.14–0.22 Å.

The As, Cr1 and Cr2 atoms occupy distorted tetrahedra, that of As being the least distorted; the three tetrahedra share corner O atoms to form a  $Cr_2AsO_{10}^{3-}$  anion. Atoms Cr1 and Cr2 are within 0.03 Å of their tetrahedral charge centers along the polar axis and hence have polarizations that nearly cancel. The As atom is within 0.05 Å of its tetrahedral center and is

displaced  $0.167 \text{ \AA}$  from  $c/3$ . Both K atoms are coordinated by seven O atoms, with  $d_{\text{K-O}} \leq 3.10 \text{ \AA}$ . The force constant in tetrahedral geometry is presently unknown; if this constant is comparable to that in octahedral geometry then  $T_c$  is  $\sim 560 \text{ K}$ , assuming that the pyroelectric space group can be confirmed. Preliminary calorimetric measurements (Ylvisaker *et al.*, 2001) reveal a reversible thermally hysteretic phase transition at  $\sim 540 \text{ K}$  on heating, with  $\Delta S \lesssim 1.9 \text{ J mol}^{-1} \text{ K}^{-1}$ .

## 2.5. RbNO<sub>3</sub> phase IV family

**2.5.1. RbNO<sub>3</sub> phase IV.** The RbNO<sub>3</sub> phase IV family includes CsNO<sub>3</sub> phase II and TlNO<sub>3</sub> phase II. Three separate phase transitions at 437, 492 and 564 K have been reported for RbNO<sub>3</sub> between phase IV at room temperature and melting by phase I at  $\sim 587 \text{ K}$  (DANKA 108 645); Pohl *et al.* (1992) report a new phase, V, that remains stable or metastable over the range 296–437 K and forms above a sluggish and irreversible first-order phase transition at 346 K. Room-temperature phase IV was reported by Brown & McLaren (1962) in space group  $P3_112$  or  $P3_121$ , but the observation by Bury & McLaren (1969) of pyroelectric charge generation demonstrated that the space group was polar. Shamsuzzoha & Lucas (1982) reported the systematic absence of  $I(00l)$  for  $l \neq 3n$  using neutron diffraction, with  $I(hkl) \neq I(khl)$ , thereby eliminating all possible space-group choices but  $P3_1$  (or enantiomorphic  $P3_2$ ) for phase IV; these authors refined an earlier but unpublished structural model, determined by X-ray diffraction and referenced in their paper, in space group  $P3_1$  using 371 independent neutron diffraction measurements with  $I > 1\sigma(I)$ . With 141 variable parameters including the anisotropic extinction coefficients, the final  $R$  value was 0.068 for the atomic coordinates in Table 3(a), where an origin displacement of  $-0.0949$  has been applied along the polar axis to minimize  $\sum \Delta z_i$ . Pohl *et al.* (1992) refined the structure of phase IV with 754 independent measurements,  $I > 3\sigma(I)$ , at 296 K to give the atomic coordinates in Table 3(b), after an origin displacement of  $-0.1049$ , which corresponds to a final  $R$  value of 0.0254.

The structural criteria for ferroelectricity (§1.2) are clearly satisfied by all atomic positions in the RbNO<sub>3</sub> phase IV studies in Tables 3(a) and 3(b). The force constant in (1), and hence the possibility of predicting the value of  $T_c$ , is inapplicable to planar NO<sub>3</sub><sup>-</sup> ions and irregular RbO<sub>12</sub> decahedra. Note that  $P_s$  necessarily reduces to zero in cubic phase III at  $T_{\text{IV,III}} = 437 \text{ K}$ .

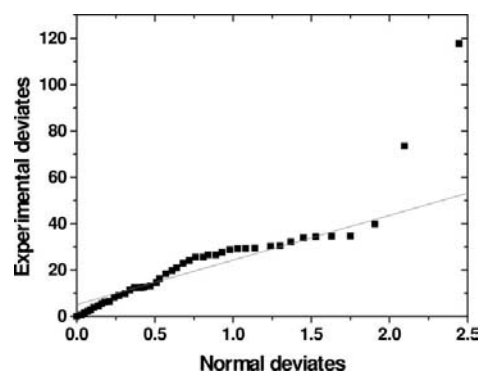

Examination of corresponding pairs of  $\Delta x$ ,  $\Delta y$  and  $\Delta z$  displacements in Tables 3(a) and 3(b), *e.g.*  $\Delta x(\text{O1})$  and  $\Delta x(\text{O9})$ , and  $\Delta z(\text{N2})$  and  $\Delta z(\text{N3})$ , reveals magnitudes that differ with high significance. The  $u_{\text{eq}}$  displacements are also large, namely  $0.26 > u_{\text{eq}} > 0.19 \text{ \AA}$  in Table 3(a) and  $0.25 > u_{\text{eq}} > 0.15 \text{ \AA}$  in Table 3(b).

Differences between atomic coordinates resulting from comparable studies are readily analyzed by means of normal probability  $Q_{\text{exp}} - Q_{\text{norm}}$  plots (Abrahams & Keve, 1971) (see Fig. 1). Comparisons are made by calculating  $Q_{\text{exp}(i)} = |\xi_i(1) - \xi_i(2)| / [\sigma^2 \xi_i(1) + \sigma^2 \xi_i(2)]^{1/2}$ , where  $\xi_i(1)$  and  $\xi_i(2)$  are

the  $i$ th atomic coordinate magnitudes reported in the first and second studies, respectively. The ranked  $Q_{\text{exp}(i)}$  are plotted against the expected value of  $Q_{\text{norm}(i)}$  for each  $i$ th normal deviate modulus. The latter can be found in the *International Tables for X-ray Crystallography* (1974). If the resulting plot is linear, with unit slope and zero intercept, then the experimental deviates can be taken to be free from systematic error, with standard uncertainties well estimated.

In the present sample of 44 deviates [ $z(\text{Rb3})$  was taken to be the origin in both studies, without standard uncertainty], the results in Fig. 1 reveal two major outliers with  $Q_{\text{exp}(i)}$  greater than  $\sim 72$  normal deviates for  $i = x(\text{O1})$  and  $z(\text{O1})$ . The systematic departure of the remaining 42 terms from linearity, although smaller, indicates the presence of systematic error. The slope of the array shows that the combined uncertainties in atomic/nuclear positions, excluding the O1-atom coordinates, are underestimated by a factor of 19.2 (9). The O1 coordinates, however, differ by as much as  $118\sigma$  or 6.1 joint standard uncertainties after compensating for the underestimation. Such large differences suggest a systematic error beyond normal instrumental error, possibly due to the existence of more than one set of metastable equilibrium positions in phase IV at room temperature under different preparation conditions. Pohl *et al.* (1992) report a sluggish transition to a new phase at  $\sim 346 \text{ K}$ , in which the orientation of one of the three independent NO<sub>3</sub><sup>-</sup> ions changes as the space group changes to  $P3_2$ .  $Q_{\text{exp}} - Q_{\text{norm}}$  differences larger than normal are consistent with metastable specimens.

Brown & McLaren (1962) propose a transformation at  $T_{\text{IV,III}} = 437 \text{ K}$  on heating, in which the  $c$  axis in phase IV becomes the  $[111]$  cube-diagonal in phase III, the trigonal  $[101]$  forming the cubic  $[100]$ ; an increase of  $\sim 10^3 \Omega^{-1}$  in conductance was also noted on heating through  $T_{\text{IV,III}}$ , with a symmetry change at 492 K as the conductance decreases by  $\sim 1.5 \times 10^3 \Omega^{-1}$  between cubic phase III and tetragonal phase II. A neutron diffraction study on a single crystal of phase III at 461 K by Shamsuzzoha & Lucas (1987) was unable to distinguish definitively between models with disordered NO<sub>3</sub><sup>-</sup>

**Figure 1**

Normal probability plot of the atomic coordinates independently determined for RbNO<sub>3</sub> phase IV by Shamsuzzoha & Lucas (1982) and by Pohl *et al.* (1992). The dotted line obtained by linear regression has a slope of 22.6 (5) at a confidence level of 99.2%.

**Table 3**

(a) Atomic positions for RbNO<sub>3</sub> in phase IV (Shamsuzzoha & Lucas, 1982) at room temperature, with hypothetical  $x'$ ,  $y'$  and  $z'$  coordinates and  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  and  $u_{\text{eq}}$  displacements in Å.

ions in space groups  $P\bar{4}3m$ ,  $P432$  or  $Pm3m$ , although the data favored the latter. Pohl *et al.* (1992) report that phase III is cubic, with CsCl structure,  $Z = 1$ , in space group  $Pm3m$ . It is noted that, if phase IV transforms to space group  $P3_112$  at  $T < T_{\text{IV,III}}$ , the only cubic supergroups of subgroups 3 and 32 are  $m3m$  and 432. This apparently simple phase system, including the possible existence of space group  $P3_121$  over a narrow thermal range, remains to be investigated further.

**2.5.2. CsNO<sub>3</sub> phase II.** Five entries for CsNO<sub>3</sub> phase II, based on separate structural investigations, are included in ICSD release 2002/2. PHSSA 16 K175 gives  $T_{\text{II,I}} = 427$  K and ACSCE 40 1512 gives 434 K. The most recent structural study of CsNO<sub>3</sub> phase II (Pohl & Gross, 1993), using 1036 independent  $F_{\text{obs}}$  and a model based on these authors' RbNO<sub>3</sub> phase IV results, led to  $R = 0.0187$  for the coordinates presented in Table S4 (adjusted by an origin shift of -0.1523 to minimize  $\sum \Delta z_i$ ). Comparison with Tables 3(a) and 3(b) confirms that RbNO<sub>3</sub> phase IV and CsNO<sub>3</sub> phase II are

isostructural; the closest similarity is found between the results of Pohl & Gross (1993) and Pohl *et al.* (1992), although several atoms are related differently by the supergroup in CsNO<sub>3</sub> and in RbNO<sub>3</sub>. CsNO<sub>3</sub> phase II satisfies the criteria in §1.2.

