

Fig. 5. Illustration of the proposed hexagonal structure ( $D_{6 h}^{4}$ ) of $\mathrm{YbD}_{2}$ at ambient temperature and pressures above $14.3 \mathrm{GPa}[\mathrm{Yb}$ ( $)$ ) and $\mathrm{D}(\mathbf{\Delta})]$. The deuterium atoms are arranged in a d.h.c.p. lattice [2(a) and $2(d)$ positions] with stacking sequence $A B A^{\prime} C$, and the Yb atoms in an h.c.p. lattice [2(c) positions] in the $B$ and $C$ layers of the deuterium lattice. Note that the drawing has been expanded along $\mathbf{c}$ for illustrative purposes; the $c / a$ ratio of $\mathrm{YbD}_{2}$ equals 1.34 at 17 GPa and ambient temperature. When comparing Figs. 3 and 5, $x=\left(\frac{1}{4}\right)$ and $\left(\frac{3}{4}\right)$ correspond to $B$ and $C$ layers, $x=\left(\frac{1}{2}\right)$ and (0) or (1) correspond to $A^{\prime}$ and $A$ layers.

## Conclusions

This neutron powder diffraction study of $\mathrm{YbD}_{2}$ and $\mathrm{YbH}_{2}$ has confirmed the previous assumption that at ambient temperature and pressure the crystal structure is $D_{2 h}^{16}$ (Pnma) with all atoms in the 4(c) positions. The lattice constants of both compounds are in agreement with those previously determined by X-ray experiments (Korst \& Warf, 1956; Warf \& Hardcastle, 1966; Staun Olsen et al., 1981). The
positional parameters of the Yb atoms were found to agree with those reported for $\mathrm{CaD}_{2}$ (Bergsma \& Loopstra, 1962). The deuterium positions in $\mathrm{YbD}_{2}$ (and $\mathrm{YbH}_{2}$ ) determined by powder profile analysis of our data are more accurate but in reasonable agreement with those estimated for $\mathrm{CaD}_{2}$ (Bergsma \& Loopstra, 1962) giving nearest-in-plane ( $y=\frac{1}{4}$ or $\frac{3}{4}$ ) $\mathrm{Yb}-\mathrm{D}$ distances of $2.21,2.31$ and $2.37 \AA$, and nearest-out-of-plane distances of 2.25, 2.52 and $2.57 \AA$.

By inference from the structure of $\mathrm{YbD}_{2}$ at ambient temperature and pressure, we suggest that the roomtemperature hexagonal structure observed in $\mathrm{YbH}_{2}$ at pressures above $\sim 14.3 \mathrm{GPa}$ (Staun Olsen et al., 1981) is $D_{6 h}^{4}\left(P 6_{3} / \mathrm{mmc}\right)$ with the metal atoms in $2(c)$ positions and the hydrogen atoms in $2(a)$ and $2(d)$ positions.

It is a pleasure to thank B. Buras, R. G. Hazell and H. Skriver for their interest and valuable comments concerning this work. We are also indebted to G. A. Mackenzie for help with the EDINP program and to L. Gerward and J. Staun Olsen for useful discussions. Special thanks are due to B. Lundtoft and F. Krebs Larsen for making the X-ray analysis.

# Tetrasodium Divanadate, $\mathbf{N a}_{\mathbf{4}}\left[\mathbf{V}_{\mathbf{2}} \mathbf{O}_{\mathbf{7}}\right]$ 

By Katsuo Kato and Eiji Takayama
National Institute for Research in Inorganic Materials, 1-1 Namiki, Sakura-mura, Niihari-gun, Ibaraki-ken 305, Japan
(Received 19 May 1983; accepted 14 July 1983)

$2.68 \mathrm{~mm}^{-1}, F(000)=2336, T=298 \mathrm{~K}$. Final $R=$ 0.050 for 6949 unique observed reflections. One of the two independent $\mathrm{V}_{2} \mathrm{O}_{7}$ groups has a nearly eclipsed conformation with a V-O-V angle of 149.4 (1) ${ }^{\circ}$,

[^0]while the other is nearly staggered with $\mathrm{V}-\mathrm{O}-\mathrm{V}$ $133.4(1)^{\circ}$. Two $\mathrm{Na}^{+}$ions in special positions are surrounded octahedrally by six O atoms; other $\mathrm{Na}^{+}$ ions are coordinated rather irregularly by five to seven O atoms.

