with anisotropic temperature factors (fixed positional and thermal parameters for H atoms), final $R=0.028$ and $R_{w}=0.030 ;{ }^{*} F(000)=500$.

Discussion. Table 1 shows the final atomic parameters. Fig. 1 shows a perspective drawing (Johnson, 1965) of the molecule. The coordination around the U atoms is the usual centrosymmetric distorted hexagonal bipyramid, $\mathrm{O}(5)$ and $\mathrm{O}\left(5^{\mathrm{i}}\right)$ being at $0.462(6) \AA$ from the plane defined by the other four O atoms around U . Table 2 contains a list of bond lengths and bond angles.

Most calculations were carried out with the XRAY70 system (Stewart, Kundell \& Baldwin, 1970) on the Univac 1108 computer of the MEC (Madrid). Thanks are due to Professor S. Garcia-Blanco for his sponsorship.

> * Lists of structure factors, anisotropic thermal parameters and unrefined H-atom parameters have been deposited with the British Library Lending Division as Supplementary Publication No. SUP 38092 (18 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2 HU , England.

$0.71069 \AA, \mu=5.63 \mathrm{~mm}^{-1}, 294 \mathrm{~K}$. Final $R=0.048$, $R_{w F}=0.052$ for 3428 unique reflections. There are two independent molecules per unit cell and the crystal structure consists of discrete tetramers, in which © 1983 International Union of Crystallography
individual molecules are linked through weak $\mathrm{Te} \cdots \mathrm{Cl}$ interactions.

Introduction. Crystallographic studies of organotellurium(IV) halides have shown intermolecular associations through interactions between Te and halogen atoms. Weak but significant $\mathrm{Te} \cdots \mathrm{Br}$ interactions were noted in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2} \mathrm{TeBr}_{2}$ (Christofferson \& McCullough, 1958), stronger $\mathrm{Te} \cdots \mathrm{I}$ interactions in several diiodides such as $\left(p-\mathrm{ClC}_{6} \mathrm{H}_{4}\right)_{2} \mathrm{TeI}_{2}$ (Chao \& $\mathrm{McCullough}, 1962$ ) and significant $\mathrm{Te} \cdots \mathrm{Cl}$ interactions in some dichlorides including $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2} \mathrm{TeCl}_{2}$ (Alcock \& Harrison, 1982), $\left(o-\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{Cl}_{2}\right)_{2} \mathrm{TeCl}_{2}$ and (o$\left.\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{Cl}\right)\left(p-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4}\right) \mathrm{TeCl}_{2}$ (Cameron, Amero \& Cordes, 1980). However, the arrangements of the individual molecules within these systems vary considerably, having been described variously as layers, infinite chains and tetramers.