**2.5.3. TlNO<sub>3</sub> phase II.** The atomic coordinates of TlNO<sub>3</sub> phase II, which is stable between 352 and 417 K, were determined by Sastry & Sequeira (1997). With  $a = 10.435$  Å and  $c = 7.451$  Å at 388 K in space group  $P3_1$ , the coordinates are comparable to those in Tables 3(a) and 3(b), although the paper does not refer to the work of Pohl & Gross (1993). Measurements such as those outlined in §1.3.1 should be made for all family members.

## 2.6. (NH<sub>4</sub>)<sub>2</sub>Tm(NO<sub>3</sub>)<sub>5</sub> and family

The double nitrate (NH<sub>4</sub>)<sub>2</sub>Tm(NO<sub>3</sub>)<sub>5</sub> and its family members, including Rb<sub>2</sub>Sc(NO<sub>3</sub>)<sub>5</sub> and Rb<sub>2</sub>Y(NO<sub>3</sub>)<sub>5</sub>, are

considered out of database sequence in view of the similarity to the  $\text{RbNO}_3$  phase IV family (see §2.5).

**2.6.1.  $(\text{NH}_4)_2\text{M}(\text{NO}_3)_5$ .** The structure was solved by Manek & Meyer (1993a) on the basis of 3209 independent  $F_{\text{obs}} \gtrsim 2\sigma(F_{\text{obs}})$  and refined to  $R = 0.062$  and  $wR = 0.034$  for the atomic coordinates in Table S5(a)<sup>1</sup> after an origin shift of 0.1914 to minimize  $\Sigma\Delta z_i$ . The largest displacement component of any atom from a corresponding Wyckoff position in space group  $P3_121$  is found for the O10/O15 pair; each atom has  $\Delta y = 1.25 \text{ \AA}$ . In addition, 20 components have  $\Delta\xi \gtrsim 0.5 \text{ \AA}$  with  $0.33 \gtrsim u_{\text{eq}} \gtrsim 0.11 \text{ \AA}$ . Both independent  $\text{NH}_4^+$  ions, in general 3(a) positions, undergo maximum  $\Delta\xi$  component displacements of 0.68  $\text{\AA}$  in satisfying the 6(c) Wyckoff position of space group  $P3_121$ . All subgroup–supergroup displacements in  $(\text{NH}_4)_2\text{M}(\text{NO}_3)_5$  hence satisfy the ferroelectricity criteria given in §1.2.

**2.6.2.  $\text{Rb}_2\text{Y}(\text{NO}_3)_5$ .** Crystals were grown from component nitrates heated to  $\sim 600 \text{ K}$ , and the structure was refined by Manek & Meyer (1993b) using 2849 independent reflections with  $F_{\text{obs}} \gtrsim 2\sigma(F_{\text{obs}})$  to give  $R = 0.121$  and  $wR = 0.072$ . The resulting atomic coordinates, after an origin shift of  $-0.0350$  to minimize  $\Sigma\Delta z_i$ , are presented in Table S5(b). The choice of  $a$  and  $b$  axes is enantiomorphically related to that in Table S5(a). Unlike in  $(\text{NH}_4)_2\text{M}(\text{NO}_3)_5$ , which contains supergroup-related  $\text{NH}_4^+$  ions, the Rb2 and Y atoms in  $\text{Rb}_2\text{Y}(\text{NO}_3)_5$  (atomic numbers 37 and 39) appear to be related by the 6(c) Wyckoff position, which suggests chemical identity. The large  $R$  value and coordination number reported, with  $Y = 10$ ,  $\text{Rb1} = 8$ ,  $\text{Rb2} = 6$ , and  $0.2 \lesssim u_{\text{all atoms}} \lesssim 0.4 \text{ \AA}$ , may be consistent with misassignment. All but eight atoms have displacement components with  $\Delta\xi < 1 \text{ \AA}$  (see Table S5b); of these eight atoms, the displacements  $\Delta x(\text{O8})$ ,  $\Delta x(\text{O11}) \simeq 1.7 \text{ \AA}$  and  $\Delta y(\text{O8})$ ,  $\Delta y(\text{O11}) \simeq 1.8 \text{ \AA}$  are the largest, with six other  $\Delta\xi$  values being  $\sim 1.2 \text{ \AA}$ . If reinvestigation confirms the structure and  $\text{Rb}_2\text{Y}(\text{NO}_3)_5$  is shown to exhibit ferroelectricity then an upper limit of  $\sim 1.2 \text{ \AA}$ , or even  $\sim 1.5 \text{ \AA}$ , for maximum atomic displacements at phase transitions may be too small. However, comparable  $\Delta\xi$  magnitudes are smaller in the other family members.

**2.6.3.  $\text{Rb}_2\text{Sc}(\text{NO}_3)_5$ .** The structure was refined by Meyer & Stockhause (1994) to  $R = 0.065$  using 2292 independent reflections with  $F_{\text{obs}} > 2\sigma(F_{\text{obs}})$  to give the atomic coordinates shown in Table S5(c); an origin shift of  $-0.0098$  has been applied to minimize  $\Sigma\Delta z_i$ . The  $\Delta\xi$  displacements in Table S5(c), as in Tables S5(a) and S5(b), are generally consistent with the criteria for ferroelectricity given in §1.2. Like the Rb2 and Y atoms in  $\text{Rb}_2\text{Y}(\text{NO}_3)_5$  (§2.6.2), the Rb2 and Sc atoms in  $\text{Rb}_2\text{Sc}(\text{NO}_3)_5$  are related by a 6(c) Wyckoff position in the supergroup. It is noted that the largest  $\Delta z$  value is  $\sim 0.85 \text{ \AA}$  for atoms O11, O14 and O15. The thermal/static displacement range  $0.32 \gtrsim u^{33} \gtrsim 0.16 \text{ \AA}$  along the polar direction is such that  $T_c$  may prove lower than the  $\Delta\xi$  displacements imply, although the atomic arrangement does not allow  $T_c$  to be estimated by (1).

Tables S5(a), S5(b) and S5(c) show that the unit cell, chemical formula and structure of all three double nitrates are comparable and likely to be ferroelectric, although metastable

equilibrium positions may exist in one or more, such as in  $\text{RbNO}_3$  phase IV (see §2.5). Structural confirmation would suggest that other members of the  $\text{Rb}_2\text{Ln}(\text{NO}_3)_5$  family ( $\text{Ln} = \text{Eu}–\text{Lu}$ ) can be identified as potential ferroelectrics (see also §1.3.1).

## 2.7. $\text{Na}_3\text{ReO}_5$

A total of 1091 independent reflections with  $F_{\text{obs}}^2 > 2\sigma(F_{\text{obs}}^2)$  were measured and corrected for absorption by Vielhaber & Hoppe (1992). Solution followed by refinement led to  $R = 0.0614$  and  $wR = 0.0608$ . The structure contains distorted triangular bipyramidal  $\text{ReO}_5^{3-}$  ions, in which  $z(\text{O3}, \text{O4}, \text{O5}) \simeq z(\text{Re})$  with  $z(\text{O1})$ ,  $z(\text{O2}) \simeq z(\text{Re}) \pm 1.4 \text{ \AA}$ , hence  $z(\text{O-atom charge center}) \simeq z(\text{Re}) \pm 0.03 \text{ \AA}$ . The resulting  $\text{ReO}_5^{3-}$  ionic contribution to  $P_s$  is thus small, as is the contribution of the  $\text{Na}^+$  ions (see Table S6, in which the origin has been displaced  $-0.0042$  along the  $c$  axis to minimize  $\Sigma\Delta z_i$ ). Three atoms occupy special 3(a) or 3(b) positions in space group  $P3_121$ <sup>1</sup> under displacements  $\Delta y(\text{Rb}) = 0.23 \text{ \AA}$ ,  $\Delta y(\text{Na1}) = 0.33 \text{ \AA}$ ,  $\Delta x(\text{O2}) = 0.95 \text{ \AA}$  and  $\Delta z(\text{O2}) = 1.45 \text{ \AA}$  from the positions in  $P3_1$ . The remaining atoms then form pairs related by the 6(c) position in space group  $P3_121$  for displacements no larger than  $0.59 \text{ \AA}$ . All atoms in the structure as refined hence satisfy the criteria for ferroelectric behavior given in §1.2. Confirmation of the structural details is desirable, as is application of the methods noted in §1.3.1.

## 2.8. $\text{Nd}_{14}(\text{GeO}_4)_2(\text{BO}_3)_6\text{O}_8$ and family

Ilyukhin & Dzhurinskii (1994) reported the structures of the rare-earth borogermanates  $\text{Nd}_{14}(\text{GeO}_4)_2(\text{BO}_3)_6\text{O}_8$  and  $\text{Sm}_{14}(\text{GeO}_4)_2(\text{BO}_3)_6\text{O}_8$  in space group  $P3_1$ . The Nd compound was measured at 295 K and refined to  $R = 0.079$  on the basis of 3902 independent reflections; the Sm compound at 170 K was refined to  $R = 0.042$  using 2219 reflections, with  $I_{\text{obs}} > 2\sigma(I_{\text{obs}})$  for both.