Introduction. Glazyrin \& Fotiev (1964) studied the optical propertics of $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$ and concluded that this compound crystallizes in the monoclinic system. $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$ was found later by Barker \& Hooper (1973) to undergo a phase transition at 702 K . The powder X-ray diffraction patterns of both low- and hightemperature forms were given by them. Our sample of $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$, obtained by cooling a melt slowly to 873 K and then rapidly to room temperature, gave a powder pattern similar to, but not identical with that of their low-temperature form. The sample was highly hygroscopic as described in Gmelin's Handbuch der anorganischen Chemie (1967). The present study was undertaken as the structure of $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$ itself was still unknown while that of its hydrate, $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7} .18 \mathrm{H}_{2} \mathrm{O}$, has recently been determined by Bjoernberg (1979).

Experimental. Synthetic material, crystal of irregular shape, $0.25 \times 0.30 \times 0.30 \mathrm{~mm}$, enclosed in thin-wall ( 0.01 mm ) glass capillary. Four-circle Rigaku diffractometer. Lattice constants based on 22 reflections with $67<2 \theta<78^{\circ}$. No absorption correction. Intensity measurement to $(\sin \theta) / \lambda=0.91 \AA^{-1}$ within range -27 $\leq h \leq 27,0 \leq k \leq 10,-58 \leq l \leq 58$ carried out in several separate runs; intensities reduced to common scale using standard reflections $2,0,26,80 \overline{8}, 82 \overline{8}$ and 531 ; 18786 reflections measured, 4984 unobserved [ $I<\sigma(I)$ or too weak to be scanned], 6949 considered observed. Structure solved by Patterson method. Atomic coordinates, anisotropic thermal parameters and a scale factor refined by least-squares method based on $F . R=0.050$, $w R=0.034, \quad S=3 \cdot 18 ; \quad w=1 / \sigma^{2} \quad[\sigma=\sigma(I) F /(2 I)]$. Parameter shift in final cycle $\leq 0.001 \sigma . \Delta \rho=-2 \cdot 1-$ $1 \cdot 1 \mathrm{e} \AA^{-3}$. Atomic scattering factors of Cromer \& Mann (1968) with dispersion corrections of Cromer \& Liberman (1970). Computer programs used: URLAP in soft-ware system of diffractometer for determination of lattice constants, local version of ORFFE (Busing, Martin \& Levy, 1964) for calculation of bond lengths and angles, and other unpublished programs written by one of the authors.

Discussion. The positional and equivalent isotropic thermal parameters are listed in Table 1.* Fig. 1 shows a [010] projection of the structure. The asymmetric unit consists of two $\mathrm{V}_{2} \mathrm{O}_{7}$ groups and nine $\mathrm{Na}^{+}$ions. The

[^1]$\mathrm{V}_{2} \mathrm{O}_{7}$ groups are illustrated in Fig. 2 which also shows interatomic distances and angles. The group including $V(1)$ and $V(2)$ has a nearly eclipsed conformation, while the other is nearly staggered.

Fig. I. Structure of $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$ projected onto (010). The numbers indicate the $y$ coordinates of atoms in units of $\frac{b}{100}$.

Calvo \& Faggiani (1975) surveyed the V-O bond lengths and $\mathrm{V}-\mathrm{O}-\mathrm{V}$ bond angles in various divalent metal ion divanadates and concluded that the average bridging $\mathrm{V}-\mathrm{O}$ bond length increases with decreasing $\mathrm{V}-\mathrm{O}-\mathrm{V}$ angle while the average terminal $\mathrm{V}-\mathrm{O}$ bond length shows no systematic variations. The average bridging $\mathrm{V}-\mathrm{O}$ bond lengths and $\mathrm{V}-\mathrm{O}-\mathrm{V}$ angles in the $M_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$ compounds given in Table 5 of their paper as well as those in $\mathrm{Mg}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$ (Gopal \& Calvo, 1974), $\mathrm{Ca}_{2} \mathrm{~V}_{2} \mathrm{O}_{7} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Konnert \& Evans, 1975) and $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$ (this work) are plotted in Fig. 3. For $\mathrm{Mg}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$, the data are taken only from the one side of the anion where the interaction with a fifth O atom is probably not significant. In Fig. 3 also the average length of all $\mathrm{V}-\mathrm{O}$ bonds in each $\mathrm{V}_{2} \mathrm{O}_{7}$ group is plotted against the $\mathrm{V}-\mathrm{O}-\mathrm{V}$ angle. It is the total average $\mathrm{V}-\mathrm{O}$ bond length rather than the average of the bridging bonds only that increases steadily as the $\mathrm{V}-\mathrm{O}-\mathrm{V}$ angle decreases. The former may be expected to reflect the

Fig. 2. Interatomic distances $(\AA)$, bond angles and torsion angles $\left({ }^{\circ}\right)$ in $\mathrm{V}_{2} \mathrm{O}_{7}$ groups. E.s.d.'s are $0.002 \dot{\mathrm{~A}}$ and $0.1^{\circ}$. The numbers in the circles are the atom numbers of the O atoms. Symmetry code for $\mathrm{V}(1), \mathrm{O}(1), \mathrm{O}(2), \mathrm{O}(3): \frac{1}{2}+x, \frac{1}{2}+y, z$.

