Les atomes de sodium se trouvent au centre de bipyramides triangulaires d'atomes de fluor et ont la coordinence 5 . Ces polyèdres de fluor sont joints par les sommets, selon $\mathbf{c}$, par les atomes $\mathrm{F}(7)$ qui ne sont donc reliés qu'à deux atomes de sodium. Cet écart à la loi de répartition électrostatique des charges (Pauling, 1929) dans un cristal ionique est à rapprocher des observations précédentes concernant les composés $\mathrm{Li}_{3} \mathrm{ThF}_{7}$ (Cousson, Pagès \& Chevalier, 1978), $\mathrm{Na}_{7} \mathrm{Zr}_{6} \mathrm{~F}_{31}$ et $\mathrm{K}_{7} \mathrm{Th}_{6} \mathrm{~F}_{31}$ (Burns, Ellison \& Levy, 1968; Brunton, 1971b; Zachariasen \& Penneman, 1980) et ( $\mathrm{Na}, \mathrm{Li})_{7} \mathrm{Th}_{6} \mathrm{~F}_{3}$ (Brunton \& Sears, 1969) et demeure jusqu’à présent sans explication.

En conclusion, l'étude structurale de ce nouveau fluorure d'actinide obtenu par synthèse hydrothermale a permis de comprendre son isotypie avec le composé $\mathrm{CsU}_{6} \mathrm{~F}_{25}$ et de determiner sa formule $-\mathrm{NaNp}_{3} \mathrm{~F}_{13}-a$ priori imprévisible.

#### Abstract

M_{r}=1098.4\), triclinic, $P \overline{1}, a=9.4245$ (5), $b=9.9759$ (9), $c=7.8877$ (4) $\AA, \alpha=110.58$ (1), $\beta=$ $103 \cdot 27(1), \gamma=97 \cdot 80(1)^{\circ}, V=658 \cdot 5 \AA^{3}, Z=2, D_{c}=$ $5.54 \mathrm{Mg} \mathrm{m}^{-3}$, Мо $K a, \lambda=0.71069 \AA, \mu=176.39 \mathrm{~cm}^{-1}$, $F(000)=928, R=0.032$ for 3682 reflections. The structure consists of $\mathrm{TeO}_{3}^{2-}$ and $\mathrm{Te}_{3} \mathrm{O}_{8}^{4-}$ ions which form $\mathrm{Te}_{8} \mathrm{O}_{22}^{12-}$ rings around a centre of symmetry with $\mathrm{Te}-\mathrm{O}$ bonds of about $2.7 \AA$ length. The $\mathrm{Ba}^{2+}$ ions couple these rings together. The $\mathrm{TeO}_{3}^{2-}$ ion has the usual pyramidal shape, the $\mathrm{Te}_{3} \mathrm{O}_{8}^{4-}$ ion has a pseudotwofold axis instead of the twofold axis found previously in $\mathrm{Zn}_{2} \mathrm{Te}_{3} \mathrm{O}_{8}$ and $\mathrm{Nb}_{2} \mathrm{Te}_{3} \mathrm{O}_{11}$.

Introduction. In the course of an investigation of the crystal structures of alkaline-earth tellurates and tellurites we found a barium compound which was present in all products resulting from solid-state reactions between $\mathrm{BaCO}_{3}$ and $\mathrm{TeO}_{2}$ in weight ratios from 1:1 to 1:2. Heating a $1: 2$ mixture at 1000 K over 8 d resulted in a single-phase product. Indexing of the Guinier powder pattern ( $\mathrm{Cu} K \alpha$, internal standard $\alpha-\mathrm{SiO}_{2}$ ) by means of the program ITO (Visser, 1969) led to the triclinic unit cell mentioned above. These cell dimensions differed from all known tellurates and tellurites of
barium, $\mathrm{BaTeO}_{4}$ (Sleight, Foris \& Licis, 1972), $\mathrm{BaTe}_{2} \mathrm{O}_{6}$ (Kocak, Platte \& Trömel, 1979a), $\mathrm{BaTeO}_{3} \mathrm{I}$ (Folger, 1975; Kocak, Platte \& Trömel, 1979b), $\mathrm{BaTeO}_{3}$ II (Kocak, Platte \& Trömel, 1979b) and $\mathrm{BaTeO}_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ (Rottensten Nielsen, Grønbaek Hazell \& Rasmussen, 1971). As we were able to isolate tiny crystals from the product we decided to undertake a structure determination of the compound, in spite of the fact that its formula was unknown.