**2.8.1.  $\text{Nd}_{14}(\text{GeO}_4)_2(\text{BO}_3)_6\text{O}_8$ .** The final atomic coordinates of the Nd compound (as given in Table S7, in which an origin shift of  $-0.0122$  has been applied along the polar axis to minimize  $\Sigma\Delta z_i$ ) show that all 14 independent Nd atoms (atom Nd14 was reported to be split between two partially occupied sites 0.51  $\text{\AA}$  apart, 63% in the Nd14 site and 37% in the Nd14' site) form related pairs with  $0.7 \gtrsim \Delta\xi \gtrsim 0.4 \text{ \AA}$  of a general Wyckoff 6(c) position in space group  $P3_121$ . In addition, 32 of the 34 O atoms and four of the six B atoms form similarly related pairs with  $1.4 \gtrsim \Delta\xi \gtrsim 0.3 \text{ \AA}$  from 6(c) positions and  $x$ ,  $y(\text{Ge1}) \simeq y$ ,  $x(\text{Ge2})$ . Atoms O24, O25 and O26 are reported to be split between pairs of sites  $\lesssim 1.4 \text{ \AA}$  apart, each with 50% occupancy; split pairs are related to single O atoms by Wyckoff 6(c) positions with  $2.0 \gtrsim \Delta\xi \gtrsim 0.3 \text{ \AA}$ . Assuming that the approach to space group  $P3_121$  by 50 of the 56 independent atoms (including three B and two O atoms) is indicative of a possible transition to higher symmetry, then added translations of  $a_1/2$ ,  $a_2/2$  or  $c/2$  produce paired 6(c) relationships in all remaining atomic coordinates, with maximum displacements of  $\sim 1.5 \text{ \AA}$ . Thus,  $z(\text{Ge2})$  can be replaced by  $\frac{1}{2} + z$ ,  $z(\text{O27})$  by  $\frac{1}{2} + z$ ,  $x(\text{O30})$  by  $\frac{1}{2} + x$ ,  $y(\text{O30})$  by  $\frac{1}{2} + y$ ,  $z(\text{B1})$

by  $\frac{1}{2} + z$ ,  $z(\text{B3})$  by  $\frac{1}{2} + z$  and  $z(\text{B4})$  by  $\frac{1}{2} + z$  (as in Table S7). Comparable results follow if the  $x$ ,  $y$  or  $z$  coordinate of the other member of each pair of related atoms is replaced by  $\frac{1}{2} + x$ ,  $\frac{1}{2} + y$  or  $\frac{1}{2} + z$ . Structural reinvestigation is necessary to confirm the possibility of such replacement.

The resulting  $\Delta x$ ,  $\Delta y$  and  $\Delta z$  displacements of all atoms in Table S7 fully satisfy the structural criteria for ferroelectricity given in §1.2. The Nd atoms occupy a variety of O polyhedra, ranging from distorted octahedral for Nd13 through 7- ( $\times 3$ ), 8- ( $\times 5$ ), 9- ( $\times 4$ ) and 11-coordination (the number of each kind of polyhedron is given in parentheses). The Ge atoms form distorted tetrahedra, with  $d_{\text{Ge-O}}$  ranging from 1.753 to 2.013 Å and angles of 105.6–114.3°. The B atoms lie near the centers of the O triangles, with  $d_{\text{B-O}}$  ranging from 1.338 to 1.374 Å (except for atom B6, which has six  $d_{\text{B-O}}$ , three from 100% and three from 50% occupied O sites, ranging from 1.340 to 1.427 Å) and angles ranging from 114.1 to 129.5° (22–158° for B6). The force constant in (1) is unknown for tetrahedral and triangular sites, and hence  $T_c$  cannot be estimated for this structure.

X-ray scattering by 14 Nd atoms (atomic number 60) dominates that by Ge, B and O atoms, opening the possibility that some lighter-atom coordinates may be misassigned by  $a/2$  or  $c/2$ , as noted above. Half-cell shifts in seven coordinates for six lighter atoms of the 170 coordinates varied are likely to have little effect on the final value of  $R$ , although the coordinates reported give normal  $\langle d_{\text{Nd-O}} \rangle$ ,  $\langle d_{\text{Ge-O}} \rangle$  and  $\langle d_{\text{B-O}} \rangle$  distances of 2.454, 1.775 and 1.352 Å, respectively.

**2.8.2.  $\text{Sm}_{14}(\text{GeO}_4)_2(\text{BO}_3)_6\text{O}_8$ .** The atomic coordinates at 170 K presented by Ilyukhin & Dzhurinskii (1994) are nearly identical to those in Table S7 and hence are also consistent with ferroelectricity. Further structural study of this family is expected to be revealing, particularly with regard to the possibility of phase transitions with integral change in cell volume, as in the case of  $\text{YMnO}_3$  (Abrahams, 2001; see also §1.3.1).

## 2.9. $\text{CsHgCl}_3$ family

**2.9.1.  $\text{CsHgCl}_3$ .** Structural refinement reported by Albarski *et al.* (2000), without reference to the previous study of  $\text{Cs}_{0.7}(\text{NH}_4)_{0.3}\text{HgCl}_3$  by Kabadou *et al.* (1998) (see §2.9.2), was based on 1724 independent reflections with  $I > 2\sigma(I)$  and led to  $R = 0.0228$  and  $wR = 0.0501$ . The resulting atomic coordinates are transformed in space group  $P3_2$  and reordered in Table S8(a) for direct comparison with those of Kabadou *et al.* (1998) in Table S8(b) (an origin displacement of 0.18701 has been applied in order to minimize  $\Sigma\Delta z$  for all atoms). Table S8(a) shows that the three independent Cs and three Hg atoms meet the symmetry of space group  $P3_212$  for  $0.18 \gtrsim \Delta\xi \gtrsim 0.04$  Å with  $u_{\text{eq}}(\text{Cs,Hg}) \leq 0.24$  Å, while the largest displacement among the nine independent Cl atoms is 0.59 Å for atom Cl3 with  $u_{\text{eq}}(\text{Cl3}) = 0.23$  Å. The structural criteria for ferroelectricity given in §1.2 are hence satisfied.

**2.9.2.  $\text{Cs}_{0.7}(\text{NH}_4)_{0.3}\text{HgCl}_3$ .** The structure of this substituted family member was solved in space group  $P3_2$  by Kabadou *et al.* (1998) and refined by the use of 700 independent reflections

with  $I_{\text{obs}} > 2\sigma(I_{\text{obs}})$ . The final  $R$  value was 0.057 for the atomic coordinates in Table S8(b) (the origin has been displaced by 0.0012 to minimize  $\Sigma\Delta z$  for all atoms). The largest displacement among the three independent Cs and Hg atoms for a transition to space group  $P3_212$  is  $\Delta z(\text{Cs1}) = 0.17$  Å, whereas  $u_{\text{eq}}(\text{Cs1}) = 0.21$  Å (*cf.* §2.9.1). However, the 12 Cl atomic displacement components with  $0.54 \geq \Delta\xi \geq 0.17$  Å, together with 27 geometrically located H atoms that have  $1.07 \geq \Delta\xi \geq 0.24$  Å, satisfy the structural ferroelectricity criteria of §1.2. All Cs sites are reported to be 70% occupied by  $\text{Cs}^+$  and 30% occupied by  $\text{NH}_4^+$ . The atomic coordinates of the Cs, Hg and Cl atoms in both family members are very similar (see Tables S8a and S8b). The successful partial substitution of  $\text{NH}_4^+$  (octahedral radius  $\simeq 1.61$  Å) for  $\text{Cs}^+$  ( $\sim 1.67$  Å) suggests the possible substitution of  $\text{Rb}^+$  ( $\sim 1.52$  Å) and  $\text{Tl}^+$  ( $\sim 1.50$  Å) as extensions of the  $\text{CsHgCl}_3$  family.

All three Hg atoms in both structures occupy distorted octahedra formed by six Cl atoms, with axes inclined to the polar direction; each Hg atom is located within 0.03 Å of a special plane at  $z = \frac{1}{6}, \frac{1}{2}$  or  $\frac{5}{6}$ . The net displacement of atom Hg1 from its octahedral charge center is 0.25 Å, that of atom Hg2 is 0.23 Å and that of atom Hg3 is 0.07 Å based on Table S8(b). Corresponding displacements based on Table S8(a) are 0.10, 0.16 and 0.10 Å respectively. Assuming that both reports are equally reliable, with no significant change caused by  $\text{NH}_4^+$  ion substitution, then the largest atomic displacement is that of the Hg2/Cl6 octahedron, with  $\Delta z_{\text{max}} = 0.195$  Å. Assuming that (1) is directly applicable to Cl octahedra results in a value of  $T_c = 760$  K, with an uncertainty of comparable magnitude. It is notable that Kabadou *et al.* (1998) report an anomalous peak at 449 K in the dielectric permittivity of  $\text{Cs}_{0.7}(\text{NH}_4)_{0.3}\text{HgCl}_3$ , over the frequency range  $10^3$ – $10^6$  Hz, with maximum strength at  $\sim 5$  kHz. Measurements as outlined in §1.3.1 may show that the dielectric anomaly occurs at  $T_c$ .

## 2.10. $\text{Ba}_2\text{Cu}_2\text{AlF}_{11}$

The structure was solved in space group  $P3_2$  and refined by Dupont *et al.* (1998) using 2476 reflections with  $F_{\text{obs}} > 4\sigma(F_{\text{obs}})$ . The final  $R$  value is 0.062 for the atomic coordinates in Table S9 (an origin shift of 0.2151 has been applied in order to minimize  $\Sigma\Delta z$  for all 16 atoms). The Cu atoms form distorted edge-sharing octahedra that give  $\text{Cu}_2\text{F}_9$  entities linked to regular  $\text{AlF}_6$  octahedra, which results in twisted chains along the polar direction. Examination of Table S9 shows that the location of each atom is related to a corresponding Wyckoff position in space group  $P3_212$ . The maximum atomic displacement components between such positions are  $\Delta x(\text{F8,F9}) \simeq 0.6$ ,  $\Delta y(\text{F1,F2}) \simeq 0.6$  and  $\Delta z(\text{F3,F6}) \simeq 0.9$  Å, with  $\Delta z(\text{Al}) \simeq 1.2$  Å (between the Al-atom location in space group  $P3_2$  and Wyckoff position  $x, 2x, \frac{1}{3}$  in the supergroup). All  $\Delta\xi$  are less than required in §1.2, and hence  $\text{Ba}_2\text{Cu}_2\text{AlF}_{11}$  meets the structural criteria for ferroelectricity. Although the large magnitude of  $\Delta z(\text{Al})$  is indicative of a high  $T_c$ ,  $z(\text{Al})$  differs by only 0.225 Å from the charge center of its F octahedron, which corresponds to  $T_c \simeq 1015$  K in (1). The large  $\Delta z(\text{Al})$  and the normal displa-

cement of Al from its octahedral center suggest the possibility of an integral change in lattice parameter at  $T_c$ , such as the factor of 3 in unit-cell volume at the phase transition of  $\text{YMnO}_3$  (from space group  $P6_3cm$  to  $P6_3/mmc$  at its Curie point; Łukasiewicz & Karat-Kalicińska, 1974). High-temperature X-ray diffraction measurements together with those outlined in §1.3.1 may be revealing.