Experimental. Preparation as described by Chadha \& Miller (1982) followed by crystallization by slow evaporation of methylene chloride solution, density measured by flotation in $\mathrm{CCl}_{4} / \mathrm{CH}_{3} \mathrm{I}, 0.46 \times 0.38 \times$ 0.29 mm , Syntex $P 2_{1}$ diffractometer, highly oriented graphite monochromator, data collected and processed as described earlier (Khan, Steevensz, Tuck, Noltes \& Corfield, 1980); intensities of three monitor reflections did not change significantly during data collection; space group $P$ I used, later assumed correct because of successful refinement; 5186 reflections ( $2 \theta_{\text {max }}=50^{\circ}$, $h \pm k \pm l$, , $3428 \quad[I>3 \sigma(I)] \quad$ unique, Lorentz, polarization, absorption (minimum and maximum 3.73 and 7.11 ) corrections; positions of Te atoms obtained from a sharpened Patterson synthesis, positions of remaining non- H determined from a difference Fourier map; anisotropic blocked-matrix least-squares, minimizing $\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}, 190$ parameters in each cycle [these comprised parameters of the eight $\mathrm{Te}, \mathrm{Cl}$ and Br of both molecules, those of the C atoms and the $B(\mathrm{H})$ for one molecule, and a scale factor], $R=0.05$; difference map at this stage showed peaks at some plausible H -atom positions, H atoms included in subsequent refinement in ideal positions $(\mathrm{C}-\mathrm{H}=$ $0.95 \AA, \quad \mathrm{CCH}=120.0^{\circ}$ ) with individual isotropic temperature factors, $R=0.048$ for 3428 reflections, $R_{w F}=0.052$; in final two cycles of refinement largest shift/error 0.05 , final difference map had no features of chemical significance, largest peak 0.8 e $\AA^{-3}, F(000)=$ 808, $w=1 /\left[\sigma^{2}(F)+\rho F^{2}\right]$, final $\rho=0.02$; scattering factors for all non- H atoms, including anomalousdispersion correction for $\mathrm{Te}, \mathrm{Br}, \mathrm{Cl}$, obtained from Ibers \& Hamilton (1974), for H from Stewart, Davidson \& Simpson (1965); programs used included SHELX (Fourier and least-squares calculations, Sheldrick, 1977), XANADU (Roberts \& Sheldrick, 1975), ORTEP (Johnson, 1965), $A B S O R B$ (Templeton \& Templeton, 1973).

Discussion. The final atomic coordinates for non- H atoms are given in Table 1,* and important distances and angles are in Table 2.

In the solid state, ( $p$-bromophenyl)dichloro(phenyl)tellurium(IV) exists as discrete tetramers as a result of significant secondary $\mathrm{Te} \cdots \mathrm{Cl}$ interactions (Fig. 1). There are two independently determined $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\left(p-\mathrm{BrC}_{6} \mathrm{H}_{4}\right) \mathrm{TeCl}_{2}$ molecules within the tetramer which display slight structural differences (Fig. 2). The tetrameric arrangement and secondary interactions are illustrated in Fig. $1(a)$. The structure is very similar to that of $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{OTeCl}_{2}$ (Korp, Bernal, Turley \& Martin, 1980) where a step-like structure with three different $\mathrm{Te}-\mathrm{Cl}$ bond lengths was also noted. The structures of other species, such as $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{TeCl}_{2}$ (Christofferson, Sparks \& McCullough, 1958), (p$\left.\mathrm{ClC}_{6} \mathrm{H}_{4}\right)_{2} \mathrm{TeI}_{2}$ (Chao \& McCullough, 1962),