Experimental. Platelet, $0.025 \times 0.025 \times 0.005 \mathrm{~cm}$, Nonius CAD-4, graphite-monochromated Mo $K \alpha, \theta-$ $2 \theta$ scan, 3781 measured, 99 with $I<3 \sigma(I), 3682$ unique. From the intensities it was obvious that a subcell was present with $a=3.8658, b=3.9683$, $c=3.8563 \AA, \alpha=109.65, \beta=104.73, \gamma=110.77^{\circ}$, and a volume $1 / 14$ of the true cell, containing one heavy atom. It is related to the true cell by the transformation $4 / 14,-2 / 14,4 / 14 ; 2 / 14,6 / 14,2 / 14$; $-5 / 14,-1 / 14,2 / 14$. In accordance with this a Patterson synthesis revealed per unit cell fourteen maxima of approximately equal weight. All of these can be transformed to lie on one straight line through the origin with coordinates $x=n / 14, y=8 n / 14, z=8 n / 14$ (C) 1983 International Union of Crystallography
( $n=1, \ldots, 14$ ). In addition, the Patterson peaks indicated that these coordinates are very nearly correct in the $x$ and $y$ directions, but much less so along z. Assuming a centre of symmetry, the fact that the atoms are on a straight line leaves a choice between two possible origin positions: either at a heavy atom or between two heavy atoms. The latter choice led to convergence in least-squares refinement, based on $F$. In the starting model the coordinates of the $n$th heavy atom were represented by: $0.071 n-0.036$, $0.214 n-0.107,0.571 n-0.286(n=1, \ldots, 14)$. In the initial least-squares refinement for all seven atoms, Te scattering factors were used (Cromer \& Mann, 1968). Refinement based on the full reflection set gave poor results. It was then decided to start refinement with a reflection set with $l \leq 2$, to reduce the influence of the lack of precision of the $z$ coordinates. This refinement led to convergence ( $R=0 \cdot 24$ ). The resulting coordinate set showed considerable shifts in the $z$ positions of atoms 2, 4, and 5 . Subsequent refinement using all reflections gave an $R$ of 0.13 . Fourier difference maps revealed the positions of the oxygen atoms which enabled us to decide that the atoms 1,6 , and 7 are Ba atoms. As we clearly found eleven oxygen atoms the formula of the compound is $\mathrm{Ba}_{3} \mathrm{Te}_{4} \mathrm{O}_{11}$. Maximum LS shift to error $=0.027$, maximum $/$ minimum height $=$ $2 \cdot 2-2.8$ e $\AA^{-3}$. Final refinement ( 165 parameters) with anisotropic temperature factors, absorption and extinction corrections [transmission factors $0.08-0.423$, secondary-extinction parameter (Larson, 1967) 5.68 $\times 10^{-6}$ ] yielded an $R$ of 0.032.* Atomic dispersion factors were taken from International Tables for X-ray Crystallography (1974). Corrections for Lorentz and polarization effects were applied. All computations were carried out with XRAY (Stewart, 1976).

Discussion. Final coordinates are given in Table 1, selected bond lengths and angles in Table 2. A projection of the unit-cell contents along $\mathbf{b}$ is depicted in Fig. 1, which also gives the numbering of the atoms.

As can be seen in Fig. 2 and Table 1, the structure contains $\mathrm{Te}_{3} \mathrm{O}_{8}^{4-}$ ions and $\mathrm{TeO}_{3}^{2-}$ ions. Co-existence of these two ions has not previously been found. The $\mathrm{TeO}_{3}^{2-}$ ion has the usual pyramidal shape. A comparison with other barium tellurites is given in Table 3. The $\mathrm{Te}_{3} \mathrm{O}_{8}^{4-}$ ion has previously only been found in $\mathrm{Zn}_{2} \mathrm{Te}_{3} \mathrm{O}_{8}$ (Hanke, 1966) and $\mathrm{Nb}_{2} \mathrm{Te}_{3} \mathrm{O}_{11}$ (Galy \& Lindqvist, 1979). In both cases the structure had a crystallographic twofold axis through the central Te atom of the $\mathrm{Te}_{3} \mathrm{O}_{8}$ group. In $\mathrm{Ba}_{3} \mathrm{Te}_{4} \mathrm{O}_{11}$ this is not the case, and hence the $\mathrm{Te}_{3} \mathrm{O}_{8}$ group is more irregular, but Fig. 2 shows that a pseudo-twofold axis is still present.

[^0]$\mathrm{Te}(2)$ has two equatorial oxygens at 1.85 (1) $\AA$. A similar arrangement is found in $\mathrm{Zn}_{2} \mathrm{Te}_{3} \mathrm{O}_{8}$ [ $\mathrm{Te}-$ $\mathrm{O}_{\text {eq }}=1.83(3) \AA$ ] and in $\mathrm{Nb}_{2} \mathrm{Te}_{3} \mathrm{O}_{11}$ [ $\mathrm{Te}-\mathrm{O}_{\text {eq }}=$

Fig. 1. A projection of the unit-cell contents along $\mathbf{b}$.
1.84 (2) $\AA]$.Compared with these latter compounds the bond lengths for the non-equatorial oxygens of the central Te differ substantially in length, $\mathrm{Te}(2)-\mathrm{O}(3)$ being 2.048 (6) $\AA$ and $\mathrm{Te}(2)-\mathrm{O}$ (6) 2.250 (6) $\AA$. The $\mathrm{Te}(3)-\mathrm{O}$ (6) distance, $1 \cdot 880$ (7) $\AA$, is considerably shorter than $\mathrm{Te}(1)-\mathrm{O}(3), 1-967$ (7) $\AA$. In Table 4, using the numbering given in Fig. 3, a comparison is given with the bond lengths and angles around the central Te atom in known $\mathrm{Te}_{3} \mathrm{O}_{8}$ units (angle 12 means the angle between bond numbers 1 and 2). The atoms $\mathrm{Te}(1)$ and $\mathrm{Te}(3)$ have normal threefold coordination as shown in Table 4. The $\mathrm{TeO}_{3}$ and $\mathrm{Te}_{3} \mathrm{O}_{8}$ units are linked to form a $\mathrm{Te}_{8} \mathrm{O}_{22}$ ring by bonds $\mathrm{Te}(4)-\mathrm{O}\left(7^{\prime}\right)$, 2.718 (5) $\AA$, and $\mathrm{Te}(1)-\mathrm{O}(11), 2.629$ (7) $\AA$. These rings lie around a centre of symmetry on the $c$ axis. Fig. 2 gives a view of the ring. The barium atoms are situated between these rings. $\mathrm{Ba}(1)$ and $\mathrm{Ba}(2)$ are 7 coordinated and have a mean $\mathrm{Ba}-\mathrm{O}$ distance of $2.79(1) \AA, \mathrm{Ba}(3)$ is 8 coordinated with a mean $\mathrm{Ba}-\mathrm{O}$ distance of 2.76 (1) $\AA$.