## 2.11. KYF<sub>4</sub> family

**2.11.1. KYF<sub>4</sub>.** A selected subset of 1286 absorption-corrected reflections with  $I_{\text{obs}} > 3.3\sigma(I_{\text{obs}})$ , from a total of 3045 measured at room temperature, were used by Le Fur *et al.* (1992*a*) in solving the structure. The full data set led to a final  $R_F$  value of 0.038 for the atomic coordinates in Table 4 (an origin shift of  $-0.3195$  minimizes  $\Sigma\Delta z_i$ ). Table 4 shows that the largest  $\Delta z$  displacement between an atom in space group  $P3_1$  and its corresponding position in supergroup  $P3_121$  is  $0.48 \text{ \AA}$ , for atoms F4, F6, F10 and F12. Corresponding values of  $\Delta z$  for the metal atoms range from  $\sim 0.01$  to  $0.30 \text{ \AA}$  for K atoms and from  $0.12$  to  $0.16 \text{ \AA}$  for Y atoms. The largest  $\Delta x$  or  $\Delta y$  displacements range from  $1.0$  to  $1.2 \text{ \AA}$  for atoms F2, F8, F3, F5, F9, F11, F10 and F12. The criteria for ferroelectricity given in §1.2 are clearly satisfied, and hence the methods in §1.3.1 are applicable.

Three Y atoms form monocapped  $\text{YF}_7$  trigonal prisms with  $\langle d_{\text{Y-F}} \rangle = 2.225 \text{ \AA}$ , three pentagonal  $\text{YF}_7$  bipyramids have  $\langle d_{\text{Y-F}} \rangle = 2.227 \text{ \AA}$ , and six independent K atoms occupy distorted  $\text{KF}_8$  cubes with  $\langle d_{\text{K-F}} \rangle = 2.759 \text{ \AA}$ . The Y-atom contribution to the force constant,  $\kappa$  in (1), with less ionic bonds, is expected to exceed the K-atom contribution. The maximum displacement by a Y atom from the charge center of its  $\text{YF}_7$  pentagonal bipyramidal is  $0.176 \text{ \AA}$  (Y1). Assuming that  $\kappa$  is identical to that in (1) gives  $T_c \simeq 610 \text{ K}$ , with a nominal uncertainty of  $\sim 50 \text{ K}$  that is increased by an unknown factor as a result of the eight  $\Delta x(\text{F})$ ,  $\Delta y(\text{F})$  displacements greater than  $1 \text{ \AA}$  (see Table 4).

**2.11.2. KY<sub>0.95</sub>Er<sub>0.05</sub>F<sub>4</sub>.** Le Fur *et al.* (1992*b*) reported this structure, refined using 2667 reflections with  $I_{\text{obs}} > 3.5\sigma(I_{\text{obs}})$  to final values of  $R = 0.032$  and  $wR = 0.035$ . Half of the  $\text{LnF}_7$  bipyramids were found to contain an unsubstituted Y atom; the other half contain 90% Y and 10% Er. Comparison of corresponding atomic coordinates following an origin shift of  $-0.3435$  (the atomic numbering and order differ in the two studies, with F12 in the  $\bar{y}, x - y, \frac{1}{3} - z$  location relative to  $x, y, z$  in Table 4) reveals no differences greater than  $0.08 \text{ \AA}$  in  $x$ ,  $0.07 \text{ \AA}$  in  $y$  and  $0.08 \text{ \AA}$  in  $z$ . The properties of  $\text{KY}_{0.95}\text{Er}_{0.05}\text{F}_4$  are hence expected to resemble closely those of  $\text{KYF}_4$ .

## 2.12. SrS<sub>2</sub>O<sub>6</sub>·4H<sub>2</sub>O

Fábry (1995) reported the  $\text{SrS}_2\text{O}_6 \cdot 4\text{H}_2\text{O}$  structure in a unit cell with doubled  $a_1$  and  $a_2$  axes and space group  $P3_2$ , based on the presence of numerous weak reflections, in contrast to earlier determinations (ZEKGA 135 399; ASBSD B47 12) in the smaller cell with space group  $P6_2$  or  $P6_422$ , respectively. A total of 10 330 independent  $I_{\text{all}}$ , 5789 with  $I_{\text{obs}} > 3\sigma(I)$ , were used in the refinement, for which the Sr- and OW-atom posi-

tions, where OW denotes an O atom belonging to a water of hydration, were taken directly from the smaller cell. The dithionate ions appeared disordered in the smaller cell but are compatible with eight different ordered arrangements in the larger cell, one being favored by the intensity data. Refinement then led to  $R_{\text{all}} = 0.111$  and  $R_{\text{obs}} = 0.044$  for the atomic coordinates in Table S10. Refinement in the alternative space groups  $P3_1$ ,  $P6_2$ ,  $P6_4$ ,  $P6_222$  and  $P6_422$  gave larger indicator values; results in space group  $P3_121$  were not reported.

Table S10 (in which the reported origin is displaced by  $0.33011$  to minimize  $\Sigma\Delta z$ ) contains no  $\Delta z$  values greater than  $u_{\text{eq}}$ . All  $\Delta\xi$  magnitudes required to satisfy space-group  $P3_121$  symmetry are less than the corresponding  $u_{\text{eq}}$  in half of the 52 independent atoms, including the four Sr atoms. The remaining 26 atoms, however, have  $1.63 \geq \Delta x$ ,  $\Delta y \geq 0.17 \text{ \AA}$ . If the structure determination is reliable, then the atomic positions generally satisfy the criteria of §1.2. Since  $\Delta z_{\text{max}} = 0.14 \text{ \AA}$ ,  $T_c$  is not likely to be high if the potential barrier associated with the larger  $\Delta x$  and  $\Delta y$  displacements is readily overcome, in which case, ferroelectric hysteresis may be readily observable at room temperature (see §1.3.1).

## 2.13. Cu<sub>3</sub>PbTeO<sub>6</sub>(OH)<sub>2</sub>

The structure of the mineral parakhinite,  $\text{Cu}_3\text{PbTeO}_6(\text{OH})_2$ , was determined (Burns *et al.*, 1995) by the use of 744 symmetry-independent reflections with  $I_{\text{obs}} \geq 2.5\sigma(I_{\text{obs}})$ , corrected by an empirical absorption factor and modeling the crystal as a plate. An additional 380 reflections with a plate-glancing angle of less than  $11^\circ$  were discarded. All crystals examined were twinned, thus preventing the observation of uniaxial interference figures. An earlier report (AMMIA 63 1016) gave the space group as  $P6_222$  or  $P6_422$ , but a structure solution could be found in neither. Burns *et al.* (1995) suggest that the twinning may originate in a possible transition from a higher-temperature phase with  $P6_2$  symmetry. Structural refinement in  $P3_2$  gave final values of  $R = 0.081$  and  $wR = 0.087$  for the coordinates in Table S11 (with an origin shift of  $0.3103$  to minimize  $\Sigma\Delta z$ ). The locations of all 13 independent atoms, except the H atoms, which were not determined, are related to corresponding positions in space group  $P3_212$ , with  $\Delta x_{\text{max}} = 1.41 \text{ \AA}$  for atoms Cu2 and Cu3,  $\Delta y_{\text{max}} = 0.95 \text{ \AA}$  for Te, and  $\Delta z_{\text{max}} = 0.71 \text{ \AA}$  for Te. The  $1.41 \text{ \AA}$  displacement exceeds the range noted in §1.2, and hence spontaneous polarization reversal at room temperature may not be possible but will become more likely at higher temperatures if  $|\Delta\xi|$  decreases appreciably on heating.

Burns *et al.* (1995) inferred that H atoms were bonded to OH1 and OH2; it can be seen from Table S11 that, if the structure and space-group-supergroup relationship are confirmed, with hypothetical coordinates  $x, 2x, \frac{1}{3}$  for each ( $x \simeq 0.474$  for H1 and  $0.211$  for H2), H1 forms a symmetrical bond between O3 and OH1, and H2 forms a symmetrical bond between O1 and OH2, unless either or both H atoms are disordered.

The asymmetric unit contains an irregular  $\text{TeO}_6$  octahedron, three independently distorted  $\text{CuO}_6$  octahedra and one irre-

**Table 4**

Atomic positions for KYF<sub>4</sub> at room temperature (Le Fur *et al.*, 1992*a*), with hypothetical  $x'$ ,  $y'$  and  $z'$  coordinates and  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  and  $u^{33}$  displacements in Å.

$a = 14.060$  (10) and  $c = 10.103$  (10) Å;  $z^* = z - 0.3195$ , with  $\Delta x = (x - x')a$ ,  $\Delta y = (y - y')a$  and  $\Delta z = (z^* - z)c$ .

† See footnote 1 for equivalent positions.

gular PbO<sub>6</sub>(OH)<sub>2</sub> polyhedron; all have small effective polarizations because of the near-coincidence of  $z(\text{Te})$ ,  $z(\text{Cu})$  and  $z(\text{Te})$  with their polyhedral O-atom charge centers, despite the fact that  $\Delta z(\text{Te}) = 0.71$  Å and  $\Delta z(\text{Cu1}) = 0.67$  Å. Cu<sub>3</sub>Pb-TeO<sub>6</sub>(OH) is hence a candidate for testing, as noted in §1.3.1.

### 2.14. HRe(CO)<sub>4</sub>

*Ab initio* solution of the X-ray powder diffraction pattern of  $\alpha$ -poly[ReH(CO)<sub>4</sub>]<sub>n</sub> followed by Rietveld refinement (Masciocchi *et al.*, 2000) gave  $R_p = 0.055$ ,  $wR_p = 0.071$  and  $R_F = 0.054$ . The resulting atomic coordinates are given in Table S12, with an origin shift of −0.0084 that minimizes  $\Sigma \Delta z$  for the three independent Re atoms. Recognition of a 3<sub>1</sub> or 3<sub>2</sub> axis in the Patterson function led to analysis in space group  $P3_1$ , which revealed three independent Re atoms. Use of either of the supergroups  $P3_121$  or  $P3_112$  ‘dramatically worsened pattern matching’ in subsequent refinement.