$\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2} \mathrm{TeBr}_{2}$ (Christofferson \& McCullough, 1958) and particularly $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2} \mathrm{TeCl}_{2}$ (Alcock \& Harrison, 1982), which might have been assumed to be more closely related to $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\left(p-\mathrm{BrC}_{6} \mathrm{H}_{4}\right) \mathrm{TeCl}_{2}$, are slightly different with no more than two $\mathrm{Te}-X$ bond lengths reported in each case and identical monomeric units. As with $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{OTeCl}_{2}$ (Korp et al., 1980) the three $\mathrm{Te}-\mathrm{Cl}$ bond lengths are associated with different degrees of secondary $\mathrm{Te} \cdots \mathrm{Cl}$ interactions. This can be clearly seen from the numbering of the Cl atoms in part of the tetramer in Fig. 1(a). Thus only $\mathrm{Cl}(3)$ has no contact with a neighboring Te atom within the sum of their van der Waals radii ( $4.0 \AA$ ) and $\mathrm{Te}(2)-\mathrm{Cl}(3)$ is the shortest bond $[2.437(3) \AA]$. Both $\mathrm{Te}(1)-\mathrm{Cl}(1)$ and $\mathrm{Te}(1)-\mathrm{Cl}(2)$ are significantly longer [2.530 (2) and 2.496 (2) $\AA$ respectively] and each has one secondary close encounter $\mathrm{Te}(2) \cdots \mathrm{Cl}(1)$ [3.500 (2) $\AA]$ and $\mathrm{Te}(2) \cdots \mathrm{Cl}\left(2^{\prime}\right) \quad[3.592(2) \AA]$. The slightly longer primary bond is associated with the shorter secondary bond so that the sum of the two bonds forming a bridge between molecules is $\sim 6.0 \AA$. This is similar to the average sum of the two bridging $\mathrm{Te}-\mathrm{Cl}$ distances in the tetrameric unit of solid $\mathrm{TeCl}_{4}(5.9 \AA$ ) (Buss \& Krebs, 1971), which has a cubane-type structure. The ratio of the unbridged $\mathrm{Te}-\mathrm{Cl}$ bond length to the secondary bond in the unsymmetric bridge is very similar to that found for the $\mathrm{Xe}-\mathrm{F}$ bond lengths in one form of $\mathrm{XeF}_{6}$ in which individual $\mathrm{XeF}_{6}$ molecules are also linked into tetrameric units by an unsymmetric bridge (Wells, 1975). The bridging system in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\left(p-\mathrm{BrC}_{6} \mathrm{H}_{4}\right) \mathrm{TeCl}_{2}$ also involves two secondary close encounters for $\mathrm{Cl}(4)$ $[3.413$ (3) and $3.723(2) \AA$ ] leading to the longest
terminal bond, $\mathrm{Te}(2)-\mathrm{Cl}(4)$. Thus both environments about Te are essentially distorted octahedra. In molecules 1 , which form the center of the bridging step system, there are essentially two equal-length $\mathrm{Te}-\mathrm{Cl}$ terminal bonds while in molecules 2 the two terminal $\mathrm{Te}-\mathrm{Cl}$ bond lengths differ considerably (Fig. 2). The atoms on the central step, which include $\mathrm{C}(11), \mathrm{C}(21)$, $\mathrm{Te}(1), \mathrm{Cl}\left(4^{\prime}\right), \mathrm{Te}\left(1^{\prime}\right), \mathrm{C}\left(11^{\prime}\right), \mathrm{C}\left(2^{\prime}\right)$ and $\mathrm{Cl}(4)$ (Fig. $1 a$ ), are approximately in a plane. The $\mathrm{Te}(1) \cdots \mathrm{Te}\left(1^{\prime}\right)$ distance of 4.720 (2) $\AA$ leaves ample room for the lone pair on each Te atom, even if they are stereochemically active and pointing towards each other.

The structural parameters of the two independently determined molecules are given in Table 2 and a view of the molecules showing the relationships of the planes of the phenyl and bromophenyl rings in Fig. 2. As in all $R_{2} \mathrm{Te} X_{2}$ molecules, the monomeric unit may be based on a distorted trigonal bipyramid with the Cl atoms occupying the axial positions and the two phenyl rings and the supposed lone pair occupying the three equatorial positions. The $\mathrm{Te}-\mathrm{C}$ bond lengths [average $2 \cdot 11$ (1) $\AA$ § are all essentially equal (see Table 2 ) and, as with the other $R_{2} \mathrm{Te} X_{2}$ molecules, are close to that predicted from the sum of the single-bond covalent

Fig. 1. Unit-cell packing of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\left(p-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Br}\right) \mathrm{TeCl}_{2}$ indicating (a) the step-like structure of tetramers and (b) the relative orientation of the phenyl rings. H atoms are omitted for clarity.