Fig. 3. Relation between average $\mathrm{V}-\mathrm{O}$ distance and $\mathrm{V}-\mathrm{O}-\mathrm{V}$ angle of $\mathrm{V}_{2} \mathrm{O}_{7}$ groups in various compounds. Open symbols for the average of bridging bonds and filled ones for the average of all $\mathrm{V}-\mathrm{O}$ bonds. Curve drawn by eye. Single circles: $\mathrm{M}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$ compounds (see text); triangles: $\mathrm{Mg}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$; squares: $\mathrm{Ca}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$.$2 \mathrm{H}_{2} \mathrm{O}$; double circles: $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}$.

|  | Coordination <br> number | Min. | $\mathrm{Na}-\mathrm{O}$ distances <br> Mean | Max. |
| :--- | :---: | :---: | :---: | :---: |
| $\mathrm{Na}(1)$ | 6 | $2.360(2)$ | 2.403 | $2.464(2)$ |
| $\mathrm{Na}(2)$ | 6 | $2.289(2)$ | 2.498 | $2.876(2)$ |
| $\mathrm{Na}(3)$ | 7 | $2.290(2)$ | 2.605 | $3.076(3)$ |
| $\mathrm{Na}(4)$ | 7 | $2.312(2)$ | 2.648 | $3.122(2)$ |
| $\mathrm{Na}(5)$ | 5 | $2.283(2)$ | 2.382 | $2.543(2)$ |
| $\mathrm{Na}(6)$ | 6 | $2.323(2)$ | 2.524 | $2.681(2)$ |
| $\mathrm{Na}(7)$ | 6 | $2.362(2)$ | 2.543 | $2.734(3)$ |
| $\mathrm{Na}(8)$ | 6 | $2.300(2)$ | 2.464 | $2.672(2)$ |
| $\mathrm{Na}(9)$ | 7 | $2.351(2)$ | 2.653 | $2.970(3)$ |

inherent behaviour of the $\mathrm{V}_{2} \mathrm{O}_{7}$ group more distinctly, because rather large fluctuations in separate bonds affected by environmental conditions are compensated by each other (Shannon \& Calvo, 1973).

The $\mathrm{Na}-\mathrm{O}$ distances are listed in Table 2, where the largest $\mathrm{Na}-\mathrm{O}$ distance not exceeding any $\mathrm{Na}-\mathrm{Na}$ or $\mathrm{Na}-\mathrm{V}$ distances is taken as the maximum distance for each $\mathrm{Na}^{+}$ion. Except for $\mathrm{Na}(1)$ and $\mathrm{Na}(2)$, which lie in special positions and are surrounded octahedrally by six O atoms, the coordination polyhedra of the $\mathrm{Na}^{+}$ ions are considerably distorted.

The hydrate, $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7} \cdot 18 \mathrm{H}_{2} \mathrm{O}$, contains $\mathrm{Na}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)$, and $\mathrm{V}_{2} \mathrm{O}_{7}$ groups giving a structural formula $\left[\mathrm{Na}_{2}-\right.$ $\left(\mathrm{H}_{2} \mathrm{O}\right)_{9} \mathrm{l}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}$. The structure, which is disordered with respect to the orientation of the anion and the position of one of the cation groups (Bjoernberg, 1979), has, as a whole, no similarities to the present structure.

If the pentavalent V in $\mathrm{Na}_{4} \mathrm{~V}_{2} \mathrm{O}_{7}$ is substituted by a quadrivalent cation, say Si , and one of the $\mathrm{Na}^{+}$ ions simultaneously by a trivalent cation $(R)$, a compound of related composition, $\mathrm{Na}_{3} R \mathrm{Si}_{2} \mathrm{O}_{7}$, will be obtained. The compounds $\mathrm{Na}_{3} \mathrm{ScSi}_{2} \mathrm{O}_{7}$ and $\mathrm{Na}_{3} \mathrm{YSi}_{2} \mathrm{O}_{7}$ do exist; their structures contain, however, a three-dimensional network of edge-sharing $\mathrm{Si}_{2} \mathrm{O}_{7}$ and $R \mathrm{O}_{6}$ ( $R=\mathrm{Sc}$ or Y ) groups (Voronkov, Sizova, Ilykhin \& Belov, 1973).