Examination of Table S12 reveals a range of displacement components between the refined atomic coordinates in space

group  $P3_1$  and those anticipated in space group  $P3_121$  with  $1.10 \geq \Delta x$ ,  $\Delta y \geq 0.02$  and  $0.25 \geq \Delta z \geq 0.01$  Å. The structure hence satisfies the criteria for ferroelectricity given in §1.2, although 26  $\Delta x$  and  $\Delta y$  components exceed 0.63 Å. Accepting the  $u_{\text{iso}}$  values in Table S12 (Re was assigned as 0.19 Å, the remainder 0.25 Å), the  $\Delta \xi$  displacements satisfy the criteria in §1.2 and a phase transition at moderate temperatures appears likely. Further investigation by the methods of §1.3.1 is necessary for confirmation.

### 2.15. Ni<sub>2</sub>(NH<sub>3</sub>)<sub>9</sub>Mo(CN)<sub>8</sub>·2H<sub>2</sub>O

The structure at 153 (2) K was determined by Meske & Babel (1999) and refined on the coordinates presented in Table S13, with an origin displacement of −0.12993 to minimize  $\Sigma \Delta z_i$ . The compound decomposes easily, with positional disorder exhibited by the N1/N18, O1/O2 and O3/O4 pairs. Table S13 shows that all atoms have displacement components from corresponding locations in space group  $P3_121$  of less than  $\Delta x \approx 1.7$  Å,  $\Delta y \approx 1.9$  Å and  $\Delta z \approx 1.4$  Å, with 45 having

$0.6 \gtrsim \Delta\xi \gtrsim 0.3 \text{ \AA}$  and 42 having  $\Delta\xi \lesssim 0.3 \text{ \AA}$ . The exception is  $\Delta x(\text{NH13}) = \Delta y(\text{NH13}) = 2.57 \text{ \AA}$  taking the coordinates as reported; both values reduce to  $\sim 0.4 \text{ \AA}$  if a negative sign has been omitted in the report. Many  $\Delta\xi$  displacement magnitudes along each axis are larger than usual, resulting in increased uncertainty. A new diffraction study of a fully ordered crystal is necessary for property prediction at a higher confidence level, but the methods of §1.3.1 would be definitive.

### 2.16. $\text{Ca}_{1.89}\text{Ta}_{1.80}\text{Sm}_{0.16}\text{Ti}_{0.10}\text{O}_7$ (6T polytype)

The structure of 6T- $\text{Ca}_2\text{Ta}_2\text{O}_7$ , a polytype doped with  $\sim 6 \text{ mol\% Sm}_2\text{Ti}_2\text{O}_7$ , has recently been reported by Grey & Roth (2000). Initial determination of the Ca/Ta ordering based on Rietveld methods and an experimental powder pattern led to a model with only metal atoms that refined in space group  $P3_121$  to  $R = 0.13$  for 2660 reflections with  $F > 4\sigma(F)$ . O atoms located from difference maps completed the model, which refined to  $R = 0.07$ . Unusually large displacement factors ( $0.17 \leq u_{\text{iso}} \leq 0.22 \text{ \AA}$ ) for several O atoms led to refinement in space group  $P3_1$ , with final  $R$  values of 0.038 (0.051 for all reflections) after a change in origin (see below). Unlike the 5M polytype (formed by  $\text{Ca}_2\text{Ta}_2\text{O}_7$  doped with  $\sim 10 \text{ mol\% Sm}_2\text{Ti}_2\text{O}_7$ ), significant ordering of Sm and Ti atoms into specific Ca and Ta sites was not reported. The final coordinates in Table S14(a) show that, of a total of 132 independent atomic coordinates, 53 are displaced from related locations in space group  $P3_121$  by  $0.56 \geq \Delta\xi \geq 0.11 \text{ \AA}$ , with 52 of the remaining  $\Delta\xi$  being  $\leq 0.05 \text{ \AA}$ . All displacements satisfy the structural criteria for ferroelectricity given in §1.2, although Table S14(a) shows that a phase transition from  $P3_1$  to  $P3_121$  would equate Ca and Ta atoms in two pairs of atomic positions.

Resolution of this difficulty (Grey, 2002) is achieved by an origin change of  $+(\frac{1}{3}, \frac{2}{3}, \frac{1}{6})$  (see Table S14b). A total of 123 atomic coordinates following refinement in space group  $P3_1$  differ from those in  $P3_121$  by  $\Delta\xi \leq 0.03 \text{ \AA}$ , with  $\Delta\xi$  generally less than  $u_{\text{iso}}$ . The largest  $\Delta\xi$  is  $\sim 0.12 \text{ \AA}$  for  $\Delta x(\text{Ta3})$ ,  $\Delta y(\text{Ta3})$ ,  $\Delta z(\text{Ca1})$  and  $\Delta z(\text{Ca12})$ . Refinement of the  $P3_1$  model gave a significantly better fit than the best  $R$  value (0.05) in space group  $P3_121$ , with its high thermal parameters, and hence the criteria of §1.2 are satisfied. The diffraction evidence thus favors ferroelectricity in this polytype, but investigation as outlined in §1.3.1 is necessary for confirmation.

## 3. Known ferroelectrics and related predictions in space group $P3_1$

### 3.1. Stillwellite family

The ICSD release 2002/2 reports 16 determinations of materials structurally related to the mineral stillwellite, space group  $P3_1$ ,  $a \simeq c \simeq 7 \text{ \AA}$ , and formula  $X[\text{BO}(\text{MO}_4)]$ , where  $X = \text{La}$  and other rare-earth metals with  $M = \text{Ge}$  or  $\text{Si}$ , or  $X = \text{Ba}$  or  $\text{Pb}$  with  $M = \text{As}$ . Composition of the mineral generally includes a range of elements, the study by Callegari *et al.* (1992) reporting  $X = 0.56 \text{ Ce}$ ,  $0.34 \text{ La}$ ,  $0.04 \text{ Th}$  and  $0.02 \text{ Ca}$  (see Table S15a). Burns *et al.* (1993) report  $0.50 \text{ Ce}$ ,  $0.32 \text{ La}$ ,

$0.08 \text{ Nd}$ ,  $0.05 \text{ Th}$ ,  $0.03 \text{ Pr}$ ,  $0.01 \text{ Ca}$  and  $0.01 \text{ Sm}$  (see Table S15b).

After the stillwellite structure was found to satisfy the criteria in §1.2, and hence could be predicted to be ferroelectric, a literature search revealed that  $\text{LaBGeO}_5$  had been reported to undergo a ferroelectric phase transition at 790–800 K (Stefanovich *et al.*, 1992; Onodera *et al.*, 1993), with  $P_s = 2.7 \times 10^{-2} \text{ C m}^{-2}$ .<sup>5</sup> Strukov *et al.* (1997, 1998) subsequently reported  $T_c = 802 \text{ K}$  with  $\Delta S = 0.95 (3) \text{ J mol}^{-1} \text{ K}^{-1}$  and  $P_s = 2.4 (8) \times 10^{-2} \text{ C m}^{-2}$ , magnitudes consistent with the displacements in Table S15(c).

**3.1.1. (Ce,La)BSiO<sub>5</sub>.** The atomic coordinates in Table S15(a), with an origin shift of 0.0096 along the polar  $c$  axis to minimize  $\Sigma\Delta z_i$ , are based on 1070 unique  $I_{\text{exp}}$ , of which 1043 have  $I_{\text{exp}} \geq 5\sigma(I_{\text{exp}})$ . The final  $R$  value is 0.015 for all  $I_{\text{exp}}$  and 0.014 for the observed set. There are 11 displacements with  $\Delta\xi \geq u_{\text{iso}}$ , the largest being for atom O5 ( $\Delta x = 0.40 \text{ \AA}$  and  $\Delta z = 0.29 \text{ \AA}$ ) and the next largest being for the B atom ( $\Delta y = 0.12 \text{ \AA}$ ). Callegari *et al.* (1992) note that the absolute configuration of their specimen corresponds to  $P3_2$ , but gave the results in  $P3_1$ . The refinement by Burns *et al.* (1993) used 1003 independent  $F > 5\sigma(F)$  with  $R = 0.027$  and  $wR = 0.033$ . The sense of their  $x$  and  $y$  coordinates is reversed, equivalent positions with atomic renumbering are used, and the origin is displaced by 0.8326 for direct comparison with the values in Table S15(a). All coordinates in both tables agree closely, the primary difference between the two sets being the disorder reported in Table S15(b) for the atom at the O5 site; the data are also comparable to earlier results (KRISAJ 12 258). The maximum  $\Delta\xi$  displacements between positions in space group  $P3_1$  and in the supergroup are again reported in atom O5 (and atom O5'), with  $|\Delta z| \simeq 0.33 \text{ \AA}$  and  $|\Delta x| = |\Delta y| \simeq 0.20 \text{ \AA}$ , which are comparable with  $\Delta\xi(\text{O5})$  in Table S15(a). The structural criteria for ferroelectricity given in §1.2 are hence satisfied by both mineral stillwellite determinations.

**3.1.2. LaBGeO<sub>5</sub>.** The structure of synthetic  $\text{LaBGeO}_5$ , which is isostructural with mineral stillwellite, was determined by Kaminskii *et al.* (1990) and Belokoneva *et al.* (1991, 1997). Refinement gave the atomic coordinates in Table S15(c), following an origin shift of 0.8505 along the polar axis to minimize  $\Sigma\Delta z_i$ , with  $R = 0.030$  and  $wR = 0.028$  on refinement with 1407 unique reflections. Table S15(c) shows all atoms with  $0.40 \geq \Delta\xi \geq 0 \text{ \AA}$  at the transition from space group  $P3_1$  to  $P3_121$ . As with mineral stillwellite,  $|\Delta z(\text{O5})| = 0.24 \text{ \AA}$  is the largest polar displacement, with  $\Delta x(\text{O5}) = 0.40 \text{ \AA}$ . All other  $\Delta x$  and  $\Delta y$  are less than  $0.08 \text{ \AA}$ . The criteria given in §1.2 for the existence of ferroelectricity are thus again satisfied.