Fig. 2. ORTEP plot of the two independent molecules, 1 (top) and 2 , of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\left(p-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Br}\right) \mathrm{TeCl}_{2}$. The atoms are drawn with $50 \%$ probability ellipsoids.
radii. The $\mathrm{C}-\mathrm{Te}-\mathrm{C}$ angle is also within the range found for these species and given the differences in $\mathrm{Te}-\mathrm{Cl}$ bond lengths and the secondary interactions in the two molecules, it is not surprising that it is slightly different in the two molecules [ 96.1 (4) ${ }^{\circ}$ in 1 and $94.0(4)^{\circ}$ in 2]. This angle is less than the ideal of $120^{\circ}$ and the distortion can be explained on the basis of lone-pair-bond-pair repulsions being greater than bond-pair-bond-pair repulsions. The dihedral angles involving the phenyl planes also differ slightly in the two molecules although the basic arrangements are similar, the phenyl and bromophenyl rings being in a 'propeller' rather than 'butterfly' arrangement. The dihedral angle between the TeCC plane and the phenyl ring is $41.9^{\circ}$ * in molecule 1 and $32.1^{\circ}$ in molecule 2 while that between the TeCC plane and the bromophenyl ring is $144.7^{\circ}$ and $129.4^{\circ}$ respectively. In the fused-ring system of $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{OTeCl}_{2}$, the two independent molecules have similar angles at $\mathrm{Te}\left[90.7\left(3^{\circ}\right)\right]$ and the fused rings are folded so that they are $29.2^{\circ}$ from coplanarity (i.e. have dihedral angle of ca $151^{\circ}$ ). The much smaller CTeC angle and slight fold are presumably associated with the relatively rigid system. There is no such internal rigidity in force in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)(p$ $\left.\mathrm{BrC}_{6} \mathrm{H}_{4}\right) \mathrm{TeCl}_{2}$ so that the dihedral angle between the two rings ( $124.4^{\circ}$ in 1 and $120.5^{\circ}$ in 2) reflects a greater departure from planarity. The differences in all dihedral angles presumably reflect the overriding feature, which is clearly seen in Fig. $1(b)$, where the phenyl ring on molecule 1 lies parallel to the bromophenyl ring on molecule 2, while the phenyl ring on molecule 2 lies normal to the bromophenyl ring on molecule 1 . Within the step-like structure, this arrangement probably minimizes non-bonding interactions between the ring systems on the same or adjacent molecules leading to an alternation of bromophenyl and phenyl rings around the tetrameric unit.

It has been almost universally suggested that the $\mathrm{Te}-X$ bond lengths in $R_{2} \mathrm{Te} X_{2}$ compounds are unusually long even allowing for the fact that there is involvement in secondary interactions. However, the $\mathrm{Te}-\mathrm{Cl}$ bond length of 2.437 (3) $\AA$ is close to or larger than the expected value for a $\mathrm{Te}-\mathrm{Cl}$ bond $(2.36 \AA)$ if a pseudo-trigonal bipyramidal environment is assumed. (For equivalent bonds in, for example, gaseous $\mathrm{PCl}_{5}$ the axial bonds are always longer than those in the equatorial plane. In $\mathrm{PCl}_{5}$, there is a $10 \%$ increase in the covalent radius of $\mathrm{P}_{\mathrm{ax}}$ compared to $\mathrm{P}_{\mathrm{eq}}$, and the same is

[^2]true for the radii in other related species, such as $\mathrm{SF}_{4}$, which have a lone pair. This difference can be rationalized as arising from the use of the less stable $d$ orbitals of the central atom in hybridization involving the axial bonds or as arising from the formation of $2 e-3$ center bonds along the axis.) Whatever the rationale, the effective covalent radius of Te will be expected to be larger, by approximately $10 \%$, along the axis than in the equatorial plane. Assuming the latter radius to be $1.34 \AA$ from the $\mathrm{Te}-\mathrm{C}$ bond length $(1.34+0.78=2 \cdot 12 \AA)$, a value of $1.47 \AA$ can be calculated for $\mathrm{Te}_{\mathrm{ax}}$ leading to a predicted $\mathrm{Te}-\mathrm{Cl}$ bond length of $2.47 \AA$, which is slightly larger than the experimental value $[2.437$ (3) $\AA$ ] for the $\mathrm{Te}-\mathrm{Cl}$ bond not involved in secondary interactions but still smaller than for those involved in such additional bonding.