**3.1.3. PrBGeO<sub>5</sub> phase II.** Strukov *et al.* (1997) report a first-order ferroelectric–ferroelectric phase transition in  $\text{PrBGeO}_5$  at  $\sim 800 \text{ K}$ , with an integral change in cell volume, and a second-order ferroelectric–nonferroelectric phase transition at  $T_c = 1016 \text{ K}$ . Belokoneva *et al.* (1998) also detected phase transitions at  $\sim 823$  and  $\sim 1023 \text{ K}$  and determined the structure of all three phases in the course of a neutron powder

<sup>5</sup>  $P_s$  magnitudes are customarily given in units of  $10^{-2} \text{ C m}^{-2}$ , although SI nomenclature requires units such as  $\text{mC m}^{-2}$ .

diffraction study. Phase II forms above 823 K in space group  $P3_1$ , and phase III forms below 823 K (see §3.1.4). Rietveld fitting of the powder profile for phase II at 923 K led to the atomic coordinates presented in Table S16(a), after an origin shift of 0.842 to minimize  $\Sigma\Delta z_i$ , with  $R_{\text{prof}} = 0.055$  and  $wR_{\text{prof}} = 0.061$  for 2503 observations. The distribution of atomic displacements from phase II to the postulated structure in space group  $P3_121$  is comparable to that reported in §§3.1.1 and 3.1.2, the largest magnitudes again being  $\Delta x(\text{O5}) = 0.38$  and  $\Delta z(\text{O5}) = 0.28$  Å. The  $\Delta z$  displacements are fully consistent with the experimental Curie temperature.

**3.1.4. PrBGeO<sub>5</sub> phase III.** The space group of phase III (see §3.1.3) is also  $P3_1$  as in phase II but with  $a_{\text{III}} \simeq 3^{1/2}a_{\text{II}}$  for a unit cell of tripled volume (Belokoneva *et al.*, 1998). The structure of phase III was determined at 293 K from single-crystal X-ray diffraction and high-resolution neutron powder diffraction data. Table S16(b) contains the final atomic coordinates refined using 2849 independent single-crystal reflections to  $R = 0.038$  and  $wR = 0.038$  and modified by an origin shift of 0.6807. The coordinates for atoms O13, O14 and O15 derived from neutron powder diffraction data are substituted in Table S16(b) for the single-crystal X-ray diffraction values, since the latter were reported without uncertainties. The neutron powder Rietveld refinement used 5957 profile values and gave  $R_{\text{profile}} = 0.072$  and  $wR_{\text{profile}} = 0.063$ ; the X-ray single-crystal data used 2827 independent  $F_{\text{obs}}$  and gave a final value of  $R \simeq 0.04$ .

It is of interest to determine whether phase III satisfies the criteria in §1.2 for a hypothetical transition to nonferroelectric supergroup phase I, in view of the intermediate formation of ferroelectric phase II. Table S16(b) shows that the  $\Delta\xi$  values for two pairs of O atoms, namely O1/O2 and O4/O5, are unusually large for such a transition ( $2.10 \geq |\Delta x, \Delta y| \geq 1.96$  Å). No other value of  $\Delta x$  or  $\Delta y$  is larger than 1.3 Å and no  $\Delta z$  magnitude exceeds 1.04 Å. Although the criteria are not satisfied by phase III, the implication of these large displacements is obviated by the intervention of phase II before the nonferroelectric state is reached. The first-order transition at  $T_{\text{III,II}} \simeq 810$  K was reported by Stefanovich *et al.* (1995) to exhibit strong thermal hysteresis, with anomalies in dielectric permittivity and loss at the phase transition. Phases II and III generate second harmonics. All atomic displacements in Tables S16(a) and S16(b) are consistent with this report.

**3.1.5. LaBSiO<sub>5</sub>.** The remaining reports of stillwellite-type structures in space group  $P3_1$  concern the compositions CeBSiO<sub>5</sub>, LaBSiO<sub>5</sub>, BaBaO<sub>5</sub> and PbBaO<sub>5</sub>. The earliest study was based on two-dimensional projections of the CeBSiO<sub>5</sub> structure (KRISA 12 258). Similarities in the lattice constants and structures of synthetic LaBSiO<sub>5</sub> and LaBGeO<sub>5</sub>, together with the small peak observed at ~400 K in the dielectric permittivity by Ono *et al.* (1996), suggested space groups  $P3_121$  above and  $P3_1$  below the transition. The structure determined at 293 K was based on 2047 independent reflections with  $F_{\text{obs}} > 3\sigma(F_{\text{obs}})$  and refined to a final  $wR(F)$  value of 0.068 for the atomic coordinates in Table S17(a), which are shifted 0.0008 along the polar axis; refinement at

443 K in space group  $P3_121$  with 1064 independent  $F_{\text{obs}}$  gave a final  $wR(F)$  value of 0.058. The closeness of these coordinates to the values determined in LaBGeO<sub>5</sub> at ~295 K (Table S15c), to those of Samygina *et al.* (1993) (also KRISAJ 38 61) in the structural determinations of synthetic LaBSiO<sub>5</sub> in Table S17(b) and to those of Belokoneva *et al.* (1996) in Table S17(c) confirms that LaBGeO<sub>5</sub> and LaBSiO<sub>5</sub> are isostructural at room temperature.

Ono *et al.* (1996) noted that no atom in LaBSiO<sub>5</sub> at 293 K is significantly displaced from the experimental locations determined at 443 K in space group  $P3_121$ . The atomic coordinates of LaBSiO<sub>5</sub> in Table S17(a) confirm this observation, with  $\Delta x, \Delta y, \Delta z \leq 0.014$  Å for all atoms with respect to the hypothetical structure in space group  $P3_121$ . By contrast, the LaBGeO<sub>5</sub> arrangement in space group  $P3_1$  clearly differs from the supergroup structure, with  $\Delta z(\text{O5}) \simeq 0.24$  Å (see Table S15c). Furthermore, each  $\Delta\xi \leq u^{ii}$  in Table S17(a), and in Tables S17(b) and S17(c), and no atomic coordinate differs significantly from those determined in the supergroup (see Table S17d).

The dielectric permittivity anomaly in LaBSiO<sub>5</sub> reported by Ono *et al.* (1996) was confirmed by Strukov *et al.* (1998), with transition temperature 412 K and entropy change  $\Delta S = 1.05$  (3) J mol<sup>-1</sup> K<sup>-1</sup>, in agreement with the possibility noted earlier (CAMIA 31 147) that LaBSiO<sub>5</sub> may be ferroelectric. Stefanovich *et al.* (1998) report that LaBSiO<sub>5</sub> generates second harmonics robustly from 300 to ~415 K, at which temperature their occurrence decreases sharply by a factor of ~4 and remains constant to at least 520 K. The physical evidence of a phase transition in LaBSiO<sub>5</sub> at ~410 K is hence indubitable. Ferroelectric hysteresis in the lower-temperature phase has not yet been reported; it is possible that LaBSiO<sub>5</sub> forms twins as it undergoes a transition to subgroup C2 below  $T_c \simeq 410$  K (Belokoneva, 2002). Further investigation of LaBSiO<sub>5</sub> is expected.

**3.1.6.  $\beta$ -LaBSiO<sub>5</sub>.** A fourth independent structural determination of LaBSiO<sub>5</sub> was reported by Chi *et al.* (1997). Their sample was prepared by heating the mixed oxides with V<sub>2</sub>O<sub>5</sub> in an evacuated quartz tube. The presence of Si in the resulting purple–pink crystals was attributed to the quartz. Refinement of 1094 unique reflections with  $I_{\text{obs}} \geq 3\sigma(I_{\text{obs}})$  gave  $R = 0.017$  and  $wR = 0.022$  for the atomic coordinates listed in Table S18(a), after an origin shift of -0.0064 to minimize  $\Sigma\Delta z_i$ . Inspection of the table shows that, despite maximum displacement magnitudes of 1.12 Å and 18 other displacements with  $0.7 \gtrsim \Delta\xi \gtrsim 0.5$  Å, the coordinates fulfill the structural criteria for ferroelectricity given in §1.2. It is notable, however, that the coordinates of  $\beta$ -LaBSiO<sub>5</sub> differ widely from those in phase II of  $\alpha$ -LaBSiO<sub>5</sub>; furthermore, the supergroup in the ferroelectric phase transition is space group  $P3_112$  rather than  $P3_121$ . The possibility of structural modification by V or traces of Si remains to be investigated, as do the dielectric properties of  $\beta$ -LaBSiO<sub>5</sub>.

**3.1.7. PbBaO<sub>5</sub>.** The structure was determined by Park & Bluhm (1996a), who refined 951 symmetry-independent reflections with  $F_{\text{obs}} > 4\sigma(F_{\text{obs}})$  to final values of  $R = 0.060$  and  $wR2 = 0.092$ . The atomic coordinates after an origin transla-

tion of 0.3019 along the polar axis are given in Table S18(b). PbBaAsO<sub>5</sub> is isostructural with  $\beta$ -LaBSiO<sub>5</sub> (cf. §3.1.6) but is fully ordered. All atomic displacements required for a transition to centrosymmetric space group  $P3_112$ , as with  $\beta$ -LaBSiO<sub>5</sub>, are consistent with the structural criteria for ferroelectricity given in §1.2;  $\Delta\xi_{\max} \approx 1.2$  Å for the same atom in both structures. If both independent determinations are reliable then the displacements noted are consistent with polarization reversal, and  $\beta$ -LaBSiO<sub>5</sub> and PbBaAsO<sub>5</sub> are new ferroelectric candidates.

**3.1.8. BaBaAsO<sub>5</sub>.** Park & Bluhm (1996b) determined the structure using a total of 461 independent reflections with  $F_{\text{obs}} > 4\sigma(F_{\text{obs}})$ , with final refinement to  $R = 0.053$  and  $wR2 = 0.096$ . The chemical formula and unit-cell dimensions of BaBaAsO<sub>5</sub> are similar to those of  $\beta$ -LaBSiO<sub>5</sub> and PbBaAsO<sub>5</sub> (see §§3.1.6 and 3.1.7), and also those of stillwellite, LaBGeO<sub>5</sub> and LaBSiO<sub>5</sub> (see §§3.1.1–3.1.3 and 3.1.5). The structure of BaBaAsO<sub>5</sub> exhibits both resemblances to and differences from the stillwellite family. Many of the atomic coordinates in Table S18(c), in which the origin is shifted  $\sim 0.0030$  to minimize  $\Sigma\Delta z_i$ , are comparable to those in  $\beta$ -LaBSiO<sub>5</sub> and PbBaAsO<sub>5</sub> on transformation. However,  $y(\text{Ba})$  and  $y(\text{As})$  in BaBaAsO<sub>5</sub> differ by  $\sim 1.5$  and  $\sim 1.4$  Å, respectively, from  $y(\text{Pb})$  and  $y(\text{As})$  in PbBaAsO<sub>5</sub>, with  $z(\text{O5})$ ,  $z(\text{O2})$  and  $z(\text{O4})$  differing by  $\sim 1.9$ ,  $2.0$  and  $2.6$  Å. Nevertheless, the largest  $\Delta\xi$  displacement magnitudes in Table S18(c) are comparable to those in  $\beta$ -LaBSiO<sub>5</sub> and PbBaAsO<sub>5</sub>, with all  $\Delta x \lesssim 0.9$  Å,  $\Delta y \lesssim 0.8$  Å and  $\Delta z \lesssim 0.2$  Å. All atomic displacements in BaBaAsO<sub>5</sub> required for a transition to the supergroup fully satisfy the criteria in §1.2, and hence the compound is a new candidate for ferroelectricity.

## 4. Incorrect or dubious structures in space groups $P3_1$ and $P3_2$

### 4.1. KTIF<sub>4</sub>

The space group  $P3_1$  for KTIF<sub>4</sub> was selected by Hebecker (1975) from six possible choices based on model building; supporting physical measurements were not reported. The final  $R$  value was 0.105 for all 491 independent reflections. The resulting atomic coordinates, adjusted by an origin shift of 0.139 along the polar axis to minimize  $\Sigma\Delta z_i$ , are presented in Table S19. All atoms in KTIF<sub>4</sub> have  $\Delta\xi_{\max} \lesssim u_{\text{iso}}$ , except atom F8, which has  $\Delta x$  and  $\Delta y$  of  $\sim 0.6$  Å, with  $u_{\text{iso}} \approx 0.2$  Å. A major physical property is unlikely to depend on a single atom with displacements of low significance. Atom F8 forms part of both TIF<sub>7</sub> distorted pentagonal bipyramids; the T11–F1 and T11–F8 distances are 2.46 and 2.49 Å, respectively, whereas the longest T12–F distance is 2.32 Å. Structural redetermination at higher accuracy may eliminate the anomalous  $\Delta\xi$  values.

### 4.2. Fe<sub>7</sub>Se<sub>8</sub> family

**4.2.1. Fe<sub>7</sub>Se<sub>8</sub>.** Andresen & Leciejewicz (1964) determined the structure of Fe<sub>7</sub>Se<sub>8</sub> at 493, 293 and 4.2 K in the course of an early neutron diffraction study of magnetic ordering.

Attempts at accommodating the Se atoms in space groups  $P6_2$  or  $P6_4$ , as suggested previously (JUPSA 12 929), failed, but a fit was obtained on the basis of the NiAs structure in space group  $P3_1$  or  $P3_2$  (see Table S20a). All calculated spacings match the observed lines in the published neutron powder pattern. The arrangement reported, however, corresponds *exactly* to space group  $P3_121$  (see Table S20). An independent X-ray diffraction study, without reference to the neutron paper, was reported (ACBCA 35 1210) in 1979 on a twinned single crystal. Despite apparent  $6/mmm$  Laue symmetry, the twin laws were recognized and the structure was determined with enantiomorphic domains in  $P3_121$  and  $P3_221$  to give a final  $wR$  value of 0.036 over all 527 independent  $F_{\text{obs}}$ .

**4.2.2. Fe<sub>7</sub>S<sub>8</sub>.** The structure of synthetic pyrrhotite was determined by Fleet (1971) using 317 Weissenberg-derived  $F_{\text{obs}}$  corrected for twinning, with a final  $R$  value of 0.108. An initial relationship noted between the refined Fe atomic coordinates and those in Table S20(a) was strengthened by shifting the origin by 0.3364 and replacing Fe7( $xyz$ ) by Fe7( $xy\bar{z}$ ); in addition, an origin shift of 0.1712 was applied to the S atoms (see Table S20b). The difference of  $\sim z/6$  between these two shifts leaves many structure factors unaffected and all Fe atoms coordinated to six S atoms at distances ranging from 2.15 to 2.61 Å, which are comparable to those reported. The atomic arrangement in Table S20(b), with  $0.23 \geq \Delta\xi \geq 0.03$  Å and  $u_{\text{iso}} \approx 0.10$  Å, does not differ significantly from that in supergroup  $P3_121$ . Alternative models are possible and the final choice requires a full structural reinvestigation. Nevertheless, all models are likely to be consistent with supergroup symmetry.

### 4.3. B<sub>2</sub>O<sub>3</sub>

Structural models proposed previously (ACBCA 24 1032; ACSAA 7 611; ACCRA 5 389) for B<sub>2</sub>O<sub>3</sub> were shown by Gurr *et al.* (1970) to be incorrect. In a new structural determination that used 130 independent reflections with  $F_{\text{obs}} > 2\sigma(F_{\text{obs}})$ ,  $I(00l)$  was reported with  $l \neq 3n$  as the only absence. Two space groups, namely  $P3_1$  and  $P3_2$ , were considered in solving the structure, and the former was chosen. The final atomic coordinates, corresponding to  $R = 0.0494$ , are presented in Table S21, which includes an origin shift of 0.7972 to minimize  $\Sigma\Delta z$ . Table S21 reveals that all atomic coordinates are within 0.02 Å of the corresponding locations in supergroup  $P3_121$ . Since  $0.13 > u_{\text{iso}} > 0.09$  Å for all atoms, it can be concluded that the present space-group assignment is in error.

### 4.4. Na<sub>4</sub>Ca<sub>4</sub>Si<sub>6</sub>O<sub>18</sub>

The structure of mineral low-combeite, Na<sub>4</sub>Ca<sub>4</sub>Si<sub>6</sub>O<sub>18</sub>, was reported by Fischer & Tillmanns (1983) in space group  $P3_1$ ; the determination was based on 2669 independent reflections with  $I > 2\sigma(I)$  and a final  $R$  value of 0.07. The resulting atomic coordinates (Table S22) show that there are 19 displacements with  $1.8 \gtrsim \Delta\xi \gtrsim 0.4$  Å, and  $\Delta\xi \lesssim 3u_{\text{iso}}$  for the remaining 80 displacements. It is unlikely that these  $\Delta\xi$  values would stabilize the structure in subgroup  $P3_1$  in view of the preponderance of otherwise minor displacements from  $P3_121$ .

A subsequent study of synthetic low-temperature  $\text{Na}_4\text{Ca}_4\text{Si}_6\text{O}_{18}$  (ACSCREE 42 934) gave satisfactory refinement in space group  $P3_121$ , as later confirmed (ACSCREE 43 1852) by a revised study of the original data, in which disorder was noted at several Na and Ca sites.

#### 4.5. $\text{Ti}_6\text{C}_{3+\delta}$

The ordered  $\delta'$ -phase was first reported with an NaCl-type arrangement compressed along [111] of the basic cubic  $\delta$ -phase to give a unit cell with lattice parameters  $a_{\delta'} \simeq 2^{-1/2}a_{\delta}$  and  $c_{\delta'} \simeq 2 \times 3^{1/2}a_{\delta}$  (KRISA 34 1513) in space group  $P3_121$ . The initial agreement with  $R = 0.11$  for the  $\delta'$ -phase model was subsequently improved by Kukul' *et al.* (1995) using 668 reflections with  $I_{\text{obs}} > 3\sigma(I_{\text{obs}})$  to  $R = 0.070$  for the  $P3_1$  vacancy model in Table S23. A strong correlation, however, was noted between the Ti1 site-occupancy factor and  $u_{\text{iso}}(\text{Ti1})$ . The unusually high magnitude of  $u_{\text{iso}}(\text{C2})$  may indicate additional correlation. Table S23 shows that the atomic coordinates of Ti1 and Ti2 are consistent with the 6(c) Wyckoff position in  $P3_121$ , as the vacancy distribution must also be if both sites are equally occupied rather than having the postulated  $4\sigma$  difference. The  $12\sigma$  difference reported in the site occupancy of atoms C1 and C2 is fully consistent with the unrelated Wyckoff 3(a) and 3(b) locations in space group  $P3_121$ . A change in Ti site occupancy to bring the structure into conformity with space group  $P3_121$  would be significant only if the standard deviations were well estimated; the strong parameter correlation noted in the course of refinement, leading most likely to an underestimation of  $\sigma$ , suggests that the  $\delta'$ -phase structure is not pyroelectric.

#### 4.6. $\text{IrGe}_4$

A structural choice between space groups  $P3_1$  and  $P3_121$  was made by Panday & Schubert (1969) in favor of the former. Estimated  $I(hk0)-I(hk5)$  values from Weissenberg photographs were used to refine the model, the final value of  $R$  being 0.147. The atomic coordinates following an origin shift of 0.0086 to minimize  $\Sigma\Delta z$  are listed in Table S24; uncertainties were not reported but may be substantial. The largest displacement component between refined coordinates and the corresponding locations in space group  $P3_121$  is  $\Delta z(\text{Ir}) = 0.13 \text{ \AA}$ ; with  $u_{\text{iso}}(\text{Ir}) \simeq 0.08 \text{ \AA}$ ,  $\Delta z(\text{Ir})$  is most likely without significance. The editors of the ICSD also noticed that the space group was probably  $P3_121$  and that several very small thermal/static atomic displacement factors [e.g.  $u_{\text{iso}}(\text{Ge3}) \simeq 0.03 \text{ \AA}$ ] were implausible.

#### 4.7. $\text{Nb}_6\text{C}_{4.73}$

A twinned crystal of nominal composition  $\text{Nb}_6\text{C}_5$ , annealed at 1375 K under He at 0.4 Mpa, was used by Christensen (1985) for the neutron diffraction measurements. Severe extinction was reported. A total of 150 reflections with  $I > 10\sigma(I)$  were used in the refinement to give a final  $R$  value of 0.064. Twinning prevented thermal-parameter variation but each site occupancy refined satisfactorily. The atomic coordinates listed in Table S25 include an origin shift of 0.168 along

the  $c$  axis to minimize  $\Sigma\Delta z$ . The uncertainties in the  $x$ ,  $y$  and  $z$  coordinates are reported as  $\sim 0.03$ ,  $\sim 0.03$  and  $\sim 0.08 \text{ \AA}$ . Examination of the table shows that no displacement component between the coordinates reported and those expected in space group  $P3_121$  differs significantly from zero. The data are hence consistent with space group  $P3_121$ .

#### 4.8. $\text{NaCa}_3(\text{CO}_3)_2\text{F}_3\cdot\text{H}_2\text{O}$ (sheldrickite)

Grice *et al.* (1997) reported merohedral pseudo-hexagonal twinning in crystals of the recently identified mineral sheldrickite and solved the structure in space group  $P3_2$ . A total of 867 reflections with  $F > 5\sigma(F)$  gave poor agreement in space groups  $P6_222$  and  $P6_422$ ; refinement in  $P3_221$  located several atoms and reduced the value of  $R$  to 0.16, but the  $\text{CO}_3^{2-}$  ions were not found, whereas refinement in  $P3_2$  revealed the remaining heavier atoms and gave  $R = 0.046$ . All resulting atomic coordinates in  $P3_2$ , except those of the two independent undetermined H atoms, are presented in Table S26. Examination of the 47  $\Delta\xi$  component displacements between these coordinates and those satisfying the symmetry of supergroup  $P3_121$ , as given in the table, shows that all but two are less than  $0.1 \text{ \AA}$ ; since  $0.2 \gtrsim u_{\text{iso}} \gtrsim 0.1 \text{ \AA}$  for all atoms with  $\sigma(\Delta\xi)$  nominally ranging between 0.01 and  $0.03 \text{ \AA}$ , these magnitudes are probably not significant. The exceptions  $\Delta z(\text{F3}) = 0.30 (2) \text{ \AA}$  and  $\Delta x(\text{OW}) = 1.37 (1) \text{ \AA}$ , if not a result of uncorrected error in the model, such as a misplaced OW atom, satisfy the criteria given in §1.2. It is unlikely, however, that a ferroelectric crystal would have so few departures from a dipole array that otherwise cancels. The space-group choice should hence be reexamined.

#### 4.9. $\text{ZnTe}$ , phase I

The atomic coordinates of ZnTe phase I at 11.5 GPa in Table S27 were proposed by Kusaba & Weidner (1994) on the basis of an energy-dispersive X-ray diffraction pattern taken at NSLS; the model is intermediate between the structure of zinc blende and rocksalt and estimates of uncertainty were not presented. The best agreement in space group  $P3_1$  was  $R \simeq 0.40$ , the major discrepancy arising from a poor fit with the 101 line at 41 keV. Although four other space groups were noted as compatible with the only observed systematic absence, namely  $I(00l)$  for  $l \neq 3n$ , models with alternative symmetry were not mentioned. With  $u_{\text{iso}} \simeq 0.10 \text{ \AA}$  and  $0.30 \gtrsim \Delta\xi \gtrsim 0.14 \text{ \AA}$  in Table S27, and distorted interlocking tetrahedra of Te and Zn atoms in which  $d_{\text{Zn-Te}}$  ranges from 2.179 to 2.748  $\text{ \AA}$ , space group  $P3_121$  is more likely.

#### 4.10. $\text{CaCO}_3\cdot\text{H}_2\text{O}$ (monohydrocalcite)

Effenberger (1981) determined and refined the structure in a subcell with  $a' = 6.0931 (9)$ ,  $c' = 7.545 (2) \text{ \AA}$  and space group  $P3_121$  to  $R = 0.039$  using 408 independent reflections with  $F_{\text{meas}} > 3\sigma(F_{\text{meas}})$ . The supercell with  $a = 3^{1/2}a'$  and  $c = c'$  has 226 additional reflections. Refinement in the supercell with space group  $P3_1$  gave  $R = 0.086$  for the atomic coordinates in Table S28; the origin here is shifted by +0.3333 along the  $c$  axis to place  $z(\text{Ca1})$  at 0. All three independent Ca atoms, the

three water O atoms and six of the nine O atoms of the  $\text{CO}_3^{2-}$  ion are located within 0.12 Å of Wyckoff positions in space group  $P3_112$ . Since all  $u_{\text{iso}} \approx 0.13$  Å, these locations do not differ significantly from the symmetry of space group  $P3_112$ . The remaining atoms (O7, O8, O9, C1, C2 and C3) are displaced with  $\Delta\xi$  components ranging from 0.02 to 0.35 Å; the significance of these  $\Delta\xi$  values is low. If these  $\Delta\xi$  components were confirmed then  $\text{CaCO}_3 \cdot \text{H}_2\text{O}$  would satisfy the criteria in §1.2; however, it is more likely that the symmetry does not depart significantly from that of  $P3_112$ .

## 5. Nonferroelectric pyroelectric structure in space groups $P3_1$

### 5.1. $\text{Li}_7\text{Cu}_7\text{Si}_5$

The unit cell contains 21 independent Cu atoms with 12 reported as substituted by as much as 27% Si, 14 Si atoms with five substituted by up to 18% Cu, and 22 Li atoms with seven sites substituted by up to 17% Cu. The structure was solved and refined by Pavlyuk *et al.* (1995) in space group  $P3_1$  to  $R = 0.056$ , using 1207 independent reflections with  $I_{\text{obs}} \geq 3\sigma(I_{\text{obs}})$  (atomic coordinates are given in Table S29). The structure was not found to approach a symmetry higher than that stated and hence this compound is not a candidate for ferroelectricity.

## 6. Entries with incomplete coordinates in space groups $P3_1$ and $P3_2$

### 6.1. Lithiophorite

The structure of  $(\text{Al,Li})\text{MnO}_2(\text{OH})_2$  as initially reported (ACBCA 5 676) in space group  $C2/m$  corresponds to complete octahedral layers in which  $\text{MnO}_2$  layers alternate with an Li-filled  $(\text{Al,Li})(\text{OH})_2$  layer. This arrangement led Pauling & Kamb (1982) to propose a superstructure involving  $\text{Mn}^{2+}$ ,  $\text{Mn}^{4+}$  ordering with formula  $\text{Li}_6\text{Al}_{14}(\text{OH})_{42}\text{Mn}_3\text{Mn}_{18}\text{O}_{42}$  in space group  $P3_1$ , based on Pauling's electroneutrality principle. The suggested atomic coordinates are presented in Table S30. In view of the original symmetry assignment and the lack of diffraction data supporting the proposed symmetry, property prediction on structural grounds would be inappropriate.

### 6.2. $\text{K}_4\text{SiW}_{12}\text{O}_{40} \cdot 18\text{H}_2\text{O}$

Atomic coordinates for  $\text{K}_4\text{SiW}_{12}\text{O}_{40} \cdot 18\text{H}_2\text{O}$  in space group  $P3_2$  were not presented in this early study (ZEKGA 94 256). No subsequent entry for the material appears in the database, and the original entry under Collection Code #38538 was later eliminated; anhydrous  $\text{K}_4\text{SiW}_{12}\text{O}_{40}$  is reported to form in space group  $Pnma$ .

### 6.3. $\text{K}_5\text{CoW}_{12}\text{O}_{40} \cdot 20\text{H}_2\text{O}$

The structure, first reported in space group  $P6_222$  by Yannoni (1961), was recently redetermined at 150 K by Muncaster *et al.* (2000); this new study illustrates the major

role played by tetrahedral  $\text{Co}^{\text{III}}$  ions in the catalytic behavior of  $\text{CoAlPO}$ -type agents. A total of 15 171 unique reflections were measured, and the structure was independently solved in space group  $P3_1$ , after the previous choice of space group failed to give a satisfactory structure; the new model refined to  $R = 0.054$  for  $I > 2\sigma(I)$ , with  $R = 0.120$  for all data. The final atomic coordinates are presented in Table S31 for an origin shift of 0.4572 to set  $z(\text{Co}) = 5/6$ . Examination of the displacement components between the coordinates of all atoms determined (two K, 12 W, one Co, 40 O and 12 OW atoms) and the corresponding locations in space group  $P3_121$  shows that none are larger than 0.02 Å, except for those of atoms OW11 and OW12 ( $0.08 \gtrsim \Delta\xi \gtrsim 0$  Å). It is noted that  $0.24 > u_{\text{iso}} > 0.16$  Å for all atoms except six OW atoms, for which  $0.48 > u_{\text{iso}} > 0.29$  Å.

Muncaster *et al.* (2000) succeeded in locating all atoms in this large structure except for three K, eight OW and 40 H atoms. On the basis of the unambiguous evidence in Table S31 that space group  $P3_121$  fits the model equally well but with many fewer parameters than in  $P3_1$ , it is expected that these 'missing' atoms will appear if additional refinement in the supergroup is undertaken.

Access to the ICSD has been through CD-ROM DOS products, the WWW Windows version by Fachinformationszentrum (FIZ) Karlsruhe with the Institute Laue-Langevin, and the current Windows version issued jointly by FIZ and the National Institute of Standards and Technology in cooperation with the International Union of Crystallography. Support of this work by the National Science Foundation (grant Nos. DMR-9708246 and DMR-0137323) is gratefully acknowledged. It is a pleasure to thank Professor E. L. Belokoneva and Dr I. E. Grey for personal communications.
